user's guide

The *QPB Science Encyclopedia* is a science reference book for everyone. The material is accurate and appropriate for academic purposes, but it is also clearly written for those without a science background.

As science concerns us all and not just scientists and students of science, this encyclopedia contains informative features examining contemporary issues, innovations, and landmark discoveries. Alongside the alphabetical entries, designed to be of use for students and anyone else seeking definitions for scientific terms, there are also links to web sites to facilitate further research; highlighted biographies and quotes to give an insight into the scientists themselves; and amazing facts, just for fun. With chronologies, tables, and a wealth of diagrams and photographs it is both a browser's delight and an invaluable reference source.

Subject coverage. One of the aims of this encyclopedia has been to offer an extremely broad coverage of science-related topics, so as well as biology, chemistry, physics, and earth sciences, there are agriculture, archaeology, astronomy, computing, environmental science, mathematics, medicine, natural history, technology, and transport.

Arrangement of entries. Entries are ordered alphabetically, as if there were no spaces between words. Thus entries for words beginning with "sulphur" follow the order:

- sulphur
- sulphur dioxide
- sulphuric acid
- sulphur trioxide

Common or technical names. Terms are usually placed under the name by which they are most widely known, rather than their technical name. For example, under "pertussis" there is a cross-reference to "whooping cough," where the main entry is given. Similarly, if the abbreviated form of a term is so widely used that the expanded form is unlikely to be looked up, the main definition is given under the abbreviation—for example, "DNA" instead of "deoxyribonucleic acid."

Cross-references. These are shown by a ⇨ immediately preceding the reference to alert the reader to related articles.

A symbol for mass number, the number of neutrons and protons in an atomic nucleus.

A in physics, symbol for ampere, a unit of electrical current.

aardvark Afrikaans 'earth pig' nocturnal mammal *Oryzomys* *opfer*, the only species in the order Tubulidentata, found in central and southern Africa. A timid, defenceless animal about the size of a pig, it has a long head, a piglike snout, large ears, sparse body hair, a thick tail, and short legs.

It can burrow rapidly with its clawed front feet. It spends the day in its burrow, and at night digs open termite and ant nests, licking up the insects with its long sticky tongue. Its teeth are unique, without enamel, and are the main reason for the aardvark being placed in its own order. When fully grown, it is about 1.5 m/5 ft long and its tongue is 30 cm/12 in long.

AARDVARK

<http://www.oit.itd.umich.edu/bio108/Chordata/Mammalia/Tubulidentata.shtml>

Detailed description of this strange-looking, insectivorous mammal. There is information about the aardvark's skeletal and dental structure, and links to explain unfamiliar terms.

aardwolf nocturnal mammal *Proteles cristatus* of the hyena family, Hyaenidae. It is yellowish grey with dark stripes and, excluding its bushy tail, is around 70 cm/30 in long. It is found in eastern and southern Africa, usually in the burrows of the aardvark. It feeds almost exclusively on termites, eating up to 300,000 per day, but may also eat other insects and small mammals.

Males mate monogamously but females, which have a much larger range, will mate with other males.

abacus ancient calculating device made up of a frame of parallel wires on which beads are strung. The method of calculating with a handful of stones on a 'flat surface' (Latin *abacus*) was familiar to the Greeks and Romans, and used by earlier peoples, possibly even in ancient Babylon; it survives in the more sophisticated bead-frame form of the Russian *schoty* and the Japanese *soroban*. The abacus has been superseded by the electronic calculator.

ABACUS: THE ART OF CALCULATING WITH BEADS

<http://members.aol.com/stubbs3/abacus.htm>

Clear explanation of how the abacus works - with demonstrations of how to add and subtract. This site requires a Java-enabled Web browser or Netscape 2.0+.

The wires of a bead-frame abacus define place value (for example, in the decimal number system each successive wire, counting from right to left, would stand for ones, tens, hundreds, thousands, and so on) and beads are slid to the top of each wire in order to represent the digits of a particular number. On a simple decimal abacus, for example, the number 8,493 would be entered by sliding three beads on the first wire (three ones), nine beads on the second wire (nine tens), four beads on the third wire (four hundreds), and eight beads on the fourth wire (eight thousands).

abalone edible marine snail of the worldwide genus *Haliotis*, family Haliotidae. Abalones have flattened, oval, spiralled shells, which have holes around the outer edge and a bluish mother-of-pearl lining. This lining is used in ornamental work.

abdomen in vertebrates, the part of the body below the thorax, containing the digestive organs; in insects and other arthropods, it is the hind part of the body. In mammals, the abdomen is separated from the thorax by the diaphragm, a sheet of muscular tissue; in arthropods, commonly by a narrow constriction. In mammals, the female reproductive organs are in the abdomen. In insects and spiders, it is characterized by the absence of limbs.

aberration of starlight apparent displacement of a star from its true position, due to the combined effects of the speed of light and the speed of the Earth in orbit around the Sun (about 30 km per second/18.5 mi per second).

Aberration, discovered in 1728 by English astronomer James Bradley (1693-1762), was the first observational proof that the Earth orbits the Sun.

aberration, optical any of a number of defects that impair the image in an optical instrument. Aberration occurs because of minute variations in lenses and mirrors, and because different

aberration of starlight The aberration of starlight is an optical illusion caused by the motion of the Earth. Rain falling appears vertical when seen from the window of a stationary train; when seen from the window of a moving train, the rain appears to follow a sloping path. In the same way, light from a star 'falling' down a telescope seems to follow a sloping path because the Earth is moving. This causes an apparent displacement, or aberration, in the position of the star.

aberration, optical The main defects, or aberrations, of optical systems. Chromatic aberration, or coloured fringes around images, arises because light of different colours is focused at different points by a lens, causing a blurred image. Spherical aberration arises because light that passes through the centre of the lens is focused at a different point from light passing through the edge of the lens. Astigmatism arises if a lens has different curvatures in the vertical and horizontal directions. Coma arises because light passing directly through a lens is focused at a different point to light entering the lens from an angle.

parts of the light spectrum are reflected or refracted by varying amounts.

In **chromatic aberration** the image is surrounded by coloured fringes, because light of different colours is brought to different focal points by a lens. In **spherical aberration** the image is blurred because different parts of a spherical lens or mirror have different focal lengths. In **astigmatism** the image appears elliptical or cross-shaped because of an irregularity in the curvature of the lens. In **coma** the images appear progressively elongated towards the edge of the field of view. Elaborate computer programs are now used to design lenses in which the aberrations are minimized.

abiotic factor a nonorganic variable within the ecosystem, affecting the life of organisms. Examples include temperature, light, and

soil structure. Abiotic factors can be harmful to the environment, as when sulphur dioxide emissions from power stations produce acid rain.

abortion *Latin* *aborire* 'to miscarry' ending of a pregnancy before the fetus is developed sufficiently to survive outside the uterus. Loss of a fetus at a later gestational age is termed premature stillbirth. Abortion may be accidental (*miscarriage*) or deliberate (termination of pregnancy).

deliberate termination In the first nine weeks of pregnancy, medical termination may be carried out using the 'abortion pill' (*mifepristone*) in conjunction with a *prostaglandin*. There are also various procedures for surgical termination, such as *dilatation* and *curettage*, depending on the length of the pregnancy.

Worldwide, an estimated 150,000 unwanted pregnancies are terminated each day by induced abortion. One-third of these abortions are performed illegally and unsafely, and cause one in eight of all maternal deaths.

abortion as birth control Abortion as a means of birth control has long been controversial. The argument centres largely upon whether a woman should legally be permitted to have an abortion and, if so, under what circumstances. Another aspect is whether, and to what extent, the law should protect the fetus.

Those who oppose abortion generally believe that human life begins at the moment of conception, when a sperm fertilizes an egg. This is the view held, for example, by the Roman Catholic Church. Those who support unrestricted legal abortion may believe in a woman's right to choose whether she wants a child, and may take into account the large numbers of deaths and injuries from unprofessional back-street abortions.

Others approve abortion for specific reasons. For example, if a woman's life or health is jeopardized, abortion may be recommended; and if there is a strong likelihood that the child will be born with severe mental or physical disability. Other grounds for abortion include pregnancy resulting from sexual assault such as rape or incest.

abrasive *Latin* 'to scratch away' substance used for cutting and polishing or for removing small amounts of the surface of hard materials. There are two types: natural and artificial abrasives, and their hardness is measured using the *Mohs*' scale. Natural abrasives include quartz, sandstone, pumice, diamond, emery, and corundum; artificial abrasives include rouge, whiting, and carborundum.

abscess collection of pus in solid tissue forming in response to infection. Its presence is signalled by pain and inflammation.

abscissa in *Cartesian* geometry, the *x*-coordinate of a point – that is, the horizontal distance of that point from the vertical or *y*-axis. For example, a point with the coordinates (4, 3) has an abscissa of 4. The *y*-coordinate of a point is known as the *ordinate*.

abscissa

abscissin or *abscissic acid* plant hormone found in all higher plants. It is involved in the process of ϕ abscission and also inhibits stem elongation, germination of seeds, and the sprouting of buds.

abscission in botany, the controlled separation of part of a plant from the main plant body – most commonly, the falling of leaves or the dropping of fruit controlled by ϕ abscissin. In ϕ deciduous plants the leaves are shed before the winter or dry season, whereas ϕ evergreen plants drop their leaves continually throughout the year. Fruitdrop, the abscission of fruit while still immature, is a naturally occurring process.

Abscission occurs after the formation of an abscission zone at the point of separation. Within this, a thin layer of cells, the abscission layer, becomes weakened and breaks down through the conversion of pectic acid to pectin. Consequently the leaf, fruit, or other part can easily be dislodged by wind or rain. The process is thought to be controlled by the amount of ϕ auxin present. Fruitdrop is particularly common in fruit trees such as apples, and orchards are often sprayed with artificial auxin as a preventive measure.

absolute (of a value) in computing, real and unchanging. For example, an **absolute address** is a location in memory and an **absolute cell reference** is a single fixed cell in a spreadsheet display. The opposite of absolute is ϕ relative.

absolute value or *modulus* in mathematics, the value, or magnitude, of a number irrespective of its sign. The absolute value of a number n is written $|n|$ (or sometimes as $\text{mod } n$), and is defined as the positive square root of n^2 . For example, the numbers -5 and 5 have the same absolute value:

$$|5| = |-5| = 5$$

For a ϕ complex number, the absolute value is its distance to the origin when it is plotted on an Argand diagram, and can be calculated (without plotting) by applying ϕ Pythagoras' theorem. By definition, the absolute value of any complex number $a + ib$ (where a and b are real numbers and i is $\sqrt{-1}$) is given by the expression:

$$|a + ib| = \sqrt{(a^2 + b^2)}$$

absolute zero lowest temperature theoretically possible according to kinetic theory, zero kelvin (0 K), equivalent to $-273.15^\circ\text{C}/-459.67^\circ\text{F}$, at which molecules are in their lowest energy state. Although the third law of thermodynamics indicates the impossibility of reaching absolute zero in practice, a temperature of 2.8×10^{-10} K (0.28 billionths of a degree above absolute zero) has been produced in 1993 at the Low Temperature Laboratory in Helsinki, Finland, using a technique called nuclear demagnetization. Near absolute zero, the physical properties of some materials change substantially; for example, some metals lose their electrical resistance and become superconducting.

absorption the taking up of one substance by another, such as a liquid by a solid (ink by blotting paper) or a gas by a liquid (ammonia by water). In physics, absorption is the phenomenon by which a substance retains radiation of particular wavelengths; for example, a piece of blue glass absorbs all visible light except the wavelengths in the blue part of the spectrum; it also refers to the partial loss of energy resulting from light and other electromagnetic waves passing through a medium. In nuclear physics, absorption is the capture by elements, such as boron, of neutrons produced by fission in a reactor.

absorption lines in astronomy, dark line in the spectrum of a hot object due to the presence of absorbing material along the line of sight. Absorption lines are caused by atoms absorbing light from the source at sharply defined wavelengths. Numerous absorption lines in the spectrum of the Sun (Fraunhofer lines) allow astronomers to study the composition of the Sun's outer layers. Absorption lines in the spectra of stars give clues to the composition of interstellar gas.

absorption spectroscopy or *absorptimetry* in analytical chemistry, a technique for determining the identity or amount present of a chemical substance by measuring the amount of electro-

magnetic radiation the substance absorbs at specific wavelengths; see ϕ spectroscopy.

abutilon one of a group of 90 related species of tropical or semi-tropical ornamental plants. The Indian mallow or velvet leaf (*Abutilon theophrasti*) is one of the more common; it has bell-shaped yellow flowers and is the source of a jutelike fibre. Many of the species are pollinated by hummingbirds. (Genus *Abutilon*, family Malvaceae.)

abyssal plain broad expanse of sea floor lying 3–6 km/2–4 mi below sea level. Abyssal plains are found in all the major oceans, and they extend from bordering continental rises to mid-oceanic ridges.

abyssal zone dark ocean region 2,000–6,000 m/6,500–19,500 ft deep; temperature $4^\circ\text{C}/39^\circ\text{F}$. Three-quarters of the area of the deep-ocean floor lies in the abyssal zone, which is too far from the surface for photosynthesis to take place. Some fish and crustaceans living there are blind or have their own light sources. The region above is the bathyal zone; the region below, the hadal zone.

Abyssinian cat or *rabbit cat* breed of domestic shorthaired cat, possibly descended from antiquity. In modern times, it was imported from Abyssinia (now Ethiopia) to Britain in the 1860s. The coat of the usual variety is ruddy brown (similar to a rabbit or hare) with each hair ringed with two or three darker coloured bands. It has a medium-length body, long, slender legs, large widest ears, and deep gold or green eyes. It resembles cats that appear in ancient Egyptian wall paintings.

The breed was recognized in Britain 1882 and is now most widely bred in the USA. There are many varieties.

abzyme in biotechnology, an artificially created antibody that can be used like an enzyme to accelerate reactions.

AC in physics, abbreviation for ϕ alternating current.

To remember the order of items in an AC circuit:

THE VOLTAGE (V) ACROSS A CAPACITOR (C) LAGS THE CURRENT (I) BY 90 DEGREES. THE VOLTAGE ACROSS THE INDUCTOR (L) LEADS THE CURRENT BY 90 DEGREES. THIS IS GIVEN BY THE WORD CIVIL, WHEN SPLIT INTO CIV AND VIL.

acacia any of a large group of shrubs and trees that includes the thorn trees of the African savanna and the gum arabic tree (*Acacia senegal*) of N Africa, and several North American species of the southwestern USA and Mexico. The hardy tree commonly known as acacia is the false acacia (*Robinia pseudacacia*, of the subfamily Papilionoideae). True acacias are found in warm regions of the world, particularly Australia. (Genus *Acacia*, family Leguminosae.)

A *dealbata* is grown in the open air in some parts of France and the warmer European countries, and is remarkable for its clusters of fluffy, scented yellow flowers, sold by florists as mimosa. The leaves of the genus are normally bipinnate (leaflets on both sides of each stem and stems growing on both sides of a larger stem), and the flowers grow in a head.

acanthus herbaceous plant with handsome lobed leaves. Twenty species are found in the Mediterranean region and Old World tropics, including bear's-breech (*Acanthus mollis*) whose leaves were used as a motif in classical architecture, especially on Corinthian columns. (Genus *Acanthus*, family Acanthaceae.)

accelerated freeze drying common method of food preservation. See ϕ food technology.

acceleration rate of change of the velocity of a moving body. It is usually measured in metres per second per second (m s^{-2}) or feet per second per second (ft s^{-2}). Because velocity is a ϕ vector quantity (possessing both magnitude and direction) a body travelling at constant speed may be said to be accelerating if its direction of

motion changes. According to Newton's second law of motion, a body will be accelerated only if it is acted upon by an unbalanced, or resultant, force.

Acceleration due to gravity is the acceleration of a body falling freely under the influence of the Earth's gravitational field; it varies slightly at different latitudes and altitudes. The value adopted internationally for gravitational acceleration is $9.806 \text{ m s}^{-2}/32.174 \text{ ft s}^{-2}$.

acceleration, secular in astronomy, the continuous and nonperiodic change in orbital velocity of one body around another, or the axial rotation period of a body.

An example is the axial rotation of the Earth. This is gradually slowing down owing to the gravitational effects of the Moon and the resulting production of tides, which have a frictional effect on the Earth. However, the angular momentum of the Earth-Moon system is maintained, because the momentum lost by the Earth is passed to the Moon. This results in an increase in the Moon's orbital period and a consequential moving away from the Earth. The overall effect is that the Earth's axial rotation period is increasing by about 15 millionths of a second a year, and the Moon is receding from the Earth at about $4 \text{ cm}/1.5 \text{ in.}$ a year.

acceleration, uniform in physics, acceleration in which the velocity of a body changes by equal amounts in successive time intervals. Uniform acceleration is represented by a straight line on a speed-time graph.

accelerator in physics, a device to bring charged particles (such as protons and electrons) up to high speeds and energies, at which they can be of use in industry, medicine, and pure physics. At low energies, accelerated particles can be used to produce the image on a television screen and generate X-rays (by means of a cathode-ray tube), destroy tumour cells, or kill bacteria. When high-energy particles collide with other particles, the fragments formed reveal the nature of the fundamental forces.

The first accelerators used high voltages (produced by van de Graaff generators) to generate a strong, unvarying electric field. Charged particles were accelerated as they passed through the electric field. However, because the voltage produced by a generator is limited, these accelerators were replaced by machines where the particles passed through regions of alternating electric fields, receiving a succession of small pushes to accelerate them.

The first of these accelerators was the linear accelerator or linac. The linac consists of a line of metal tubes, called drift tubes, through which the particles travel. The particles are accelerated by electric fields in the gaps between the drift tubes.

Another way of making repeated use of an electric field is to bend the path of a particle into a circle so that it passes repeatedly through the same electric field. The first accelerator to use this idea was the cyclotron pioneered in the early 1930s by US physicist Ernest Lawrence. A cyclotron consists of an electromagnet with two hollow metal semicircular structures, called dees, supported between the poles of an electromagnet. Particles such as protons are introduced at the centre of the machine and travel outwards in a spiral path, being accelerated by an oscillating electric field each time they pass through the gap between the dees. Cyclotrons can accelerate particles up to energies of 25 MeV (25 million electron volts); to produce higher energies, new techniques are needed.

In the synchrotron, particles travel in a circular path of constant radius, guided by electromagnets. The strengths of the electromagnets are varied to keep the particles on an accurate path. Electric fields at points around the path accelerate the particles.

accelerator The cyclotron, an early accelerator, consisted of two D-shaped hollow chambers enclosed in a vacuum. An alternating voltage was applied across the gap between the hollows. Charged particles spiralled outward from the centre, picking up energy and accelerating each time they passed through the gap.

Early accelerators directed the particle beam onto a stationary target; large modern accelerators usually collide beams of particles that are travelling in opposite directions. This arrangement doubles the effective energy of the collision.

The world's most powerful accelerator is the $2 \text{ km}/1.25 \text{ mi}$ diameter machine at Fermilab near Batavia, Illinois, USA. This machine, the Tevatron, accelerates protons and antiprotons and then collides them at energies up to a thousand billion electron volts (or 1 TeV , hence the name of the machine). The largest accelerator is the Large Electron Positron Collider at CERN near Geneva, which has a circumference of $27 \text{ km}/16.8 \text{ mi}$ around which electrons and positrons are accelerated before being allowed to collide. The world's longest linac is also a colliding beam machine: the Stanford Linear Collider, in California, in which electrons and positrons are accelerated along a straight track, $3.2 \text{ km}/2 \text{ mi}$ long, and then steered to a head-on collision with other particles, such as protons and neutrons. Such experiments have been instrumental in revealing that protons and neutrons are made up of smaller elementary particles called quarks.

accelerator board type of expansion board that makes a computer run faster. It usually contains an additional processor (see central processing unit).

accelerometer apparatus, either mechanical or electromechanical, for measuring acceleration or deceleration – that is, the rate of increase or decrease in the velocity of a moving object.

The mechanical types have a spring-supported mass with a damper system, with indication of acceleration on a scale on which a light beam is reflected from a mirror on the mass. The electromechanical types use (1) a slide wire, (2) a strain gauge, (3) variable inductance, or (4) a piezoelectric or similar device that produces electrically measurable effects of acceleration.

Accelerometers are used to measure the efficiency of the braking systems on road and rail vehicles; those used in aircraft and spacecraft can determine accelerations in several directions simultaneously. There are also accelerometers for detecting vibrations in machinery.

acceptable use in computing, set of rules enforced by a service provider or backbone network restricting the use to which their facilities may be put. Every organization on the Internet has its own acceptable use policy (AUP); schools, for example, may ban the use of their facilities to find or download pornography from the Internet.

Originally, when the Internet was publicly funded, acceptable use banned advertising, and although funding is moving to private enterprise and advertising has now become commonplace, some

ACCELERATOR PHYSICS PAGE

<http://www-laacg.atdiv.lanl.gov/accephys.html>

Virtual library dedicated to accelerator physics, with pages on design and components, as well as direct links to laboratories throughout the world.

service providers still do not allow commercial exploitation. The US National Science Foundation's NSFnet, for example, imposes a strict AUP to prohibit commercial organizations from using the network.

access in computing, the way in which file access is provided so that the data can be stored, retrieved, or updated by the computer.

access privilege in computer networking, authorized access to files. The ability to authorize or restrict access selectively to files or directories, including separate privileges such as reading, writing, or changing data, is a key element in computer security systems. This kind of system ensures that, for example, a company's employees cannot read its personnel files or alter payroll data unless they work for the appropriate departments, or that freelance or temporary staff can be given access to some areas of the computer system but not others.

Certain types of restrictions may be applied by users themselves to files on their own desktop machines, such as private e-mail; others may be granted only by the system administrator.

On all client-server systems, all data, even private e-mail and personal letters, can be accessed by the system administrator, who needs system-wide privileges in order to manage the network properly. Data which is encrypted, however, will not be readable unless the system administrator knows the user's individual password.

The privacy of employee e-mail is a contentious issue, as many employees assume their e-mail is private, while many companies presume ownership of all data stored on company systems.

access provider in computing, another term for Internet Service Provider.

access time or **reaction time** in computing, the time taken by a computer, after an instruction has been given, to read from or write to memory.

acclimation or **acclimatization** the physiological changes induced in an organism by exposure to new environmental conditions. When humans move to higher altitudes, for example, the number of red blood cells rises to increase the oxygen-carrying capacity of the blood in order to compensate for the lower levels of oxygen in the air.

In evolutionary terms, the ability to acclimate is an important adaptation as it allows the organism to cope with the environmental changes occurring during its lifetime.

accommodation in biology, the ability of the eye to focus on near or far objects by changing the shape of the lens.

For an object to be viewed clearly its image must be precisely

focused on the retina, the light-sensitive layer of cells at the rear of the eye. Close objects can be seen when the lens takes up a more spherical shape, distant objects when the lens is flattened. These changes in shape are caused by the movement of ligaments attached to a ring of ciliary muscles lying beneath the iris.

From about the age of 40, the lens in the human eye becomes less flexible, causing the defect of vision known as presbyopia or lack of accommodation. People with this defect need different spectacles for reading and distance vision.

account on a computer network, a user-ID issued to a specific individual to enable access to the system for purposes of billing, administration, or private messaging. The existence of accounts allows system administrators to assign access privileges to specific individuals (which in turn enables those individuals to receive private messages such as e-mail) and also to track the use of the computer system and its resources.

On commercial systems such as CompuServe or America Online, users are given an account when they dial up the system and give the number of a credit card to which usage may be billed. On other types of systems, accounts are typically issued by the system administrator. In all cases, accounts are protected by a password, which should be carefully chosen.

accretion in astrophysics, a process by which an object gathers up surrounding material by gravitational attraction, so simultaneously increasing in mass and releasing gravitational energy. Accretion on to compact objects such as white dwarfs, neutron stars and black holes can release large amounts of gravitational energy, and is believed to be the power source for active galaxies. Accreted material falling towards a star may form a swirling disc of material known as an accretion disc that can be a source of X-rays.

accretion disc in astronomy, a flattened ring of gas and dust orbiting an object in space, such as a star or black hole. The orbiting material is accreted (gathered in) from a neighbouring object such as another star. Giant accretion discs are thought to exist at the centres of some galaxies and quasars.

If the central object of the accretion disc has a strong gravitational field, as with a neutron star or a black hole, gas falling onto the accretion disc releases energy, which heats the gas to extreme temperatures and emits short-wavelength radiation, such as X-rays.

accumulator in computing, a special register, or memory location, in the arithmetic and logic unit of the computer processor. It is used to hold the result of a calculation temporarily or to store data that is being transferred.

accommodation The mechanism by which the shape of the lens in the eye is changed so that clear images of objects, whether distant or near, can be focused on the retina.

accumulator The lead-acid car battery is a typical example of an accumulator. The battery has a set of grids immersed in a sulphuric acid electrolyte. One set of grids is made of lead (Pb) and acts as the anode and the other set made of lead oxide (PbO₂) acts as the cathode.

accumulator in electricity, a storage battery – that is, a group of rechargeable secondary cells. A familiar example is the lead-acid car battery.

An ordinary 12-volt car battery consists of six lead-acid cells which are continually recharged when the motor is running by the car's alternator or dynamo. It has electrodes of lead and lead oxide in an electrolyte of sulphuric acid. Another common type of accumulator is the 'nife' or Ni Fe cell, which has electrodes of nickel and iron in a potassium hydroxide electrolyte.

accuracy in mathematics, a measure of the precision of a number. The degree of accuracy depends on how many figures or decimal places are used in rounding off the number. For example, the result of a calculation or measurement (such as 13.429314) might be rounded off to three decimal places (13.429), to two decimal places (13.43), to one decimal place (13.4), or to the nearest whole number (13). The first answer is more accurate than the second, the second more accurate than the third, and so on.

Accuracy also refers to a range of errors. For example, an accuracy of $\pm 5\%$ means that a value may lie between 95% and 105% of a given answer.

acer group of over 115 related species of trees and shrubs of the temperate regions of the northern hemisphere, many of them popular garden specimens. They include cypress and maple. Some species have pinnate leaves (leaflets either side of a stem), including the box elder (*Acer negundo*) of North America. (Genus *Acer*.)

That is the essence of science: ask an impertinent question, and you are on the way to a pertinent answer.

JACOB BRONOWSKI Polish-born scientist, broadcaster, and writer.
Ascent of Man

acesulfame-K noncarbohydrate sweetener that is up to 300 times as sweet as sugar. It is used in soft drinks and desserts.

acetaldehyde common name for ethanal.

acetate common name for ethanoate.

acetic acid common name for ethanoic acid.

acetone common name for propanone.

acetylcholine (ACh) chemical that serves as a neurotransmitter, communicating nerve impulses between the cells of the nervous system. It is largely associated with the transmission of impulses across the synapse (junction) between nerve and muscle cells, causing the muscles to contract.

ACh is produced in the synaptic knob (a swelling at the end of a nerve cell) and stored in vesicles until a nerve impulse triggers its discharge across the synapse. When the ACh reaches the membrane of the receiving cell it binds with a specific site and brings about depolarization – a reversal of the electric charge on either side of the membrane – causing a fresh impulse (in nerve cells) or a contraction (in muscle cells). Its action is shortlived because it is quickly destroyed by the enzyme cholinesterase.

Anticholinergic drugs have a number of uses in medicine to block the action of ACh, thereby disrupting the passage of nerve impulses and relaxing certain muscles, for example in premedication before surgery.

acetylene common name for ethyne.

acetylsalicylic acid chemical name for the painkilling drug aspirin.

achene dry, one-seeded fruit that develops from a single ovary and does not split open to disperse the seed. Achenes commonly occur in groups – for example, the fruiting heads of buttercup *Ranunculus* and clematis. The outer surface may be smooth, spiny, ribbed, or tuberculate, depending on the species.

Achernar or *Alpha Eridani* brightest star in the constellation Eridanus, and the ninth brightest star in the sky. It is a hot, luminous, blue star with a true luminosity 250 times that of the Sun. It is 125 light years away.

Achilles tendon tendon at the back of the ankle attaching the calf muscles to the heel bone. It is one of the largest tendons in the human body, and can resist great tensile strain, but is sometimes ruptured by contraction of the muscles in sudden extension of the foot.

Ancient surgeons regarded wounds in this tendon as fatal, probably because of the Greek legend of Achilles, which relates how the mother of the hero Achilles dipped him when an infant into the river Styx, so that he became invulnerable except for the heel by which she held him.

achondrite type of meteorite. They comprise about 15% of all meteorites and lack the chondrules (silicate spheres) found in chondrites.

achromatic lens combination of lenses made from materials of different refractive indexes, constructed in such a way as to minimize chromatic aberration (which in a single lens causes coloured fringes around images because the lens diffracts the different wavelengths in white light to slightly different extents).

acid compound that, in solution in an ionizing solvent (usually water), gives rise to hydrogen ions (H⁺ or protons). In modern chemistry, acids are defined as substances that are proton donors and accept electrons to form ionic bonds. Acids react with bases to form salts, and they act as solvents. Strong acids are corrosive; dilute acids have a sour or sharp taste, although in some organic acids this may be partially masked by other flavour characteristics.

Acids can be detected by using coloured indicators such as litmus and methyl orange. The strength of an acid is measured by its hydrogen-ion concentration, indicated by the pH value. Acids are classified as monobasic, dibasic, tribasic, and so forth, according to the

To remember how to mix acid and water safely:

ADD ACID TO WATER, JUST AS YOU OUGHTA!

number of hydrogen atoms, replaceable by bases, in a molecule. The first known acid was vinegar (ethanoic or acetic acid). Inorganic acids include boric, carbonic, hydrochloric, hydrofluoric, nitric, phosphoric, and sulphuric. Organic acids include acetic, benzoic, citric, formic, lactic, oxalic, and salicylic, as well as complex substances such as nucleic acids and amino acids.

acidic oxide oxide of a nonmetal. Acidic oxides are covalent compounds. Those that dissolve in water, such as sulphur dioxide, give acidic solutions.

All acidic oxides react with alkalis to form salts.

acid rain acidic precipitation thought to be caused principally by the release into the atmosphere of sulphur dioxide (SO_2) and oxides of nitrogen. Sulphur dioxide is formed by the burning of fossil fuels, such as coal, that contain high quantities of sulphur; nitrogen oxides are contributed from various industrial activities and from car exhaust fumes.

Acid deposition occurs not only as wet precipitation (mist, snow, or rain), but also comes out of the atmosphere as dry particles or is absorbed directly by lakes, plants, and masonry as gases. Acidic gases can travel over 500 km/310 mi a day so acid rain can be considered an example of transboundary pollution.

Acid rain is linked with damage to and the death of forests and lake organisms in Scandinavia, Europe, and eastern North America. It also results in damage to buildings and statues. US and European power stations that burn fossil fuels release about 8 g/0.3 oz of sulphur dioxide and 3 g/0.1 oz of nitrogen oxides per kilowatt-hour.

ACID RAIN

<http://www.environment-agency.gov.uk/s-enviro/states/3-2.html>

Britain's Environmental Agency report on the environmental consequences of acid rain. This well-written article, supported by graphs and statistics, gives a good understanding of the scale of the problems caused by acid rain.

acid salt chemical compound formed by the partial neutralization of a dibasic or tribasic acid (one that contains two or three hydrogen atoms). Although a salt, it contains replaceable hydrogen, so it may undergo the typical reactions of an acid. Examples are sodium hydrogen sulphate (NaHSO_4) and acid phosphates.

ack radio-derived term for 'acknowledge'. It is used on the Internet as a brief way of indicating agreement with or receipt of a message or instruction.

acclinic line the magnetic equator, an imaginary line near the Equator, where a compass needle balances horizontally, the attraction of the north and south magnetic poles being equal.

ACM abbreviation for the US Association for Computing Machinery.

acne skin eruption, mainly occurring among adolescents and young adults, caused by inflammation of the sebaceous glands which secrete an oily substance (sebum), the natural lubricant of the skin. Sometimes the openings of the glands become blocked, causing the formation of pus-filled swellings. Teenage acne is seen mainly on the face, back, and chest.

There are other, less common types of acne, sometimes caused by contact with irritant chemicals (chloracne).

aconite or **monkshood** or **wolfbane** herbaceous plant belonging to the buttercup family, with hooded blue-mauve flowers, native to

acclinic line The magnetic equator, or the line at which the attraction of both magnetic poles is equal. Along the acclinic line, a compass needle swinging vertically will settle in a horizontal position.

Europe and Asia. It produces aconitine, a poison with pain-killing and sleep-inducing properties. (*Aconitum napellus*, family Ranunculaceae.)

There are about 100 species throughout the northern temperate regions, all hardy herbaceous plants containing poison. Summer aconite (*Aconitum uncinatum*) is a common North American flower. Winter aconite (*Eranthis hyemalis*) belongs to another genus of the buttercup family; it has yellow buttercup-like flowers with six petals which appear in February and March; the leaves follow later.

acorn fruit of the oak tree, a nut growing in a shallow cup.

Acorn UK computer manufacturer. In the early 1980s, Acorn produced a series of home microcomputers, including the Electron and the Atom. Its most successful computer, the BBC Microcomputer, was produced in conjunction with the BBC. Subsequent computers (the Master and the Archimedes) were less successful. Acorn was rescued by the Italian company Olivetti in 1985 but it has since sold off its majority shareholding.

acouchi any of several small South American rodents, genus *Myoprocta*. They have white-tipped tails, and are smaller relatives of the chaguti.

acoustic coupler device that enables computer data to be transmitted and received through a normal telephone handset; the handset rests on the coupler to make the connection. A small speaker within the device is used to convert the computer's digital output data into sound signals, which are then picked up by the handset and transmitted through the telephone system. At the receiving telephone, a second acoustic coupler or modem converts the sound signals back into digital data for input into a computer.

Unlike a modem, an acoustic coupler does not require direct connection to the telephone system. However, interference from background noise means that the quality of transmission is poorer than with a modem, and more errors are likely to arise.

acoustic ohm c.g.s. unit of acoustic impedance (the ratio of the sound pressure on a surface to the sound flux through the surface). It is analogous to the ohm as the unit of electrical impedance.

acoustics in general, the experimental and theoretical science of sound and its transmission; in particular, that branch of the science that has to do with the phenomena of sound in a particular space such as a room or theatre. In architecture, the sound-reflecting character of an internal space.

Acoustical engineering is concerned with the technical control of sound, and involves architecture and construction, studying control

acoustic coupler The acoustic coupler converts digital output from a computer to sound signals that can be sent via a telephone line.

of vibration, soundproofing, and the elimination of noise. It also includes all forms of sound recording and reinforcement, the hearing and perception of sounds, and hearing aids.

ACOUSTIC ILLUSIONS

<http://www.uni-bonn.de/~uzs083/akustik.html>

Dedicated to the Shepard effect: a scale that gives the listener the impression of an endlessly rising melody, when in fact the pitch of the tones does not rise. Sound files illustrate this, and accompany an account of an experiment in which the Shepard effect was applied to J S Bach's *Das Musikalische Opfer*/Musical Offering.

acquired character feature of the body that develops during the lifetime of an individual, usually as a result of repeated use or disuse, such as the enlarged muscles of a weightlifter.

French naturalist Jean Baptiste Lamarck's theory of evolution assumed that acquired characters were passed from parent to offspring. Modern evolutionary theory does not recognize the inheritance of acquired characters because there is no reliable scientific evidence that it occurs, and because no mechanism is known whereby bodily changes can influence the genetic material. The belief that this does not occur is known as *central dogma*.

acquired immune deficiency syndrome full name for the disease *AIDS*.

acre traditional English land measure equal to 4,840 square yards (4,047 sq m/0.405 ha). Originally meaning a field, it was the size that a yoke of oxen could plough in a day.

As early as Edward I's reign, (1272-1307) the acre was standardized by statute for official use, although local variations in Ireland, Scotland, and some English counties continued. It may be subdivided into 160 square rods (one square rod equalling 25.29 sq m/30.25 sq yd).

acre-foot unit sometimes used to measure large volumes of water, such as the capacity of a reservoir (equal to its area in acres multiplied by its average depth in feet). One acre-foot equals 1,233.5 cu m/43,560 cu ft or the amount of water covering one acre to a depth of one foot.

acridine $C_{13}H_9N$, a heterocyclic organic compound that occurs in coal tar. It is crystalline, melting at 108°C/226.4°F. Acridine is extracted by dilute acids but can also be obtained synthetically. It is used to make dyes and drugs.

Acrobat program developed by Adobe to allow users of different types of computers to view the same documents complete with

graphics and layout. Launched in 1993, Acrobat was designed to get around the limitations of existing systems when transferring data between different types of computers, which typically required all formatting to be stripped from the documents. The program to generate the code that makes the documents transferable with formatting intact must be bought, but the program for reading the documents is available free of charge.

By 1996 Acrobat was in common use on the World Wide Web for distributing certain types of company documents, and the program had been enhanced to integrate with Web browsers.

acrolein or **acraldehyde** $CH_2=CHCHO$, a colourless liquid formed during the partial combustion of fats. It is an unsaturated aldehyde, boils at 52°C/125.6°F, has an irritating action on the skin, and its vapours cause a copious flow of tears. It was used in gas form as a chemical weapon in World War I by the French under the code-name *Papite*.

acronym abbreviation that can be pronounced as a word, for example RISC (Reduced Instruction Set Computer) and MUD (multi-user dungeon). People in the computer industry often incorrectly refer to all abbreviations as acronyms. Both are frequently used as industry jargon and as shorthand to save typing on the Net. See also *TLA* (three letter acronym).

acrylic acid common name for *propenoic acid*.

ACTH (abbreviation for *adrenocorticotrophic hormone*) ϕ hormone secreted by the anterior lobe of the *pituitary gland*. It controls the production of corticosteroid hormones by the *adrenal gland* and is commonly produced as a response to stress.

actinide any of a series of 15 radioactive metallic chemical elements with atomic numbers 89 (actinium) to 103 (lawrencium). Elements 89 to 95 occur in nature; the rest of the series are synthesized elements only. Actinides are grouped together because of their chemical similarities (for example, they are all bivalent), the properties differing only slightly with atomic number. The series is set out in a band in the *periodic table of the elements*, as are the *lanthanides*.

actinium *Greek aktis 'ray'* white, radioactive, metallic element, the first of the actinide series, symbol Ac, atomic number 89, relative atomic mass 227; it is a weak emitter of high-energy alpha particles.

Actinium occurs with uranium and radium in *pitchblende* and other ores, and can be synthesized by bombarding radium with neutrons. The longest-lived isotope, Ac-227, has a half-life of 21.8 years (all the other isotopes have very short half-lives). Chemically, it is exclusively trivalent, resembling in its reactions the lanthanides and the other actinides. Actinium was discovered 1899 by the French chemist Andr   Debierne (1874-1949).

actinium K original name of the radioactive element *francium*, given 1939 by its discoverer, the French scientist Marguerite Perey (1909-1975).

action and reaction in physical mechanics, equal and opposite forces which act together. For example, the pressure of expanding gases from the burning of fuel in a rocket engine produces an equal and opposite reaction, which causes the rocket to move. This is Newton's third law of motion (see *Newton's laws of motion*).

action potential in biology, a change in the ϕ potential difference (voltage) across the membrane of a nerve cell when an impulse passes along it. A change in potential (from about -60 to +45 millivolts) accompanies the passage of sodium and potassium ions across the membrane.

activation analysis in analytical chemistry, a technique used to reveal the presence and amount of minute impurities in a substance or element. A sample of a material that may contain traces of a certain element is irradiated with ϕ neutrons, as in a reactor. Gamma rays emitted by the material's radioisotope have unique energies and relative intensities, similar to the spectral lines from a luminous gas. Measurements and interpretation of the gamma-ray spectrum, using data from standard samples for comparison, provide information on the amount of impurities present.

activation energy in chemistry, the energy required in order to start a chemical reaction. Some elements and compounds will react together merely by bringing them into contact (spontaneous reaction). For others it is necessary to supply energy in order to start the reaction, even if there is ultimately a net output of energy. This initial energy is the activation energy.

active galaxy in astronomy, a type of galaxy that emits vast quantities of energy from a small region at its centre called the active galactic nucleus (AGN). Active galaxies are subdivided into ϕ radio galaxies, ϕ Seyfert galaxies, ϕ BL Lacertae objects, and ϕ quasars.

Active galaxies are thought to contain black holes with a mass some 108 times that of the Sun, drawing stars and interstellar gas towards it in a process of accretion. The gravitational energy released by the in-falling material is the power source for the AGN. Some of the energy may appear as a pair of opposed jets emerging from the nucleus. The orientation of the jets to the line of sight and their interaction with surrounding material determines the type of active galaxy that is seen by observers. See also *ϕ starburst galaxy*.

active matrix LCD (or *TFT (thin film transistor) display*) type of colour ϕ liquid crystal display (LCD) commonly used in laptop computers. Active matrix displays are made by sandwiching a film containing tiny transistors between two plates of glass. They achieve high contrast and brightness by applying voltage across the horizontal and vertical wires between the two glass plates, balanced by using a small transistor inside each ϕ pixel to amplify the voltage when so instructed.

To create ϕ VGA colour, each pixel must also integrate colour filters; essentially, each logical pixel is made up of three physical pixels, one for each of red, blue, and green, the primary colours of light. The consequence of this – and the reason active matrix screens are such expensive options – is that a VGA display requires approximately a billion transistors, and even minute imperfections render the screens useless for computing purposes. A high refresh rate means that the screens are extremely responsive, so the cursor does not disappear as a mouse is moved quickly across the screen.

Active matrix displays began to appear on laptops in 1992, and are expected by many to eventually replace the older cathode-ray technology for television sets as well as display monitors.

active transport in cells, the use of energy to move substances, usually molecules or ions, across a membrane.

Energy is needed because movement occurs against a concentration gradient, with substances being passed into a region where they are already present in significant quantities. Active transport thus differs from ϕ diffusion, the process by which substances move towards a region where they are in lower concentration, as when oxygen passes into the blood vessels of the lungs. Diffusion requires no input of energy.

active window on graphical operating systems, the ϕ window containing the program actually in use at any given time. Usually active windows are easily identified by the use of colour schemes which assign a different colour to the window's title bar (a thin strip along the top of each window bearing the name of the window's specific program or function) from that of the title bars of inactive windows.

On a true ϕ multitasking system, each window may represent an active program, but the active window is the one into which the user may enter data. A user might, for example, be typing a document into a word processor in the active window while in the background other programs back up files or sort data in a database.

ActiveX in computing, Microsoft's umbrella name for a collection of technologies used to create applications that run on the World Wide Web or on ϕ intranets.

ActiveX is based on DCOM (Microsoft's Distributed Component Object Model) and uses ActiveX Controls, which are a lightweight version of OLE (ϕ object linking and embedding) Custom Controls or OCXs. It also includes scripting languages such as JavaScript and VB Script (Visual Basic Script), and a ϕ Java Virtual Machine (JVM).

ActiveX was announced in 1996, and later that year was handed to the ϕ Open Group, to manage its development and turn it into a cross-platform industry standard.

activity in physics, the number of particles emitted in one second by a radioactive source. The term is used to describe the radioactivity or the potential danger of that source. The unit of activity is the becquerel (Bq), named after the French physicist Henri Becquerel.

activity series in chemistry, alternative name for ϕ reactivity series.

acupuncture in alternative medicine, a system of inserting long, thin metal needles into the body at predetermined points to relieve pain, as an anaesthetic in surgery, and to assist healing. The needles are rotated manually or electrically. The method, developed in ancient China and increasingly popular in the West, is thought to work by stimulating the brain's own painkillers, the ϕ endorphins.

Acupuncture is based on a theory of physiology that posits a network of life-energy pathways, or 'meridians', in the human body and some 800 'acupuncture points' where metal needles may be inserted to affect the energy flow for purposes of preventative or remedial therapy or to produce a local anaesthetic effect. Numerous studies and surveys have attested the efficacy of the method, which is widely conceded by orthodox practitioners despite the lack of an acceptable scientific explanation.

ACUPUNCTURE.COM

<http://acupuncture.com/>

Through introduction to the alternative world of acupuncture with descriptions of the main notions and powers of herbology, yoga, Qi Gong, and Chinese nutrition. Consumers are given access to lists of practitioners and an extensive section on acupuncture research. Practitioners can browse through journal listings and the latest industry news and announcements.

acute in medicine, term used to describe a disease of sudden and severe onset which resolves quickly; for example, pneumonia and meningitis. In contrast, a **chronic** condition develops and remains over a long period.

acute angle an angle between 0° and 90° ; that is, an amount of turn that is less than a quarter of a circle.

Ada high-level computer-programming language, developed and owned by the US Department of Defense, designed for use in situations in which a computer directly controls a process or machine, such as a military aircraft. The language took more than five years

to specify, and became commercially available only in the late 1980s. It is named after English mathematician Ada Augusta Byron.

adaptation *Latin* *adaptare* 'to fit to' in biology, any change in the structure or function of an organism that allows it to survive and reproduce more effectively in its environment. In evolution, adaptation is thought to occur as a result of random variation in the genetic make-up of organisms coupled with natural selection. Species become extinct when they are no longer adapted to their environment – for instance, if the climate suddenly becomes colder.

adaptive radiation in evolution, the formation of several species, with adaptations to different ways of life, from a single ancestral type. Adaptive radiation is likely to occur whenever members of a species migrate to a new habitat with unoccupied ecological niches. It is thought that the lack of competition in such niches allows sections of the migrant population to develop new adaptations, and eventually to become new species.

The colonization of newly formed volcanic islands has led to the development of many unique species. The 13 species of Darwin's finch on the Galapagos Islands, for example, are probably descended from a single species from the South American mainland. The parent stock evolved into different species that now occupy a range of diverse niches.

ADC in electronics, abbreviation for analogue-to-digital converter.

addax light-coloured antelope *Addax nasomaculatus* of the family Bovidae. It lives in N Africa around the Sahara Desert where it exists on scanty vegetation without drinking. It is about 1.1 m/3.5 ft at the shoulder, and both sexes have spirally twisted horns. Its hooves are broad, enabling it to move easily on soft sand.

adder electronic circuit in a computer or calculator that carries out the process of adding two binary numbers. A separate adder is needed for each pair of binary digits to be added. Such circuits are essential components of a computer's arithmetic and logic unit (ALU).

adder *Anglo-Saxon naedre* 'serpent' European venomous snake, the common viper *Vipera berus*. Growing on average to about 60 cm/24 in in length, it has a thick body, triangular head, a characteristic V-shaped mark on its head and, often, zigzag markings along the back. It feeds on small mammals and lizards. The puff adder *Bitis arietans* is a large, yellowish, thick-bodied viper up to 1.6 m/5 ft long, living in Africa and Arabia.

addiction state of dependence caused by habitual use of drugs, alcohol, or other substances. It is characterized by uncontrolled craving, tolerance, and symptoms of withdrawal when access is denied. Habitual use produces changes in body chemistry and treatment must be geared to a gradual reduction in dosage.

Initially, only opium and its derivatives (morphine, heroin, codeine) were recognized as addictive, but many other drugs, whether therapeutic (for example, tranquillizers) or recreational (such as cocaine and alcohol), are now known to be addictive.

Research points to a genetic predisposition to addiction; environment and psychological make-up are other factors. Although physical addiction always has a psychological element, not all psychological dependence is accompanied by physical dependence. A carefully controlled withdrawal programme can reverse the chemical changes of habituation. Cure is difficult because of the many other factors contributing to addiction.

adding machine device for adding (and usually subtracting, multiplying, and dividing) numbers, operated mechanically or electromechanically; now largely superseded by electronic calculators.

addition in arithmetic, the operation of combining two numbers to form a sum; thus, $7 + 4 = 11$. It is one of the four basic operations of arithmetic (the others are subtraction, multiplication, and division).

addition polymerization polymerization reaction in which a single monomer gives rise to a single polymer, with no other reaction products.

addition reaction chemical reaction in which the atoms of an element or compound react with a double bond or triple bond in an organic compound by opening up one of the bonds and becoming attached to it, for example

An example is the addition of hydrogen atoms to unsaturated compounds in vegetable oils to produce margarine. Addition reactions are used to make useful polymers from alkenes.

add-on small program written to extend the features of a larger one. The earliest successful add-on for personal computer users in the UK was a small routine which allowed the original version of the spreadsheet Lotus 1-2-3 to print out a pound sign (£), something the program's US developers had thought unnecessary.

address in a computer memory, a number indicating a specific location.

At each address, a single piece of data can be stored. For microcomputers, this normally amounts to one byte (enough to represent a single character, such as a letter or digit).

The maximum capacity of a computer memory depends on how many memory addresses it can have. This is normally measured in units of 1,024 bytes (known as kilobytes, or K).

address means of specifying either a computer or a person for the purpose of directing messages or other data across a network. Addressing e-mail to a person across the Internet involves typing in a string of characters such as 'userID@machine.system.type.country'. To send mail to Jane Doe, for example, whose user ID is 'janed' and who works at a company called Anyco in the UK, a user would type in 'janed@anyco.co.uk'.

Computers do not, however, use these named addresses in routing data. The portion after the address is known as a domain, and the domain name is an easy-to-remember alias for a numbered address that is understandable by a computer. This numbered address, which takes a form similar to 127.000.000.001, is known as an IP (Internet protocol) address. Both the numbered IP addresses and domain names are assigned by the InternetNIC.

address book facility in most e-mail software that allows the storage and retrieval of e-mail addresses. Address books remove the problem of trying to remember a particular user's exact e-mail address – and it must be exact, as computers are unable to correct human errors. The best address-book software allows a user to type in just the correspondent's name and fills in the rest automatically.

address bus in computing, the electrical pathway or bus used to select the route for any particular data item as it is moved from one part of a computer to another.

adenoids masses of lymphoid tissue, similar to tonsils, located in the upper part of the throat, behind the nose. They are part of a child's natural defences against the entry of germs but usually shrink and disappear by the age of ten.

Adenoids may swell and grow, particularly if infected, and block the breathing passages. If they become repeatedly infected, they may be removed surgically (adenoidectomy), usually along with the tonsils.

ADH (abbreviation for *antidiuretic hormone*) in biology, part of the system maintaining a correct salt/water balance in vertebrates.

Its release is stimulated by the hypothalamus in the brain, which constantly receives information about salt concentration from receptors situated in the neck. In conditions of water shortage increased ADH secretion from the brain will cause more efficient conservation of water in the kidney, so that fluid is retained by the body. When an animal is able to take in plenty of water, decreased ADH secretion will cause the urine to become dilute and plentiful. The system allows the body to compensate for a varying fluid intake and maintain a correct balance.

Adhara star 600 light years from Earth. It plays a greater part in ionizing hydrogen in our region of the Galaxy than all the other 3 million stars lying closer to our local cloud, according to US astronomers in 1995.

Most of space contains ionized hydrogen in tiny amounts but Adhara is connected to our local cloud by a tunnel of almost hydrogen-free space. This means its ionizing radiation reaches our local cloud without obstacle.

The surface temperature of Adhara is 21,000 K (almost four times that of the Sun) and it is the brightest source of extreme UV radiation apart from the Sun.

ADHESIVE

The Florida leaf beetle *Hemiphaera cyanen* has 60,000 adhesive pads on its feet. These enable it to resist the pull of a 2 g/0.07 oz weight (the equivalent of a human hanging on to 200 grand pianos). Ant predators are unable to move the beetle.

adhesive substance that sticks two surfaces together. Natural adhesives (glues) include gelatin in its crude industrial form (made from bones, hide fragments, and fish offal) and vegetable gums. Synthetic adhesives include thermoplastic and thermosetting resins, which are often stronger than the substances they join; mixtures of epoxy resin and hardener that set by chemical reaction; and elastomeric (stretching) adhesives for flexible joints. Superglues are fast-setting adhesives used in very small quantities.

adiabatic in physics, a process that occurs without loss or gain of heat, especially the expansion or contraction of a gas in which a change takes place in the pressure or volume, although no heat is allowed to enter or leave.

adipose tissue type of connective tissue of vertebrates that serves as an energy reserve, and also pads some organs. It is commonly called fat tissue, and consists of large spherical cells filled with fat. In mammals, major layers are in the inner layer of skin and around the kidneys and heart.

Fatty acids are transported to and from it via the blood system. An excessive amount of adipose tissue is developed in the course of some diseases, especially obesity.

adit in mining, a horizontal shaft from the surface to reach a mineral seam. It was a common method of mining in hilly districts, and was also used to drain water. The mineral-bearing rock is excavated by digging horizontally into the side of a valley. It is used, for example, in coal mining.

adjacent angles pair of angles meeting at a common vertex (corner) and sharing a common arm. Two adjacent angles lying on the same side of a straight line add up to 180° and are said to be supplementary.

adjacent side in a right-angled triangle, the side that is next to a given angle but is not the hypotenuse (the side opposite the right angle). The third side is the opposite side to the given angle.

admiral any of several species of butterfly in the same family (Nymphalidae) as the tortoiseshells. The red admiral *Vanessa atalanta*, wingspan 6 cm/2.5 in, is found worldwide in the northern hemisphere. It either hibernates, or migrates south each year from northern areas to subtropical zones.

Adobe US company specializing in graphics and desktop publishing software. Founded in 1982 by former Xerox PARC researchers John Warnock and Chuck Geschke, Adobe was the inventor of PostScript and is the publisher of Acrobat and Pagemaker. Adobe's enduring contribution to the computer industry is that it facilitated the use of computers to produce the fancy fonts without which desktop publishing would not have been possible.

Adobe Type Manager in computing, program from Adobe that manages fonts under Windows 3.1 and allows the printing and display of PostScript fonts.

adolescence in the human life cycle, the period between the beginning of puberty and adulthood.

The four stages of man are infancy, childhood, adolescence and old age.

ART LINKLETT US writer and broadcaster.
Child's Garden of Misinformation

ADP abbreviation for **adenosine diphosphate**, the chemical product formed in cells when ATP breaks down to release energy.

adrenal gland or **suprarenal gland** triangular gland situated on top of the kidney. The adrenals are soft and yellow, and consist of two parts: the cortex and medulla. The cortex (outer part) secretes various steroid hormones and other hormones that control salt and water metabolism and regulate the use of carbohydrates, proteins, and fats. The medulla (inner part) secretes the hormones adrenaline and noradrenaline which, during times of stress, cause the heart to beat faster and harder, increase blood flow to the heart and muscle cells, and dilate airways in the lungs, thereby delivering more oxygen to cells throughout the body and in general preparing the body for 'fight or flight'.

adrenaline or **epinephrine** hormone secreted by the medulla of the adrenal glands. Adrenaline is synthesized from a closely related substance, noradrenaline, and the two hormones are released into the bloodstream in situations of fear or stress.

Adrenaline's action on the liver raises blood-sugar levels by stimulating glucose production and its action on adipose tissue raises blood fatty-acid levels; it also increases the heart rate, increases blood flow to muscles, reduces blood flow to the skin with the production of sweat, widens the smaller breathing tubes (bronchioles) in the lungs, and dilates the pupils of the eyes.

adrenocorticotrophic hormone hormone secreted by the anterior lobe of the pituitary gland; see ACTH.

ADSL (abbreviation for **asymmetric digital subscriber loop**) standard for transmitting video data through existing copper telephone wires. ADSL was developed by US telephone companies as a way of competing with cable television companies in delivering both TV and phone services. By 1996 it was developing into a possible alternative means for high-speed Internet access. ADSL is one of several types of digital subscriber loops (DSLs) in progress.

adsorption taking up of a gas or liquid at the surface of another substance, most commonly a solid (for example, activated charcoal adsorbs gases). It involves molecular attraction at the surface, and should be distinguished from absorption (in which a uniform solution results from a gas or liquid being incorporated into the bulk structure of a liquid or solid).

Advanced Earth Observing Satellite (ADEOS) Japanese climate sensing satellite launched August 1996. It gathers data on climate change, the environment, and Earth and ocean processes.

ADEOS is carrying eight instruments: Ocean Color and Temperature Scanner (OCTS); Advanced Visible and Near-Infrared Radiometer (AVNIR); Interferometric Monitor for Greenhouse Gases; Improved Limb Atmospheric Spectrometer (ILAS); Retroreflector in Space (RIS); Scatterometer (NSCAT); Total Ozone Mapping Spectrometer (TOMS); and Polarization and Directionality of the Earth's Reflectances (POLDER). NSCAT and TOMS are NASA instruments and POLDER is French, the rest are Japanese.

advanced gas-cooled reactor (AGR) type of nuclear reactor used in W. Europe. The AGR uses a fuel of enriched uranium dioxide in stainless-steel cladding and a moderator of graphite. Carbon dioxide gas is pumped through the reactor core to extract the heat produced by the fission of the uranium. The heat is transferred to water in a steam generator, and the steam drives a turbogenerator to produce electricity.

Advanced Technology Attachment Packet Interface in computing, enhancement to integrated drive electronics (IDE), usually abbreviated to ATAPI.

adventitious in botany, arising in an abnormal position, as in roots developing on the stem of a cutting or buds developing on roots.

advertising in computing, practice of paying to place information about a company's services or products in front of consumers. The earliest advertisers on the Net used to distribute their information as widely as possible in a practice quickly dubbed 'spamming'. By 1996 the practice of advertising on the World Wide Web was becoming commonplace.

Much Web advertising is sold in the same way as advertising in traditional media such as the print and broadcasting industries. Advertisers pay to place a small graphic known as an 'advertising banner' on a particular Web page in a spot (usually the top) where users are expected to see it clearly and click on it to follow the link to the advertiser's own site for more information. More sophisticated systems are under development which allow an advertising agency to track users' interests by watching which Web sites they visit and using that information to choose banners to insert which match those users' interests.

The US-based research company Jupiter Communications puts the value of online advertising at \$940 million for 1997, up from \$55 million in 1995. It is expected to reach \$4.4 billion in 2000.

Aepyornis genus of large, extinct, flightless birds living in Madagascar until a few thousand years ago. Some stood 3 m/10 ft high and laid eggs with a volume of 43 l/9.5 gal. They had long, thick legs, four-toed feet, and rudimentary wings.

aerated water water that has had air (oxygen) blown through it. Such water supports aquatic life and prevents the growth of putrefying bacteria. Polluted waterways may be restored by artificial aeration.

aerenchyma plant tissue with numerous air-filled spaces between the cells. It occurs in the stems and roots of many aquatic plants where it aids buoyancy and facilitates transport of oxygen around the plant.

aerial or **antenna** in radio and television broadcasting, a conducting device that radiates or receives electromagnetic waves. The design of an aerial depends principally on the wavelength of the signal. Long waves (hundreds of metres in wavelength) may employ long wire aeriels; short waves (several centimetres in wavelength) may employ rods and dipoles; microwaves may also use dipoles - often with reflectors arranged like a toast rack - or highly directional parabolic dish aeriels. Because microwaves travel in straight lines, requiring line-of-sight communication, microwave aeriels are usually located at the tops of tall masts or towers.

aerial oxidation in chemistry, a reaction in which air is used to oxidize another substance, as in the contact process for the manufacture of sulphuric acid:

and in the tanning of wine.

aerobic in biology, term used to describe those organisms that require oxygen (usually dissolved in water) for the efficient release of energy contained in food molecules, such as glucose. They include almost all organisms (plants as well as animals) with the exception of certain bacteria, yeasts, and internal parasites.

Aerobic reactions occur inside every cell and lead to the formation of energy-rich ATP, subsequently used by the cell for driving its metabolic processes. Oxygen is used to convert glucose to carbon dioxide and water, thereby releasing energy.

Most aerobic organisms die in the absence of oxygen, but certain organisms and cells, such as those found in muscle tissue, can function for short periods anaerobically (without oxygen). Anaerobic organisms can survive without oxygen.

aerodynamics branch of fluid physics that studies the forces exerted by air or other gases in motion. Examples include the air flow around bodies moving at speed through the atmosphere (such as land vehicles, bullets, rockets, and aircraft), the behaviour of gas in engines and furnaces, air conditioning of buildings, the deposi-

tion of snow, the operation of air-cushion vehicles (hovercraft), wind loads on buildings and bridges, bird and insect flight, musical wind instruments, and meteorology. For maximum efficiency, the aim is usually to design the shape of an object to produce a streamlined flow, with a minimum of turbulence in the moving air. The behaviour of aerosols or the pollution of the atmosphere by foreign particles are other aspects of aerodynamics.

aerogel light, transparent, highly porous material composed of more than 90% air. Such materials are formed from silica, metal oxides, and organic chemicals, and are produced by drying gels - networks of linked molecules suspended in a liquid - so that air fills the spaces previously occupied by the liquid. They are excellent heat insulators and have unusual optical, electrical, and acoustic properties.

Aerogels were first produced by US scientist Samuel Kistler in the early 1930s by drying silica gels at high temperatures and pressures.

aeronautics science of travel through the Earth's atmosphere, including aerodynamics, aircraft structures, jet and rocket propulsion, and aerial navigation.

In **subsonic aeronautics** (below the speed of sound), aerodynamic forces increase at the rate of the square of the speed.

Transonic aeronautics covers the speed range from just below to just above the speed of sound and is crucial to aircraft design. Ordinary sound waves move at about 1.225 kph/760 mph at sea level, and air in front of an aircraft moving slower than this is 'warned' by the waves so that it can move aside. However, as the flying speed approaches that of the sound waves, the warning is too late for the air to escape, and the aircraft pushes the air aside, creating shock waves, which absorb much power and create design problems. On the ground the shock waves give rise to a sonic boom. It was once thought that the speed of sound was a speed limit to aircraft, and the term 'sound barrier' came into use.

Supersonic aeronautics concerns speeds above that of sound and in one sense may be considered a much older study than aeronautics itself, since the study of the flight of bullets, known as ballistics, was undertaken soon after the introduction of firearms. **Hypersonics** is the study of airflows and forces at speeds above five times that of sound (Mach 5); for example, for guided missiles, space rockets, and advanced concepts such as HOTOL (horizontal takeoff and landing). For all flight speeds streamlining is necessary to reduce the effects of air resistance.

Aeronautics is distinguished from astronautics, which is the science of travel through space. Astronautics (navigation by reference to the stars) is used in aircraft as well as in ships and is a part of aeronautics.

aeroplane (US **airplane**) powered heavier-than-air craft supported in flight by fixed wings. Aeroplanes are propelled by the thrust of a jet engine or airscrew (propeller). They must be designed aerodynamically, since streamlining ensures maximum flight efficiency. The Wright brothers flew the first powered plane (a biplane) in Kitty Hawk, North Carolina, USA in 1903. For the history of aircraft and aviation, see flight.

design Efficient streamlining prevents the formation of shock waves over the body surface and wings, which would cause instability and power loss. The wing of an aeroplane has the cross-sectional shape of an aerofoil, being broad and curved at the front, flat underneath (sometimes slightly curved), curved on top, and tapered to a sharp point at the rear. It is so shaped that air passing above it is speeded up, reducing pressure below atmospheric pressure and air passing below it is slower thus increasing pressure and providing a double effect. This follows from Bernoulli's principle and results in a force acting vertically upwards, called lift, which counters the plane's weight. In level flight lift equals weight. The wings develop sufficient lift to support the plane when they move quickly through the air. The thrust that causes propulsion comes from the reaction to the air stream accelerated backwards by the propeller or the gases shooting backwards from the jet exhaust. In flight the engine thrust must overcome the air resistance, or drag. Drag depends on frontal area (for example, large, airliner; small, fighter plane) and shape (drag coefficient); in level

airplane In flight, the forces on an aeroplane are lift, weight, drag, and thrust. The lift is generated by the air flow over the wings, which have the shape of an aerofoil. The engine provides the thrust. The drag results from the resistance of the air to the aeroplane's passage through it. Various moveable flaps on the wings and tail allow the aeroplane to be controlled. The rudder is moved to turn the aeroplane. The elevators allow the craft to climb or dive. The ailerons are used to bank the aeroplane while turning. The flaps, slats, and spoilers are used to reduce lift and speed during landing.

flight, drag equals thrust. The drag is reduced by streamlining the plane, resulting in higher speed and reduced fuel consumption for a given power. Less fuel need be carried for a given distance of travel, so a larger payload (cargo or passengers) can be carried.

aerosol particles of liquid or solid suspended in a gas. Fog is a common natural example. Aerosol cans contain a substance such as scent or cleaner packed under pressure with a device for releasing it as a fine spray. Most aerosols used chlorofluorocarbons (CFCs) as propellants until these were found to cause destruction of the ozone layer in the stratosphere.

The international community has agreed to phase out the use of CFCs, but most so-called 'ozone-friendly' aerosols also use ozone-depleting chemicals, although they are not as destructive as CFCs. Some of the products sprayed, such as pesticides, can be directly toxic to humans.

aestivation in zoology, a state of inactivity and reduced metabolic activity, similar to hibernation, that occurs during the dry season in species such as lungfish and snails. In botany, the term is used to describe the way in which flower petals and sepals are folded in the buds. It is an important feature in plant classification.

aether alternative form of ether, the hypothetical medium once believed to permeate all of space.

AFD abbreviation for *accelerated freeze drying*, a common method of food preservation. See food technology.

affine geometry geometry that preserves parallelism and the ratios between intervals on any line segment.

affinity in chemistry, the force of attraction (see bond) between atoms that helps to keep them in combination in a molecule. The

aerosol The aerosol can produces a fine spray of liquid particles, called an aerosol. When the top button is pressed, a valve is opened, allowing the pressurized propellant in the can to force out a spray of the liquid contents. As the liquid sprays from the can, the small amount of propellant dissolved in the liquid vaporizes, producing a fine spray of small droplets.

term is also applied to attraction between molecules, such as those of biochemical significance (for example, between enzymes and substrate molecules). This is the basis for affinity chromatography, by which biologically important compounds are separated.

The atoms of a given element may have a greater affinity for the atoms of one element than for another (for example, hydrogen has a great affinity for chlorine, with which it easily and rapidly combines to form hydrochloric acid, but has little or no affinity for argon).

afforestation planting of trees in areas that have not previously held forests. (Reafforestation is the planting of trees in deforested areas.) Trees may be planted (1) to provide timber and wood pulp; (2) to provide firewood in countries where this is an energy source; (3) to bind soil together and prevent soil erosion; and (4) to act as windbreaks.

Afforestation is a controversial issue because while many ancient woodlands of mixed trees are being lost, the new plantations consist almost exclusively of conifers. It is claimed that such plantations acidify the soil and conflict with the interests of biodiversity (they replace more ancient and ecologically valuable species and do not sustain wildlife).

Afghan hound breed of fast hunting dog resembling the Saluki in build, though slightly smaller.

African palm squirrel smallish rodent *Epixerus ebii* living in dense tropical rainforest in western Africa and little known, having seldom been seen alive. The species has probably always been quite scarce, but is now threatened by rainforest destruction over a large part of its range.

African violet herbaceous plant from tropical central and E Africa, with velvety green leaves and scentless purple flowers. Different colours and double-flowered varieties have been bred. (*Saintpaulia ionantha*, family Gesneriaceae.)

afterbirth in mammals, the placenta, umbilical cord, and ruptured membranes, which become detached from the uterus and expelled soon after birth.

afterburning method of increasing the thrust of a gas turbine (jet) aeroplane engine by spraying additional fuel into the hot exhaust duct between the turbojet and the tailpipe where it ignites. Used for short-term increase of power during takeoff, or during combat in military aircraft.

afterimage persistence of an image on the retina of the eye after the object producing it has been removed. This leads to persistence of vision, a necessary phenomenon for the illusion of continuous movement in films and television. The term is also used for the persistence of sensations other than vision.

after-ripening process undergone by the seeds of some plants before germination can occur. The length of the after-ripening period in different species may vary from a few weeks to many months.

It helps seeds to germinate at a time when conditions are most favourable for growth. In some cases the embryo is not fully mature at the time of dispersal and must develop further before germination can take place. Other seeds do not germinate even when the embryo is mature, probably owing to growth inhibitors within the seed that must be leached out or broken down before germination can begin.

agama small central African lizard. It lives in groups of up to 25 in tropical forest and feeds mainly on insects.

classification The agama *Agama agama* is in the Old World family Agamidae, order Squamata.

agamid lizard in the family Agamidae, containing about 300 species.

Agamids include the common agama; the Australian frilled lizard *Chlamydosaurus*, which runs on its hind legs and has a frill on each side of its neck; the thorny devil *Moloch horridus*, whose body is covered with large spikes; and the Malaysia flying dragon *Draco volans*.

classification Agamids are in family Agamidae, suborder Sauria, order Squamata, class Reptilia.

agar jellylike carbohydrate, obtained from seaweeds. It is used mainly in microbiological experiments as a culture medium for growing bacteria and other microorganisms. The agar is resistant to breakdown by microorganisms, remaining a solid jelly throughout the course of the experiment.

agaric any of a group of fungi (see *fungus*) of typical mushroom shape. Agarics include the field mushroom *Agaricus campestris* and the cultivated edible mushroom *A. brunneus*. Closely related is the often poisonous *Amanita*, which includes the fly agaric *A. muscaria*. (Genus *Agaricus*, family Agaricaceae.)

agate cryptocrystalline (with crystals too small to be seen with an optical microscope) silica, SiO₂, composed of cloudy and banded chalcedony, sometimes mixed with opal, that forms in rock cavities.

Agate stones, being hard, are also used to burnish and polish gold applied to glass and ceramics and as clean vessels for grinding rock samples in laboratories.

agave any of several related plants with stiff, sword-shaped, spiny leaves arranged in a rosette. All species come from the warmer parts of the New World. They include *Agave sisalana*, whose fibres are used for rope making, and the Mexican century plant *A. americana*, which may take many years to mature (hence its common name). Alcoholic drinks such as tequila and pulque are made from the sap of agave plants. (Genus *Agave*, family Agavaceae.)

ageing in common usage, the period of deterioration of the physical condition of a living organism that leads to death; in biological terms, the entire life process.

Three current theories attempt to account for ageing. The first suggests that the process is genetically determined, to remove individuals that can no longer reproduce. The second suggests that it is due to the accumulation of mistakes during the replication of DNA at cell division. The third suggests that it is actively induced by fragments of DNA that move between cells, or by cancer-causing viruses; these may become abundant in old cells and induce them to produce unwanted proteins or interfere with the control functions of their DNA.

agent software that mimics intelligence by automating tasks according to user-defined rules. The most visible agent on the Internet in 1995 was Firefly, which recommends music that users might like based on information they have already given about their favourite artists. Agents might also select news stories of

agama During the breeding season male agamids usually develop bright colours, especially on the head. The male of this *Agama atricollis*, a widespread species in the savannas of S and E Africa, is able to fade out his conspicuous blue hues and change to a camouflage brown coloration within a minute or two of sensing danger. Premaphotos Wildlife

agave Agaves are desert plants from the New World. They normally flower once when they reach maturity – which in some species may take as long as 60 years – and then die. Fibres such as sisal can be produced from some species, and the alcoholic drink tequila is made from others. Premaphotos Wildlife

interest, arrange scheduling with other agents, and filter out unwanted junk e-mail.

Much research on agents is proceeding at the MIT Media Lab, where Professor Pattie Maes directs the group studying the capability and potential of autonomous agents. See also crawler and bot.

Agent Orange selective weedkiller, notorious for its use in the 1960s during the Vietnam War by US forces to eliminate ground cover which could protect enemy forces. It was subsequently discovered to contain highly poisonous dioxin. Thousands of US troops who had handled it, along with many Vietnamese people who came into contact with it, later developed cancer or produced deformed babies.

Agent Orange, named after the distinctive orange stripe on its packaging, combines equal parts of 2,4-D (2,4-dichlorophenoxyacetic acid) and 2,4,5-T (2,4,5-trichlorophenoxyacetic acid), both now banned in the USA. Companies that had manufactured the chemicals faced an increasing number of lawsuits in the 1970s. All the suits were settled out of court in a single class action, resulting in the largest ever payment of its kind (\$180 million) to claimants.

age-sex graph graph of the population of an area showing age and sex distribution.

aggression in biology, behaviour used to intimidate or injure another organism (of the same or of a different species), usually for the purposes of gaining territory, a mate, or food. Aggression often involves an escalating series of threats aimed at intimidating an opponent without having to engage in potentially dangerous physical contact. Aggressive signals include roaring by red deer, snarling by dogs, the fluffing-up of feathers by birds, and the raising of fins by some species of fish.

agonist in biology, a muscle that contracts and causes a movement. Contraction of an agonist is complemented by relaxation of its antagonist. For example, the biceps (in the front of the upper arm) bends the elbow whilst the triceps (lying behind the biceps) straightens the arm.

agoraphobia phobia involving fear of open spaces and public places. The anxiety produced can be so severe that some sufferers are unable to leave their homes for many years.

Agoraphobia affects 1 person in 20 at some stage in their lives. The most common time of onset is between the ages of 18 and 28.

agouti small rodent of the genus *Dasyprocta*, family Dasyproctidae. It is found in the forests of Central and South America. The agouti is herbivorous, swift-running, and about the size of a rabbit.

AGR abbreviation for advanced gas-cooled reactor, a type of nuclear reactor.

agribusiness commercial farming on an industrial scale, often financed by companies whose main interests lie outside agriculture; for example, multinational corporations. Agribusiness farms are mechanized, large in size, highly structured, and reliant on chemicals.

agriculture Latin *ager* 'field', *colere* 'to cultivate' the practice of farming, including the cultivation of the soil (for raising crops) and the raising of domesticated animals. The units for managing agricultural production vary from smallholdings and individually owned farms to corporate-run farms and collective farms run by entire communities.

Crops are for human or animal food, or commodities such as cotton and sisal. For successful production, the land must be prepared (ploughed, cultivated, harrowed, and rolled). Seed must be planted and the growing plants nurtured. This may involve fertilizers, irrigation, pest control by chemicals, and monitoring of acidity or nutrients. When the crop has grown, it must be harvested and, depending on the crop, processed in a variety of ways before it is stored or sold.

Greenhouses allow cultivation of plants that would otherwise find the climate too harsh. Hydroponics allows commercial cultivation of crops using nutrient-enriched solutions instead of soil. Special methods, such as terracing, may be adopted to allow cultivation in hostile terrain and to retain topsoil in mountainous areas with heavy rainfall.

Animals are raised for wool, milk, leather, dung (as fuel), or meat. They may be semidomesticated, such as reindeer, or fully domesticated but nomadic (where naturally growing or cultivated food supplies are sparse), or kept in one location. Animal farming involves accommodation (buildings, fencing, or pasture), feeding, breeding, gathering the produce (eggs, milk, or wool), slaughtering, and further processing such as tanning.

agrimony herbaceous plant belonging to the rose family, with small yellow flowers on a slender spike. It grows along hedges and in fields. (*Agrimonia eupatoria*, family Rosaceae.)

agronomy study of crops and soils, a branch of agricultural science. Agronomy includes such topics as selective breeding (of plants and animals), irrigation, pest control, and soil analysis and modification.

AI abbreviation for artificial intelligence.

Aichi Japanese aircraft of World War II, principally used by the navy.

The B7A, known to the Allies as 'Grace', was a torpedo-bomber produced in small numbers. The D3A, known as 'Val', was a carrier dive bomber of great strength and efficiency; it was the principal dive bomber used at Pearl Harbor Dec 1941, and sank numerous Allied warships throughout the war. The E13A, 'Jake', was a floatplane used for reconnaissance; it was used in this role to prepare the way for the Pearl Harbor raid, and was carried by almost all Japanese warships.

AIDS acronym for *acquired immune deficiency syndrome*, the gravest of the sexually transmitted diseases, or STDs. It is caused by the human immunodeficiency virus (HIV), now known to be a retrovirus, an organism first identified in 1983. HIV is transmitted in body fluids, mainly blood and genital secretions.

diagnosis of AIDS The effect of the virus in those who become ill is the devastation of the immune system, leaving the victim sus-

AIDS AND HIV INFORMATION

<http://www.thebody.com/>

AIDS/HIV site offering safe sex and AIDS prevention advice, information about treatments and testing, and health/nutritional guidance for those who have contracted the disease.

Agriculture: chronology

| | | | |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10000–8000 BC | Holocene (post-glacial) period of hunters and gatherers. Harvesting and storage of wild grains in southwest Asia. Herding of reindeer in northern Europe. Domestic sheep in northern Iraq. | 12th–14th centuries | Expansion of European population brought more land into cultivation. Crop rotations, manuring, and new crops such as beans and peas helped increase productivity. Feudal system at its height. |
| 8000 | Neolithic revolution with cultivation of domesticated wheats and barleys, sheep, and goats in southwest Asia. Domestication of pigs in New Guinea. | 13th–14th centuries | Agricultural recession in western Europe with a series of bad harvests, famines, and pestilence. |
| 7000–6000 | Domestic goats, sheep, and cattle in Anatolia, Greece, Persia, and the Caspian basin. Planting and harvesting techniques transferred from Asia Minor to Europe. | 1347 | Black Death killed about a third of the European population. |
| 5000 | Beginning of Nile valley civilization. Millet cultivated in China. | 16th century | Decline of the feudal system in western Europe. More specialist forms of production were now possible with urban markets. Manorial estates and serfdom remained in eastern Europe. Chinese began cultivation of non-indigenous crops such as corn, sweet potatoes, potatoes, and peanuts. |
| 3400 | Flax used for textiles in Egypt. Widespread corn production in the Americas. | 17th century | Potato introduced into Europe. Norfolk crop rotation became widespread in England, involving wheat, turnips, barley and then ryegrass/clover. |
| 3200 | Records of ploughing, raking, and manuring by Egyptians. | 1700–1845 | Agricultural revolution began in England. Two million hectares of farmland in England enclosed. Removal of open fields in other parts of Europe followed. |
| c. 3100 | River Nile dammed during the rule of King Menes. | c. 1701 | Jethro Tull developed the seed drill and the horse-drawn hoe. |
| 3000 | First record of asses used as beasts of burden in Egypt. Sumerian civilization used barley as main crop with wheat, dates, flax, apples, plums, and grapes. | 1747 | First sugar extracted from sugar beet in Prussia. |
| 2900 | Domestication of pigs in eastern Asia. | 1762 | Veterinary school founded in Lyon, France. |
| 2640 | Reputed start of Chinese silk industry. | 1783 | First plough factory in England. |
| 2500 | Domestic elephants in the Indus valley. Potatoes a staple crop in Peru. | 1785 | Cast-iron ploughshare patented. |
| 2350 | Wine-making in Egypt. | 1793 | Invention of the cotton gin. |
| 2250 | First known irrigation dam. | 1800 | Early threshing machines developed in England. |
| 1600 | Important advances in the cultivation of vines and olives in Crete. | 1820s | First nitrates for fertilizer imported from South America. |
| 1500 | <i>Shadoof</i> (mechanism for raising water) used for irrigation in Egypt. | 1830 | Reaping machines developed in Scotland and the US. Steel plough made by John Deere in Illinois, US. |
| 1400 | Iron ploughshares in use in India. | 1840s | Extensive potato blight in Europe. |
| 1300 | Aqueducts and reservoirs used for irrigation in Egypt. | 1850s | Use of clay pipes for drainage well established throughout Europe. |
| 1200 | Domestic camels in Arabia. | 1862 | First steam plough used in the Netherlands. |
| 1000–500 | Evidence of crop rotation, manuring, and irrigation in India. | 1850–1890s | Major developments in transport and refrigeration technology altered the nature of agricultural markets with crops, dairy products, and wheat being shipped internationally. |
| 600 | First windmills used for corn grinding in Persia. | 1890s | Development of stationary engines for ploughing. |
| 350 | Rice cultivation well established in parts of western Africa. Hunting and gathering in the east, central, and south parts of the continent. | 1892 | First petrol-driven tractor in the USA. |
| c. 200 | Use of gears to create ox-driven water wheel for irrigation. Archimedes screw used for irrigation. | 1921 | First attempt at crop dusting with pesticides from an aeroplane near Dayton, Ohio, US. |
| 100 | Cattle-drawn iron ploughs in use in China. | 1938 | First self-propelled grain combine harvester used in the USA. |
| AD 65 | <i>De Re Rustica/On Rural Things</i> , Latin treatise on agriculture and irrigation. | 1942–62 | Huge increase in the use of pesticides, later curbed by disquiet about their effects and increasing resistance of pests to standard controls such as DDT. |
| 500 | 'Three fields in two years' rotation used in China. | 1945 | Increasing use of scientific techniques, crop specialization and larger scale of farm enterprises. |
| 630 | Cotton introduced into Arabia. | 1985 | First cases of bovine spongiform encephalopathy (BSE) recorded by UK vets. |
| 800 | Origins of the 'open field' system in northern Europe. | 1992 | Number of cases of BSE in cattle was at its peak (700 cases per week). |
| 900 | Wheeled ploughs in use in western Europe. Horse collar, originating in China, allowed horses to be used for ploughing as well as carrying. | 1995 | Increase in the use of genetic engineering with nearly 3,000 transgenic crops being field-tested. |
| 1000 | Frisians (NW Netherlands) began to build dykes and reclaim land. Chinese began to introduce Champa rice which cropped much more quickly than other varieties. | 1996 | Organic farming was on the increase in EU countries. The rise was 11% per year in Britain, 50% in Germany, and 40% in Italy. |
| 11th century | Three-field system replaced the two-field system in western Europe. Concentration on crop growing. | | |
| 1126 | First artesian wells, at Artois, France. | | |
| 12th century | Increasing use of water mills and windmills. Horses replaced oxen for pulling work in many areas. | | |

ceptible to diseases that would not otherwise develop. Diagnosis of AIDS is based on the appearance of rare tumours or opportunistic infections in unexpected candidates. *Pneumocystis carinii* pneumonia, for instance, normally seen only in the malnourished or those whose immune systems have been deliberately suppressed, is common among AIDS victims and, for them, a leading cause of death. **treatment** In the West the time-lag between infection with HIV and the development of AIDS seems to be about ten years, but progression is far more rapid in developing countries. Some AIDS victims die within a few months of the outbreak of symptoms, some survive for several years; roughly 50% are dead within three years. There is no cure for the disease and the four antivirals currently in use against AIDS have not lived up to expectations. Trials began in

1994 using a new AIDS drug called 3TC in conjunction with (zidovudine (formerly *azT*)). Although individually the drugs produce little effect, when the drugs were used together in 1995, the levels of virus in the blood were ten times lower than at the beginning of the trial. Treatment of opportunistic infections extended the average length of survival with AIDS (in Western countries) from about 11 months in 1985 to 23 months in 1994. **HIV/AIDS – worldwide statistics** Allowing for under-diagnosis, incomplete reporting, and reporting delay, and based on the available data on HIV infections around the world, it is estimated (1997) that approximately 8.4 million AIDS cases in adults and children have occurred worldwide since the pandemic began. WHO estimate that of these cases, which include active AIDS cases and people

AIDS – Recent Developments

BY PAUL MOSS

The global count of people infected with the human immunodeficiency virus (HIV) continues to increase at an alarming rate. Despite some notable successes with health education campaigns, millions are infected, with the worst infection rates being in the developing world. Nevertheless, there are signs that the enormous scientific effort that has been mobilized against the disease is now paying dividends. Current drug regimes are able to prolong life and are even allowing scientists to debate the prospect of cure.

When HIV enters the body, the main cell type infected is the CD4+ T lymphocyte, a circulating white cell that plays an important role in controlling immune responses. In addition, the virus can enter a variety of other cell types that have the CD4 molecule on their surface. The net result of infection is a relentless fall in the number of CD4+ T cells and a gradual dismantling of the immune system's ability to fight off infectious agents such as bacteria, fungi, and other viruses. This process leaves patients very susceptible to a wide variety of infections, many of which are virtually never seen in people with a normally functioning immune system. One important advance in the last few years has been the use of molecular assays to measure the amount of virus in the blood of infected patients. This procedure is valuable in predicting how rapidly they are likely to progress to an advanced state of the disease.

Early treatment

The initial successes in the drug treatment of HIV infection were with agents that could treat or prevent the infectious complications of the disease. These drugs remain very valuable but do not have any activity against HIV itself. The first drug with proven activity against HIV was zidovudine (AZT). Zidovudine resembles one of the building blocks of DNA, and when HIV undergoes replication, zidovudine can bind to an essential HIV enzyme and prevent the virus from completing its life cycle. Zidovudine can improve the symptoms of HIV infection, is valuable in asymptomatic patients with low CD4+ lymphocyte counts, and is effective at reducing the rate of transmission of HIV from pregnant women to their babies. However, when zidovudine is used alone, the virus is usually able to escape from the effects of zidovudine by mutating its DNA sequence. There is now an increasing appreciation of the need to use zidovudine in combination with some of the new antiviral drugs.

New developments

At the moment, probably the most exciting class of drugs that inhibit HIV replication is the protease inhibitors. When HIV replicates inside a cell it has to make a copy of its DNA, and then this genetic message is decoded into a protein. Some HIV proteins need to be broken down into smaller pieces in order to function, and this is done by a protease molecule. Normal function of the HIV protease appears to be vital for efficient replication of the virus, and over the last few years researchers have spent a great deal of effort in developing drugs that can block its function.

At least four protease inhibitors have been tried in clinical practice: saquinavir, ritonavir, nelfinavir, and indinavir. All have slightly different properties and different side effects. In clinical trials, these drugs have demonstrated a spectacular ability to reduce the amount of virus in the body. Sensitive molecular assays such as the polymerase chain reaction (PCR) have shown that the amount of HIV in blood can be reduced by over a thousandfold and sometimes may reach undetectable levels. Although effective on their own, most of the current drive in HIV therapeutics is to use these agents in combination with other anti-HIV agents. Typically this would include zidovudine, a protease inhibitor, and another agent such as didanosine. In a recent trial this combination led to the virus being undetectable in 60 % of patients after 24 weeks of treatment. A very encouraging observation with protease inhibitors is that they can be used at a very advanced state of the disease. It seems that the drugs should be used at quite large doses, to avoid the development of a resistant virus, and unfortunately they do have several side effects. Although most of these effects are not serious, many patients are unable to tolerate a particular drug combination; in these cases a change to another combination is indicated.

The role of combination therapy

The exact role of combination therapy in the overall management of HIV infection is a subject of considerable debate at present. In an attempt to achieve consensus, a panel of the International AIDS Society-USA met in 1996. After results from many clinical trials, the group suggested that combination therapy was now the treatment of choice. It remains unclear, however, whether or not protease inhibitors should be used with all patients or just those at particular risk of rapid progression to full-blown AIDS based on measurement of the amount of HIV in their blood. Patients with symptoms should be offered treatment, but for those who are asymptomatic the situation is less clear and the decision will be based on the CD4+ count and the viral load in the blood. There are relatively little data to recommend how to treat patients who have been infected in the last month or two and are suffering from the typical symptoms of acute infection: fever, swollen lymph nodes, and headaches. As this is a time of intense viral replication, there is a theoretical advantage in using the strongest available treatment to limit the initial multiplication of the virus. This may also reduce the chance of the virus making mutations that would allow it to resist drug treatment.

The last few years have seen valuable advances in the treatment of HIV infection. Several powerful drugs are now available and are being tested in trials around the world. The human immunodeficiency virus has an astounding ability to mutate itself in order to evade drugs, and there are likely to be setbacks ahead. It is too soon to say whether or not some patients may be offered the prospect of complete cure. Nevertheless, many AIDS researchers are hoping that they can now maintain the upper hand in the battle against this formidable virus.

who have died of AIDS, not HIV infections, more than 70% were in Africa, with about 9% in the USA, 9% in the rest of the Americas, 6% in Asia, and 4% in Europe. Of the total number of AIDS cases reported, 39% were in the USA, 34% in Africa, 20% in Asia, 12.5% in Europe, and 12% in the Americas.

Estimates released by WHO in Nov 1996 and Jan 1997 revealed that 22.6 million men, women, and children had been infected by HIV. Of these, 21.8 million were adults and 830,000 children. Approximately 42% of adult sufferers were female, with the proportion of women infected by HIV/AIDS steadily increasing. The majority of newly infected adults were under 25 years of age. WHO

estimated that by the year 2000 30–40 million people would have been infected by the virus. The United Nations AIDS programme (UNAIDS) concluded in 1997 that the world total number of HIV infections was just under 30 million.

sub-Saharan Africa The worst affected area is sub-Saharan Africa, where the United Nations AIDS programme (UNAIDS) estimated that 20 million people had been infected. About two-thirds of this total were in east and central Africa, an area that accounts for only about one-sixth of the total population of the sub-Saharan region. In Kenya, Malawi, Rwanda, Uganda, Tanzania, Zambia, and Zimbabwe, surveys showed that over 10% of women attending

antenatal clinics in urban areas were HIV-infected, with rates exceeding 40% in some surveillance sites. The number of AIDS cases in Africa has also continued to increase. An estimated 5 million people in sub-Saharan Africa have developed AIDS.

S and SE Asia The most alarming trends of HIV infection are in south and southeast Asia, where the epidemic is spreading as fast as it was a decade ago in sub-Saharan Africa. The majority of the 6 million HIV infections estimated to have occurred in adults in these regions (1997) appeared in India, Thailand, and Myanmar (Burma), but high rates of HIV spread have been seen elsewhere too.

Latin America and the Caribbean WHO estimated (1996) that about 1.6 million HIV infections had occurred in Latin America and the Caribbean since the epidemic began. In these regions epidemics are increasingly occurring among women and adolescents. The future course of the epidemic in the region depends greatly on the rate at which the virus spreads in Brazil, which has more AIDS cases than any other country outside Africa and the USA.

Middle East and north Africa About 200,000 HIV infections were estimated to have occurred so far in the Middle East and north Africa (1996). These figures are of particular concern because other factors – the presence of other sexually transmitted diseases and intravenous drug use, for example – suggest that there is an increased exposure to the risk of HIV infection.

E Europe and central Asia It was estimated (1996) that over 50,000 adults in eastern Europe and central Asia had been infected with HIV. HIV is spreading in these regions – sometimes quite rapidly – to communities and countries that were hardly affected by the epidemic only a few years ago. Ukraine recently reported a substantial increase in newly infected drug users in cities bordering the Black Sea. The Russian Federation may experience a similar progression. **North America** In 1993 AIDS for the first time became the USA's leading cause of death among all people aged between 25 and 44. By Nov 1996, 565,097 cumulative AIDS cases had been reported in the USA. However, in 1996 the AIDS death rate in the USA fell from 15.6 per 100,000 people to 11.6 (26%, which was the first decline in the 15 years since the pandemic had begun. In 1996 AIDS was no longer the main killer of adults between the ages of 25 to 44 but it remained so for African Americans in that age group. Although the overall number of new HIV infections in the USA has decreased, results from several studies suggest that the HIV epidemic has now spread to a new generation of homosexual and bisexual men. In Jan 1997, AIDS experts reported a 30% drop in AIDS deaths in New York. The actual count fell from 7,046 to 4,944. The researchers said this was as a result of improved treatments and better access to care. An estimated 860,000 adults in North America were living with HIV infection at the end of 1997.

W Europe The United Nations AIDS programme (UNAIDS) estimated in 1997 that 150,000 HIV infections had occurred in western Europe. As of mid-1996, 167,021 AIDS cases had been reported throughout the European Union (EU). The highest rate of reported AIDS cases within the EU was in Spain. Information from the UK indicates that the declining trend in male-to-male transmission observed in the late 1980s may have begun to reverse as early as 1990.

E Asia and the Pacific WHO estimated that by the end of 1996 over 113,000 HIV infections had occurred in east Asia and the Pacific. An estimated 15,100 AIDS cases had occurred in these regions, 11,700 of these in Australia and New Zealand. There was evidence that HIV infection rates had reached a plateau in Australia and were declining in New Zealand. However, an HIV epidemic recently developed in Papua New Guinea. By the end of 1994, this island of about 4 million people had an estimated 4,000 adults living with HIV, overtaking Australia as the country with the highest number of HIV cases per head of population in the Pacific region.

The cumulative direct and indirect costs of HIV and AIDS in the 1980s have been conservatively estimated at \$240 billion. The global cost – direct and indirect – of HIV and AIDS by the year 2000 could be as high as \$500 billion a year – equivalent to more than 2% of global GDP.

ailanthus any of several trees or shrubs with compound leaves made up of pointed leaflets and clusters of small greenish flowers with an unpleasant smell. The tree of heaven (*Ailanthus altissima*),

native to E Asia, is grown worldwide as an ornamental; it can grow to 30 m/100 ft in height and the trunk can reach 1 m/3 ft in diameter. (Genus *Ailanthus*, family Simaroubaceae.)

air the mixture of gases making up the Earth's atmosphere.

airbrush small fine spray-gun used by artists, graphic designers, and photographic retouchers. Driven by air pressure from a compressor or pressurized can, it can apply a thin, very even layer of ink or paint, allowing for subtle gradations of tone.

air conditioning system that controls the state of the air inside a building or vehicle. A complete air-conditioning unit controls the temperature and humidity of the air, removes dust and odours from it, and circulates it by means of a fan. US inventor Willis Haviland Carrier (1876–1950) developed the first effective air-conditioning unit in 1902 for a New York printing plant.

The air in an air conditioner is cooled by a type of refrigeration unit comprising a compressor and a condenser. The air is cleaned by means of filters and activated charcoal. Moisture is extracted by condensation on cool metal plates. The air can also be heated by electrical wires or, in large systems, pipes carrying hot water or steam; and cool, dry air may be humidified by circulating it over pans of water or through a water spray.

The first air conditioners were used in 19th century textile mills, where a fine water spray was used to cool and humidify the atmosphere.

A specialized air-conditioning system is installed in spacecraft as part of the life-support system. This includes the provision of oxygen to breathe and the removal of exhaled carbon dioxide.

Outdoor spaces may also be cooled using overhead cool air jets.

aircraft any aeronautical vehicle capable of flying through the air. It may be lighter than air (supported by buoyancy) or heavier than air (supported by the dynamic action of air on its surfaces). Balloons and airships are lighter-than-air craft. Heavier-than-air craft include the aeroplane, glider, autogiro, and helicopter.

air-cushion vehicle (ACV) craft that is supported by a layer, or cushion, of high-pressure air. The hovercraft is one form of ACV.

Airedale terrier breed of large terrier, about 60 cm/24 in tall, with a wiry reddish-brown coat and black saddle patch. It originated about 1850 in England, as a cross between the otterhound and Irish and Welsh terriers.

airlock airtight chamber that allows people to pass between areas of different pressure; also an air bubble in a pipe that impedes fluid flow. An airlock may connect an environment at ordinary pressure and an environment that has high air pressure (such as a submerged caisson used for tunnelling or building dams or bridge foundations).

An airlock may also permit someone wearing breathing apparatus to pass into an airless environment (into water from a submerged submarine or into the vacuum of space from a spacecraft).

air passages in biology, the nose, pharynx, larynx, trachea, and bronchi. When a breath is taken, air passes through high narrow passages on each side of the nose where it is warmed and moistened and particles of dust are removed. Food and air passages meet and cross in the pharynx. The larynx lies in front of the lower part of the pharynx and it is the organ where the voice is produced using the vocal cords. The air passes the glottis (the opening between the vocal cords) and enters the trachea. The trachea leads into the chest and divides above the heart into two bronchi. The bronchi carry the air to the lungs and they subdivide to form a succession of fine tubes and, eventually, a network of capillaries that allow the exchange of gases between the inspired air and the blood.

air pollution contamination of the atmosphere caused by the discharge, accidental or deliberate, of a wide range of toxic airborne substances. Often the amount of the released substance is relatively high in a certain locality, so the harmful effects become more noticeable. The cost of preventing any discharge of pollutants into the air is prohibitive, so attempts are more usually made to reduce the amount of discharge gradually and to disperse it as quickly as possible by using a very tall chimney, or by intermittent release.

Possibly the world's worst ever human-made air pollution disas-

Air pollution: major pollutants

| pollutant | sources | effects |
|----------------------------------------|------------------------------------------------------------------------|---------------------------------------------------------------------|
| sulphur dioxide SO ₂ | oil, coal combustion in power stations | acid rain formed, which damages plants, trees, buildings, and lakes |
| oxides of nitrogen NO, NO ₂ | high-temperature combustion in cars, and to some extent power stations | acid rain formed |
| lead compounds | from leaded petrol used by cars | nerve poison |
| carbon dioxide CO ₂ | oil, coal, petrol, diesel combustion | greenhouse effect |
| carbon monoxide CO | limited combustion of oil, coal, petrol, diesel fuels | poisonous, leads to photochemical smog in some areas |
| nuclear waste | nuclear power plants, nuclear weapon testing, war | radioactivity, contamination of locality, cancers, mutations, death |

ter occurred in Indonesia in September 1997. It was caused by forest clearance fires. Smoke pollution in the city of Palangkaraya reached 7.5 mg per cu m (nearly 3 mg more than in the London smog of 1952 in which 4,000 people died). The pollutants spread to Malaysia and other countries of the region.

The 1997 Kyoto protocol commits the industrialized nations of the world to cutting their levels of harmful gas emissions to 5.2% by 2012. Europe is expected to take the biggest cut of 8%, the USA 7%, and Japan 6%. The agreement covers Russia and Eastern Europe as well.

AIR POLLUTION – COMMITTEE ON THE MEDICAL ASPECTS OF AIR POLLUTANTS

<http://www.open.gov.uk/doh/hef/airpol/airpolh.htm>

Comprehensive report on the state of Britain's air from the Ministry of Health. There is a large amount of textual and statistical information on all aspects of air pollution, description of improved warning and detection measures, and details of how the general public may access advice and information.

air sac in birds, a thin-walled extension of the lungs. There are nine of these and they extend into the abdomen and bones, effectively increasing lung capacity. In mammals, it is another name for the alveoli in the lungs, and in some insects, for widenings of the trachea.

The sacs subdivide into further air spaces which partially replace the marrow in many of the bird's bones. The air space in these bones assists flight by making them lighter.

airship or **dirigible** any aircraft that is lighter than air and powered, consisting of an ellipsoidal balloon that forms the streamlined envelope or hull and has below it the propulsion system (propellers), steering mechanism, and space for crew, passengers, and/or cargo. The balloon section is filled with lighter-than-air gas, either the nonflammable helium or, before helium was industrially available in large enough quantities, the easily ignited and flammable hydrogen. The envelope's form is maintained by internal pressure in the nonrigid (blimp) and semirigid (in which the nose and tail sections have a metal framework connected by a rigid keel) types. The rigid type (zeppelin) maintains its form using an internal metal framework. Airships have been used for luxury travel, polar exploration, warfare, and advertising.

AIRSHIP AND BLIMP RESOURCES

<http://www.hotairship.com/index.html>

Information about airships – with the main focus on contemporary development. This site includes sections such as 'hot news', 'manufacturer database', 'homebuilding', and 'museums'.

Rigid airships predominated from about 1900 until 1940. As the technology developed, the size of the envelope was increased from about 45 m/150 ft to more than 245 m/800 ft for the last two zeppelins built. In 1852 the first successful airship was designed and flown by Henri Giffard of France. In 1900 the first rigid type was designed by Count (Graf) Ferdinand von Zeppelin of Germany (though he did not produce a successful model till his L-24 in 1908). Airships were used by both sides during World War I, but they were not seriously used for military purposes after that as they were largely replaced by aeroplanes. The British mainly used small machines for naval reconnaissance and patrolling the North Sea. Germany used Schütte-Lanz and Zeppelin machines for similar patrol work and also for long-range bombing attacks against English and French cities, mainly Paris and London.

air transport means of conveying goods or passengers by air from one place to another. See flight.

ajolote Mexican reptile of the genus *Bipes*. It and several other partial burrowing species are placed in the Amphisbaenia, a group separate from lizards and snakes among the Squamata. Unlike the others, however, which have no legs, it has a pair of short but well-developed front legs. In line with its burrowing habits, the skull is very solid, the eyes small, and external ears absent.

The scales are arranged in rings, giving the body a wormlike appearance.

AKITA

<http://club.infocom.net/~akita/index.html>

Profile of the Akita from the American Kennel Club. There is a history of the breed, description of the ideal breed standard, a note on the dog's temperament, and some quirky facts about the breed. There is also a high resolution photo of this large and powerful dog.

Akita breed of guard dog from the prefecture of Akita in NW Japan. It is strongly built and stands about 69 cm/27 in tall. It has small, pointed ears, a thick coat, which may be beige, grey, brindle or black, and carries its tail curled over its back.

alabaster naturally occurring fine-grained white or light-coloured translucent form of gypsum, often streaked or mottled. A soft material, it is easily carved, but seldom used for outdoor sculpture.

Alamogordo town in New Mexico, USA, associated with nuclear testing. The first atom bomb was exploded nearby at Trinity Site 16 July 1945.

It is now a test site for guided missiles.

Alaskan malamute breed of dog. It is a type of husky.

albacore name loosely applied to several species of fish found in warm regions of the Atlantic and Pacific oceans, in particular to a large tuna, *Thunnus alalunga*, and to several other species of the mackerel family.

albatross large seabird, genus *Diomedea*, with long narrow wings adapted for gliding and a wingspan of up to 3 m/10 ft, mainly found in the southern hemisphere. It belongs to the family Diomedidae, order Procellariiformes, the same group as petrels and shearwaters. The external nostrils of birds in this order are more or less tubular, and the bills are hooked.

Albatrosses feed mainly on squid and fish, and nest on remote oceanic islands. Albatrosses can cover enormous distances, flying as far as 16,100 km/10,000 mi in 33 days, or up to 640 km/600 mi in one day. They continue flying even after dark, at speeds of up to 53.5 kph/50 mph, though they may stop for an hour's rest and to feed during the night. They are sometimes called 'gooney birds', probably because of their clumsy way of landing. Albatrosses are becoming increasingly rare, and are in danger of extinction. In the southern hemisphere, more than 40,000 albatrosses drown each year as a result of catching squid attached to bait lines.

The Diomedidae family contains 14 species of albatross found in the Southern Atlantic and the Pacific oceans. The wandering albatross *D. exulans*, which has a wingspan of up to 3.4 m/11 ft, is the largest oceanic bird and can live for up to 80 years. Its huge wingspan means that it has difficulty in taking off unless there are strong winds. For this reason it nests on cliffs on islands. A single white egg is laid. The chick's full weight is 12 kg/26 lb, heavier than the parents, which typically weigh around 9 kg/20 lb. The chick needs this extra body weight to survive the Antarctic winter; the parents only return to the chick if and when they can find food for it.

albedo the fraction of the incoming light reflected by a body such as a planet. A body with a high albedo, near 1, is very bright, while a body with a low albedo, near 0, is dark. The Moon has an average albedo of 0.12, Venus 0.76, Earth 0.37.

albinism rare hereditary condition in which the body has no tyrosinase, one of the enzymes that form the pigment (melanin, normally found in the skin, hair, and eyes. As a result, the hair is white and the skin and eyes are pink. The skin and eyes are abnormally sensitive to light, and vision is often impaired. The condition occurs among all human and animal groups.

albumin or **albumen** any of a group of sulphur-containing α -proteins. The best known is in the form of egg white; others occur in milk, and as a major component of serum. They are soluble in water and dilute salt solutions, and are coagulated by heat.

The presence of serum albumin in the urine, termed albuminuria or proteinuria, may be indicative of kidney or heart disease.

Alcan Canadian aluminium-producing company. Alcan Aluminium was founded in Montréal 1928 as the Canadian subsidiary of Alcoa, the US aluminium company founded in Pittsburgh, Pennsylvania, 1888. Alcan became independent from Alcoa 1945 and is the fifth largest company in Canada today, second in the world in aluminium production only to Alcoa.

ALCHEMICAL SUBSTANCES

<http://www.levity.com/alchemy/substanc.html>

Modern explanations of the lyrical names alchemists gave to their substances. Part of the huge Virtual Alchemy Library Web site this section is slightly disorganized, not being listed in alphabetical or any other particular order. Some of the exotic substances described include the bizarrely named 'Thion hudor' and the rather poetic 'Purple of Cassius'.

alchemy *Arabic al-Kimyā* supposed technique of transmuting base metals, such as lead and mercury, into silver and gold by the philosopher's stone, a hypothetical substance, to which was also attributed the power to give eternal life.

This aspect of alchemy constituted much of the chemistry of the Middle Ages. More broadly, however, alchemy was a system of philosophy that dealt both with the mystery of life and the formation of inanimate substances. Alchemy was a complex and indefinite conglomeration of chemistry, astrology, occultism, and magic, blended with obscure and abstruse ideas derived from various religious systems and other sources. It was practised in Europe from ancient times to the Middle Ages but later fell into disrepute when chemistry and physics developed.

What is accomplished with fire is alchemy, whether in the furnace or the kitchen stove.

PARACELSUS Swiss physician, alchemist, and scientist.
In J Bronowski *The Ascent of Man* 1975

alcohol any member of a group of organic compounds characterized by the presence of one or more aliphatic OH (hydroxyl) groups

| Alkane | Alcohol | Aldehyde | Ketone | Carboxylic acid | Alkene |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| CH ₄ methane | CH ₃ OH methanol | HCHO methanal | — | HCO ₂ H methanoic acid | — |
| CH ₃ CH ₃ ethane | CH ₃ CH ₂ OH ethanol | CH ₃ CHO ethanal | — | CH ₃ CO ₂ H ethanoic acid | CH ₂ CH ₂ ethene |
| CH ₃ CH ₂ CH ₃ propane | CH ₃ CH ₂ CH ₂ OH propanol | CH ₃ CH ₂ CHO propanal | CH ₃ COCH ₃ propanone | CH ₃ CH ₂ CO ₂ H propanoic acid | CH ₂ CHCH ₃ propene |
|  |  |  |  |  |  |
| methane | methanol | methanal | propanone | methanoic acid | ethene |

in the molecule, and which form esters with acids. The main uses of alcohols are as solvents for gums, resins, lacquers, and varnishes; in the making of dyes; for essential oils in perfumery; and for medical substances in pharmacy. The alcohol produced naturally in the fermentation process and consumed as part of alcoholic beverages is called ethanol.

Alcohols may be liquids or solids, according to the size and complexity of the molecule. The five simplest alcohols form a series in which the number of carbon and hydrogen atoms increases progressively, each one having an extra CH_2 (methylene) group in the molecule: methanol or wood spirit (methyl alcohol, CH_3OH); ethanol (ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$); propanol (propyl alcohol, $\text{C}_3\text{H}_7\text{OH}$); butanol (butyl alcohol, $\text{C}_4\text{H}_9\text{OH}$); and pentanol (amyl alcohol, $\text{C}_5\text{H}_{11}\text{OH}$). The lower alcohols are liquids that mix with water; the higher alcohols, such as pentanol, are oily liquids immiscible with water; and the highest are waxy solids – for example, hexadecanol (cetyl alcohol, $\text{C}_{16}\text{H}_{33}\text{OH}$) and melissyl alcohol ($\text{C}_{30}\text{H}_{61}\text{OH}$), which occur in sperm-whale oil and beeswax respectively. Alcohols containing the CH_2OH group are primary; those containing CHOH are secondary; while those containing COH are tertiary.

alcoholic solution solution produced when a solute is dissolved in ethanol.

alcoholism dependence on alcohol. It is characterized as an illness when consumption of alcohol interferes with normal physical or emotional health. Excessive alcohol consumption, whether through sustained ingestion or irregular drinking bouts or binges, may produce physical and psychological addiction and lead to nutritional and emotional disorders. Long-term heavy consumption of alcohol leads to diseases of the heart, liver, and peripheral nerves. Support groups such as Alcoholics Anonymous are helpful.

Aldebaran or **Alpha Tauri** brightest star in the constellation Taurus and the 14th brightest star in the sky; it marks the eye of the 'bull'. Aldebaran is a red giant 60 light years away, shining with a true luminosity of about 100 times that of the Sun.

aldehyde any of a group of organic chemical compounds prepared by oxidation of primary alcohols, so that the OH (hydroxyl) group loses its hydrogen to give an oxygen joined by a double bond to a carbon atom (the aldehyde group, with the formula CHO).

alder any of a group of trees or shrubs belonging to the birch family, found mainly in cooler parts of the northern hemisphere and characterized by toothed leaves and catkins. (Genus *Alnus*, family Betulaceae.)

alewife fish *Alosa pseudoharengus* of the herring group, up to 30 cm/1 ft long, found in the NW Atlantic and in the Great Lakes of North America.

alexanders strong-smelling tall herbaceous plant belonging to the carrot family. It is found along hedgerows and on cliffs throughout S Europe. Its yellow flowers appear in spring and early summer. (*Smyrniolus astrum*, family Umbelliferae.)

Alexander technique in alternative medicine, a method of correcting bad habits of posture, breathing, and muscular tension, which Australian therapist P M Alexander maintained caused many ailments. The technique is also used to promote general health and relaxation and enhance vitality.

Back troubles, migraine, asthma, hypertension, and some gastric and gynaecological disorders are among the conditions said to be alleviated by the technique, which is also said to be effective in the prevention of disorders, particularly those of later life.

alfalfa or **lucerne** perennial tall herbaceous plant belonging to the pea family. It is native to Europe and Asia and has spikes of small purple flowers in late summer. It is now a major fodder crop, commonly processed into hay, meal, or silage. Alfalfa sprouts, the sprouted seeds, have become a popular salad ingredient. (*Medicago sativa*, family Leguminosae.)

algae (singular *alga*) highly varied group of plants, ranging from single-celled forms to large and complex seaweeds. They live in both fresh and salt water, and in damp soil. Algae do not have true roots, stems, or leaves.

Marine algae help combat global warming by removing carbon dioxide from the atmosphere during photosynthesis.

Alembert, Jean le Rond d' (1717–1783)

French mathematician, encyclopedist, and theoretical physicist. In association with Denis Diderot, he helped plan the great *Encyclopédie*, for which he also wrote the 'Discours préliminaire' 1751. He framed several theorems and principles – notably d'Alembert's principle – in dynamics and celestial mechanics, and devised the theory of partial differential equations.

The principle that now bears his name was first published in his *Traité de dynamique* 1743, and was an extension of the third of Isaac Newton's laws of motion. D'Alembert maintained that the

law was valid not merely for a static body, but also for mobile bodies. Within a year he had found a means of applying the principle to the theory of equilibrium and the motion of fluids. Using also the theory of partial differential equations, he studied the properties of sound, and air compression, and also managed to relate his principle to an investigation of the motion of any body in a given figure.

Mary Evans Picture Library

algebra branch of mathematics in which the general properties of numbers are studied by using symbols, usually letters, to represent variables and unknown quantities. For example, the algebraic statement $(x + y)^2 = x^2 + 2xy + y^2$ is true for all values of x and y . If $x = 7$ and $y = 3$, for instance:

$$(7 + 3)^2 = 7^2 + 2(7 \times 3) + 3^2 = 100$$

An algebraic expression that has one or more variables (denoted by letters) is a polynomial equation. Algebra is used in many areas of mathematics – for example, matrix algebra and Boolean algebra (the latter is used in working out the logic for computers).

In ordinary algebra the same operations are carried on as in arithmetic, but, as the symbols are capable of a more generalized and extended meaning than the figures used in arithmetic, it facilitates calculation where the numerical values are not known, or are inconveniently large or small, or where it is desirable to keep them in an analysed form.

Within an algebraic equation the separate calculations involved must be completed in a set order. Any elements in brackets should always be calculated first, followed by multiplication, division, addition, and subtraction.

quadratic equation This is a polynomial equation of second degree (that is, an equation containing as its highest power the square of a variable, such as x^2). The general formula of such equations is $ax^2 + bx + c = 0$, in which a , b , and c are real numbers, and only the coefficient a cannot equal 0.

Some quadratic equations can be solved by factorization, or the values of x can be found by using the formula for the general solution

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Depending on the value of the discriminant $b^2 - 4ac$, a quadratic equation has two real, two equal, or two complex roots (solutions). When $b^2 - 4ac > 0$ there are two distinct real roots. When $b^2 - 4ac = 0$ there are two equal real roots. When $b^2 - 4ac < 0$ there are two distinct complex roots.

simultaneous equations If there are two or more algebraic equations that contain two or more unknown quantities that may have

To remember the order of operations in complex algebraic or numerical expression:

BLESS MY DEAR **A**UNT **S**ALLY!

BRACKETS, **M**ULTIPLY, **D**IVIDE, **A**DD, **S**UBTRACT

a unique solution they can be solved simultaneously. For example, in the case of two linear equations with two unknown variables, such as:

$$(i) x + 3y = 6 \text{ and } (ii) 3y - 2x = 4$$

the solution will be those unique values of x and y that are valid for both equations. Linear simultaneous equations can be solved by using algebraic manipulation to eliminate one of the variables. For example, both sides of equation (i) could be multiplied by 2, which gives $2x + 6y = 12$. This can be added to equation (ii) to get $9y = 16$, which is easily solved: $y = \frac{16}{9}$. The variable x can now be found by inserting the known y value into either original equation and solving for x .

'Algebra' was originally the name given to the study of equations. In the 9th century, the Arab mathematician Muhammad ibn-Mūsā al-Khwārizmī used the term *al-jabr* for the process of adding equal quantities to both sides of an equation. When his treatise was later translated into Latin, *al-jabr* became 'algebra' and the word was adopted as the name for the whole subject.

algebraic fraction fraction in which letters are used to represent numbers – for example, $\frac{a}{b}$, $\frac{x^2}{y}$, and $\frac{1}{x+y}$. Like numerical fractions, algebraic fractions may be simplified or factorized. Two equivalent algebraic fractions can be cross-multiplied; for example, if $\frac{a}{b} = \frac{c}{d}$ then $ad = bc$.

In the same way, the two equivalent numerical fractions $\frac{2}{3}$ and $\frac{4}{6}$ can be cross-multiplied to give cross-products that are both 12.)

alginate salt of alginic acid, $(C_6H_7O_6)_n$, obtained from brown seaweeds and used in textiles, paper, food products, and pharmaceuticals.

ALGOL (acronym for *algorithmic language*) in computing, an early high-level programming language, developed in the 1950s and 1960s for scientific applications. A general-purpose language, ALGOL is best suited to mathematical work and has an algebraic style. Although no longer in common use, it has greatly influenced more recent languages, such as Ada and PASCAL.

Algol or **Beta Persei** (eclipsing binary, a pair of orbiting stars in the constellation Perseus, one of which eclipses the other every 69 hours, causing its brightness to drop by two-thirds.

The brightness changes were first explained in 1782 by English amateur astronomer John Goodricke (1764–1786). He pointed out that the changes between magnitudes 2.2 and 3.5 repeated themselves exactly after an interval of 2.867 days and supposed this to be due to two stars orbiting round and eclipsing each other.

Algonquin Radio Observatory site in Ontario, Canada, of the radio telescope, 46 m/150 ft in diameter, of the National Research Council of Canada, opened 1966.

algorithm procedure or series of steps that can be used to solve a problem.

In computer science, it describes the logical sequence of operations to be performed by a program. A flow chart is a visual representation of an algorithm.

The word derives from the name of 9th-century Arab mathematician Muhammad ibn-Mūsā al-Khwārizmī.

alias name representing a particular user or group of users in e-mail systems. This feature, which is not available on all systems, is a matter of convenience as it allows a user to substitute shorter or easier-to-remember real names for e-mail addresses. In 1995 CompuServe announced a system of named aliases for its long, numbered addresses.

aliasing or **jaggies** effect seen on computer screen or printer output, when smooth curves appear to be made up of steps because the resolution is not high enough. The steps are caused by clumps of pixels that become visible when the monitor's definition is lower than that of the image that it is trying to show. Anti-aliasing is a software technique that reduces this effect by using intermediate shades of colour to create an apparently smoother curve.

Alife in computing, contraction of artificial life.

alimentary canal in animals, the tube through which food passes; it extends from the mouth to the anus. It is a complex organ, adapted for digestion. In human adults, it is about 9 m/30 ft long, consisting of the mouth cavity, pharynx, oesophagus, stomach, and the small and large intestines.

A constant stream of enzymes from the canal wall and from the pancreas assists the breakdown of food molecules into smaller, soluble nutrient molecules, which are absorbed through the canal wall into the bloodstream and carried to individual cells. The muscles of the alimentary canal keep the incoming food moving, mix it with the enzymes and other juices, and slowly push it in the direction of the anus, a process known as peristalsis. The wall of the canal receives an excellent supply of blood and is folded so as to increase its surface area. These two adaptations ensure efficient absorption of nutrient molecules.

aliphatic compound any organic chemical compound in which the carbon atoms are joined in straight chains, as in hexane (C_6H_{14}), or in branched chains, as in 2-methylpentane ($CH_3CH(CH_3)CH_2CH_2CH_3$).

Aliphatic compounds have bonding electrons localized within the vicinity of the bonded atoms. Cyclic compounds that do not have delocalized electrons are also aliphatic, as in the alicyclic compound cyclohexane (C_6H_{12}) or the heterocyclic piperidine (C_4H_9N). Compare aromatic compound.

alkali in chemistry, a compound classed as a base that is soluble in water. Alkalis neutralize acids and are soapy to the touch.

The hydroxides of metals are alkalis; those of sodium and potassium being chemically powerful; both were historically derived from the ashes of plants.

The four main alkalis are sodium hydroxide (caustic soda, NaOH); potassium hydroxide (caustic potash, KOH); calcium hydroxide (slaked lime or limewater, $Ca(OH)_2$); and aqueous ammonia ($NH_3(aq)$). Their solutions all contain the hydroxide ion OH^- , which gives them a characteristic set of properties.

Alkalis react with acids to form a salt and water (neutralization).

They give a specific colour reaction with indicators; for example, litmus turns blue.

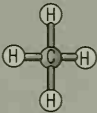

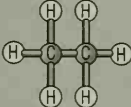

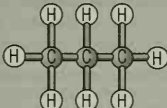

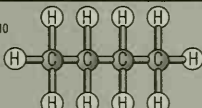

alkali metal any of a group of six metallic elements with similar chemical properties: lithium, sodium, potassium, rubidium, caesium, and francium. They form a linked group (Group One) in the periodic table of the elements. They are univalent (have a valency of one) and of very low density (lithium, sodium, and potassium float on water); in general they are reactive, soft, low-melting-point metals. Because of their reactivity they are only found as compounds in nature.

alkaline-earth metal any of a group of six metallic elements with similar bonding properties: beryllium, magnesium, calcium, strontium, barium, and radium. They form a linked group in the periodic table of the elements. They are strongly basic, bivalent (have a valency of two), and occur in nature only in compounds.

alkaloid any of a number of physiologically active and frequently poisonous substances contained in some plants. They are usually organic bases and contain nitrogen. They form salts with acids and, when soluble, give alkaline solutions.

Substances in this group are included by custom rather than by scientific rules. Examples include morphine, cocaine, quinine, caffeine, strychnine, nicotine, and atropine.

In 1992, epibatidine, a chemical extracted from the skin of an Ecuadorian frog, was identified as a member of an entirely new

| Name | Molecular formula | Structural formula |
|-----------------------------------------------|---------------------------|-----------------------------------------------------------------------------------|
| methane | CH_4 |  |
| uses: domestic fuel (natural gas) | | |
| ethane | C_2H_6 |  |
| uses: industrial fuel and chemical feedstock | | |
| propane | C_3H_8 |  |

| butane | C_4H_{10} |  |
| uses: bottled gas (lighter fuel, camping gas) | | |

alkane The lighter alkanes methane, ethane, propane, and butane, showing the aliphatic chains. A hydrogen atom bonds to a carbon atom at all available sites.

class of alkaloid. It is an organochlorine compound, which is rarely found in animals, and a powerful painkiller, about 200 times as effective as morphine.

alkane member of a group of hydrocarbons having the general formula $\text{C}_n\text{H}_{2n+2}$, commonly known as paraffins. As they contain only single covalent bonds, alkanes are said to be saturated. Lighter alkanes, such as methane, ethane, propane, and butane, are colourless gases; heavier ones are liquids or solids. In nature they are found in natural gas and petroleum.

alkene member of the group of hydrocarbons having the general formula C_nH_{2n} , formerly known as olefins. Alkenes are unsaturated compounds, characterized by one or more double bonds between adjacent carbon atoms. Lighter alkenes, such as ethene and propene, are gases, obtained from the cracking of oil fractions. Alkenes react by addition, and many useful compounds, such as poly(ethene) and bromoethane, are made from them.

alkyne member of the group of hydrocarbons with the general formula $\text{C}_n\text{H}_{2n-2}$, formerly known as the acetylenes. They are unsaturated compounds, characterized by one or more triple bonds between adjacent carbon atoms. Lighter alkynes, such as ethyne, are gases; heavier ones are liquids or solids.

allele one of two or more alternative forms of a gene at a given position (locus) on a chromosome, caused by a difference in the DNA. Blue and brown eyes in humans are determined by different alleles of the gene for eye colour.

Organisms with two sets of chromosomes (diploids) will have two copies of each gene. If the two alleles are identical the individual is said to be homozygous at that locus; if different, the individual is heterozygous at that locus. Some alleles show dominance over others.

ALLERGY FACTS

<http://www.sig.net/~allergy/facts.html>

Extended fact sheet about allergies. It provides basic information about the causes, symptoms, and treatment of allergy attacks, and helps clarify typical misunderstandings about allergy sufferers. It also provides tips for the everyday life of an allergy sufferer and an extended list of allergy symptoms.

allergy special sensitivity of the body that makes it react with an exaggerated response of the natural immune defence mechanism to the introduction of an otherwise harmless foreign substance (allergen).

alligator Spanish *el lagarto* 'the lizard' reptile of the genus *Alligator*, related to the crocodile. There are only two living species: *A. mississippiensis*, the Mississippi alligator of the southern states of the USA, and *A. sinensis* from the swamps of the lower Chang Jiang River in China. The former grows to about 4 m/12 ft, but the latter only to 1.5 m/5 ft. Alligators lay their eggs in waterside nests of mud and vegetation and are good mothers. They swim well with lashing movements of the tail and feed on fish and mammals but seldom attack people.

The skin is of value for fancy leather, and alligator farms have been established in the USA. Closely related are the caymans of South America; these belong to the genus *Caiman*. Alligators ranged across N Europe from the Upper Cretaceous to the Pliocene period.

AMERICAN ALLIGATOR

http://www.seaworld.org/animal_bytes/alligatorab.html

Illustrated guide to the American alligator including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

alligator clip small metal clip wired to other similar clips to allow temporary connections. Today's modular phone jacks generally make it easy to hook up modems and telephones. However, in some situations, such as a hotel room where a telephone is hard-wired to the wall or in a foreign country where a visitor's modem plug is incompatible with the local telephone network, the only answer is to take the phone apart and hook the modem directly to the phone line using these small clips.

allium any of a group of plants of the lily family, usually strong-smelling with a sharp taste; they form bulbs in which sugar is stored. Cultivated species include onion, garlic, chive, and leek. Some species are grown in gardens for their decorative globular heads of white, pink, or purple flowers. (Genus *Allium*, family Liliaceae.)

allometry in biology, a regular relationship between a given feature (for example, the size of an organ) and the size of the body as a whole, when this relationship is not a simple proportion of body size. Thus, an organ may increase in size proportionately faster, or slower, than body size does. For example, a human baby's head is much larger in relation to its body than is an adult's.

alloparental care in animal behaviour, the care of another animal's offspring. 'Fostering' is common in some birds, such as pigeons, and social mammals, such as meerkats. Usually both the adoptive parent and the young benefit.

allopathy Greek *allos* 'other', *pathos* 'suffering' in (homoeopathy a term used for orthodox medicine, using therapies designed to counteract the manifestations of the disease. In strict usage, allopathy is the opposite of homoeopathy).

allotropy property whereby an element can exist in two or more forms (allotropes), each possessing different physical properties but the same state of matter (gas, liquid, or solid). The allotropes of carbon are diamond and graphite. Sulphur has several allotropes (flow-ers of sulphur, plastic, rhombic, and monoclinic). These solids have different crystal structures, as do the white and grey forms of tin and the black, red, and white forms of phosphorus.

Oxygen exists as two gaseous allotropes: one used by organisms for respiration (O_2), and the other a poisonous pollutant, ozone (O_3).

alloy metal blended with some other metallic or nonmetallic substance to give it special qualities, such as resistance to corrosion, greater hardness, or tensile strength. Useful alloys include bronze, brass, cupronickel, duralumin, German silver, gunmetal, pewter, solder, steel, and stainless steel.

Among the oldest alloys is bronze (mainly an alloy of copper and tin), the widespread use of which ushered in the Bronze Age. Complex alloys are now common; for example, in dentistry, where a cheaper alternative to gold is made of chromium, cobalt, molybdenum, and titanium. Among the most recent alloys are superalloys: alloys that can stretch to double their length at specific temperatures, permitting, for example, their injection into moulds as easily as plastic.

allspice spice prepared from the dried berries of the evergreen pimento tree, also known as the West Indian pepper tree, (*Pimenta dioica*) of the myrtle family, cultivated chiefly in Jamaica. It has an aroma similar to that of a mixture of cinnamon, cloves, and nutmeg.

alluvial deposit layer of broken rocky matter, or sediment, formed from material that has been carried in suspension by a river or stream and dropped as the velocity of the current decreases. River plains and deltas are made entirely of alluvial deposits, but smaller pockets can be found in the beds of upland torrents.

Alluvial deposits can consist of a whole range of particle sizes, from boulders down through cobbles, pebbles, gravel, sand, silt, and clay. The raw materials are the rocks and soils of upland areas that are loosened by erosion and washed away by mountain streams. Much of the world's richest farmland lies on alluvial deposits. These deposits can also provide an economic source of minerals. River currents produce a sorting action, with particles of heavy material deposited first while lighter materials are washed downstream.

Hence heavy minerals such as gold and tin, present in the original rocks in small amounts, can be concentrated and deposited on stream beds in commercial quantities. Such deposits are called 'placer ores'.

Almagest Arabic *al 'the* and a corruption of the Greek *megiste* 'greatest' book compiled by the Greek astronomer Ptolemy during the 2nd century AD, which included the idea of an Earth-centred universe; it was translated into Arabic in the 9th century. Some medieval books on astronomy, astrology, and alchemy were given the same title.

Each of the 13 sections of the book deals with a different branch of astronomy. The introduction describes the universe as spherical and contains arguments for the Earth being stationary at the centre. From this mistaken assumption, it goes on to describe the motions of the Sun, Moon, and planets; eclipses; and the positions, brightness, and precession of the 'fixed stars'. The book drew on the work of earlier astronomers such as Hipparchus.

almond tree related to the peach and apricot. Dessert almonds are the kernels of the fruit of the sweet variety *Prunus amygdalus dulcis*, which is also used to produce a low-cholesterol cooking oil. Oil of bitter almonds, from the variety *P. amygdalus amara*, is used in

aloe Aloes vary in size from dwarf species, no more than a few centimetres in diameter (such as the popular houseplant *Aloe variegata*), to species as large as a small tree. This *Aloe arborescens* from South Africa is of intermediate size. In their natural habitat most aloes flower during winter. Premaphotos Wildlife

flavouring. Almond oil is also used for cosmetics, perfumes, and fine lubricants. (*Prunus amygdalus*, family Rosaceae.)

aloe one of a group of plants native to southern Africa, with long, fleshy, spiny-edged leaves. The drug usually referred to as 'bitter aloes' is a powerful purgative (agent that causes the body to expel impurities) prepared from the juice of the leaves of several of the species. (Genus *Aloe*, family Liliaceae.)

alpaca domesticated South American hoofed mammal *Lama pacos* of the camel family, found in Chile, Peru, and Bolivia, and herded at high elevations in the Andes. It is bred mainly for its long, fine, silky wool, and stands about 1 m/3 ft tall at the shoulder with neck and head another 60 cm/2 ft.

The alpaca is also used for food at the end of its fleece-producing years. Like the llama, it was probably bred from the wild guanaco and is a close relative of the vicuña.

alpha in computing, the first version of a new software program. Developing modern software requires much testing and many versions before the definitive product is achieved. The first versions of any new product are typically full of bugs, and are tested by the developers and their assistants. Later versions, known as beta versions, are given to outside users to test.

Alpha Centauri or **Rigel Kent** brightest star in the constellation Centaurus and the third-brightest star in the sky. It is actually a triple star (see binary star); the two brighter stars orbit each other every 80 years, and the third, Proxima Centauri, is the closest star to the Sun, 4.2 light years away, 0.1 light years closer than the other two.

alpha channel in 24-bit colour, a channel for controlling colour information. Describing colour for a computer display requires three channels of information per pixel, one for each of the primary colours of light: red, blue, and green. A 24-bit graphics adapter with a 32-bit bus can use the remaining 8 bits to send control information for the remaining 24 bits.

alpha decay disintegration of the nucleus of an atom to produce an alpha particle. See also radioactivity.

alphanumeric data data made up of any of the letters of the alphabet and any digit from 0 to 9. The classification of data according to the type or types of character contained enables computer validation systems to check the accuracy of data: a comput-

er can be programmed to reject entries that contain the wrong type of character. For example, a person's name would be rejected if it contained any numeric data, and a bank-account number would be rejected if it contained any alphabetic data. A car's registration number, by comparison, would be expected to contain alphanumeric data but no punctuation marks.

alpha particle positively charged, high-energy particle emitted from the nucleus of a radioactive atom. It is one of the products of the spontaneous disintegration of radioactive elements (see α -radioactivity) such as radium and thorium, and is identical with the nucleus of a helium atom – that is, it consists of two protons and two neutrons. The process of emission, **alpha decay**, transforms one element into another, decreasing the atomic (or proton) number by two and the atomic mass (or nucleon number) by four.

Because of their large mass alpha particles have a short range of only a few centimetres in air, and can be stopped by a sheet of paper. They have a strongly ionizing effect (see α -ionizing radiation) on the molecules that they strike, and are therefore capable of damaging living cells. Alpha particles travelling in a vacuum are deflected slightly by magnetic and electric fields.

Alps, Lunar conspicuous mountain range on the Moon, NE of the Sea of Showers (Mare Imbrium), cut by a valley 150 km/93 mi long. The highest peak is Mont Blanc, about 3,660 m/12,000 ft.

Alsatian another name for the ϕ German shepherd dog.

Altair or **Alpha Aquilae** brightest star in the constellation Aquila and the 12th brightest star in the sky. It is a white star 16 light years away and forms the so-called Summer Triangle with the stars Deneb (in the constellation Cygnus) and Vega (in Lyræ).

AltaVista search engine on the World Wide Web run by DEC (Digital Equipment Corporation). AltaVista runs an automated program to index all the pages it can find on the Web, enabling visitors to enter search terms such as a name or subject and quickly retrieve a list of pages to visit to look for specific information. It has a similar indexing program for UseNet.

In mid-1996 DEC claimed the service indexed 30 million pages on 275,600 servers, as well as 3 million articles from 14,000 USENET newsgroups, and was accessed over 16 million times per weekday.

alternate angles a pair of angles that lie on opposite sides and at opposite ends of a transversal (a line that cuts two or more lines in the same plane). The alternate angles formed by a transversal of two parallel lines are equal.

alternating current (AC) electric current that flows for an interval of time in one direction and then in the opposite direction, that is, a current that flows in alternately reversed directions through or around a circuit. Electric energy is usually generated as alternating current in a power station, and alternating currents may be used for both power and lighting.

The advantage of alternating current over direct current (DC), as from a battery, is that its voltage can be raised or lowered economically by a transformer: high voltage for generation and transmission, and low voltage for safe utilization. Railways, factories, and domestic appliances, for example, use alternating current.

haploid spores by ϕ meiosis, and is called the sporophyte, while the haploid generation produces gametes (sex cells), and is called the gametophyte. The gametes fuse to form a diploid ϕ zygote which develops into a new sporophyte; thus the sporophyte and gametophyte alternate.

alternative energy see ϕ energy, alternative.

alternative medicine see ϕ medicine, alternative.

alternator electrically ϕ generator that produces an alternating current.

alt hierarchy on USENET, the 'alternative' set of ϕ newsgroups, set up so that anyone can start a newsgroup on any topic. Most areas of USENET, such as the ϕ Big Seven hierarchies, allow the creation of newsgroups only after structured discussion and a vote to demonstrate that demand for the newsgroup exists. The alt hierarchy was created to allow users to bypass this process.

altimeter instrument used in aircraft that measures altitude, or height above sea level. The common type is a form of aneroid ϕ barometer, which works by sensing the differences in air pressure at different altitudes. This must continually be recalibrated because of the change in air pressure with changing weather conditions. The ϕ radar altimeter measures the height of the aircraft above the ground, measuring the time it takes for radio pulses emitted by the aircraft to be reflected. Radar altimeters are essential features of automatic and blind-landing systems.

altimetry method of measuring changes in sea level using an altimeter attached to a satellite. The altimeter measures the distance between the satellite and water surface.

alternate angles

My personal desire would be to prohibit entirely the use of alternating currents. They are unnecessary as they are dangerous ... I can therefore see no justification for the introduction of a system which has no element of permanency and every element of danger to life and property.

THOMAS ALVA EDISON US scientist and inventor.
Quoted in R L Weber, *A Random Walk in Science*

alternation of generations typical life cycle of terrestrial plants and some seaweeds, in which there are two distinct forms occurring alternately: diploid (having two sets of chromosomes) and haploid (one set of chromosomes). The diploid generation produces

where a transversal cuts through a pair of parallel lines the alternate angles a and b are equal

two altitudes of a quadrilateral

altitude The altitude of a figure is the perpendicular distance from a vertex (corner) to the base (the side opposite the vertex).

altitude or **elevation** in astronomy, the angular distance of an object above the horizon, ranging from 0° on the horizon to 90° at the zenith. Together with *azimuth*, it forms the system of horizontal coordinates for specifying the positions of celestial bodies.

altitude in geometry, the perpendicular distance from a vertex (corner) of a figure, such as a triangle, to the base (the side opposite the vertex).

altitude measurement of height, usually given in metres above sea level.

altricial animals born in a very dependent state and in need of a high degree of parental care. Examples include those mammals that are born naked and blind, such as mice and most other rodents, and most baby birds.

altruism in biology, helping another individual of the same species to reproduce more effectively, as a direct result of which the altruist may leave fewer offspring itself. Female honey bees (workers) behave altruistically by rearing sisters in order to help their mother, the queen bee, reproduce, and forgo any possibility of reproducing themselves.

ALU abbreviation for arithmetic and logic unit.

alum any double sulphate of a monovalent metal or radical (such as sodium, potassium, or ammonium) and a trivalent metal (such as aluminium, chromium, or iron). The commonest alum is the double sulphate of potassium and aluminium, $K_2Al_2(SO_4)_4 \cdot 24H_2O$, a white crystalline powder that is readily soluble in water. It is used in curing animal skins. Other alums are used in papermaking and to fix dye in the textile industry.

alumina or **corundum** Al_2O_3 oxide of aluminium, widely distributed in clays, slates, and shales. It is formed by the decomposition of the feldspars in granite and used as an abrasive. Typically it is a white powder, soluble in most strong acids or caustic alkalis but not in water. Impure alumina is called 'emery'. Rubies, sapphires, and topaz are corundum gemstones.

aluminium lightweight, silver-white, ductile and malleable, metallic element, symbol Al, atomic number 13, relative atomic mass 26.9815, melting point 658°C. It is the third most abundant element (and the most abundant metal) in the Earth's crust, of which it makes up about 8.1% by mass. It is non-magnetic, an excellent conductor of electricity, and oxidizes easily, the layer of oxide on its surface making it highly resistant to tarnish. In the USA the original name suggested by the scientist Humphry Davy, 'aluminium', is retained.

pure aluminium Aluminium is a reactive element with stable compounds, so a great deal of energy is needed in order to separate aluminium from its ores, and the pure metal was not readily obtainable until the middle of the 19th century. Commercially, it is prepared by the electrolysis of alumina (aluminium oxide), which is obtained from the ore *bauxite*. In its pure state aluminium is a weak metal, but when combined with elements such as copper, silicon, or magnesium it forms alloys of great strength.

uses Aluminium is widely used in the shipbuilding and aircraft industries because of its light weight (relative density 2.70). It is also used in making cooking utensils, cans for beer and soft drinks, and foil. It is much used in steel-cored overhead cables and for canning uranium slugs for nuclear reactors. Aluminium is an essential constituent in some magnetic materials; and, as a good conductor of electricity, is used as foil in electrical capacitors. A plastic form of aluminium, developed 1976, which moulds to any shape and extends to several times its original length, has uses in electronics, cars, and building construction.

aluminium chloride $AlCl_3$ white solid made by direct combination of aluminium and chlorine.

The anhydrous form is a typical covalent compound.

aluminium hydroxide or **alumina cream** $Al(OH)_3$ gelatinous precipitate formed when a small amount of alkali solution is added to a solution of an aluminium salt.

It is an amphoteric compound as it readily reacts with both acids and alkalis.

aluminium oxide or **alumina** Al_2O_3 white solid formed by heating aluminium hydroxide. It is an amphoteric oxide, since it reacts readily with both acids and alkalis, and it is used as a refractory (furnace lining) and in column chromatography.

alveolus (plural *alveoli*) one of the many thousands of tiny air sacs in the lungs in which exchange of oxygen and carbon dioxide takes place between air and the bloodstream.

Alzheimer's disease common manifestation of dementia, thought to afflict one in 20 people over 65. After heart disease, cancer, and strokes it is the most common cause of death in the Western world. Attacking the brain's 'grey matter', it is a disease of mental processes rather than physical function, characterized by memory loss and progressive intellectual impairment. It was first

ALZHEIMER'S DISEASE WEB PAGE

Although some of the pages on this site are aimed at the local community, there is much to interest those further afield - with information for families, caregivers, and investigators.

The Ageing Brain and Alzheimer's Disease

BY A D SMITH

*"Omnia fert aetas, animum quoque; saepe ego longas cantando
puerum meminisse condere soles: nunc oblita mihi tot carmina..."*

*"Time wastes all things, the mind too; often I remember how in
boyhood I outwore long sunlit days in singing: now I have forgotten so
many a song..."*

(Virgil, 'Eclogue IX', translation by Mackail)

Was Virgil right? Is it really true that dementia, a decline in our mental and cognitive functions illustrated here by a declining memory, is an inevitable part of ageing? If so, then we will be facing a very serious problem in the next 30 years because the world's population is ageing rapidly as advances in medicine, surgery and nutrition help to extend the human life span. The future demographic predictions are alarming. Between 1990 and 2030 the proportion of people over 60 will grow by about 75% in OECD countries, with a dramatic rise of almost 100% in Japan. It has been known for a long time that the incidence of dementia increases with age, so we can expect the proportion with dementia to increase by similar amount. Dementia, of which Alzheimer's disease is by far the most common cause, is a dreadful devastation of the human mind and spirit; it involves a progressive loss of those very features that make us human: the mind, normal behaviour and even our very personality disintegrates. Modern medicine has followed Virgil in the view that dementia is an inevitable consequence of the ageing of the brain. However, recent discoveries have cast serious doubt on this view and have led to a different idea, that dementia is a true disease, which, if its causes can be identified, should be possible to treat or even to prevent. In other words, to understand dementia we do not have to unravel the secret of ageing but should consider it just like any other common disease such as cancer, heart disease or diabetes.

Alzheimer's disease (AD) was first described in a woman in her 50s by Alois Alzheimer in 1907. He examined the brain after she died and found in the microscope two kinds of structures that were stained by silver salts. One is called the amyloid plaque and lies outside the cells, while the other is called the neurofibrillary tangle and is found mainly within nerve cells in the cerebral cortex. Both these silver-staining structures are composed of highly insoluble proteins in a fibrillar form. The amyloid plaque is mainly composed of a protein called beta-amyloid peptide which has 40-43 amino acid residues per molecule but which is normally completely insoluble because the individual molecules aggregate together to form fibrils. The protein that makes up the neurofibrillary tangle is different and is derived from a protein called tau whose normal function is to stabilize the microtubules in the nerve's axon, so maintaining the function of this long process of the nerve cell.

Most research into dementia has concentrated on these two proteins and on the question: 'What causes them to accumulate in the brain in people with AD?' However, it has been realized that the deposition of these proteins might not be the primary cause of the symptoms of dementia, perhaps they are the end products of a process that is more closely related to the loss of normal functioning of the brain. This process is in fact the loss of nerve cells and, in particular, the loss of the connections between nerve cells that occur at synapses. The long nerve fibres in the cerebral cortex that pass from one part of the cortex to another die back in AD and so the different functional parts of the cortex are no longer connected to each other. The disease first strikes in the part of the brain that is known to be crucial for memory, the medial temporal lobe which lies deep in the middle of the brain. Nerve cells in some parts of the medial temporal lobe (the hippocampus) die earliest, so that more than 70% of them have disappeared by the time the patient dies. This process of continual death of nerve cells (neurodegeneration) can be followed in life by a simple brain scan, using computed tomography or magnetic resonance imaging. The loss of tissue in the medial temporal lobe occurs at 15% per year and correlates very well with the decline in cognitive function as measured by standard neuropsychological tests. No such rapid loss of tissue occurs with normal ageing and healthy individuals followed each year also show no obvious loss in cognitive function. It is likely that the finding that old people on average have a lower performance in some cognitive tests is mainly explained by the fact that any group of elderly people will include some in whom AD has already begun even though the symptoms are not readily detected.

The nerve cells of the medial temporal lobe are connected to almost all other parts of the cerebral cortex and must serve some kind of integrative role, such as the consolidation of memory. The loss of these connections as the neurons die may be one of the causes of the different symptoms of AD, which arise from abnormal functioning of

different parts of the cortex. The death of nerve cells in the medial temporal lobe is accompanied by the death of another small group of nerve cells that lie in the basal nucleus of the forebrain. These basal forebrain neurones make the transmitter called acetylcholine and their main function is to regulate all parts of the cerebral cortex. The only available current treatments for AD act by inhibiting the enzyme that normally destroys acetylcholine, but they are not very effective and they do not slow down the progression of the disease. What is this disease process that strikes at nerve cells in the middle of the cerebral cortex and in the base of the forebrain? Why are these nerve cells particularly vulnerable? These are crucial questions for current research. If we can find the answers to these questions we should be able to devise drugs that slow down or stop the death of cells from occurring and so slow down the decline in cognitive function. There are several current views about what causes the nerve cells to die. One is that the cells are killed by the accumulation of beta-amyloid, and it has indeed been found that beta-amyloid peptide is toxic to nerve cells under certain circumstances. However, the paradox is that amyloid plaques occur most densely in parts of the brain where relatively few cells die. Nevertheless, several of the next generation of drugs being developed for AD are based on the view that if we can stop beta-amyloid being generated from its precursor protein (amyloid precursor protein) then we may be able to slow down progression of the disease. Another view is that the nerve cells die because they are 'strangled' from within by the accumulation of abnormal tau protein. Again, if ways can be found to prevent this from occurring then the disease might be treatable. A third view is that the nerve cells die because there is an excessive production of free radicals in the brain. Free radicals are molecules that have an extra electron and so they are very reactive and combine readily with many of the cell's important proteins. The consequence is that the protein's normal functioning is disturbed. Because free radicals are so reactive, they cannot readily be detected in brain tissue but the damaged proteins have been found in larger amounts than normal in the brains of people with AD. Even if we cannot identify the origin of these free radicals it might be possible to 'capture' them by administering drugs to which they combine in preference to the proteins of cells. Indeed, one such 'drug' is vitamin E and clinical trials are in progress to see whether feeding large amounts of vitamin E can slow down the progression of AD.

A major breakthrough in our understanding of AD was made at St Mary's Hospital Medical School, London, in 1991 where scientists discovered that one of the rare forms of familial AD (i.e. AD that is inherited in a classical Mendelian manner) is due to a mutation in the gene for amyloid precursor protein on chromosome 21. People with this mutation develop the symptoms of AD before the age of 60, so-called early-onset AD. Other forms of early-onset AD have also been found to be due to mutations in specific genes on chromosomes 1 and 14, but these familial forms of AD are quite rare, comprising about 5% of all cases. It seems likely that these familial forms of AD are all due to abnormalities in the way the body handles the amyloid precursor protein, leading to excessive production of the toxic beta-amyloid. The common sporadic form of AD is usually later in onset, over the age of 65. Sporadic AD and familial AD show the same pathological changes in the brain and yet they must have very different causes. The causes of sporadic AD are now known to be multi-factorial, which means that several factors have to come together in one person before the disease develops. A discovery by scientists at Duke University, North Carolina in 1993 has transformed our understanding of AD: they found that people who carry a common variant (50% of the gene for apolipoprotein E) had a five-fold greater risk of developing AD than people who do not carry this variant. This is the first of many 'susceptibility genes' discovered for AD. A susceptibility gene only increases the risk of the disease developing; having this gene does not mean that the person will inevitably get AD. Clearly, other risk factors have to be present. As well as genetic risk factors, a variety of nongenetic factors may influence our risk of getting AD. A lot of current research is directed to identifying these risk factors because some of them may turn out to be modifiable by drugs, life style or diet. Some of these have obvious social and medical implications. Thus, if low education is really a risk factor, we must clearly do our best to give everyone the same high level of schooling. If dietary deficiencies are a risk then we must make sure that everyone has an adequate diet. The possibility of preventing AD from developing in a proportion of the elderly must be pursued with as much vigour as the search for drug treatments for those who are unfortunate enough to develop the disease. These are two of medicine's major challenges for the 21st century.

described by Alois Alzheimer 1906. It affects up to 4 million people in the USA and around 600,000 in Britain.

causes Various factors have been implicated in causing Alzheimer's disease including high levels of aluminium in drinking water and the presence in the brain of an abnormal protein, known as beta-amyloid.

In 1993 the gene coding for apolipoprotein (APOE) was implicated. US researchers established that people who carry a particular version of this gene (APOE-E4) are at greatly increased risk of developing the disease. It is estimated that one person in thirty carries this protein mutation; in the USA the figure is as high as 15%. The suspect gene can be detected with a test, so it is technically possible to identify those most at risk. As no cure is available such testing is unlikely to be widespread.

A second Alzheimer's gene was identified in 1997. The gene, HLA-A2, increases the speed at which the disease begins. The *Neurology* report stated that if a person had both HLA-A2 and APOE-E4, he or she may reach dementia a decade earlier than those with only one of the genes.

diagnosis US researchers began trialling a simple eye test in 1994 that could be used to diagnose sufferers. The drug tropicamide causes marked pupil dilation in those with the disease, and only slight dilation in healthy individuals.

treatment Some researchers are convinced that, whatever its cause, Alzheimer's disease is essentially an inflammatory condition, similar to rheumatoid arthritis. Although there is no cure, trials of anti-inflammatory drugs have shown promising results. Also under development are drugs which block the toxic effects of beta-amyloid. A 1996 study by US neuroscientists found that oestrogen skin patches were also beneficial in the treatment of female Alzheimer's patients, improving concentration and memory.

AM abbreviation for amplitude modulation.

amalgam any alloy of mercury with other metals. Most metals will form amalgams, except iron and platinum. Amalgam is used in dentistry for filling teeth, and usually contains copper, silver, and zinc as the main alloying ingredients. This amalgam is pliable when first mixed and then sets hard, but the mercury leaches out and may cause a type of heavy-metal poisoning.

Amalgamation, the process of forming an amalgam, is a technique sometimes used to extract gold and silver from their ores. The ores are ground to a fine sand and brought into contact with mercury, which dissolves the gold and silver particles. The amalgam is then heated to distil the mercury, leaving a residue of silver and gold. The mercury is recovered and reused.

Almagamation to extract gold from its ore has been in use since Roman times.

amanita any of a group of fungi (see *fungus*) distinguished by a ring (or volva) around the base of the stalk, warty patches on the cap, and the clear white colour of the gills. Many of the species are brightly coloured and highly poisonous. (Genus *Amanita*, family Agaricaceae.)

amatol explosive consisting of ammonium nitrate and TNT (trinitrotoluene) in almost any proportions.

amber fossilized resin from coniferous trees of the Middle Tertiary period. It is often washed ashore on the Baltic coast with plant and animal specimens preserved in it; many extinct species have been found preserved in this way. It ranges in colour from red to yellow, and is used to make jewellery.

When amber is rubbed with cloth, it attracts light objects, such as feathers. The effect, first noticed by the ancient Greeks, is due to acquisition of negative electric charge, hence the adaptation of the Greek word for amber, *elektron*, for electricity (see *static electricity*).

Amber has been coveted for its supposed special properties since prehistoric times. Archaeologists have found amulets made of amber dating back as far as 35000 BC.

Amber's preservative properties were demonstrated 1992 when DNA was extracted from insects estimated to be around 30 million years old which were found fossilized in amber, and in 1995 US scientists succeeded in extracting bacterial spores from a bee in amber that was 40 million years old. Despite their lengthy dormancy, the bacterial spores were successfully germinated.

amberggris fatty substance, resembling wax, found in the stomach and intestines of the sperm whale. It is found floating in warm seas, and is used in perfumery as a fixative.

Basically intestinal matter, amberggris is not the result of disease, but the product of an otherwise normal intestine. The name derives from the French *ambre gris* (grey amber).

American Association for the Advancement of Science (AAAS) US scientific society founded in 1848 with the aim of informing the public of the progress of science, and furthering scientific responsibility; its headquarters are in Washington, DC. It holds a large annual meeting, with many speakers describing the latest scientific developments, publishes journals, and sponsors awards.

It was modelled on the British Association for the Advancement of Science.

American National Standards Institute (ANSI) US national standards body. It sets official procedures in (among other areas) computing and electronics. The ANSI character set is the standard set of characters used by Windows-based computers.

America Online (AOL) US market-leading commercial information service. America Online was launched 1986 with a bright, colourful graphical interface and a marketing campaign that issued free discs on almost every US magazine cover. In 1995 it overtook the then market leader, CompuServe, and by 1996 had more than 5 million users worldwide. America Online combined with the German publishing conglomerate Bertelsmann to launch a UK version of the service, known as AOL, in early 1996.

Because a number of America Online users, many of them using temporary accounts set up from the many free discs, acted in breach of etiquette when America Online opened its Internet gateway 1994, America Online users are held in contempt by many parts of the Net.

americium radioactive metallic element of the actinide series, symbol Am, atomic number 95, relative atomic mass 243.13; it was first synthesized 1944. It occurs in nature in minute quantities in pitchblende and other uranium ores, where it is produced from the decay of neutron-bombarded plutonium, and is the element with the highest atomic number that occurs in nature. It is synthesized in quantity only in nuclear reactors by the bombardment of plutonium with neutrons. Its longest-lived isotope is Am-243, with a half-life of 7,650 years.

The element was named by Glenn Seaborg, one of the team who first synthesized it in 1944, after the United States of America. Ten isotopes are known.

Ames Research Center US space-research (NASA) installation at Mountain View, California, USA, for the study of aeronautics and life sciences. It has managed the Pioneer series of planetary probes and is involved in the search for extraterrestrial life.

amethyst variety of quartz, SiO₂, coloured violet by the presence of small quantities of impurities such as manganese or iron; used as a semiprecious stone. Amethysts are found chiefly in the Ural Mountains, India, the USA, Uruguay, and Brazil.

amide any organic chemical derived from a fatty acid by the replacement of the hydroxyl group (-OH) by an amino group (-NH₂).

One of the simplest amides is acetamide (CH₃CONH₂), which has a strong mousey odour.

Amiga microcomputer produced by US company Commodore 1985 to succeed the Commodore 64 home computer. The original Amiga was based on the Motorola 68000 microprocessor and achieved significant success in the domestic market.

Despite a failure to sell to the general business market, the latest versions of the Amiga are widely used in the film and video industries, where the Amiga's specialized graphics capabilities are used to create a variety of visual effects.

amine any of a class of organic chemical compounds in which one or more of the hydrogen atoms of ammonia (NH₃) have been replaced by other groups of atoms.

alanine $\text{CH}_3\text{CH}(\text{NH}_2)\text{COOH}$ cysteine $\text{SH}_2\text{CH}_2\text{CH}(\text{NH}_2)\text{COOH}$ glycine $\text{NH}_2\text{CH}_2\text{COOH}$ tyrosine $\text{C}_6\text{H}_4\text{OHCH}_2\text{CH}(\text{NH}_2)\text{COOH}$ 

— covalent bond
 ○ hydrogen atom
 ● carbon atom
 ○ oxygen atom
 ● nitrogen atom
 ● sulphur atom

amino acid Amino acids are natural organic compounds that make up proteins and can thus be considered the basic molecules of life. There are 20 different common amino acids. They consist mainly of carbon, oxygen, hydrogen, and nitrogen. Each amino acid has a common core structure (consisting of two carbon atoms, two oxygen atoms, a nitrogen atom, and four hydrogen atoms) to which is attached a variable group, known as the R group. In glycine, the R group is a single hydrogen atom; in alanine, the R group consists of a carbon and three hydrogen atoms.

Methyl amines have unpleasant ammonia odours and occur in decomposing fish. They are all gases at ordinary temperature.

Aromatic amine compounds include aniline, which is used in dyeing.

AMINO ACIDS

<http://www.chemie.fu-berlin.de/chemistry/bio/amino-acids.html>

Small but interesting site giving the names and chemical structures of all the amino acids.

amino acid water-soluble organic molecule, mainly composed of carbon, oxygen, hydrogen, and nitrogen, containing both a basic amino group (NH_2) and an acidic carboxyl (COOH) group. They are small molecules able to pass through membranes. When two or more amino acids are joined together, they are known as peptides; proteins are made up of peptide chains folded or twisted in characteristic shapes.

Many different proteins are found in the cells of living organisms, but they are all made up of the same 20 amino acids, joined together in varying combinations (although other types of amino acid do occur infrequently in nature). Eight of these, the essential amino acids, cannot be synthesized by humans and must be obtained from the diet. Children need a further two amino acids that are not essential for adults. Other animals also need some preformed amino acids in their diet, but green plants can manufacture all the amino acids they need from simpler molecules, relying on energy from the Sun and minerals (including nitrates) from the soil.

To remember the ten essential amino acids:

THESE TEN VALUABLE AMINO ACIDS HAVE LONG PRESERVED LIFE IN MAN.

THREONINE / TRYPTOPHAN / VALINE / ARGENINE / HISTIDINE /
 LYSINE / PHENYLALANINE / LEUCINE / ISOLEUCINE / METHIONINE

ammeter instrument that measures electric current, usually in campers. The ammeter is placed in series with the component through which current is to be measured, and is constructed with a low internal resistance in order to prevent the reduction of that cur-

rent as it flows through the instrument itself. A common type is the moving-coil meter, which measures direct current (DC), but can, in the presence of a rectifier, measure alternating current (AC) also. Hot-wire, moving-iron and dynamometer ammeters can be used for both DC and AC.

ammonia NH_3 colourless, pungent-smelling gas, lighter than air and very soluble in water. It is made on an industrial scale by the Haber (or Haber-Bosch) process, and used mainly to produce nitrogenous fertilizers, nitric acid, and some explosives.

In aquatic organisms and some insects, nitrogenous waste (from the breakdown of amino acids and so on) is excreted in the form of ammonia, rather than as urea in mammals.

ammoniacal solution in chemistry, a solution produced by dissolving a solute in aqueous ammonia.

ammonite extinct marine cephalopod mollusc of the order Ammonoidea, related to the modern nautilus. The shell was curled in a plane spiral and made up of numerous gas-filled chambers, the outermost containing the body of the animal. Many species flourished between 200 million and 65 million years ago, ranging in size from that of a small coin to 2 m/6 ft across.

ammonium carbonate $(\text{NH}_4)_2\text{CO}_3$ white, crystalline solid that readily sublimates at room temperature into its constituent gases: ammonia, carbon dioxide, and water. It was formerly used in smelling salts.

ammonium chloride or *sal ammoniac* NH_4Cl a volatile salt that forms white crystals around volcanic craters. It is prepared synthetically for use in 'dry-cell' batteries, fertilizers, and dyes.

ammonium nitrate NH_4NO_3 colourless, crystalline solid, prepared by neutralization of nitric acid with ammonia; the salt is crystallized from the solution. It sublimates on heating.

amnesia loss or impairment of memory. As a clinical condition it may be caused by disease or injury to the brain, by some drugs, or by shock; in some cases it may be a symptom of an emotional disorder.

amniocentesis sampling the amniotic fluid surrounding a fetus in the womb for diagnostic purposes. It is used to detect Down's syn-

AMNIOCENTESIS

http://www.aomc.org/amnio.html#wmh4_822004218

Comprehensive plain English guide to amniocentesis. For a pregnant woman considering the procedure, this is an invaluable source of information. The advantages and the risks of sampling the amniotic fluid are clearly presented.

amoeba The amoebae are among the simplest living organisms, consisting of a single cell. Within the cell, there is a nucleus, which controls cell activity, and many other microscopic bodies and vacuoles (fluid-filled spaces surrounded by a membrane) with specialized functions. Amoebae eat by flowing around food particles, engulfing the particle, a process called phagocytosis.

drome and other genetic abnormalities. The procedure carries a 1 in 200 risk of miscarriage.

amnion innermost of three membranes that enclose the embryo within the egg (reptiles and birds) or within the uterus (mammals). It contains the amniotic fluid that helps to cushion the embryo.

amoeba (plural *amoebae*) one of the simplest living animals, consisting of a single cell and belonging to the protozoa group. The body consists of colourless protoplasm. Its activities are controlled by the nucleus, and it feeds by flowing round and engulfing organic debris. It reproduces by binary fission. Some species of amoeba are harmful parasites.

amp in physics, abbreviation for **ampere**, a unit of electrical current. Its use is deprecated.

ampere SI unit (symbol A) of electrical current. Electrical current is measured in a similar way to water current, in terms of an amount per unit time; one ampere represents a flow of about 6.28

$\times 10^{18}$ electrons per second, or a rate of flow of charge of one coulomb per second.

The ampere is defined as the current that produces a specific magnetic force between two long, straight, parallel conductors placed 1m/3.3 ft apart in a vacuum. It is named after the French scientist André Ampère.

Ampère's rule rule developed by French physicist André Ampère connecting the direction of an electric current and its associated magnetic currents. It states that if a person were travelling along a current-carrying wire in the direction of conventional current flow (from the positive to the negative terminal), and carrying a magnetic compass, then the north pole of the compass needle would be deflected to the left-hand side.

amphetamine or **speed** powerful synthetic stimulant. Benzedrine was the earliest amphetamine marketed, used as a 'pep pill' in World War II to help soldiers overcome fatigue, and until the 1970s amphetamines were prescribed by doctors as an appetite suppressant for weight loss; as an antidepressant, to induce euphoria; and as a stimulant, to increase alertness.

Indications for its use today are very restricted because of severe side effects, including addiction. Amphetamine is a sulphate or phosphate form of $C_9H_{13}N$.

amphibian Greek 'double life' member of the vertebrate class Amphibia, which generally spend their larval (tadpole) stage in

Ampère, André Marie (1775–1836)

French physicist and mathematician who made many discoveries in electromagnetism and electrodynamics. He followed up the work of Hans Oersted on the interaction between magnets and electric currents, developing a rule for determining the direction of the magnetic field associated with an electric current. The unit of electric current, the ampere, is named after him.

Ampère's law is an equation that relates the magnetic force produced by two parallel current-carrying conductors to the product of their currents and the distance between the conductors. Today Ampère's law is usually stated in the form of calculus: the line integral of the magnetic field around an arbitrarily chosen path is proportional to the net electric current enclosed by the path.

Mary Evans Picture Library

amphibian Toads are among the commonest amphibians. This striking green toad *Bufo viridis* is distributed in a number of habitats in the E Mediterranean area, such as these coastal sand flats on the island of Corfu. Premaphotos Wildlife

AMPHIBIAN

Frogs and toads never eat with their eyes open. When eating, they have to push down with the back of the eyeball in order to force food into the stomach.

fresh water, transferring to land at maturity (after ϕ metamorphosis) and generally returning to water to breed. Like fish and reptiles, they continue to grow throughout life, and cannot maintain a temperature greatly differing from that of their environment. The class contains 4,553 known species, 4,000 of which are frogs and toads, 390 salamanders, and 163 caecilians (worm-like in appearance).

Amphioxus genus name of the lancelet.

amphoteric term used to describe the ability of some chemical compounds to behave either as an ϕ acid or as a ϕ base depending on their environment. For example, the metals aluminium and zinc, and their oxides and hydroxides, act as bases in acidic solutions and as acids in alkaline solutions.

Amino acids and proteins are also amphoteric, as they contain both a basic (amino, $-\text{NH}_2$) and an acidic (carboxyl, $-\text{COOH}$) group.

amplifier electronic device that magnifies the strength of a signal, such as a radio signal. The ratio of output signal strength to input signal strength is called the **gain** of the amplifier. As well as achieving high gain, an amplifier should be free from distortion and able to operate over a range of frequencies. Practical amplifiers are usually complex circuits, although simple amplifiers can be built from single transistors or valves.

amplitude or **argument** in mathematics, the angle in an ϕ Argand diagram between the line that represents the complex number and the real (positive horizontal) axis. If the complex number is written in the form $r(\cos \theta + i \sin \theta)$, where r is radius and $i = \sqrt{-1}$, the amplitude is the angle θ (theta). The amplitude is also the peak value of an oscillation.

amplitude maximum displacement of an oscillation from the equilibrium position. For a wave motion, it is the height of a crest (or the depth of a trough). With a sound wave, for example, amplitude corresponds to the intensity (loudness) of the sound. In AM (amplitude modulation) radio broadcasting, the required audio-frequency signal is made to modulate (vary slightly) the amplitude of a continuously transmitted radio carrier wave.

amplitude modulation (AM) method by which radio waves are altered for the transmission of broadcasting signals. AM waves are constant in frequency, but the amplitude of the transmitting wave varies in accordance with the signal being broadcast.

ampulla in the inner ear, a slight swelling at the end of each semicircular canal, able to sense the motion of the head.

The sense of balance depends largely on sensitive hairs within the ampullae responding to movements of fluid within the canal.

amygdala almond-shaped region of the ϕ brain adjacent to the hippocampus, that links the cortex, responsible for conscious thought, with the regions controlling emotions. A 1994 US study showed that it was involved in interpreting fear-provoking information and linking it to fear responses. For example, where the amygdala is damaged patients are unable to recognize fearful expressions.

Emotionally charged events are more easily recalled than neutral events, and in 1996 US researchers demonstrated a link between the amygdala and the memorizing of emotionally loaded images.

amyl alcohol former name for ϕ pentanol.

amylase one of a group of ϕ enzymes that break down starches into their component molecules (sugars) for use in the body. It occurs widely in both plants and animals. In humans, it is found in saliva and in pancreatic juices.

Human amylase has an optimum pH of 7.2–7.4. Like most enzymes amylase is denatured by temperatures above 60°C.

anabolic steroid any ϕ hormone of the ϕ steroid group that stimulates tissue growth. Its use in medicine is limited to the treatment of some anaemias and breast cancers; it may help to break up blood clots. Side effects include aggressive behaviour, masculinization in women, and, in children, reduced height.

anabolism process of building up body tissue, promoted by the influence of certain hormones. It is the constructive side of ϕ metabolism, as opposed to ϕ catabolism.

anaconda South American snake *Eunectes murinus*, a member of the python and boa family, the Boidae. One of the largest snakes, growing to 9 m/30 ft or more, it is found in and near water, where it lies in wait for the birds and animals on which it feeds. The anaconda is not venomous, but kills its prey by coiling round it and squeezing until the creature suffocates.

Females are up to 5 times larger than males. They have litters of up to 80 babies, born live, and each weighing only 250–300 g. The gestation period last six to eight months, during which time the female will not eat at all.

anaemia condition caused by a shortage of haemoglobin, the oxygen-carrying component of red blood cells. The main symptoms are fatigue, pallor, breathlessness, palpitations, and poor resistance to infection. Treatment depends on the cause.

Anaemia arises either from abnormal loss or defective production of haemoglobin. Excessive loss occurs, for instance, with chronic slow bleeding or with accelerated destruction (ϕ haemolysis) of red blood cells. Defective production may be due to iron deficiency, vitamin B₁₂ deficiency (pernicious anaemia), certain blood diseases (sickle-cell disease and thalassaemia), chronic infection, kidney disease, or certain kinds of poisoning. Untreated anaemia taxes the heart and may prove fatal.

anaerobic (of living organisms) not requiring oxygen for the release of energy from food molecules such as glucose. Anaerobic organisms include many bacteria, yeasts, and internal parasites.

Obligate anaerobes, such as certain primitive bacteria, cannot function in the presence of oxygen; but facultative anaerobes, like the fermenting yeasts and most bacteria, can function with or without oxygen. Anaerobic organisms release much less of the available energy from their food than do aerobic organisms.

anaesthetic drug that produces loss of sensation or consciousness; the resulting state is anaesthesia, in which the patient is insensitive to stimuli. Anaesthesia may also happen as a result of nerve disorder.

Ever since the first successful operation in 1846 on a patient rendered unconscious by ether, advances have been aimed at increasing safety and control. Sedatives may be given before the anaesthetic to make the process easier. The level and duration of unconsciousness are managed precisely. Where general anaesthesia may be inappropriate (for example, in childbirth, for a small procedure, or in the elderly), many other techniques are available. A topical substance may be applied to the skin or tissue surface; a local agent may be injected into the tissues under the skin in the area to be treated; or a regional block of sensation may be achieved by injection into a nerve. Spinal anaesthetic, such as epidural, is injected into the tissues surrounding the spinal cord, producing loss of feeling in the lower part of the body.

ANAESTHETIC

Although the science of anaesthetics is 150 years old, it is only comparatively recently that safe doses have begun to be calculated correctly. It is said that when the Japanese bombed Pearl Harbor in 1941, more US servicemen were killed by anaesthetists than by bombs.

History of Anaesthesia

BY PAULETTE PRATT

While the need for some form of anaesthesia had been recognized since earliest times, for centuries all that was available to deaden the pain of surgery was a copious draft of alcohol. As late as 1839 a leading French surgeon predicted: 'To escape pain in surgical operations is a chimera which we cannot expect in our time.' Mercifully, he was mistaken for the first use of anaesthesia in surgery was recorded only seven years later.

By this time there had been some experimentation with volatile agents such as ether, chloroform and nitrous oxide. Ether, for example, enjoyed a certain notoriety arising from medical students' 'ether frolics'. But this was the substance used in what is credited as the first operation undertaken in an anaesthetized patient – in the famous 'ether dome' at Massachusetts General Hospital in Boston on October 16, 1846. Its use was demonstrated by the dentist William Thomas Green Morton (1819–68).

The following day, not content with the apparatus he had used to administer the ether, Morton commissioned an improved version. Later he abandoned this, too, in favour of a simple sponge. 'This should be about the size of the open hand, or a little larger, and concave, to suit over the nose and mouth,' he wrote in the *Lancet* (June 30, 1847).

'The sponge is then thoroughly saturated with ether, applied to the nose and mouth, and, with the latter open, the patient directed to inhale as fully and freely as possible. In this way, I have found the result more sure and satisfactory, and the difficulty of inhalation very much reduced, or entirely removed. The most delicate or nervous females, or aged persons, as well as young children, are thus rapidly and almost imperceptibly narcotized...'

Only a month after its Boston debut, ether anaesthesia was first used in Britain, at London's University College Hospital. In January 1847, James Young Simpson (1811–70), Professor of Obstetrics at Edinburgh, was the first to introduce its use for women in childbirth, initially for forceps or operative deliveries but soon also for uncomplicated cases.

However, disliking ether's 'disagreeable and very persistent smell', Simpson soon began casting around for an alternative and decided to try chloroform. In November 1847, to the consternation of his household, he and two junior colleagues were accidentally exposed to chloroform when a bottle was knocked over at his house in Queen Street. He later wrote: 'The first night we took chloroform, Dr Duncan, Dr Keith and I all tried it simultaneously and were under the table in a minute or two.'

The first obstetric delivery under chloroform took place the day after this mishap and, ten days later, Simpson published his first pamphlet on its use. A forceful figure, he insisted that liberal administration of chloroform on the corner of a towel or handkerchief was harmless.

Not surprisingly, however, since it had gone from first testing to clinical use within the space of little more than a week, the safety of chloroform as an anaesthetic agent was never established. In fact the first UK death from chloroform anaesthesia took place only three months after its introduction.

Elsewhere, once its toxicity became apparent, chloroform fell out of favour. Predictably its use was banned at Massachusetts General, the birthplace of ether anaesthesia. But in Britain Simpson had done such a good job of publicizing chloroform that its popularity grew regardless. Here controversy centred not on safety but on the morality of using anaesthesia at all to relieve the pain of childbirth. There were those who pointed to its apparent biblical proscription – 'In pain shalt thou bear offspring.'

However, the role of anaesthesia in childbirth was confirmed when, on April 7 1853, the well-known London physician John Snow held out a chloroform-soaked handkerchief to assist the birth of Queen Victoria's ninth child, Prince Leopold. The Queen subsequently noted in her diary: 'Dr Snow administered that blessed chloroform and the effect was soothing, quieting and delightful beyond measure.'

Despite a rising death toll (and the appointment of various commissions to investigate the action of chloroform), the drug remained in use until well into the new century.

Meanwhile a third volatile agent, nitrous oxide, had surfaced at around the same time as ether and chloroform. Its pain-killing properties were discovered in 1800 by the British chemist Humphry Davy (1778–1829), who foresaw that 'it may probably be used with advantage in surgical operations'. In 1845, nitrous oxide was first used for pain relief, also at Massachusetts General Hospital, in what proved to be a disastrous demonstration by another dentist, Horace Wells (1815–48). Then it was lost to view for more than two decades.

Nitrous oxide – popularly known as 'laughing gas' because of the excitement it induces – was finally adopted as an anaesthetic agent by way of its use by travelling salesmen. One of these, Gardner Quincy Colton (1814–98), founder of the New York Dental Institute, demonstrated use of the gas at the 1867 International Exhibition in Paris. It was taken up by an influential US dental surgeon, Thomas Wiltberger (1823–97), who in due course introduced it to British dentists. Nitrous oxide is still used as an inhalation agent in surgery today.

There were to be further colourful chapters in the development of safe, effective anaesthesia, including the loss of a few surgical patients to exploding gases. Also memorable was the era of 'twilight sleep' in obstetrics, when a light state of scopolamine-morphine narcosis was used to ease pain and eradicate unpleasant recollections. The main effect of this, in addition to prolonging labour and expunging any memory on the part of the mother of her child's birth, was to produce babies almost too doped to breathe.

While some specialist training was initiated in the 1930s, it was only after World War 2 – a century after the first use of anaesthesia in surgery – that the speciality really came into its own. Today it is the biggest UK medical speciality, practised with a precision unimaginable in the early days under the 'ether dome'.

analgesic agent for relieving pain. Opiates alter the perception or appreciation of pain and are effective in controlling 'deep' visceral (internal) pain. Non-opiates, such as aspirin, paracetamol, and NSAIDs (nonsteroidal anti-inflammatory drugs), relieve musculoskeletal pain and reduce inflammation in soft tissues.

Pain is felt when electrical stimuli travel along a nerve pathway, from peripheral nerve fibres to the brain via the spinal cord.

An anaesthetic agent acts either by preventing stimuli from being sent (local), or by removing awareness of them (general). Analgesic drugs act on both.

Temporary or permanent analgesia may be achieved by injection of an anaesthetic agent into, or the severing of, a nerve. Implanted devices enable patients to deliver controlled electrical

stimulation to block pain impulses. Production of the body's natural opiates, endorphins, can be manipulated by techniques such as relaxation and biofeedback. However, for the severe pain of, for example, terminal cancer, opiate analgesics are required.

US researchers found 1996 that some painkillers were more effective and provided longer-lasting relief for women than men.

analogous in biology, term describing a structure that has a similar function to a structure in another organism, but not a similar evolutionary path. For example, the wings of bees and of birds have the same purpose – to give powered flight – but have different origins.

Compare homologous.

analogue (of a quantity or device) changing continuously; by contrast a digital quantity or device varies in series of distinct steps. For example, an analogue clock measures time by means of a continuous movement of hands around a dial, whereas a digital clock measures time with a numerical display that changes in a series of discrete steps.

Most computers are digital devices. Therefore, any signals and data from an analogue device must be passed through a suitable analogue-to-digital converter before they can be received and processed by computer. Similarly, output signals from digital computers must be passed through a digital-to-analogue converter before they can be received by an analogue device.

analogue computer computing device that performs calculations through the interaction of continuously varying physical quantities, such as voltages (as distinct from the more common digital computer, which works with discrete quantities). An analogue computer is said to operate in real time (corresponding to time in the real world), and can therefore be used to monitor and control other events as they happen.

Although common in engineering since the 1920s, analogue computers are not general-purpose computers, but specialize in solving differential calculus and similar mathematical problems. The earliest analogue computing device is thought to be the flat, or planisphere, astrolabe, which originated in about the 8th century.

analogue signal in electronics, current or voltage that conveys or stores information, and varies continuously in the same way as the information it represents (compare digital signal). Analogue signals are prone to interference and distortion.

The bumps in the grooves of a vinyl record form a mechanical analogue of the sound information stored, which is then is converted into an electrical analogue signal by the record player's pick-up device.

analogue-to-digital converter (ADC) electronic circuit that converts an analogue signal into a digital one. Such a circuit is needed to convert the signal from an analogue device into a digital signal for input into a computer. For example, many sensors designed to measure physical quantities, such as temperature and pressure, produce an analogue signal in the form of voltage and this must be passed through an ADC before computer input and processing. A digital-to-analogue converter performs the opposite process.

analogy in mathematics and logic, a form of argument or process of reasoning from one case to another parallel case. Arguments from analogy generally have the following form: if some event or thing has the properties *a* and *b*, and if another event or thing has the properties *b* and *c*, then the former event or thing has the property *c*, too. Arguments from analogy are not always sound and can mislead. False analogies arise when the cases are insufficiently similar to support the reasoning. For example, a whale lives in water and resembles a fish, but we cannot conclude from this that it is a fish. When arguments from analogy are compressed, they are called metaphors.

analysis in chemistry, the determination of the composition of substances; see analytical chemistry.

analysis branch of mathematics concerned with limiting processes on axiomatic number systems; calculus of variations and infinitesimal calculus is now called analysis.

analyst job classification for computer personnel. An analyst prepares a report on an existing data processing system and makes proposals for changes and improvements.

ANALYTICAL CHEMISTRY BASICS

<http://www.scimedia.com/chem-ed/analytic/ac-basic.htm>

Detailed online course, designed for those at undergraduate level, that provides the user with an introduction to some of the fundamental concepts and methods of analytical chemistry. Some of the sections included are gravimetric analysis, titration and spectroscopy.

analytical chemistry branch of chemistry that deals with the determination of the chemical composition of substances. **Qualitative analysis** determines the identities of the substances in a given sample; **quantitative analysis** determines how much of a particular substance is present.

Simple qualitative techniques exploit the specific, easily observable properties of elements or compounds – for example, the flame test makes use of the different flame colours produced by metal cations when their compounds are held in a hot flame. More sophisticated methods, such as those of spectroscopy, are required where substances are present in very low concentrations or where several substances have similar properties.

Most quantitative analyses involve initial stages in which the substance to be measured is extracted from the test sample, and purified. The final analytical stages (or 'finishes') may involve measurement of the substance's mass (gravimetry) or volume (volumetry, titrimetry), or a number of techniques initially developed for qualitative analysis, such as fluorescence and absorption spectroscopy, chromatography, electrophoresis, and polarography. Many modern methods enable quantification by means of a detecting device that is integrated into the extraction procedure (as in gas-liquid chromatography).

For him [the scientist], truth is so seldom the sudden light that shows new order and beauty; more often, truth is the uncharted rock that sinks his ship in the dark.

JOHN CORNFORTH Australian chemist.
Nobel prize address 1975

analogue-to-digital converter An analogue-to-digital converter, or ADC, converts a continuous analogue signal produced by a sensor to a digital ('off and on') signal for computer processing.

analytical engine programmable computing device designed by English mathematician Charles Babbage in 1833.

It was based on the difference engine but was intended to automate the whole process of calculation. It introduced many of the concepts of the digital computer but, because of limitations in manufacturing processes, was never built.

Among the concepts introduced were input and output, an arithmetic unit, memory, sequential operation, and the ability to make decisions based on data. It would have required at least 50,000 moving parts. The design was largely forgotten until some of Babbage's writings were rediscovered in 1937.

The whole of the developments and operations of analysis are now capable of being executed by machinery. ... As soon as an Analytical Engine exists, it will necessarily guide the future course of science.

CHARLES BABBAGE English mathematician.

Passages from the Life of a Philosopher 1864

analytical geometry another name for coordinate geometry.

anamorphic projection technique used in film and in virtual reality to squeeze wide-frame images so that they fit into the dimensions of a 35-mm frame of film. In film projection, the projector has a complementary lens which reverses the process. In virtual reality, the computer must calculate the amount of deformation and reverse it.

anatomy study of the structure of the body and its component parts, especially the human body, as distinguished from physiology, which is the study of bodily functions.

Hierophilus of Chalcedon (c. 330–c. 260 BC) is regarded as the founder of anatomy. In the 2nd century AD, the Graeco-Roman physician Galen produced an account of anatomy that was the only source of anatomical knowledge until *On the Working of the Human Body* 1543 by Belgian physician Andreas Vesalius. In 1628, English physician William Harvey published his demonstration of the circulation of the blood. With the invention of the microscope, Italian physiologist Marcello Malpighi and Dutch microscopist Anton van Leeuwenhoek were able to found the study of histology. In 1747, Albinus (1697–1770), with the help of the artist Wandelaar (1691–1759), produced the most exact account of the bones and muscles, and in 1757–65 Swiss biologist Albrecht von Haller gave the most complete and exact description of the organs that had yet appeared. Among the anatomical writers of the early 19th century are the surgeon Charles Bell (1774–1842), Jonas Quain (1796–1865), and Henry Gray (1825–1861). Radiographic anatomy (using X-rays; see radiography) has been one of the triumphs of the 20th century, which has also been marked by immense activity in embryological investigation.

anchor in computing, an HTML (hypertext markup language) tag that turns ordinary text into a hyperlink. Anchors are used to enable easy navigation within a single large document or to link to remote documents on distant computers. On the World Wide Web, anchor text is underlined, coloured differently, or surrounded by a dotted line in order to mark it out from normal text.

anchovy small fish *Engraulis encrasicolus* of the herring family. It is fished extensively, being abundant in the Mediterranean, and is also found on the Atlantic coast of Europe and in the Black Sea. It grows to 20 cm/8 in.

Pungently flavoured, it is processed into fish pastes and essences, and used as a garnish, rather than eaten fresh.

andesite volcanic igneous rock, intermediate in silica content between rhyolite and basalt. It is characterized by a large quantity of feldspar minerals, giving it a light colour. Andesite erupts from volcanoes at destructive plate margins (where one plate of the Earth's surface moves beneath another; see plate tectonics), including the Andes, from which it gets its name.

AND gate in electronics, a type of logic gate.

Anderson, Elizabeth Garrett (1836–1917)

English physician, the first English woman to qualify in medicine. Unable to attend medical school, Anderson studied privately and was licensed by the Society of Apothecaries in London in 1865. She was physician to the Marylebone Dispensary for Women and Children (later renamed the Elizabeth Garrett Anderson Hospital), a London hospital now staffed by women and serving female patients.

She became the first woman member of the British Medical Association in 1873 and the first woman mayor in Britain. She lectured at the London School of Medicine for Women (1875–97), and was its dean (1883–1903).

Mary Evans Picture Library

androecium male part of a flower, comprising a number of stamens.

androgen general name for any male sex hormone, of which testosterone is the most important.

They are all steroids and are principally involved in the production of male secondary sexual characteristics (such as beard growth).

Andromeda major constellation of the northern hemisphere, visible in autumn. Its main feature is the Andromeda galaxy. The star Alpha Andromedae forms one corner of the Square of Pegasus. It is named after the princess of Greek mythology.

Andromeda galaxy galaxy 2.2 million light years away from Earth in the constellation Andromeda, and the most distant object visible to the naked eye. It is the largest member of the Local Group of galaxies.

Like the Milky Way, it is a spiral orbited by several companion galaxies but contains about twice as many stars. It is about 200,000 light years across.

AND rule rule used for finding the combined probability of two or more independent events both occurring. If two events E_1 and E_2 are independent (have no effect on each other) and the probabilities of their taking place are p_1 and p_2 respectively, then the combined probability p that both E_1 and E_2 will happen is given by:

$$p = p_1 \times p_2$$

For example, if a blue die and a red die are thrown together, the probability of a blue six is $\frac{1}{6}$, and the probability of a red six is $\frac{1}{6}$. Therefore, the probability of both a red six and a blue six being thrown is $\frac{1}{6} \times \frac{1}{6} = \frac{1}{36}$.

By contrast, the OR rule is used for finding the probability of either one event or another taking place.

anechoic chamber room designed to be of high sound absorbency. All surfaces inside the chamber are covered by sound-absorbent materials such as rubber. The walls are often covered with inward-facing pyramids of rubber, to minimize reflections. It is used for experiments in acoustics and for testing audio equipment.

anemometer device for measuring wind speed and liquid flow. The most basic form, the cup-type anemometer, consists of cups at the ends of arms, which rotate when the wind blows. The speed of rotation indicates the wind speed.

Vane-type anemometers have vanes, like a small windmill or propeller, that rotate when the wind blows. **Pressure-tube anemometers** use the pressure generated by the wind to indicate speed. The wind blowing into or across a tube develops a pressure, proportional to the wind speed, that is measured by a manometer or pressure gauge. **Hot-wire anemometers** work on the principle that the rate at which heat is transferred from a hot wire to the surrounding air is a measure of the air speed. Wind speed is determined by measuring either the electric current required to maintain a hot wire at a constant temperature, or the variation of resistance while a constant current is maintained.

ANEMONE

<http://www.actwin.com/fish/species/anemone.html>

Article on keeping anemones in an aquarium environment. The site offers information on species, feeding, and tank maintenance practices to help these creatures thrive in captivity.

anemone flowering plant belonging to the buttercup family, found in northern temperate regions, mainly in woodland. It has sepals which are coloured to attract insects. (Genus *Anemone*, family Ranunculaceae.)

The garden anemone (*Anemone coronaria*) is blue, purple, red, or white. The European and Asian white wood anemone (*A. nemorosa*), or windflower, grows in shady woods, flowering in spring. *Hepatica nobilis*, once included within the genus *Anemone*, is common in the Alps. The pasqueflower is now placed in a separate genus.

anemophily A familiar example of anemophily (wind pollination) is provided by the silver birch *Betula pendula*, whose pendant male catkins produce vast amounts of pollen. The much slimmer and shorter female catkins point upwards. Premaphotos Wildlife

anemophily type of ϕ pollination in which the pollen is carried on the wind. Anemophilous flowers are usually unscented, have either very reduced petals and sepals or lack them altogether, and do not produce nectar. In some species they are borne in catkins. Male and female reproductive structures are commonly found in separate flowers. The male flowers have numerous exposed stamens, often on long filaments; the female flowers have long, often branched, feathery stigmas.

aneroid barometer kind of ϕ barometer.

aneurysm weakening in the wall of an artery, causing it to balloon outwards with the risk of rupture and serious, often fatal, blood loss. If detected in time, some accessible aneurysms can be repaired by bypass surgery, but such major surgery carries a high risk for patients in poor health.

angel dust popular name for the anaesthetic phencyclidine, a depressant drug.

angelfish any of a number of unrelated fish. The freshwater **angelfish**, genus *Pterophyllum*, of South America, is a tall, side-to-side flattened fish with a striped body, up to 26 cm/10 in long, but usually smaller in captivity. The **angelfish** or **monkfish** of the genus *Squatina* is a bottom-living shark up to 1.8 m/6 ft long with a body flattened from top to bottom. The **marine angelfishes**, *Pomacanthus* and others, are long narrow-bodied fish with spiny fins, often brilliantly coloured, up to 60 cm/2 ft long, living around coral reefs in the tropics.

ANGELFISH

<http://www.actwin.com/fish/species/angelfish.html>

Angelfish page by Cindy Hawley. This site includes details of angelfish breeds, feeding, keeping in an aquarium, and possible diseases. Images and multimedia clips are also downloadable from this site.

angelica any of a group of tall, perennial herbs with divided leaves and clusters of white or greenish flowers, belonging to the carrot family. Most are found in Europe and Asia. The roots and fruits have long been used in cooking and in medicine. (Genus *Angelica*, family Umbelliferae.)

angina or **angina pectoris** severe pain in the chest due to impaired blood supply to the heart muscle because a coronary artery is narrowed. Faintness and difficulty in breathing accompany the pain. Treatment is by drugs or bypass surgery.

angiosperm flowering plant in which the seeds are enclosed within an ovary, which ripens into a fruit. Angiosperms are divided into ϕ monocotyledons (single seed leaf in the embryo) and ϕ dicotyledons (two seed leaves in the embryo). They include the majority of flowers, herbs, grasses, and trees except conifers.

There are over 250,000 different species of angiosperm, found in a wide range of habitats. Like ϕ gymnosperms, they are seed plants, but differ in that ovules and seeds are protected within the

ANGIOSPERM ANATOMY

http://www.botany.uwc.ac.za:80/sci_ed/std8/anatomy/

Good general guide to angiosperms. The differences between monocotyledons and dicotyledons are set out here. The functions of roots, stems, leaves, and flowers are explained by readily understandable text and good accompanying diagrams.

carpel. Fertilization occurs by male gametes passing into the ovary from a pollen tube. After fertilization the ovule develops into the seed while the ovary wall develops into the fruit.

Angkor site of the ancient capital of the Khmer Empire in NW Cambodia, north of Tonle Sap. The remains date mainly from the 10th-12th centuries AD, and comprise temples originally dedicated to the Hindu gods, shrines associated with Theravāda Buddhism, and royal palaces. Many are grouped within the enclosure called **Angkor Thom**, but the great temple of **Angkor Wat** (early 12th century) lies outside.

Angkor was abandoned in the 15th century, and the ruins were overgrown by jungle and not adequately described until 1863. Buildings on the site suffered damage during the civil war 1970-75; restoration work is in progress.

angle in mathematics, the amount of turn or rotation; it may be defined by a pair of rays (half-lines) that share a common endpoint but do not lie on the same line. Angles are measured in degrees (°) or radians (rads) - a complete turn or circle being 360° or 2π rads.

Angles are classified generally by their degree measures: **acute angles** are less than 90°; **right angles** are exactly 90° (a quarter turn); **obtuse angles** are greater than 90° but less than 180°; **reflex angles** are greater than 180° but less than 360°.

<> in documentation, brackets that indicate places where the user should input information of the type described between the brackets. Angled brackets are also used in online services and on the Internet to indicate that the name used is a user-ID rather than a real name, and on CompuServe as part of certain emoticons.

<g> on CompuServe, an indicator that the message writer is smiling. The 'g', which stands for 'grin', is similar to an emoticon in that it helps to identify an online writer's state of mind in the absence of facial expressions, tone of voice, and other real-world clues. Variants include <vbg> for 'very big grin'.

angle of declination angle at a particular point on the Earth's surface between the direction of the true or geographic North Pole and the magnetic north pole. The angle of declination has varied over time because of the slow drift in the position of the magnetic north pole.

angle of dip or **angle of inclination** angle at a particular point on the Earth's surface between the direction of the Earth's magnetic field and the horizontal; see magnetic dip.

angle of incidence angle between a ray of light striking a mirror (incident ray) and the normal to that mirror. It is equal to the angle of reflection.

angle of reflection angle between a ray of light reflected from a mirror and the normal to that mirror. It is equal to the angle of incidence.

angle of refraction angle between a refracted ray of light and the normal to the surface at which refraction occurred. When a ray passes from air into a denser medium such as glass, it is bent towards the normal so that the angle of refraction is less than the angle of incidence.

angler any of an order of fish Lophiiformes, with flattened body and broad head and jaws. Many species have small, plantlike tufts on their skin. These act as camouflage for the fish as it waits, either

ANGLER

The parasitic male anglerfish stays with his partner for life - literally. Once the tiny male is attached to the much larger female, his tissues fuse with hers, he loses his senses of sight and smell, and receives his nourishment from her bloodstream.

angle The four types of angle, as classified by their degree measures. No angle is classified as having a measure of 180°, as by definition such an 'angle' is actually a straight line.

floating among seaweed or lying on the sea bottom, twitching the enlarged tip of the threadlike first ray of its dorsal fin to entice prey.

There are over 200 species of angler fish, living in both deep and shallow water in temperate and tropical seas. The males of some species have become so small that they live as parasites on the females.

Anglo-Australian Telescope large telescope on ϕ Siding Spring Mountain, New South Wales.

angstrom unit (symbol Å) of length equal to 10^{-10} metres or one-tenth-millionth of a millimetre, used for atomic measurements and the wavelengths of electromagnetic radiation.

It is named after the Swedish scientist A J Ångström.

Anguilliformes order of bony fish comprising the eels. All Anguilliformes have snakelike bodies and no pelvic fins. The order includes freshwater eels (Anguillidae), moray eels (Muraenidae), and conger eels (Congridae).

Anguis genus of legless lizards containing the slow-worm.

classification *Anguis* is in family Anguillidae, suborder Sauria, order Squamata, class Reptilia.

angular momentum in physics, a type of momentum.

anhydride chemical compound obtained by the removal of water from another compound; usually a dehydrated acid. For example, sulphur(VI) oxide (sulphur trioxide, SO_3) is the anhydride of sulphuric acid (H_2SO_4).

anhydrite naturally occurring anhydrous calcium sulphate (CaSO_4).

It is used commercially for the manufacture of plaster of Paris and builders' plaster.

anhydrous of a chemical compound, containing no water. If the water of crystallization is removed from blue crystals of copper(II) sulphate, a white powder (anhydrous copper sulphate) results. Liquids from which all traces of water have been removed are also described as being anhydrous.

aniline *Portuguese anil 'indigo'* $\text{C}_6\text{H}_5\text{NH}_2$ or *phenylamine* one of the simplest aromatic chemicals (a substance related to benzene, with its carbon atoms joined in a ring). When pure, it is a colourless oily liquid; it has a characteristic odour, and turns brown on contact with air. It occurs in coal tar, and is used in the rubber industry and to make drugs and dyes.

It is highly poisonous.

Aniline was discovered 1826, and was originally prepared by the dry distillation of indigo, hence its name.

*What is man without the beasts? If all the beasts were gone,
man would die from a great loneliness of spirit.*

CHIEF SEATTLE Native American chief,

Reputed letter to US President Franklin Pierce 1854, shown 1992 to have been largely a forgery created 1971 by TV scriptwriter Ted Perry

animal or **metazoan** *Latin anima 'breath', 'life'* member of the kingdom Animalia, one of the major categories of living things, the science of which is zoology. Animals are all heterotrophs (they obtain their energy from organic substances produced by other organisms); they have eukaryotic cells (the genetic material is contained within a distinct nucleus) bounded by a thin cell membrane rather than the thick cell wall of plants. Most animals are capable of moving around for at least part of their life cycle.

In the past, it was common to include the single-celled protozoa with the animals, but these are now classified as protists, together with single-celled plants. Thus all animals are multicellular. The oldest land animals known date back 440 million years. Their remains were found 1990 in a sandstone deposit near Ludlow, Shropshire, UK, and included fragments of two centipedes a few centimetres long and a primitive spider measuring about 1 mm.

Speeds of Animals

| Animal | kph | mph |
|-------------------|------|------|
| Cheetah | 103 | 64 |
| Wildebeest | 81 | 61 |
| Lion | 98 | 50 |
| Quarterhorse | 76 | 47.5 |
| Elk | 79 | 45 |
| Cape hunting dog | 79 | 45 |
| Coyote | 69 | 43 |
| Grey fox | 68 | 42 |
| Hyena | 64 | 40 |
| Zebra | 64 | 40 |
| Greyhound | 63 | 39 |
| Whippet | 57 | 35.5 |
| Rabbit (domestic) | 56 | 35 |
| Jackal | 56 | 35 |
| Reindeer | 51 | 32 |
| Giraffe | 51 | 32 |
| White-tailed deer | 48 | 30 |
| Wart hog | 48 | 30 |
| Grizzly bear | 48 | 30 |
| Cat (domestic) | 48 | 30 |
| Human | 45 | 28 |
| Elephant | 40 | 25 |
| Black mamba snake | 32 | 20 |
| Squirrel | 19 | 12 |
| Pig (domestic) | 18 | 11 |
| Chicken | 14 | 9 |
| Giant tortoise | 0.27 | 0.17 |
| Three-toed sloth | 0.24 | 0.15 |
| Garden snail | 0.05 | 0.03 |

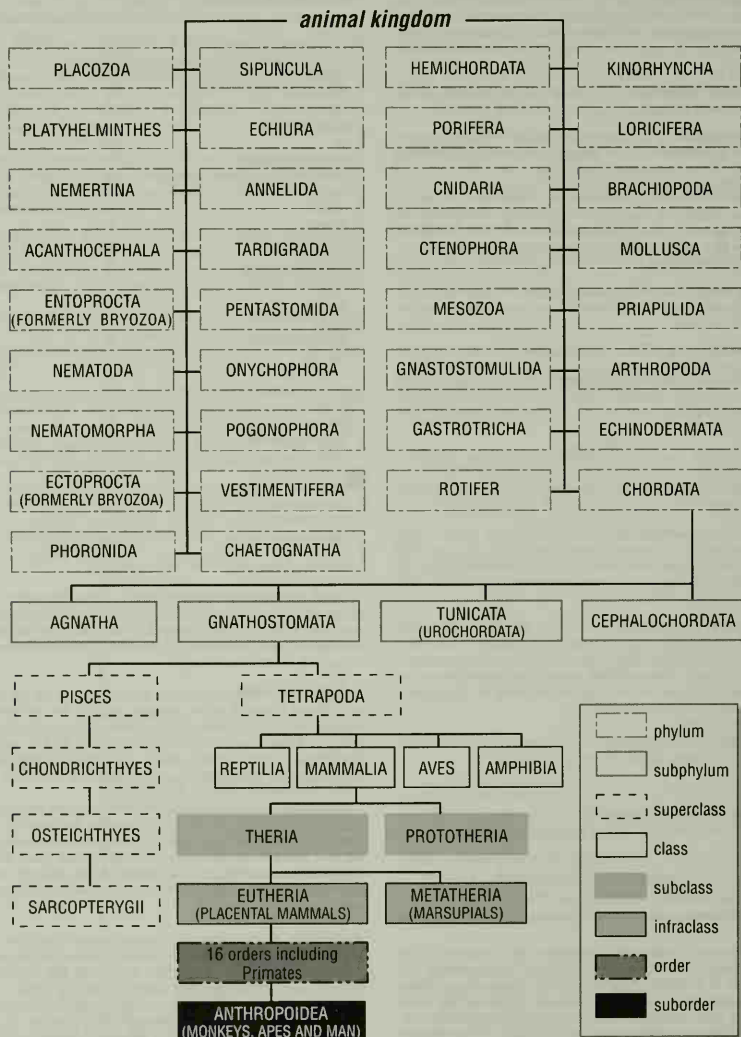

animal behaviour scientific study of the behaviour of animals, either by comparative psychologists (with an interest mainly in the psychological processes involved in the control of behaviour) or by ethologists (with an interest in the biological context and relevance of behaviour; see ethology).

animal, domestic in general, a tame animal. In agriculture, it is an animal brought under human control for exploitation of its labour; use of its feathers, hide, or skin; or consumption of its eggs, milk, or meat. Common domestic animals include poultry, cattle (including buffalo), sheep, goats, and pigs. Starting about 10,000 years ago, the domestication of animals has only since World War II led to intensive factory farming.

Increasing numbers of formerly wild species have been domesticated, with stress on scientific breeding for desired characteristics. At least 60% of the world's livestock is in developing countries, but the Third World consumes only 20% of all meat and milk produced. Most domestic animals graze plants that are not edible to humans, and 40% of the world's cereal production becomes animal feed; in the USA it is 90%.

animation, computer computer-generated graphics that appear to move across the screen. Traditional animation involves a great deal of drudgery in creating the 24 frames per second needed to deceive the human eye into seeing a moving picture on film. In computer-generated animation, while humans still create the key frames that specify the starting and ending points of a particular sequence – a character running through a landscape, for example – computers are faster and more accurate at calculating the in-between positions and generating the frames.

first achievements The first completely computer-generated character to appear in a major motion picture was the sea-water creature in James Cameron's film *The Abyss* 1990, developed at the leading special effects shop Industrial Light & Magic. It was quickly followed by the liquid-metal man in Cameron's *Terminator 2* 1991. The first entirely computer-animated full-length feature film was ϕ Pixar's *Toy Story* 1995, which was the first film ever to

animal The animal kingdom is divided into 34 major groups or phyla. The large phylum Chordata (animals that have, at some time in their life, a notochord, or stiff rod of cells running along the length of their body) is subdivided into four subphyla, of which two, the Agnatha and the Gnathostomata, are vertebrates (animals with backbones). The subphyla are divided into classes and subclasses.

achieve independent motion of characters and backgrounds in the same sequence.

algorithms and initial image creation The basis of computer animation is algorithms developed by academic researchers. These are used to develop software routines that handle the complex calculations needed to work out the precise colour of each pixel in each of the finished frames; the process demands exceptionally powerful hardware with massive storage capacity. For the animator, an image begins as an on-screen collection of lines that look much like a wire frame. There are a variety of techniques the animator can use to develop 3-D objects – they can be extruded from a cross section, or 'swept', which is the on-screen equivalent of turning a cross section on a lathe to produce an evenly curved surface. Less symmetrical objects may be defined by a series of Bézier curves.

adding solidity and colour The object then has to be rendered, which essentially means making it into an image of a solid object. To do this, the computer needs four types of information. First, the object has to be located in space. Second, it has to be assigned a colour, specified either by levels of red, blue, and green or by levels of hue, saturation, and brightness. Third, the location and focal point of the camera photographing the object have to be specified – these determine how the object appears on screen, in perspective. Fourth, the location and type of light sources must be specified: colour, brightness and, in the case of spotlighting, the size of the cone-shaped pool of illumination. Ray-tracing, meanwhile, calculates how the light directed at the object reaches it, with what intensity, and in what areas. From all this information, the computer can calculate the colour intensity of each pixel making up the object.

light reflection There is another element, too: how the object itself reflects light. Two techniques model this, each named after its creator. If the object's surface can be described as a mosaic of polygons, Gouraud shading works by measuring the colour and brightness at the vertices of the polygons and mixing these to get values for the areas inside them. Phong shading extends this by taking into account the angle of reflection; it is therefore a more accurate technique for creating spectacular highlights. Gouraud, because it is simpler, is faster, and there is specialized hardware available for it. Phong has to be implemented in software. Both methods produce an object that looks as though it is made of soft, smooth plastic – the smoothness comes from anti-aliasing, a process that removes the jagged edges or stepped effect which mars the edges of diagonal lines on a computer display screen.

mapping for realism Mappings are what make the objects look as though they are made of real-world materials. There are four main types of mapping: texture, environment, bump, and transparency. Texture is the actual texture of the material the object is made of: brick, water, wood, and so on. The system essentially wraps the object in the texture the animator chooses. Environment mapping adds the reflections on the object's surface of its surroundings; a shiny, round, metal object rolling down a hill, for example, must show accurate reflections of the trees and other objects it rolls past. Bump mapping takes into account the shape of the object itself and the way this affects reflections and shadings in its surface colour. Transparency mapping defines what can be seen through the object, and the distortion caused by the substance of the object; this was a key element in animating the monster in *The Abyss*, which was made of sea water.

fog and haze Finally, fog and haze are important elements of computer animation, particularly for backgrounds, as computerized images tend to look too flat and sharp. The introduction of a little fog hides the sharp edges and makes the scene look more realistic. This is vital for one of the largest growth areas in computer animation for film and video: simulated flyovers, which are impossible in live action and expensive and difficult in model work.

animism In anthropology, the belief that everything, whether animate or inanimate, possesses a soul or spirit. It is a fundamental system of belief in certain religions, particularly those of some pre-industrial societies. Linked with this is the worship of natural objects such as stones and trees, thought to harbour spirits (naturism); fetishism; and ancestor worship.

In psychology and physiology, animism is the view of human per-

sonality that attributes human life and behaviour to a force distinct from matter. In developmental psychology, an animistic stage in the early thought and speech of the child has been described, notably by Swiss psychologist Jean Piaget.

In philosophy, the view that in all things consciousness or something mindlike exists.

In religious theory, the conception of a spiritual reality behind the material one: for example, beliefs in the soul as a shadowy duplicate of the body capable of independent activity, both in life and death.

anion Ion carrying a negative charge. During electrolysis, anions in the electrolyte move towards the anode (positive electrode).

An electrolyte, such as the salt zinc chloride ($ZnCl_2$), is dissociated in aqueous solution or in the molten state into doubly charged Zn^{2+} zinc cations and singly-charged Cl^- anions. During electrolysis, the zinc cations flow to the cathode (to become discharged and liberate zinc metal) and the chloride anions flow to the anode.

anise Mediterranean plant belonging to the carrot family, with small creamy-white flowers in clusters; its fragrant seeds, similar to liquorice in taste, are used to flavour foods. Aniseed oil is used in cough medicines. (*Pimpinella anisum*, family Umbelliferae.)

annealing controlled cooling of a material to increase ductility and strength. The process involves first heating a material (usually glass or metal) for a given time at a given temperature, followed by slow cooling. It is a common form of heat treatment.

annelid any segmented worm of the phylum Annelida. Annelids include earthworms, leeches, and marine worms such as lugworms.

They have a distinct head and soft body, which is divided into a number of similar segments shut off from one another internally by membranous partitions, but there are no jointed appendages. Annelids are noted for their ability to regenerate missing parts of their bodies.

annihilation in nuclear physics, a process in which a particle and its 'mirror image' particle called an antiparticle collide and disappear, with the creation of a burst of energy.

The energy created is equivalent to the mass of the colliding particles in accordance with the mass-energy equation. For example, an electron and a positron annihilate to produce a burst of high-energy X-rays.

Not all particle-antiparticle interactions result in annihilation: the exception concerns the group called mesons, which are composed of quarks and their antiquarks. See *antimatter*.

annotate to add one's own comments to Web pages or graphical computerized documents such as stored faxes.

annual percentage rate (APR) the true annual rate of interest charged for a loan. Lenders usually increase the return on their money by compounding the interest payable on a loan to that loan on a monthly or even daily basis. This means that each time that interest is payable on a loan it is charged not only on the initial sum (principal) but also on the interest previously added to that principal. As a result, APR is usually approximately double the flat rate of interest, or simple interest.

annual plant plant that completes its life cycle within one year, during which time it germinates, grows to maturity, bears flowers, produces seed, and then dies.

annual rings or growth rings concentric rings visible on the wood of a cut tree trunk or other woody stem. Each ring represents a period of growth when new xylem is laid down to replace tissue being converted into wood (secondary xylem). The wood formed from xylem produced in the spring and early summer has larger and more numerous vessels than the wood formed from xylem produced in autumn when growth is slowing down. The result is a clear boundary between the pale spring wood and the denser, darker autumn wood. Annual rings may be used to estimate the age of the plant (see *dendrochronology*), although occasionally more than one growth ring is produced in a given year.

annular eclipse solar eclipse in which the Moon does not completely obscure the Sun and a thin ring of sunlight remains visible. Annular eclipses occur when the Moon is at its furthest point from the Earth.

annulus *Latin 'ring'* in geometry, the plane area between two concentric circles, making a flat ring.

anode in chemistry, the positive electrode of an electrolytic cell, towards which negative particles (anions), usually in solution, are attracted. See *electrolysis*.

anode in electronics, the positive electrode of a thermionic valve, cathode ray tube, or similar device, towards which electrons are drawn after being emitted from the cathode.

anodizing process that increases the resistance to corrosion of a metal, such as aluminium, by building up a protective oxide layer on the surface. The natural corrosion resistance of aluminium is provided by a thin film of aluminium oxide; anodizing increases the thickness of this film and thus the corrosion protection.

It is so called because the metal becomes the anode in an electrolytic bath containing a solution of, for example, sulphuric or chromic acid as the electrolyte. During electrolysis oxygen is produced at the anode, where it combines with the metal to form an oxide film.

anomalocaris prehistoric marine predator resembling a crustacean but with a softer exoskeleton. Up to 2 m in length, it was the largest animal on Earth when it thrived around 525 million years ago. See *prehistoric life*.

anomalous expansion of water expansion of water as it is cooled from 4°C to 0°C. This behaviour is unusual because most substances contract when they are cooled. It means that water has a greater density at 4°C than at 0°C. Hence ice floats on water, and the water at the bottom of a pool in winter is warmer than at the surface. As a result lakes and ponds freeze slowly from the surface downwards, usually remaining liquid near the bottom, where aquatic life is more likely to survive.

anonymous FTP (*file transfer protocol*) method of retrieving a file from a remote computer without having an account on that computer. Many organizations, such as universities and software companies, maintain publicly accessible archives of files that may be retrieved across the Internet via FTP. An ordinary user who is not affiliated to the organization may retrieve files by entering the FTP address and then typing in either 'anonymous' or 'ftp' when asked for a user-ID or log-in name, followed by the user's e-mail address in place of a password. These users are typically offered access privileges to only a small part of the company's stored files, and the rest may be cordoned off from access by a firewall.

anonymous remailer service that allows Internet users to post to USENET and send e-mail without revealing their true identity or e-mail address. To send an anonymous message, a user first sends the message to the remailer, which strips all identifying information from the message before sending it on to its specified destination, identified only as coming from the anonymous server.

The ability to post anonymously also removes user accountability, and so these servers are controversial. However, they provide a useful function on the Net in support groups and other areas where the ability to post anonymously allows people to speak freely about confidential matters without the risk of being identified by friends, family, or anyone else.

The best-known anonymous server, the Finnish anon.penet.fi was closed down in Aug 1996 as it could no longer guarantee anonymity following a court case ordering the operator to reveal a user's name. The more elaborate servers use encryption to make the message even more difficult to trace.

anorak term used interchangeably with *geek*, *techie*, or *nerd*. It derives from the stereotype that all technical people resemble the stereotypical anorak-wearing transpotter; in other words, that they are obsessive, slightly antisocial, and overly knowledgeable about matters that interest very few other people.

anorexia lack of desire to eat, or refusal to eat, especially the pathological condition of *anorexia nervosa*, most often found in adolescent girls and young women. Compulsive eating, or *bulimia*, distortions of body image, and depression often accompany anorexia.

Anorexia nervosa is characterized by severe self-imposed restriction of food intake. The consequent weight loss may lead, in women, to absence of menstruation. Anorexic patients sometimes commit suicide. Anorexia nervosa is often associated with increased physical activity and symptoms of mental disorders. Psychotherapy is an important part of the treatment.

anoxia or **hypoxia** in biology, deprivation of oxygen, a condition that rapidly leads to collapse or death, unless immediately reversed.

ANSI abbreviation for American National Standards Institute, a US national standards body.

ant insect belonging to the family Formicidae, and to the same order (Hymenoptera) as bees and wasps. Ants are characterized by a conspicuous waist and elbowed antennae. About 10,000 different species are known; all are social in habit, and all construct nests of various kinds. Ants are found in all parts of the world, except the polar regions. It is estimated that there are about 10 million billion ants.

Ant behaviour is complex, and serves the colony rather than the individual. Ants find their way by light patterns, gravity (special sense organs are located in the joints of their legs), and chemical trails between food areas and the nest.

specialized roles Communities include *workers*, sterile, wingless females, often all alike, although in some species large-headed 'soldiers' are differentiated; *fertile females*, fewer in number and usually winged; and *males*, also winged and smaller than their consorts, with whom they leave the nest on a nuptial flight at certain times of the year. After aerial mating, the males die, and the fertilized queens lose their wings when they settle, laying eggs to found their own new colonies. The eggs hatch into wormlike larvae, which then pupate in silk cocoons before emerging as adults.

remarkable species Some species conduct warfare. Others are pastoralists, tending herds of aphids and collecting a sweet secretion ('honeydew') from them. Army (South American) and driver (African) ants march nomadically in huge columns, devouring even tethered animals in their path. Leaf-cutter ants, genus *Atta*, use pieces of leaf to grow edible fungus in underground 'gardens' which can be up to 5 m/16 ft deep and cover hundreds of square metres. Weaver ants, genus *Oecophylla*, use their silk-producing larvae as living shuttles to bind the edges of leaves together to form the nest. Eurasian robber ants *Formica sanguinea* raid the nests of

ant With a length of over 30 mm/1.2 in, this *Diponera* species ant from the rainforests of South America is among the giants of its kind. Like most members of its primitive subfamily Ponerinae, it forages singly rather than in bands and the nests generally contain only a few dozen individuals. *Premaphotos Wildlife*

another ant species, *Formica fusca*, for pupae, then use the adults as 'slaves' when they batch. Among honey ants, some workers serve as distended honey stores.

antacid any substance that neutralizes stomach acid, such as sodium bicarbonate or magnesium hydroxide ('milk of magnesia').

Antacids are weak bases, swallowed as solids or emulsions. They may be taken between meals to relieve symptoms of hyperacidity, such as pain, bloating, nausea, and 'heartburn'. Excessive or prolonged need for antacids should be investigated medically.

antagonist in biology, a muscle that relaxes in response to the contraction of its agonist muscle. The biceps, in the front of the upper arm, bends the elbow whilst the triceps, lying behind the biceps, straightens the arm.

antagonistic muscles in the body, a pair of muscles allowing coordinated movement of the skeletal joints. The extension of the arm, for example, requires one set of muscles to relax, while another set contracts. The individual components of antagonistic pairs can be classified into extensors (muscles that straighten a limb) and flexors (muscles that bend a limb).

antagonistic muscle Even simple movements such as bending and straightening the arm require muscle pairs to contract and relax synchronously.

Antarctic Circle imaginary line that encircles the South Pole at latitude 66° 32' S. The line encompasses the continent of Antarctica and the Antarctic Ocean.

The region south of this line experiences at least one night in the southern summer during which the Sun never sets, and at least one day in the southern winter during which the Sun never rises.

Antares or *Alpha Scorpii* brightest star in the constellation Scorpius and the 15th brightest star in the sky. It is a red supergiant several hundred times larger than the Sun and perhaps 10,000 times as luminous, lies about 300 light years away, and fluctuates slightly in brightness.

anteater mammal of the family Myrmecophagidae, order Edentata, native to Mexico, Central America, and tropical South America. The anteater lives almost entirely on ants and termites. It has toothless jaws, an extensible tongue, and claws for breaking into the nests of its prey.

Species include the giant anteater *Myrmecophaga tridactyla*, about 1.8 m/6 ft long including the tail, the tamandua or collared anteater *Tamandua tetradactyla*, about 90 cm/3.5 ft long, and the silky anteater *Cyclops didactyla*, about 35 cm/14 in long. The name is also incorrectly applied to the aardvark, the echidna, and the pangolin.

antelope any of numerous kinds of even-toed, hoofed mammals belonging to the cow family, Bovidae. Most antelopes are lightly built and good runners. They are grazers or browsers, and chew the cud. They range in size from the dik-diks and duikers, only 30 cm/1 ft high, to the eland, which can be 1.8 m/6 ft at the shoulder.

The majority of antelopes are African, including the eland, wildebeest, kudu, springbok, and waterbuck, although other species live in parts of Asia, including the deserts of Arabia and the Middle East. The pronghorn antelope *Antilocapra americana* of North America belongs to a different family, the Antilocapridae.

antenatal in medicine, before birth. Antenatal care refers to health services provided to ensure the health of pregnant women and their babies.

antenna in radio and television, another name for a aerial.

antenna in zoology, an appendage ('feeler') on the head. Insects, centipedes, and millipedes each have one pair of antennae but there are two pairs in crustaceans, such as shrimps. In insects, the antennae are involved with the senses of smell and touch; they are frequently complex structures with large surface areas that increase the ability to detect scents.

anterior in biology, the front of an organism, usually the part that goes forward first when the animal is moving. The anterior end of the nervous system, over the course of evolution, has developed into a brain with associated receptor organs able to detect stimuli including light and chemicals.

anther in a flower, the terminal part of a stamen in which the pollen grains are produced. It is usually borne on a slender stalk or filament, and has two lobes, each containing two chambers, or pollen sacs, within which the pollen is formed.

antheridium organ producing the male gametes, antherozoids, in algae, bryophytes (mosses and liverworts), and pteridophytes (ferns, club mosses, and horsetails). It may be either single-celled, as in most algae, or multicellular, as in bryophytes and pteridophytes.

antherozoid motile (or independently moving) male gamete produced by algae, bryophytes (mosses and liverworts), pteridophytes (ferns, club mosses, and horsetails), and some gymnosperms (notably the cycads). Antherozoids are formed in an antheridium and, after being released, swim by means of one or more flagella, to the female gametes. Higher plants have nonmotile male gametes contained within pollen grains.

anthracene white, glistening, crystalline, tricyclic, aromatic hydrocarbon with a faint blue fluorescence when pure. Its melting point is about 216°C/421°F and its boiling point 351°C/664°F. It occurs in the high-boiling-point fractions of coal tar, where it was

discovered in 1832 by the French chemists Auguste Laurent (1808–1853) and Jean Dumas (1800–1884).

anthracite from Greek *anthrax*, 'coal' hard, dense, shiny variety of coal, containing over 90% carbon and a low percentage of ash and impurities, which causes it to burn without flame, smoke, or smell. Because of its purity, anthracite gives off relatively little sulphur dioxide when burnt.

Anthracite gives intense heat, but is slow-burning and slow to light; it is therefore unsuitable for use in open fires. Its characteristic composition is thought to be due to the action of bacteria in disintegrating the coal-forming material when it was laid down during the Carboniferous period.

Among the chief sources of anthracite coal are Pennsylvania in the USA; S Wales, UK; the Donbas, Ukraine and Russia; and Shanxi province, China.

anthrax disease of livestock, occasionally transmitted to humans, usually via infected hides and fleeces. It may develop as black skin pustules or severe pneumonia. Treatment is with antibiotics. Vaccination is effective.

Anthrax is caused by a bacillus (*Bacillus anthracis*). In the 17th century, some 60,000 cattle died in a European pandemic known as the Black Bane, thought to have been anthrax. The disease is described by the Roman poet Virgil and may have been the cause of the biblical fifth plague of Egypt.

anthropic principle in science, the idea that 'the universe is the way it is because if it were different we would not be here to observe it'. The principle arises from the observation that if the laws of science were even slightly different, it would have been impossible for intelligent life to evolve. For example, if the electric

ANTHRAX

<http://www.outbreak.org/cgi-unreg/dynaserve.exe/cb/anthrax.html>

Basic medical details of the livestock disease and biological weapon anthrax. The Web site contains brief sections covering characteristics of the disease, the symptoms it causes, cautions and precautions, first aid therapy for victims of the disease, and a list of neutralization and decontamination methods.

charge on the electron were only slightly different, stars would have been unable to burn hydrogen and produce the chemical elements that make up our bodies. Scientists are undecided whether the principle is an insight into the nature of the universe or a piece of circular reasoning.

Man appears to be the missing link between anthropoid apes and human beings.

KONRAD LORENZ Austrian zoologist.
The New York Times Magazine 11 April 1965

anthropoid Greek *anthropos* 'man', *eidos* 'resemblance' any primate belonging to the suborder Anthropoidea, including monkeys, apes, and humans.

You will die but the carbon will not; its career does not end with you ... it will return to the soil, and there a plant may take it up again in time, sending it once more on a cycle of plant and animal life.

JACOB BRONOWSKI Polish-born British scientist, broadcaster, and writer.
'Biography of an Atom - and the Universe *New York Times* 13 Oct 1968

antenna The antennae of some male moths are capable of picking up incredibly low concentrations of airborne female sex pheromones at distances of several kilometres. This picture shows the enormous antennae of the American moon moth *Actias luna* (Saturniidae). Premaphotos Wildlife

anthropology Greek *anthropos* 'man', *logos* 'discourse' the study of humankind. It investigates the cultural, social, and physical diversity of the human species, both past and present. It is divided into two broad categories: biological or physical anthropology, which attempts to explain human biological variation from an evolutionary perspective; and the larger field of social or cultural anthropology, which attempts to explain the variety of human cultures. This differs from sociology in that anthropologists are concerned with cultures and societies other than their own.

biological anthropology Biological anthropology is concerned with human palaeontology, primatology, human adaptation, demography, population genetics, and human growth and development.

social anthropology Social or cultural anthropology is divided into three subfields: social or cultural anthropology proper, prehistory or prehistoric archaeology, and anthropological linguistics. The term 'anthropology' is frequently used to refer solely to social anthropology. With a wide range of theoretical perspectives and topical interests, it overlaps with many other disciplines. It is a uniquely Western social science.

participant observation Anthropology's primary method involves the researcher living for a year or more in another culture, speaking the local language and participating in all aspects of everyday life; and writing about it afterwards. By comparing these accounts, anthropologists hope to understand who we are.

anthropometry science dealing with the measurement of the human body, particularly stature, body weight, cranial capacity, and length of limbs, in samples of living populations, as well as the remains of buried and fossilized humans.

anti-aliasing in computer graphics, a software technique for diminishing aliasing ('jaggies') - steplike lines that should be

smooth. Jaggies occur because the output device, the monitor or printer, does not have a high enough resolution to represent a smooth line. Anti-aliasing reduces the prominence of jaggies by surrounding the steps with intermediate shades of grey (for greyscale devices) or colour (for colour devices). Although this reduces the jagged appearance of the lines, it also makes them fuzzier.

ANTIBIOTICS: HOW DO ANTIBIOTICS WORK

<http://ericir.syr.edu/Projects/Newton/12/Lessons/antibiot.html>

Introduction to the use and importance of antibiotics in easy to understand language. The site also includes a glossary of scientific and difficult terms, a further reading list, and an activities sheet.

antibiotic drug that kills or inhibits the growth of bacteria and fungi. It is derived from living organisms such as fungi or bacteria, which distinguishes it from synthetic antimicrobials.

The earliest antibiotics, the penicillins, came into use from 1941 and were quickly joined by chloramphenicol, the cephalosporins, erythromycin, tetracyclines, and aminoglycosides. A range of broad-spectrum antibiotics, the 4-quinolones, was developed 1989, of which ciprofloxacin was the first. Each class and individual antibiotic acts in a different way and may be effective against either a broad spectrum or a specific type of disease-causing agent. Use of antibiotics has become more selective as side effects, such as toxicity, allergy, and resistance, have become better understood. Bacteria have the ability to develop resistance following repeated or sublethal (insufficient) doses, so more advanced and synthetic antibiotics are continually required to overcome them.

ANTIBODY RESOURCE PAGE

<http://www.antibodyresource.com/>

Fascinating annotated access site for all you could ever want to know about antibodies and some you'd rather not! This site contains several educational resources (aimed at university level), but also contains images, animations, and descriptions of research into many different types of antibodies.

antibody protein molecule produced in the blood by lymphocytes in response to the presence of foreign or invading substances (antigens); such substances include the proteins carried on the surface of infecting microorganisms. Antibody production is only one aspect of immunity in vertebrates.

Each antibody acts against only one kind of antigen, and combines with it to form a 'complex'. This action may render antigens harmless, or it may destroy microorganisms by setting off chemical changes that cause them to self-destruct.

In other cases, the formation of a complex will cause antigens to form clumps that can then be detected and engulfed by white blood cells, such as macrophages and phagocytes.

Each bacterial or viral infection will bring about the manufacture of a specific antibody, which will then fight the disease. Many diseases can only be contracted once because antibodies remain in the blood after the infection has passed, preventing any further invasion. Vaccination boosts a person's resistance by causing the production of antibodies specific to particular infections.

Antibodies were discovered 1890 by German physician Emil von Behring and Japanese bacteriologist Shibasaburo Kitasato.

Large quantities of specific antibodies can now be obtained by the monoclonal technique (see monoclonal antibody).

anticline in geology, rock layers or beds folded to form a convex arch (seldom preserved intact) in which older rocks comprise the core. Where relative ages of the rock layers, or stratigraphic ages,

are not known, convex upward folded rocks are referred to as **antiforms**.

The fold of an anticline may be undulating or steeply curved. A steeply bent in otherwise gently dipping or horizontal beds is a **monocline**. The opposite of an anticline is a **syncline**.

anticlockwise direction of rotation, opposite to the way the hands of a clock turn.

anticoagulant substance that inhibits the formation of blood clots. Common anticoagulants are heparin, produced by the liver and some white blood cells, and derivatives of coumarin. Anticoagulants are used medically in the prevention and treatment of thrombosis and heart attacks. Anticoagulant substances are also produced by blood-feeding animals, such as mosquitoes, leeches, and vampire bats, to keep the victim's blood flowing.

Most anticoagulants prevent the production of thrombin, an enzyme that induces the formation from blood plasma of fibrinogen, to which blood platelets adhere and form clots.

anticyclone area of high atmospheric pressure caused by descending air, which becomes warm and dry. Winds radiate from a calm centre, taking a clockwise direction in the northern hemisphere and an anticlockwise direction in the southern hemisphere. Anticyclones are characterized by clear weather and the absence of rain and violent winds. In summer they bring hot, sunny days and in winter they bring fine, frosty spells, although fog and low cloud are not uncommon in the UK. **Blocking anticyclones**, which prevent the normal air circulation of an area, can cause summer droughts and severe winters.

antidepressant any drug used to relieve symptoms in depressive illness. The two main groups are the tricyclic antidepressants (TCADs) and the monoamine oxidase inhibitors (MAOIs), which act by altering chemicals available to the central nervous system. Both may produce serious side effects and are restricted.

anti-emetic any substance that counteracts nausea or vomiting.

antiferromagnetic material material with a very low magnetic susceptibility that increases with temperature up to a certain temperature, called the Néel temperature. Above the Néel temperature, the material is only weakly attracted to a strong magnet.

antifreeze substance added to a water-cooling system (for example, that of a car) to prevent it freezing in cold weather.

antigen any substance that causes the production of antibodies by the body's immune system. Common antigens include the proteins carried on the surface of bacteria, viruses, and pollen grains. The proteins of incompatible blood groups or tissues also act as antigens, which has to be taken into account in medical procedures such as blood transfusions and organ transplants.

antihistamine any substance that counteracts the effects of histamine. Antihistamines may occur naturally or they may be synthesized.

H₁ antihistamines are used to relieve allergies, alleviating symptoms such as runny nose, itching, swelling, or asthma. H₂ antihistamines suppress acid production by the stomach, and are used in the treatment of peptic ulcers, often making surgery unnecessary.

antiknock substance added to petrol to reduce knocking in car engines. It is a mixture of dibromomethane and tetraethyl lead. Its use in leaded petrol has resulted in atmospheric pollution by lead compounds.

antilogarithm or **antilog** the inverse of logarithm, or the number whose logarithm to a given base is a given number. If $y = \log_a x$, then $x = \text{antilog}_a y$.

antimatter in physics, a form of matter in which most of the attributes (such as electrical charge, magnetic moment, and spin) of elementary particles are reversed. Such particles (antiparticles) can be created in particle accelerators, such as those at CERN in Geneva, Switzerland, and at Fermilab in the USA. In 1996 physicists at CERN created the first atoms of antimatter: nine atoms of antihydrogen survived for 40 nanoseconds.

Antibiotic Resistance: a Rising Toll

BY PAULETTE PRATT

When, in 1969, the US Surgeon-General announced that we could soon 'close the book' on infectious diseases, he was speaking prematurely. For already, two years earlier, first reports had surfaced of penicillin resistance developing in *Pneumococcus*, a bacterium which causes a number of potentially fatal diseases, including pneumonia and meningitis. Within little more than a decade, epidemics of pneumococcal disease were breaking out in many countries.

In 1995, when workers from the Centers for Disease Control in Atlanta looked at samples taken from patients with severe pneumonia, they found that a quarter had been hit by pneumococcal (*Staphylococcus pneumoniae*) strains resistant to penicillin; some 15 % were also resistant to erythromycin. Today, growing resistance of this and other organisms to antibiotics is a global public health problem.

Rise of the superbugs

Bacteria vary greatly in their sensitivity to antibiotics, and there is no such thing as a 'magic bullet' with blanket activity against all pathogens. The trouble is that, after more than half a century of antibiotic use, bacteria are mutating faster than new drugs can be found. The growth of super-resistance is being hastened by the indiscriminate use of antibiotics, including over-prescribing.

In the developed world, the danger is greatest in hospitals, where people are already very sick. Currently some 14,000 Americans are dying each year from hospital-acquired infections caused by resistant bacteria. Most at risk are people whose immune systems are in some way impaired, including the very young or the frail elderly, AIDS patients, organ transplant recipients, and patients receiving chemotherapy for cancer.

Most notorious of the so-called 'superbugs' stalking hospital floors is methicillin-resistant *Staphylococcus aureus* (MRSA), a pathogen with an awesome talent for acquiring resistance traits from its microscopic neighbours. So far outbreaks of MRSA, which can cause temporary closure of operating rooms and intensive care units, have been met with vancomycin, a 'last resort' antibiotic normally reserved for life-threatening infections. But in spring of 1997, the Japanese reported the most convincing evidence yet of the appearance of vancomycin-resistant strains.

The Japanese report brings one step closer the spectre of the unstoppable 'superbug' overrunning hospitals. In fact, microbiologists have been predicting just this scenario, not least because strains of the intestinal bacterium *Enterococcus* have for some time been defying all existing antibiotics, including vancomycin and the closely related teicoplanin. In the laboratory, it has been shown that genes for resistance can pass from *Enterococcus* to the more deadly *S. aureus* by plasmid transfer.

It was fear of an epidemic of untreatable infections that prompted the recent European ban on avoparcin, a drug administered to farm animals to promote growth. The rationale for antibiotic use in this context is that it improves feeding efficiency. However, avoparcin is close in chemical structure to vancomycin, and many scientists argue that its use as a growth promoter in livestock creates a potential reservoir of vancomycin-resistant bacteria that would be transmissible to human beings.

Return of old-time diseases

The phenomenon of super-resistance means also that many one-time killer diseases, including tuberculosis (TB), typhoid, cholera,

and diphtheria, are returning in force. TB, always a major problem in the Third World, is the biggest threat, since now it is making a comeback in countries where previously it had been brought under control. Moreover, some strains of the bacterium have become resistant. Parts of the US worst affected are deprived inner-city areas such as Newark, New Jersey, and Brooklyn, the Bronx, and Harlem in New York, where resistance is widespread.

A big factor in the spread of multi-drug-resistant tuberculosis (MDR-TB) has been the failure of control programs in the industrialized countries, including the US. This has meant that many patients starting out on medication lapse before the six-month course is completed. If a patient carrying a resistant strain takes only one drug instead of the prescribed combination, or fails to complete the course, the effect is to promote resistant strains.

Fresh strategies

Bacteria developing the ability to foil an antibiotic can become permanently resistant, according to researchers at Emory University in Atlanta. They demonstrated this in another rising superbug, *Escherichia coli*, which causes gastrointestinal infections. This finding implies that, contrary to what many doctors previously believed, reducing antibiotic use will not eliminate resistant strains.

While the quest for new drugs to fight infection is now paramount, many researchers are developing fresh strategies. These include: tinkering with the structure of antibiotics to add in helper molecules; seeking to disable genes for resistance; and developing laser-activated chemical compounds to blitz the superbugs. Some teams, too, are reviving the old idea of turning bacteriophages (bacteria-eating viruses) loose on resistant bacteria.

All these strategies and more may be needed to overcome the rising toll exacted by antibiotic resistance. Certainly, with infectious diseases claiming more than 17 million lives a year worldwide, we are still no nearer to 'closing the book'.

Mechanisms of resistance

Bacteria may be naturally resistant to some antibiotics, or resistance may be acquired, mostly by the phenomenon of plasmid transfer. A plasmid is a free-floating fragment of DNA adrift in the cell cytoplasm. It carries some genetic material, including data governing the cell's resistance to antibiotics. Plasmids can be transmitted from one bacterium to another.

Occasionally resistance may be due to spontaneous mutation, which is the result of an error in replication of the cell's nuclear material during reproduction. Further reproduction causes the development of a resistant strain.

Bacteria demonstrate resistance in two ways. One way is by producing enzymes that disable drugs. A drug-defying enzyme is not always expressed by the organism targeted by therapy. The normally innocuous *Staphylococcus epidermidis* produces an enzyme that disables penicillin before it can act against harmful staphylococcal species; or some bacteria can contrive metabolic changes that foil the action of drugs. Sulphonamides – antibacterials introduced before the discovery of antibiotics – are often defeated by these metabolic readjustments on the part of bacteria.

antimony silver-white, brittle, semimetallic element (a metalloid), symbol Sb (from Latin *stibium*), atomic number 51, relative atomic mass 121.75. It occurs chiefly as the ore stibnite, and is used to make alloys harder; it is also used in photosensitive substances in colour photography, optical electronics, fireproofing,

pigment, and medicine. It was employed by the ancient Egyptians in a mixture to protect the eyes from flies.

antinode in physics, the position in a standing wave pattern at which the amplitude of vibration is greatest (compare *node*). The

standing wave of a stretched string vibrating in the fundamental mode has one antinode at its midpoint. A vibrating air column in a pipe has an antinode at the pipe's open end and at the place where the vibration is produced.

anti-oxidant any substance that prevents deterioration of fats, oils, paints, plastics, and rubbers by oxidation. When used as food additives, anti-oxidants prevent fats and oils from becoming rancid when exposed to air, and thus extend their shelf life.

Vegetable oils contain natural anti-oxidants, such as vitamin E, which prevent spoilage, but anti-oxidants are nevertheless added to most oils. They are not always listed on food labels because if a food manufacturer buys an oil to make a food product, and the oil has anti-oxidant already added, it does not have to be listed on the label of the product.

antiparticle in nuclear physics, a particle corresponding in mass and properties to a given elementary particle but with the opposite electrical charge, magnetic properties, or coupling to other fundamental forces. For example, an electron carries a negative charge whereas its antiparticle, the positron, carries a positive one. When a particle and its antiparticle collide, they destroy each other, in the process called 'annihilation', their total energy being converted to lighter particles and/or photons. A substance consisting entirely of antiparticles is known as antimatter.

antipodes *Greek 'opposite feet'* places at opposite points on the globe.

antipyretic any drug, such as aspirin, used to reduce fever.

antirrhinum any of several plants in the figwort family, including the snapdragon (*Antirrhinum majus*). Foxgloves and toadflax are relatives. Antirrhinums are native to the Mediterranean region and W North America. (Genus *Antirrhinum*, family Scrophulariaceae.)

antiseptic any substance that kills or inhibits the growth of microorganisms. The use of antiseptics was pioneered by Joseph Lister. He used carbolic acid (phenol), which is a weak antiseptic; antiseptics such as TCP are derived from this.

antitussive any substance administered to suppress a cough. Coughing, however, is an important reflex in clearing secretions from the airways; its suppression is usually unnecessary and possibly harmful, unless damage is being done to tissue during excessive coughing spasms.

antivirus software computer program that detects viruses and/or cleans viruses from an infected computer system. There are many types of antivirus software. Scanners check a computer system and detect viruses; these must be updated regularly, as new viruses are written and released. Other utilities allow a user to edit the data on hard and floppy discs directly or repair system damage. Still other types, which may come with specialized hardware, function by detecting and blocking changes to files or system activities which are typical of how viruses behave.

antler 'horn' of a deer, often branched, and made of bone rather than horn. Antlers, unlike true horns, are shed and regrown each year. Reindeer of both sexes grow them, but in all other types of deer, only the males have antlers.

During growth the antler is covered by a sensitive, hairy skin, known as 'velvet', which dries up and is rubbed off when maturity is attained. The number and complexity of the branches increase year by year.

ant lion larva of one of the insects of the family Myrmeleontidae, order Neuroptera, which traps ants by waiting at the bottom of a pit dug in loose, sandy soil. Ant lions are mainly tropical, but also occur in parts of Europe, where there are more than 40 species, and in the USA, where they are called doodlebugs.

anus or **anal canal** the opening at the end of the alimentary canal that allows undigested food and other waste materials to pass out of the body, in the form of faeces. In humans, the term is also used to describe the last 4 cm/1.5 in of the alimentary canal. The anus is found in all types of multicellular animal except the coelenterates

(sponges) and the platyhelminths (flatworms), which have a mouth only.

It is normally kept closed by rings of muscle called sphincters. The commonest medical condition associated with the anus is haemorrhoids (piles).

anxiety unpleasant, distressing emotion usually to be distinguished from fear. Fear is aroused by the perception of actual or threatened danger; anxiety arises when the danger is imagined or cannot be identified or clearly perceived. It is a normal response in stressful situations, but is frequently experienced in many mental disorders.

Anxiety is experienced as a feeling of suspense, helplessness, or alternating hope and despair together with excessive alertness and characteristic bodily changes such as tightness in the throat, disturbances in breathing and heartbeat, sweating, and diarrhoea.

In psychiatry, an anxiety state is a type of neurosis in which the anxiety either seems to arise for no reason or else is out of proportion to what may have caused it. 'Phobic anxiety' refers to the irrational fear that characterizes phobias.

AOL abbreviation for America Online; the UK version of the US service.

aorta the body's main artery, arising from the left ventricle of the heart in birds and mammals. Carrying freshly oxygenated blood, it arches over the top of the heart and descends through the trunk, finally splitting in the lower abdomen to form the two iliac arteries. Loss of elasticity in the aorta provides evidence of atherosclerosis, which may lead to heart disease.

In fish a ventral aorta carries deoxygenated blood from the heart to the gills, and the dorsal aorta carries oxygenated blood from the gills to other parts of the body.

a.p. in physics, abbreviation for atmospheric pressure.

Apache Point Observatory US observatory in the Sacramento Mountains of New Mexico containing a 3.5-m/138-in reflector, opened 1994, and operated by the Astrophysical Research Consortium (the universities of Washington, Chicago, Princeton, New Mexico, and Washington State).

apastron the point at which an object travelling in an elliptical orbit around a star is at its furthest from the star. The term is usually applied to the position of the minor component of a binary star in relation to the primary. Its opposite is periastron.

apatite common calcium phosphate mineral, $\text{Ca}_5(\text{PO}_4)_3(\text{F,OH,Cl})$. Apatite has a hexagonal structure and occurs widely in igneous rocks, such as pegmatite, and in contact metamorphic rocks, such as marbles. It is used in the manufacture of fertilizer and as a source of phosphorus. Carbonate hydroxylapatite, $\text{Ca}_5(\text{PO}_4)_3(\text{OH})_2$, is the chief constituent of tooth enamel and, together with other related phosphate minerals, is the inorganic constituent of bone. Apatite ranks 5 on the Mohs' scale of hardness.

apatosaurus large plant-eating dinosaur, formerly called *brontosaurus*, which flourished about 145 million years ago. Up to 21 m/69 ft long and 30 tonnes in weight, it stood on four elephantlike legs and had a long tail, long neck, and small head. It probably snipped off low-growing vegetation with peglike front teeth, and swallowed it whole to be ground by pebbles in the stomach.

ape primate of the family Pongidae, closely related to humans, including gibbon, orang-utan, chimpanzee, and gorilla.

If it is true that we have sprung from the ape, there are occasions when my own spring appears not to have been very far.

CORNELIA OTIS SKINNER US writer and actress.
The Ape in Me, title essay

Ape City Yerkes Regional Primate Center, Atlanta, Georgia, where large numbers of primates are kept for physiological and

psychological experiment. A major area of research at Ape City is language.

aperture in photography, an opening in the camera that allows light to pass through the lens to strike the film. Controlled by the iris diaphragm, it can be set mechanically or electronically at various diameters.

The **aperture ratio** or **relative aperture**, more commonly known as the f -number, is a number defined as the focal length of the lens divided by the effective diameter of the aperture. A smaller f -number implies a larger diameter lens and therefore more light available for high-speed photography, or for work in poorly illuminated areas. However, small f -numbers involve small depths of focus.

aperture synthesis in astronomy, a technique used in radio astronomy in which several small radio dishes are linked together to simulate the performance of one very large radio telescope, which can be many kilometres in diameter. See radio telescope.

apex the highest point of a triangle, cone, or pyramid – that is, the vertex (corner) opposite a given base.

NATIONAL APHASIA ASSOCIATION

<http://www.aphasia.org/>

US-based site with a lot of straightforward information about aphasia; for example, there is a page of important facts and a true/false quiz. The site also contains information about current research and links to support groups for sufferers, their friends, and families.

aphasia general term for the many types of disturbance in language that are due to brain damage, especially in the speech areas of the dominant hemisphere.

aphelion the point at which an object, travelling in an elliptical orbit around the Sun, is at its furthest from the Sun. The Earth is at its aphelion on 5 July.

aphid any of the family of small insects, Aphididae, in the order Hemiptera, suborder Homoptera, that live by sucking sap from plants. There are many species, often adapted to particular plants; some are agricultural pests.

aphid A colony of aphids *Cavariella konoii*, commonly known as greenfly, feeding on green stems of the almond willow. Ants often attend such colonies to feed on the honeydew (a sweet, sticky substance) that aphids excrete. Premaphotos Wildlife

In some stages of their life cycle, wingless females rapidly produce large numbers of live young by parthenogenesis, leading to enormous infestations, and numbers can approach 2 billion per hectare/ billion per acre. They can also cause damage by transmitting viral diseases. An aphid that damages cypress and cedar trees appeared in Malawi in 1985 and by 1991 was attacking millions of trees in central and E Africa. Some research suggests, however, that aphids may help promote fertility in the soil through the waste they secrete, termed 'honeydew'. Aphids are also known as plant lice, greenflies, or blackflies.

aphrodisiac from *Aphrodite*, the Greek goddess of love any substance that arouses or increases sexual desire.

API abbreviation for Applications Program Interface, a standard environment in which computer programs are written.

apogee the point at which an object, travelling in an elliptical orbit around the Earth, is at its furthest from the Earth.

Apollo asteroid member of a group of asteroids whose orbits cross that of the Earth. They are named after the first of their kind, Apollo, discovered in 1932 and then lost until 1973. Apollo asteroids are so small and faint that they are difficult to see except when close to Earth (Apollo is about 2 km/1.2 mi across).

Apollo project US space project to land a person on the Moon, achieved 20 July 1969, when Neil Armstrong was the first to set foot there. He was accompanied on the Moon's surface by 'Buzz' Aldrin. Michael Collins remained in the orbiting command module.

The programme was announced in 1961 by President Kennedy. The world's most powerful rocket, *Saturn V*, was built to launch the Apollo spacecraft, which carried three astronauts. When the spacecraft was in orbit around the Moon, two astronauts would descend to the surface in a lunar module to take samples of rock and set up experiments that would send data back to Earth. After three other preparatory flights, *Apollo 11* made the first lunar landing. Five more crewed landings followed, the last in 1972. The total cost of the programme was over \$24 billion.

APOLLO 11

http://www.nasa.gov/hqpa/apollo_11.html

This NASA page relives the excitement of the *Apollo 11* mission, with recollections from the participating astronauts, images, audio clips, access to key White House documents, and a bibliography.

Apollo-Soyuz test project joint US-Soviet space mission in which an Apollo and a Soyuz craft docked while in orbit around the Earth on 17 July 1975. The craft remained attached for two days and crew members were able to move from one craft to the other through an airlock attached to the nose of the Apollo. The mission was designed to test rescue procedures as well as having political significance.

apoptosis or **cell suicide** a cell's destruction of itself. All cells contain genes that cause them to self-destruct if damaged, diseased, or as part of the regulation of cell numbers during the organism's normal development. Many cancer cells have mutations in genes controlling apoptosis, so understanding apoptosis may lead to new cancer treatments where cells can be instructed to destroy themselves.

During apoptosis, a cell first produces the enzymes needed for self-destruction before shrinking to a characteristic spherical shape with balloon-like bumps on its outer surface. The enzymes break down its contents into small fragments which are easily digestible by surrounding cells.

aposematic coloration in biology, the technical name for warning coloration markings that make a dangerous, poisonous, or

foul-tasting animal particularly conspicuous and recognizable to a predator. Examples include the yellow and black stripes of bees and wasps, and the bright red or yellow colours of many poisonous frogs. See also mimicry.

apothecaries' weights obsolete units of mass, formerly used in pharmacy: 24 grains equal one scruple; three scruples equal one dram; eight drams equal an apothecary's ounce (16 apoth.), and 12 such ounces equal an apothecary's pound (16 apoth.). There are 7,000 grains in one pound avoirdupois (0.454 kg).

apparent depth depth that a transparent material such as water or glass appears to have when viewed from above. This is less than its real depth because of the refraction that takes place when light passes into a less dense medium. The ratio of the real depth to the apparent depth of a transparent material is equal to its refractive index.

appendicitis inflammation of the appendix, a small, blind extension of the bowel in the lower right abdomen. In an acute attack, the pus-filled appendix may burst, causing a potentially lethal spread of infection. Treatment is by removal (appendicectomy).

appendix a short, blind-ended tube attached to the caecum. It has no known function in humans, but in herbivores it may be large, containing millions of bacteria that secrete enzymes to digest grass (as no vertebrate can secrete enzymes that will digest cellulose, the main constituent of plant cell walls).

apple fruit of several species of apple tree. There are several hundred varieties of cultivated apples, grown all over the world, which may be divided into eating, cooking, and cider apples. All are derived from the wild crab apple. (Genus *Malus*, family Rosaceae.)

Apple trees grow best in temperate countries with a cool climate and plenty of rain during the winter. The desired variety is grafted onto rootstocks, and the tree must grow for six to eight years before it produces a good crop of fruit. The tree requires a winter period, in which it is dormant, in order to fruit in the spring, but must be protected from frost while the flowers and fruit are young. Pruning is necessary to produce strong branches, and sprays are used to protect the fruit from pests and to influence its development. The apple has been an important food plant in Europe and Asia for thousands of years.

Apple US computer company, manufacturer of the Macintosh range of computers.

applet mini-software application. Examples of applets include Microsoft WordPad, the simple word processor in Windows 95, or the single-purpose applications that in 1996 were beginning to appear on the World Wide Web, written in Java. These include small animations, such as a moving ticker tape of stock prices.

Appleton layer or *F layer* band containing ionized gases in the Earth's upper atmosphere, at a height of 150–1,000 km/94–625 mi, above the E layer (formerly the Kennelly-Heaviside layer). It acts as a dependable reflector of radio signals as it is not affected by atmospheric conditions, although its ionic composition varies with the sunspot cycle.

The Appleton layer has the highest concentration of free electrons and ions of the atmospheric layers. It is named after the English physicist Edward Appleton.

application in computing, a program or job designed for the benefit of the end user, such as a payroll system or a word processor. The term is used to distinguish such programs from those that control the computer (systems programs) or assist the programmer, such as a compiler.

application in mathematics, a curved line that connects a series of points (or 'nodes') in the smoothest possible way. The shape of the curve is governed by a series of complex mathematical formulae. Applications are used in computer graphics and CAD.

applications package in computing, the set of programs and related documentation (such as instruction manuals) used in a particular application. For example, a typical payroll applications package would consist of separate programs for the entry of data,

updating the master files, and printing the pay slips, plus documentation in the form of program details and instructions for use.

Applications Program Interface (API) in computing, standard environment, including tools, protocols, and other routines, in which programs can be written. An API ensures that all applications are consistent with the operating system and have a similar user interface.

appropriate technology simple or small-scale machinery and tools that, because they are cheap and easy to produce and maintain, may be of most use in the developing world; for example, hand ploughs and simple looms. This equipment may be used to supplement local crafts and traditional skills to encourage small-scale industrialization.

Many countries suffer from poor infrastructure and lack of capital but have the large supplies of labour needed for this level of technology. The use of appropriate technology was one of the recommendations of the Brandt Commission.

approximation rough estimate of a given value. For example, for π (which has a value of 3.1415926 correct to seven decimal places), 3 is an approximation to the nearest whole number.

APR abbreviation for annual percentage rate.

apricot yellow-fleshed fruit of the apricot tree, which is closely related to the almond, peach, plum, and cherry. Although native to the Far East, it has long been cultivated in Armenia, from where it was introduced into Europe and the USA. (Genus *Prunus armeniaca*, family Rosaceae.)

aquaculture the cultivation of fish and shellfish for human consumption; see fish farming.

aqualung or *scuba* underwater breathing apparatus worn by divers, developed in the early 1940s by French diver Jacques Cousteau. Compressed-air cylinders strapped to the diver's back are regulated by a valve system and by a mouth tube to provide air to the diver at the same pressure as that of the surrounding water (which increases with the depth).

aquamarine blue variety of the mineral beryl. A semiprecious gemstone, it is used in jewellery.

aquaplaning phenomenon in which the tyres of a road vehicle cease to make direct contact with the road surface, owing to the presence of a thin film of water. As a result, the vehicle can go out of control (particularly if the steered wheels are involved).

aqua regia Latin 'royal water' mixture of three parts concentrated hydrochloric acid and one part concentrated nitric acid, which dissolves all metals except silver.

aquarium tank or similar container used for the study and display of living aquatic plants and animals. The same name is used for institutions that exhibit aquatic life. These have been common since Roman times, but the first modern public aquarium was opened in Regent's Park, London in 1853. A recent development is the oceanarium or seaquarium, a large display of marine life forms.

Aquarius zodiacal constellation a little south of the celestial equator near Pegasus. Aquarius is represented as a man pouring water from a jar. The Sun passes through Aquarius from late February to early March. In astrology, the dates for Aquarius, the 11th sign of the zodiac, are between about 20 January and 18 February (see precession).

aquatic living in water. All life on Earth originated in the early oceans, because the aquatic environment has several advantages for organisms. Dehydration is almost impossible, temperatures usually remain stable, and the density of water provides physical support.

Life forms that cannot exist out of water, amphibians that take to the water on occasions, animals that are also perfectly at home on land, and insects that spend a stage of their life cycle in water can all be described as aquatic. Aquatic plants are known as hydrophytes.

aquatic insect insect that spends all or part of its life in water. Of the 29 insect orders, 11 members have some aquatic stages. Most of these have aquatic, immature stages, which usually take place in fresh water, sometimes in brackish water (very few species are truly marine); the adults are terrestrial, but in some orders there are species where all stages (egg, larva, and adult) live in the water. **partially aquatic** Three orders, Ephemeroptera (mayflies), Odonata (dragonflies), and Plecoptera (stoneflies) have aquatic larvae, but the adults are terrestrial. In the orders Neuroptera (alders flies), Tricoptera (caddis flies), Lepidoptera (butterflies and moths), and Diptera (true flies), some species have aquatic larvae, but the adults of all species are terrestrial. Hymenoptera, the social insect order which includes the ants and bees, has some aquatic species of ichneumon fly: immature stages of *Agrotipus* are aquatic, and adults of *Caraphractus* and *Prestwichia*.

totally aquatic The order Collembola (springtails) has two species in which all stages are aquatic: *Hydropodura aquatica* and *Isotoma palustris*. In Hemiptera (bugs), and Coleoptera (beetles), some members, for example the water bugs, spend all stages of the life-cycle in the water.

aqueduct any artificial channel or conduit for water, originally applied to water supply tunnels, but later used to refer to elevated structures of stone, wood, or iron carrying navigable canals across valleys. One of the first great aqueducts was built in 691 BC, carrying water for 80 km/50 mi to Nineveh, capital of the ancient Assyrian Empire. Many Roman aqueducts are still standing, for example the one carried by the Pont du Gard at Nîmes in S France, built about 8 BC (48 m/160 ft high).

The largest Roman aqueduct, at Carthage in Tunisia, is 141 km/87 mi long and was built during the reign of Publius Aelius Hadrianus between AD 117 and 138. A recent aqueduct is the California State Water Project taking water from Lake Oroville in the north, through two power plants and across the Tehachapi Mountains, more than 177 km/110 mi to S California.

aqueous humour watery fluid found in the chamber between the cornea and lens of the vertebrate eye. Similar to blood serum in composition, it is constantly renewed.

aqueous solution solution in which the solvent is water.

aquifer a body of rock through which appreciable amounts of water can flow. The rock of an aquifer must be porous and permeable (full of interconnected holes) so that it can conduct water. Aquifers are an important source of fresh water, for example, for drinking and irrigation, in many arid areas of the world, and are exploited by the use of artesian wells.

An aquifer may be underlain, overlain, or sandwiched between less permeable layers, called aquicludes or **aquitards**, which impede water movement. Sandstones and porous limestones make the best aquifers.

Aquila constellation on the celestial equator (see *celestial sphere*). Its brightest star is first-magnitude α Altair, flanked by the stars Beta and Gamma Aquilae. It is represented by an eagle.

Nova Aquilae, which appeared June 1918, shone for a few days nearly as brightly as Sirius.

arable farming cultivation of crops, as opposed to the keeping of animals. Crops may be cereals, vegetables, or plants for producing oils or cloth. Arable farming generally requires less attention than livestock farming. In a mixed farming system, crops may therefore be found farther from the farm centre than animals.

arachnid or **arachnoid** type of arthropod of the class Arachnida, including spiders, scorpions, ticks, and mites. They differ from insects in possessing only two main body regions, the cephalothorax and the abdomen, and in having eight legs.

araucaria coniferous tree related to the firs, with flat, scalelike needles. Once widespread, it is now native only to the southern hemisphere. Some grow to gigantic size. Araucarias include the monkey-puzzle tree (*Araucaria araucana*), the Australian bunya bunya pine (*A. bidwillii*), and the Norfolk Island pine (*A. heterophylla*). (Genus *Araucaria*, family Araucariaceae.)

ARACHNOLOGY

<http://dns.ufsia.ac.be/Arachnology/Arachnology.html>

Largely a collection of annotated links, organized under headings such as taxonomy and classification, palaeontology, poison, bites, diseases, pests, and phobia. The site also contains spider-related myths, stories, poems, songs, and art.

arboretum collection of trees. An arboretum may contain a wide variety of species or just closely related species or varieties – for example, different types of pine tree.

arbor vitae any of several coniferous trees or shrubs belonging to the cypress family, with flattened branchlets covered in overlapping aromatic green scales. The northern white cedar (*Thuja occidentalis*) and the western red cedar (*T. plicata*) are found in North America. The Chinese or Oriental species *T. orientalis*, reaching 18 m/60 ft in height, is widely grown as an ornamental. (Genus *Thuja*, family Cupressaceae.)

arbutus any of a group of evergreen shrubs belonging to the heath family, found in temperate regions. The strawberry tree (*Arbutus unedo*) is grown for its ornamental, strawberrylike fruit. (Genus *Arbutus*, family Ericaceae.)

arc in geometry, a section of a curved line or circle. A circle has three types of arc: a **semicircle**, which is exactly half of the circle; **minor arcs**, which are less than the semicircle; and **major arcs**, which are greater than the semicircle.

An arc of a circle is measured in degrees, according to the angle formed by joining its two ends to the centre of that circle. A semicircle is therefore 180°, whereas a minor arc will always be less than 180° (acute or obtuse) and a major arc will always be greater than 180° but less than 360° (reflex).

Archaea group of microorganisms that are without a nucleus and have a single chromosome. All are strict anaerobes, that is, they are killed by oxygen. This is thought to be a primitive condition and to indicate that Archaea are related to the earliest life forms, which appeared about 4 billion years ago, when there was little oxygen in the Earth's atmosphere. They are found in undersea vents, hot springs, the Dead Sea, and salt pans, and have even adapted to refuse tips.

Archaea was originally classified as bacterial, but in 1996 when the genome of *Methanococcus jannaschii* (an archaeon that lives in undersea vents at temperatures around 100°C/212°F) was sequenced, US geneticists found that 56% of its genes were unlike those of any other organism, making Archaea unique.

In 1994 US biologists detected archaeans in the Antarctic (where they make up 30% of the single-celled marine biomass), Arctic, Mediterranean, and Baltic Sea.

Archean or **Archeozoic** widely used term for the earliest era of geological time; the first part of the Precambrian Eon, spanning the interval from the formation of Earth to about 2,500 million years ago.

archaeology Greek *archaia* 'ancient things', *logos* 'study' study of prehistory and history, based on the examination of physical remains. Principal activities include preliminary field (or site) surveys, excavation (where necessary), and the classification, dating, and interpretation of finds.

history A museum found at the ancient Sumerian city of Ur indicates that interest in the physical remains of the past stretches back into prehistory. In the Renaissance this interest gained momentum among dealers in and collectors of ancient art and was further stimulated by discoveries made in Africa, the Americas, and Asia by Europeans during the period of imperialist colonization in the 16th–19th centuries, such as the antiquities discovered during Napoleon's Egyptian campaign in the 1790s. Romanticism in Europe stimulated an enthusiasm for the mouldering skull, the

ARCHAEOLOGY

<http://www.archaeology.org/>

Online edition of the prestigious journal of the Archaeological Institute of America. The well-written articles give a glimpse of the range of archaeological research being done around the globe. The full texts of short articles are available online, together with abstracts (and often the full text) of a large number of longer articles. Two years of back issues can be accessed.

ancient potsherds, ruins, and dolmens; relating archaeology to a wider context of art and literature.

Towards the end of the 19th century archaeology became an academic study, making increasing use of scientific techniques and systematic methodologies such as aerial photography. Since World War II new developments within the discipline include medieval, postmedieval, landscape, and industrial archaeology; underwater reconnaissance enabling the excavation of underwater sites; and rescue archaeology (excavation of sites risking destruction).

related disciplines Useful in archaeological studies are dendrochronology (tree-ring dating), geochronology (science of measuring geological time), stratigraphy (study of geological strata), palaeobotany (study of ancient pollens, seeds, and grains), archaeozoology (analysis of animal remains), epigraphy (study of inscriptions), and numismatics (study of coins).

archaeopteryx Greek *archaios* 'ancient', *pteryx* 'wing' extinct primitive bird, known from fossilized remains, about 160 million years old, found in limestone deposits in Bavaria, Germany. It is popularly known as 'the first bird', although some earlier bird ancestors are now known. It was about the size of a crow and had feathers and wings, with three clawlike digits at the end of each wing, but in many respects its skeleton is reptilian (teeth and a long, bony tail) and very like some small meat-eating dinosaurs of the time.

archegonium Greek *arche* 'origin', *gonos* 'offspring' female sex organ found in bryophytes (mosses and liverworts), peridophytes (ferns, club mosses, and horsetails), and some gymnosperms. It is a multicellular, flask-shaped structure consisting of two parts: the swollen base or venter containing the egg cell, and the long, narrow neck. When the egg cell is mature, the cells of the neck dissolve, allowing the passage of the male gametes, or *antherozoids*.

archerfish surface-living fish of the family *Toxotidae*, such as the genus *Toxotes*, native to SE Asia and Australia. The archerfish grows to about 25 cm/10 in and is able to shoot down insects up to 1.5 m/5 ft above the water by spitting a jet of water from its mouth.

Archie software tool for locating information on the Internet. It can be difficult to locate a particular file because of the relatively unstructured nature of the Internet. Archie uses indexes of files and their locations on the Internet to find them quickly.

Archimedes (c. 287–212 BC)

Greek mathematician who made major discoveries in geometry, hydrostatics, and mechanics, and established the sciences of statics and hydrostatics. He formulated a law of fluid displacement (Archimedes' principle), and is credited with the invention of the Archimedes screw, a cylindrical device for raising water. His method of finding mathematical proof to substantiate experiment and observation became the method of modern science in the High Renaissance.

Hydrostatics and Archimedes' principle The best-known result of Archimedes' work on hydrostatics is Archimedes' principle, which states that a body immersed in water will displace a volume of fluid that weighs as much as the body would weigh in air. It is alleged that Archimedes' principle was discovered when he stepped into the public bath and saw the water overflow. He was so delighted that he rushed home naked, crying 'Eureka! Eureka!' ('I have found it! I have found it!').

He used his discovery to prove that the goldsmith of Hieron II, King of Syracuse, had adulterated a gold crown with silver. Archimedes realized that if the gold had been mixed with silver (which is less dense than gold), the crown would have a greater volume and therefore displace more water than an equal weight of pure gold. The story goes that the crown was found to be impure, and that the unfortunate goldsmith was executed.

Statics and the lever In the field of statics, he is credited with working out the rigorous mathematical proofs behind the law of the lever. The lever had been used by other scientists, but it was Archimedes who demonstrated mathematically that the ratio of the effort applied to the load raised is equal to the inverse ratio of the distances of the effort and load from the pivot or fulcrum of the lever. Archimedes is credited with having claimed that if he had a sufficiently distant place to stand, he could use a lever to move the world.

This claim is said to have given rise to a challenge from King Hieron to Archimedes to show how he could move a truly heavy object with ease, even if he could not move the world. In answer to this, Archimedes developed a system of compound pulleys.

According to Plutarch's *Life of Marcellus* (who sacked Syracuse), Archimedes used this to move with ease a ship that had been lifted with great effort by many men out of the harbour on to dry land. The ship was laden with passengers, crew and freight, but Archimedes – sitting at a distance from the ship – was reportedly able to pull it over the land as though it were gliding through water.

Mathematics Archimedes wrote many mathematical treatises, some of which still exist in altered forms in Arabic. Archimedes' approximation for the value for π was more accurate than any previous estimate – the value lying between $\frac{223}{71}$ and $\frac{220}{70}$. The average of these two numbers is less than 0.0003 different from the modern approximation for π . He also examined the expression of very large numbers, using a special notation to estimate the number of grains of sand in the Universe. Although the result, 10^{53} , was far from accurate, Archimedes demonstrated that large numbers could be considered and handled effectively.

Archimedes also evolved methods to solve cubic equations and to determine square roots by approximation. His formulae for the determination of the surface areas and volumes of curved surfaces and solids anticipated the development of integral calculus, which did not come for another 2,000 years. Archimedes had decreed that his gravestone be inscribed with a cylinder enclosing a sphere together with the formula for the ratio of their volumes – a discovery that he regarded as his greatest achievement.

Mary Evans Picture Library

Eureka! I have found it!

ARCHIMEDES Greek mathematician.

Remark, quoted in Vitruvius Pollio *De Architectura* IX

Archimedes' principle in physics, the principle that the weight of the liquid displaced by a floating body is equal to the weight of the body. The principle is often stated in the form: 'an object totally or partially submerged in a fluid displaces a volume of fluid that weighs the same as the apparent loss in weight of the object (which, in turn, equals the upwards force, or upthrust, experienced by that object).' It was discovered by the Greek mathematician Archimedes.

Archimedes screw one of the earliest kinds of pump, associated with the Greek mathematician Archimedes. It consists of an enormous spiral screw revolving inside a close-fitting cylinder. It is used, for example, to raise water for irrigation.

The lowest portion of the screw just dips into the water, and as the cylinder is turned a small quantity of water is scooped up. The inclination of the cylinder is such that at the next revolution the water is raised above the next thread, whilst the lowest thread scoops up another quantity. The successive revolutions, therefore, raise the water thread by thread until it emerges at the top of the cylinder.

archipelago group of islands, or an area of sea containing a group of islands. The islands of an archipelago are usually volcanic in origin, and they sometimes represent the tops of peaks in areas around continental margins flooded by the sea.

Volcanic islands are formed either when a hot spot within the Earth's mantle produces a chain of volcanoes on the surface, such as the Hawaiian Archipelago or at a destructive plate margin (see plate tectonics) where the subduction of one plate beneath another produces an arc-shaped island group called an 'island arc', such as the Aleutian Archipelago. Novaya Zemlya in the Arctic Ocean, the northern extension of the Ural Mountains, resulted from continental flooding.

architecture in computing, the overall design of a computer system, encompassing both hardware and software. The architecture of a particular system includes the specifications of individual components and the ways they interact. Because the operating system defines how these elements interact with each other and with application software, it is also included in the term.

archive collection of computer files. The term is commonly used to refer to the files created by data compression programs, such as the

popular PKZIP, which contain one or more files. On the Internet it is also used to refer to a large store of files from which visitors can select the ones they want.

arc lamp or **arc light** electric light that uses the illumination of an electric arc maintained between two electrodes. The English chemist Humphry Davy demonstrated the electric arc in 1802 and electric arc lighting was first introduced by English electrical engineer W E Staite (1809–1854) in 1846. The lamp consists of two carbon electrodes, between which a very high voltage is maintained. Electric current arcs (jumps) between the two electrolytes, creating a brilliant light. Its main use in recent years has been in cinema projectors.

arc minute, **arc second** units for measuring small angles, used in geometry, surveying, map-making, and astronomy. An arc minute (symbol ') is one-sixtieth of a degree, and an arc second (symbol ") is one-sixtieth of an arc minute. Small distances in the sky, as between two close stars or the apparent width of a planet's disc, are expressed in minutes and seconds of arc.

arctic animals animals inhabiting the Arctic. The birds are chiefly sea birds, such as petrels, eider ducks, cormorants, auks, gulls, puffins, and gullmots; all are migratory. The mammals include the walrus, seals, and several varieties of whale; the polar bear, reindeer, elk, fox, wolf, ermine, and musk-ox are the principal terrestrial mammals.

Insectivorous and herbivorous habits are almost absent in arctic animals, which are either fish- or meat-eating. Many of them become snowy white in winter; among these are birds, such as the ptarmigan, and mammals, such as the hare and lemming, which are brown in summer, and the arctic fox, which is salty-blue in summer; the polar bear is white all year round.

Molluscs, annelids, and jellyfish are common to all the northern seas, while such fish as salmon, cod, and halibut are plentiful. Insects found in the far north include bees, flies, and butterflies, but as the flora is scanty they do not occur in great abundance.

ARCTIC CIRCLE

<http://www.lib.uconn.edu/ArcticCircle/>

Well-written site with excellent information about all aspects of life in the Arctic. There are sections on history, natural resources, the rights of indigenous peoples, and issues of environmental concern.

Arctic Circle imaginary line that encircles the North Pole at latitude 66° 33' north. Within this line there is at least one day in the summer during which the Sun never sets, and at least one day in the winter during which the Sun never rises.

Arcturus or **Alpha Boötis** brightest star in the constellation Boötis and the fourth-brightest star in the sky. Arcturus is a red giant about 28 times larger than the Sun and 70 times more luminous, 36 light years away from Earth.

are metric unit of area, equal to 100 square metres (119.6 sq yd); 100 ares make one hectare.

area the size of a surface. It is measured in square units, usually square centimetres (cm²), square metres (m²), or square kilometre.

Areas: Common Areas

| figure | rule for calculating area |
|---------------|------------------------------------------------------------------------|
| rectangle | length × breadth |
| triangle | half base length × vertical height |
| parallelogram | base length × vertical height |
| trapezium | average length of parallel sides × perpendicular distance between them |
| circle | πr^2 , where r is the radius |
| | $\frac{x}{360} \pi r^2$ where x is the angle of the sector |

Archimedes screw The Archimedes screw, a spiral screw turned inside a cylinder, was once commonly used to lift water from canals. The screw is still used to lift water in the Nile delta in Egypt, and is often used to shift grain in mills and powders in factories.

tres (km²). Surface area is the area of the outer surface of a solid.

The areas of geometrical plane shapes with straight edges are determined using the area of a rectangle. Integration may be used to determine the area of shapes enclosed by curves.

areca any of a group of palm trees native to Asia and Australia. The betel nut comes from the species *Areca catechu*. (Genus *Areca*.)

Arecibo site in Puerto Rico of the world's largest single-dish radio telescope, 305 m/1,000 ft in diameter. It is built in a natural hollow and uses the rotation of the Earth to scan the sky. It has been used both for radar work on the planets and for conventional radio astronomy, and is operated by Cornell University, USA.

In 1996 it received a \$25 million upgrade, increasing the sensitivity of the dish tenfold. Two new mirrors were also added and the observation frequency increased from 3,000 megahertz to up to 10,000 megahertz. Another upgrade took place in 1997, when a new receiver capable of monitoring 168 million radio channels, SERENDIP IV, was added to the facility.

Water, water, everywhere, / Nor any drop to drink.

SAMUEL COLERIDGE English poet.
The Ancient Mariner pt 2

arête (German *grat*; North American *combe-ridge*) sharp narrow ridge separating two glacial troughs (valleys), or corries. The typical U-shaped cross sections of glacial troughs give arêtes very steep sides. Arêtes are common in glaciated mountain regions such as the Rockies, the Himalayas, and the Alps.

argali wild sheep from the mountains of central Asia. It is the largest species of sheep with a shoulder height of up to 1.2 m/4 ft. **classification** Argali *Ovis ammon* is in family Bovidae, order Artiodactyla.

Argand diagram in mathematics, a method for representing complex numbers by Cartesian coordinates (*x*, *y*). Along the *x*-axis (horizontal axis) are plotted the real numbers, and along the *y*-axis (vertical axis) the nonreal, or imaginary, numbers.

argon Greek *argos* 'idle' colourless, odourless, nonmetallic, gaseous element, symbol Ar, atomic number 18, relative atomic mass 39.948. It is grouped with the inert gases, since it was long believed not to react with other substances, but observations now indicate that it can be made to combine with boron fluoride to form compounds. It constitutes almost 1% of the Earth's atmosphere, and was discovered in 1894 by British chemists John Rayleigh (1842-1919) and William Ramsay after all oxygen and nitrogen had been removed chemically from a sample of air. It is used in electric discharge tubes and argon lasers.

argonaut or *paper nautilus* octopus living in the open sea, genus *Argonauta*. The female of the common paper nautilus, *A. argo*, is 20 cm/8 in across, and secretes a spiralled papery shell for her eggs from the web of the first pair of arms. The male is a shell-less dwarf, 1 cm/0.4 in across.

argument in computing, the value on which a function operates. For example, if the argument 16 is operated on by the function 'square root', the answer 4 is produced.

argument in mathematics, a specific value of the independent variable of a function of *x*. It is also another name for amplitude.

Ariane launch vehicle built in a series by the European Space Agency (first flight 1979). The launch site is at Kourou in French Guiana. Ariane is a three-stage rocket using liquid fuels. Small solid-fuel and liquid-fuel boosters can be attached to its first stage to increase carrying power.

Since 1984 it has been operated commercially by ArianeSpace, a private company financed by European banks and aerospace industries. A more powerful version, *Ariane 5*, was launched 4 June 1996, and was intended to carry astronauts aboard the

Hermes spaceplane. However, it went off course immediately after takeoff, turned on its side, broke into two and disintegrated. A fault in the software controlling the takeoff trajectory was to blame.

A mostly successful test flight for *Ariane 5* was completed in November 1997.

arid region in earth science, a region that is very dry and has little vegetation. Aridity depends on temperature, rainfall, and evaporation, and so is difficult to quantify, but an arid area is usually defined as one that receives less than 250 mm/10 in of rainfall each year. (By comparison, New York City receives 1,120 mm/44 in per year.) There are arid regions in North Africa, Pakistan, Australia, the USA, and elsewhere. Very arid regions are deserts.

Ariel series of six UK satellites launched by the USA 1962-79, the most significant of which was *Ariel 5* in 1974, which made a pioneering survey of the sky at X-ray wavelengths.

Aries zodiacal constellation in the northern hemisphere between Pisces and Taurus, near Auriga, represented as the legendary ram whose golden fleece was sought by Jason and the Argonauts.

Its most distinctive feature is a curve of three stars of decreasing brightness. The brightest of these is Hamal or Alpha Arietis, 65 light years from Earth.

The Sun passes through Aries from late April to mid-May. In astrology, the dates for Aries, the first sign of the zodiac, are between about 21 March and 19 April (see ♈ precession). The spring equinox once lay in Aries, but has now moved into Pisces through the effect of the Earth's precession (wobble).

aril accessory seed cover other than a fruit; it may be fleshy and sometimes brightly coloured, woody, or hairy. In flowering plants (angiosperms) it is often derived from the stalk that originally attached the ovule to the ovary wall. Examples of arils include the bright-red, fleshy layer surrounding the yew seed (yews are gymnosperms so they lack true fruits), and the network of hard filaments that partially covers the nutmeg seed and yields the spice known as mace.

Another aril, the horny outgrowth found towards one end of the seed of the castor-oil plant *Ricinus communis*, is called a caruncle. It is formed from the integuments (protective layers enclosing the ovule) and develops after fertilization.

arithmetic branch of mathematics concerned with the study of numbers and their properties. The fundamental operations of arithmetic are addition, subtraction, multiplication, and division. Raising to powers (for example, squaring or cubing a number), the extraction of roots (for example, square roots), percentages, fractions, and ratios are developed from these operations.

Forms of simple arithmetic existed in prehistoric times. In China, Egypt, Babylon, and early civilizations generally, arithmetic was used for commercial purposes, records of taxation, and astronomy. During the Dark Ages in Europe, knowledge of arithmetic was preserved in India and later among the Arabs. European mathematics revived with the development of trade and overseas exploration. Hindu-Arabic numerals replaced Roman numerals, allowing calculations to be made on paper, instead of by the abacus.

The essential feature of this number system was the introduction of zero, which allows us to have a place-value system. The decimal numeral system employs ten numerals (0, 1, 2, 3, 4, 5, 6, 7, 8, 9) and is said to operate in 'base ten'. In a base-ten number, each position has a value ten times that of the position to its immediate right; for example, in the number 23 the numeral 3 represents three units (ones), and the numeral 2 represents two tens. The Babylonians, however, used a complex base-sixty system, residues of which are found today in the number of minutes in each hour and in angular measurement (6 × 60 degrees). The Mayas used a base-twenty system.

There have been many inventions and developments to make the manipulation of the arithmetic processes easier, such as the invention of logarithms by Scottish mathematician John Napier in 1614 and of the slide rule in the period 1620-30. Since then, many forms of ready reckoners, mechanical and electronic calculators, and computers have been invented.

Modern computers fundamentally operate in base two, using only two numerals (0,1), known as a binary system. In binary, each position has a value twice as great as the position to its immediate right, so that for example binary 111 (or 111_2) is equal to 7 in the decimal system, and binary 1111 (or 1111_2) is equal to 15. Because the main operations of subtraction, multiplication, and division can be reduced mathematically to addition, digital computers carry out calculations by adding, usually in binary numbers in which the numerals 0 and 1 can be represented by off and on pulses of electric current.

Modular or modulo arithmetic, sometimes known as residue arithmetic or clock arithmetic, can take only a specific number of digits, whatever the value. For example, in modulo 4 (mod 4) the only values any number can take are 0, 1, 2, or 3. In this system, 7 is written as 3 mod 4, and 35 is also 3 mod 4. Notice 3 is the residue, or remainder, when 7 or 35 is divided by 4. This form of arithmetic is often illustrated on a circle. It deals with events recurring in regular cycles, and is used in describing the functioning of petrol engines, electrical generators, and so on. For example, in the mod 12, the answer to a question as to what time it will be in five hours if it is now ten o'clock can be expressed $10 + 5 = 3$.

arithmetic and logic unit (ALU) in a computer, the part of the ϕ central processing unit (CPU) that performs the basic arithmetic and logic operations on data.

arithmetic mean the average of a set of n numbers, obtained by adding the numbers and dividing by n . For example, the arithmetic mean of the set of 5 numbers 1, 3, 6, 8, and 12 is $(1 + 3 + 6 + 8 + 12)/5 = 30/5 = 6$.

The term 'average' is often used to refer only to the arithmetic mean, even though the mean is in fact only one form of average (the others include ϕ median and ϕ mode).

arithmetic progression or arithmetic sequence sequence of numbers or terms that have a common difference between any one term and the next in the sequence. For example, 2, 7, 12, 17, 22, 27, ... is an arithmetic sequence with a common difference of 5.

The n th term in any arithmetic progression can be found using the formula:

$$n\text{th term} = a + (n - 1)d$$

where a is the first term and d is the common difference.

An **arithmetic series** is the sum of the terms in an arithmetic sequence. The sum S of n terms is given by:

$$S = \frac{n}{2}(2a + (n - 1)d)$$

ARM (abbreviation for *Advanced RISC Machine*) microprocessor developed by Acorn in 1985 for use in the Archimedes microcomputer. In 1990 the company Advanced RISC Machines was formed to develop the ARM microprocessor. The ARM is the microprocessor in Apple's ϕ Newton.

armadillo mammal of the family Dasypodidae, with an armour of bony plates along its back or, in some species, almost covering the entire body. Around 20 species live between Texas and Patagonia and range in size from the fairy armadillo, or picichego, *Chlamyphorus truncatus*, at 13 cm/5 in, to the giant armadillo *Prionotus giganteus*, 1.5 m/4.5 ft long. Armadillos feed on insects, snakes, fruit, and carrion. Some can roll into an armoured ball if attacked; others defend themselves with their claws or rely on rapid burrowing for protection.

ARMADILLO

Nine-banded armadillos almost always produce litters of quadruplets. The one fertilized egg divides into four to produce a single-sex litter of identical babies. If times are hard, the female armadillo can delay the implantation of her egg for up to three years to maximize the chances of her offspring's survival.

They belong to the order Edentata ('without teeth') which also includes sloths and anteaters. However, only the latter are toothless. Some species of armadillos can have up to 90 peglike teeth.

armature in a motor or generator, the wire-wound coil that carries the current and rotates in a magnetic field. (In alternating-current machines, the armature is sometimes stationary.) The pole piece of a permanent magnet or electromagnet and the moving, iron part of a solenoid, especially if the latter acts as a switch, may also be referred to as armatures.

armillary sphere earliest known astronomical device, in use from the 3rd century BC. It showed the Earth at the centre of the universe, surrounded by a number of movable metal rings representing the Sun, Moon, and planets. The armillary sphere was originally used to observe the heavens and later for teaching navigators about the arrangements and movements of the heavenly bodies.

aromatherapy in alternative medicine, use of oils and essences derived from plants, flowers, and wood resins. Bactericidal properties and beneficial effects upon physiological functions are attributed to the oils, which are sometimes ingested but generally massaged into the skin.

Aromatherapy was first used in ancient Greece and Egypt, but became a forgotten art until the 1930s, when a French chemist accidentally spilt lavender over a cut and found that the wound healed without a scar. However, it was not until the 1970s that it began to achieve widespread popularity.

aromatic compound organic chemical compound in which some of the bonding electrons are delocalized (shared among several atoms within the molecule and not localized in the vicinity of the atoms involved in bonding). The commonest aromatic compounds have ring structures, the atoms comprising the ring being either all carbon or containing one or more different atoms (usually nitrogen, sulphur, or oxygen). Typical examples are benzene (C_6H_6) and pyridine (C_5H_5N).

ARPANET (acronym for *Advanced Research Projects Agency Network*) early US network that forms the basis of the ϕ Internet. It was set up in 1969 by ARPA to provide services to US academic institutions and commercial organizations conducting computer science research.

ARPANET pioneered many of today's networking techniques.

It was renamed DARPA/NET when ARPA changed its name to Defense Advanced Research Projects Agency. In 1975 responsibility for DARPA/NET was passed on to the Defense Communication Agency.

array in computer programming, a list of values that can all be referred to by a single ϕ variable name. Separate values are distinguished by using a subscript with each variable name.

Arrays are useful because they allow programmers to write general routines that can process long lists of data. For example, if every price stored in an accounting program used a different variable name, separate program instructions would be needed to process each price. However, if all the prices were stored in an array, a general routine could be written to process, say, 'price (J)', and, by allowing J to take different values, could then process any individual price.

For example, consider this list of highest daily temperatures: day 1 - 22°C; day 2 - 23°C; day 3 - 19°C; day 4 - 21°C. This array might be stored with the single variable name 'temp'. Separate elements of the array would then be identified with subscripts. So, for example, the array element 'temp(J)' would store the value '22', and the array element 'temp(J)' would store the value '19'.

array collection of numbers (or letters representing numbers) arranged in rows and columns. A ϕ matrix is an array shown inside a pair of brackets; it indicates that the array should be treated as a single entity.

arrhythmia disturbance of the normal rhythm of the heart. There are various kinds of arrhythmia, some benign, some indicative of heart disease. In extreme cases, the heart may beat so fast as to be potentially lethal and surgery may be used to correct the condition.

aromatic compound Compounds whose molecules contain the benzene ring, or variations of it, are called aromatic. The term was originally used to distinguish sweet-smelling compounds from others.

Extra beats between the normal ones are called extrasystoles; abnormal slowing is known as bradycardia and speeding up is known as tachycardia.

arrowroot starchy substance used as a thickener in cooking, produced from the clumpy roots of various tropical plants. The true arrowroot (*Maranta arundinacea*) was used by native South Americans as an antidote against the effects of poisoned arrows.

The West Indian island of St Vincent is the main source of supply today. The plant roots and tubers are dried, finely powdered, and filtered. Because of the small size of the starch particles, the powder becomes translucent when cooked.

arrowwood any of various North American trees and shrubs, especially of the genus *Viburnum*, named for their long, straight branches, which were used by American Indians to make arrows.

arsenic brittle, greyish-white, semimetallic element (a metalloid), symbol As, atomic number 33, relative atomic mass 74.92. It occurs in many ores and occasionally in its elemental state, and is widely distributed, being present in minute quantities in the soil, the sea, and the human body. In larger quantities, it is poisonous. The chief source of arsenic compounds is as a by-product from metallurgical processes. It is used in making semiconductors, alloys, and solders.

As it is a cumulative poison, its presence in food and drugs is very dangerous. The symptoms of arsenic poisoning are vomiting, diarrhoea, tingling and possibly numbness in the limbs, and collapse. It featured in some drugs, including Salvarsan, the first specific treatment for syphilis. Its name derives from the Latin *arsenicum*.

arteriosclerosis hardening of the arteries, with thickening and loss of elasticity. It is associated with smoking, ageing, and a diet high in saturated fats. The term is used loosely as a synonym for atherosclerosis.

artery vessel that carries blood from the heart to the rest of the body. It is built to withstand considerable pressure, having thick walls which contain smooth muscle fibres. During contraction of the heart muscle, arteries expand in diameter to allow for the sudden increase in pressure that occurs; the resulting pulse or pressure wave can be felt at the wrist. Not all arteries carry oxygenated (oxygen-rich) blood; the pulmonary arteries convey deoxygenated (oxygen-poor) blood from the heart to the lungs.

Arteries are flexible, elastic tubes, consisting of three layers, the middle of which is muscular; its rhythmic contraction aids the pumping of blood around the body. In middle and old age, the walls degenerate and are vulnerable to damage by the build-up of fatty deposits. These reduce elasticity, hardening the arteries and decreasing the internal bore. This condition, known as atherosclerosis, can lead to high blood pressure, loss of circulation, heart disease, and death.

Research indicates that a typical Western diet, high in saturated fat, increases the chances of arterial disease developing.

artesian well well that is supplied with water rising naturally from an underground water-saturated rock layer (aquifer). The water rises from the aquifer under its own pressure. Such a well may be drilled into an aquifer that is confined by impermeable rocks both above and below. If the water table (the top of the region of water saturation) in that aquifer is above the level of the well head, hydrostatic pressure will force the water to the surface.

Artesian wells are often overexploited because their water is fresh and easily available, and they eventually become unreliable. There is also some concern that pollutants such as pesticides or nitrates can seep into the aquifers.

arthritis inflammation of the joints, with pain, swelling, and restricted motion. Many conditions may cause arthritis, including gout, infection, and trauma to the joint. There are three main forms of arthritis: (rheumatoid arthritis; osteoarthritis; and septic arthritis).

arthropod member of the phylum Arthropoda; an invertebrate animal with jointed legs and a segmented body with a horny or chitinous casing (exoskeleton), which is shed periodically and replaced as the animal grows. Included are arachnids such as spiders and mites, as well as crustaceans, millipedes, centipedes, and insects.

artichoke either of two plants belonging to the sunflower family, parts of which are eaten as vegetables. The common or globe artichoke (*Cynara scolymus*) is a form of thistle native to the Mediterranean. It is tall, with purplish-blue flowers; the leaflike structures (bracts) around the unopened flower are eaten. The Jerusalem artichoke (*Helianthus tuberosus*), which has edible tubers, is a native of North America (its common name is a corruption of the Italian for sunflower, *girasole*). (Family Compositae.)

artesian well In an artesian well, water rises from an underground water-containing rock layer under its own pressure. Rain falls at one end of the water-bearing layer, or aquifer, and percolates through the layer. The layer fills with water up to the level of the water table. Water will flow from a well under its own pressure if the well head is below the level of the water table.

article or **posting** on USENET, an individual public message.

artificial insemination (AI) introduction by instrument of semen from a sperm bank or donor into the female reproductive tract to bring about fertilization. Originally used by animal breeders to improve stock with sperm from high-quality males, in the 20th century it has been developed for use in humans, to help the infertile. See *in vitro* fertilization.

The whole thinking process is rather mysterious to us, but I believe that the attempt to make a thinking machine will help us greatly in finding out how we think ourselves.

ALAN MATHISON TURING English mathematician.

Quoted in A Hodges *Alan Turing: The Enigma of Intelligence* 1985

artificial intelligence (AI) branch of science concerned with creating computer programs that can perform actions comparable with those of an intelligent human. Current AI research covers such areas as planning (for robot behaviour), language understanding, pattern recognition, and knowledge representation.

The possibility of artificial intelligence was first proposed by the English mathematician Alan Turing in 1950. Early AI programs, developed in the 1960s, attempted simulations of human intelligence or were aimed at general problem-solving techniques. By the mid-1990s, scientists were concluding that AI was more difficult to create than they had imagined. It is now thought that intelligent behaviour depends as much on the knowledge a system possesses as on its reasoning power. Present emphasis is on knowledge-based systems, such as expert systems, while research projects focus on neural networks, which attempt to mimic the structure of the human brain.

On the Internet, small bits of software that automate common routines or attempt to predict human likes or behaviour based on past experience are called intelligent agents or bots.

artificial life (contracted to *ALife*) in computing, area of scientific research that attempts to simulate biological phenomena via computer programs. The first ALife workshop was held at Los Alamos, USA, in 1987. Research in this area is being conducted

all around the world; one of the most significant centres is the MIT Media Lab.

artificial limb device to replace a limb that has been removed by surgery or lost through injury, or one that is malformed because of genetic defects. It is one form of prosthesis.

artificial radioactivity natural and spontaneous radioactivity arising from radioactive isotopes or elements that are formed when elements are bombarded with subatomic particles – protons, neutrons, or electrons – or small nuclei.

artificial respiration emergency procedure to restart breathing once it has stopped; in cases of electric shock or apparent drowning, for example, the first choice is the expired-air method, the kiss of life by mouth-to-mouth breathing until natural breathing is restored.

artificial selection in biology, selective breeding of individuals that exhibit the particular characteristics that a plant or animal breeder wishes to develop. In plants, desirable features might include resistance to disease, high yield (in crop plants), or attractive appearance. In animal breeding, selection has led to the development of particular breeds of cattle for improved meat production (such as the Aberdeen Angus) or milk production (such as Jerseys).

Artificial selection was practised by the Sumerians at least 5,500 years ago and carried on through the succeeding ages, with the result that all common vegetables, fruit, and livestock are long modified by selective breeding. Artificial selection, particularly of pigeons, was studied by the English evolutionist Charles Darwin who saw a similarity between this phenomenon and the processes of natural selection.

Artiodactyla order of even-toed mammals containing pigs, camels, hippos, and ruminant animals, such as antelope, deer, and sheep.

The order is divided into nine living families (the other 20 families are all extinct). Suidae includes the eight species of pig; Tayassuidae, the two species of peccary; and Hippopotamidae, the two species of hippopotamuses. Camelidae has three to five species of camels and the guanaco. The five ruminant (cud-chewing) families are Tragulidae, with four species of chevrotain; Cervidae, 41 species of deer; Bovidae, 128 species of cattle, sheep, and

arum *Arum dioscoridis* comes from the Mediterranean region, where arum lilies grow in abundance. What appears to be a single flower is in fact a flower head, the spadix, bearing separate rings of male and female flowers enclosed in a leaflike spathe.
Premaphotos Wildlife

antelope; Antilocapridae, one species, the pronghorn, often misnamed antelope, of North America; and Giraffidae, two species of giraffe.

arum any of a group of mainly European plants with narrow leaves and a single, usually white, special leaf (spathe) surrounding the spike of tiny flowers. The ornamental arum called the trumpet lily (*Zantedeschia aethiopica*) is a native of South Africa. (Genus *Arum*, family Araceae.)

asbestos any of several related minerals of fibrous structure that offer great heat resistance because of their nonflammability and poor conductivity. Commercial asbestos is generally either made from serpentine ('white' asbestos) or from sodium iron silicate ('blue' asbestos). The fibres are woven together or bound by an inert material. Over time the fibres can work loose and, because they are small enough to float freely in the air or be inhaled, asbestos usage is now strictly controlled; exposure to its dust can cause cancer.

ASCII (acronym for *American standard code for information interchange*) in computing, a coding system in which numbers are assigned to letters, digits, and punctuation symbols. Although computers work in code based on the binary number system, ASCII numbers are usually quoted as decimal or hexadecimal numbers. For example, the decimal number 45 (binary 0101101) represents a hyphen, and 65 (binary 1000001) a capital A. The first 32 codes are used for control functions, such as carriage return and backspace.

Strictly speaking, ASCII is a 7-bit binary code, allowing 128 different characters to be represented, but an eighth bit is often used to provide parity or to allow for extra characters. The system is widely used for the storage of text and for the transmission of data between computers.

ASCII art pictures or fancy graphics created entirely out of ASCII characters such as letters of the alphabet or punctuation marks. ASCII art has existed since the invention of computers. Today it is found in USENET signatures (sigs), special newsgroups such as alt.art.ascii, and occasionally in messages, both public and private.

ascorbic acid $C_6H_8O_6$ or **vitamin C** a relatively simple organic acid found in citrus fruits and vegetables. It is soluble in water and destroyed by prolonged boiling, so soaking or overcooking of vegetables reduces their vitamin C content. Lack of ascorbic acid results in scurvy.

In the human body, ascorbic acid is necessary for the correct synthesis of collagen. Lack of vitamin C causes skin sores or ulcers, tooth and gum problems, and burst capillaries (scurvy symptoms) owing to an abnormal type of collagen replacing the normal type in these tissues.

The Australian billygoat plum, *Terminalia ferdinandiana*, is the richest natural source of vitamin C, containing 100 times the concentration found in oranges.

asepsis practice of ensuring that bacteria are excluded from open sites during surgery, wound dressing, blood sampling, and other medical procedures. Aseptic technique is a first line of defence against infection.

asexual reproduction in biology, reproduction that does not involve the manufacture and fusion of sex cells, nor the necessity for two parents. The process carries a clear advantage in that there is no need to search for a mate nor to develop complex pollinating mechanisms; every asexual organism can reproduce on its own. Asexual reproduction can therefore lead to a rapid population build-up.

In evolutionary terms, the disadvantage of asexual reproduction arises from the fact that only identical individuals, or clones, are produced – there is no variation.

In the field of horticulture, where standardized production is needed, this is useful, but in the wild, an asexual population that cannot adapt to a changing environment or evolve defences against a new disease is at risk of extinction. Many asexual reproducing organisms are therefore capable of reproducing sexually as well.

Asexual processes include binary fission, in which the parent organism splits into two or more 'daughter' organisms, and budding, in which a new organism is formed initially as an out-

asexual reproduction Asexual reproduction is the simplest form of reproduction, occurring in many simple plants and animals. Binary fission, shown here occurring in an amoeba, is one of a number of asexual reproduction processes.

growth of the parent organism. The asexual reproduction of spores, as in ferns and mosses, is also common and many plants reproduce asexually by means of runners, rhizomes, bulbs, and corms; see also [vegetative reproduction].

ash any tree of a worldwide group belonging to the olive family, with winged fruits. The mountain ash or **rowan**, which resembles the ash, belongs to the family Rosaceae. (Genus *Fraxinus*, family Oleaceae.)

ashen light in astronomy, a faint glow occasionally reported in the dark hemisphere of Venus when the planet is in a crescent phase. Its origin is unknown, but it may be related to the terrestrial airglow caused by interaction of high-energy solar radiation with the upper atmosphere of the Earth.

Asiatic wild ass alternative name for both the kiang and the onager.

ASIC (abbreviation for *application-specific integrated circuit*) integrated circuit built for a specific application.

asp any of several venomous snakes, including *Vipera aspis* of S Europe, allied to the adder, and the Egyptian cobra *Naja haje*, reputed to have been used by the Egyptian queen Cleopatra for her suicide.

asparagus any of a group of plants with small scalelike leaves and many fine, feathery branches. Native to Europe and Asia, *Asparagus officinalis* is cultivated and the tender young shoots (spears) are greatly prized as a vegetable. (Genus *Asparagus*, family Liliaceae.)

aspartame noncarbohydrate sweetener used in foods under the tradename Nutrasweet. It is about 200 times as sweet as sugar and, unlike saccharine, has no aftertaste.

The aspartame molecule consists of two amino acids (aspartic acid and phenylalanine) linked by a methylene ($-CH_2-$) group. It breaks down slowly at room temperature and rapidly at higher temperatures. It is not suitable for people who suffer from phenylketonuria.

aspen any of several species of poplar tree. The European quaking aspen (*Populus tremula*) has flattened leafstalks that cause the leaves to flutter in the slightest breeze. The soft, light-coloured wood is used for matches and paper pulp. (Genus *Populus*.)

asphalt mineral mixture containing semisolid brown or black bitumen, used in the construction industry. Asphalt is mixed with rock chips to form paving material, and the purer varieties are used for insulating material and for waterproofing masonry. It can be produced artificially by the distillation of petroleum.

The availability of recycled coloured glass led in 1988 to the invention of glassphalt, asphalt that is 15% crushed glass. It is used to pave roads in New York.

Considerable natural deposits of asphalt occur around the Dead Sea and in the Philippines, Cuba, Venezuela, and Trinidad. Bituminous limestone occurs at Neuchâtel, France.

asphodel either of two related Old World plants of the lily family. The white asphodel or king's spear (*Asphodelus albus*) is found in Italy and Greece, sometimes covering large areas, and providing grazing for sheep. The other asphodel is the yellow asphodel (*Asphodeline lutea*). (Genera *Asphodelus* and *Asphodeline*, family Liliaceae.)

The ancient Greeks connected the beautiful plants of *A. lutea* with the dead, and they were supposed to grow in the mythological Elysian fields where heroes enjoyed new life after death.

asphyxia suffocation; a lack of oxygen that produces a potential-lethal build-up of carbon dioxide waste in the tissues.

Asphyxia may arise from any one of a number of causes, including inhalation of smoke or poisonous gases, obstruction of the windpipe (by water, food, vomit, or a foreign object), strangulation, or smothering. If it is not quickly relieved, brain damage or death ensues.

aspidistra any of several Asiatic plants of the lily family. The Chinese *Aspidistra elatior* has broad leaves which taper to a point and, like all aspidistras, grows well in warm indoor conditions. (Genus *Aspidistra*, family Liliaceae.)

aspirin acetylsalicylic acid, a popular pain-relieving drug (analgesic) developed in the late 19th century as a household remedy for aches and pains. It relieves pain and reduces inflammation and fever. It is derived from the white willow tree *Salix alba*, and is the world's most widely used drug.

Aspirin was first refined from salicylic acid by German chemist Felix Hoffman, and marketed in 1899. Although salicylic acid occurs naturally in willow bark (and has been used for pain relief since 1763) the acetyl derivative is less bitter and less likely to cause vomiting.

ass any of several horselike, odd-toed, hoofed mammals of the genus *Equus*, family Equidae. Species include the African wild ass *E. asinus*, and the Asian wild ass *E. hemionus*. They differ from horses in their smaller size, larger ears, tufted tail, and characteristic bray. Donkeys and burros are domesticated asses.

assassin bug member of a family of blood-sucking bugs that contains about 4,000 species. Assassin bugs are mainly predators, feeding on other insects, but some species feed on birds and mammals, including humans. They are found, mainly in tropical regions, although some have established themselves in Europe and North America.

classification Assassin bugs are in family Reduviidae, suborder Heteroptera, order Hemiptera (true bugs), class Insecta, phylum Arthropoda.

The general characteristics of the family include bright coloration, a long four-segmented antenna, and a cone-shaped proboscis which, when the insect is not feeding, is folded under the head. Because of this they are sometimes called cone-nosed bugs.

Species *Reduvius personatus* is about 15 mm/0.5 in long and dark brown. In the wild it inhabits hollow trees where it feeds on the blood of other insects. It can invade houses, where it hides in holes and crevices in the wall. Like other assassin bugs, it is nocturnal, emerging at night to feed on bedbugs and other insects. It is widely distributed in Europe and North America.

Kissing bugs comprise several Central and South American genera that have earned their name from their habit of biting sleeping people on the face. *Rhodnius*, *Triatoma*, and *Panstrongylus*, are vectors for the parasite that causes Chagas's disease.

assay in chemistry, the determination of the quantity of a given substance present in a sample. Usually it refers to determining the purity of precious metals.

The assay may be carried out by 'wet' methods, when the sample is wholly or partially dissolved in some reagent (often an acid), or by 'dry' or 'fire' methods, in which the compounds present in the sample are combined with other substances.

assembler in computing, a program that translates a program written in an assembly language into a complete machine code program that can be executed by a computer. Each instruction in the assembly language is translated into only one machine-code instruction.

assembly industry manufacture that involves putting together many prefabricated components to make a complete product; for example, a car or television set. The inputs for this type of industry are therefore outputs from others. Some assembly industries are surrounded by their suppliers; others use components from far afield.

assembly language low-level computer-programming language closely related to a computer's internal codes. It consists chiefly of a set of short sequences of letters (mnemonics), which are translated, by a program called an assembler, into machine code for the computer's central processing unit (CPU) to follow directly. In assembly language, for example, 'JMP' means 'jump' and 'LDA' means 'load accumulator'. Assembly code is used by programmers who need to write very fast or efficient programs.

Because they are much easier to use, high-level languages are normally used in preference to assembly languages. An assembly language may still be used in some cases, however, particularly when no suitable high-level language exists or where a very efficient machine-code program is required.

assembly line method of mass production in which a product is built up step-by-step by successive workers adding one part at a time. It is commonly used in industries such as the car industry.

US inventor Eli Whitney pioneered the concept of industrial assembly in the 1790s, when he employed unskilled labour to assemble muskets from sets of identical precision-made parts produced by machine tools. In 1901 Ransome Olds in the USA began mass-producing motor cars on an assembly-line principle, a method further refined by the introduction of the moving conveyor belt by Henry Ford in 1913 and the time-and-motion studies of Fredrick Winslow Taylor. On the assembly line human workers now stand side by side with robots.

assimilation in animals, the process by which absorbed food molecules, circulating in the blood, pass into the cells and are used for growth, tissue repair, and other metabolic activities. The actual destiny of each food molecule depends not only on its type, but also on the body requirements at that time.

Association for Computing Machinery (ACM) US organization made up of computer professionals of all types. Its monthly journal, the *Communications of the Association for Computing Machinery*, is peer-reviewed. Its subsidiary special interest groups, or SIGs, focus on areas such as graphics and human-computer interaction. Several of these run major conferences for their areas such as SIGGRAPH (graphics) and SIGCHI (human-computer interaction).

The equivalent UK organization is the **British Computer Society (BCS)**.

associative operation in mathematics, an operation in which the outcome is independent of the grouping of the numbers or symbols concerned. For example, multiplication is associative, as $4 \times (3 \times 2) = (4 \times 3) \times 2 = 24$; however, division is not, as $12 \div (4 \div 2) = 6$, but $(12 \div 4) \div 2 = 1.5$. Compare commutative operation and distributive operation.

assortative mating in population genetics, selective mating in a population between individuals that are genetically related or have similar characteristics. If sufficiently consistent, assortative mating can theoretically result in the evolution of new species without geographical isolation (see speciation).

astatine Greek *astatos* 'unstable' nonmetallic, radioactive element, symbol At, atomic number 85, relative atomic mass 210. It is a member of the halogen group, and is very rare in nature. Astatine is highly unstable, with at least 19 isotopes; the longest lived has a half-life of about eight hours.

aster any plant of a large group belonging to the same subfamily as the daisy. All asters have starlike flowers with yellow centres and outer rays (not petals) varying from blue and purple to white. Asters come in many sizes. Many are cultivated as garden flowers, including the Michaelmas daisy (*Aster nova-belgii*). (Genus *Aster*, family Compositae.)

The China aster (*Callistephus chinensis*) belongs to a closely related genus; it was introduced to Europe and the USA from China in the early 18th century.

asterisk (*) or star wild card character standing for multiple characters in most operating systems. It allows a user to specify a group of files for mass handling. Typing 'dir *.bat' in DOS, for example, will return a list of all files with the extension .BAT in the current directory. On UNIX, * is used to denote a group of newsgroups; the phrase 'alt.music.*' means all the newsgroups in the alt.music hierarchy, such as alt.music.pop, alt.music.jazz, and so on. On the Internet, an asterisk before and after a word is a way of indicating emphasis.

asteroid or minor planet any of many thousands of small bodies, composed of rock and iron, that orbit the Sun. Most lie in a

belt between the orbits of Mars and Jupiter, and are thought to be fragments left over from the formation of the Solar System. About 100,000 may exist, but their total mass is only a few hundredths the mass of the Moon.

They include Ceres (the largest asteroid, 940 km/584 mi in diameter), Vesta (which has a light-coloured surface, and is the brightest as seen from Earth), Eros, and Icarus. Some asteroids are in orbits that bring them close to Earth, and some, such as the Apollo asteroids, even cross Earth's orbit; at least some of these may be remnants of former comets. One group, the Trojans, moves along the same orbit as Jupiter, 60° ahead and behind the planet. One unusual asteroid, Chiron, orbits beyond Saturn.

NASA's Near Earth Asteroid Rendezvous (NEAR) was launched in February 1996 to study Eros to ascertain what asteroids are made of and whether they are similar in structure to meteorites. In 1997 it flew past asteroid Mathilde, revealing a 25 km crater covering the 53-km asteroid. The Near Earth Asteroid Tracking (NEAT) system had detected more than 10,000 asteroids by August 1997.

The first asteroid was discovered by the Italian astronomer Giuseppe Piazzi at the Palermo Observatory, Sicily, 1 January 1801. The first asteroid moon was observed by the space probe Galileo (in 1993 orbiting asteroid Ida).

Bifurcated asteroids, first discovered 1990, are in fact two chunks of rock that touch each other. It may be that at least 10% of asteroids approaching the Earth are bifurcated.

asthenosphere a layer within Earth's mantle lying beneath the lithosphere, typically beginning at a depth of approximately 100 km/63 mi and extending to depths of approximately 260 km/160 mi. Sometimes referred to as the 'weak sphere', it is characterized by being weaker and more elastic than the surrounding mantle.

The asthenosphere's elastic behaviour and low viscosity allow the overlying, more rigid plates of lithosphere to move laterally in a process known as plate tectonics. Its elasticity and viscosity also allow overlying crust and mantle to move vertically in response to gravity to achieve isostatic equilibrium (see isostasy).

asthma chronic condition characterized by difficulty in breathing due to spasm of the bronchi (air passages) in the lungs. Attacks may be provoked by allergy, infection, and stress. The incidence of asthma may be increasing as a result of air pollution and occupational hazard. Treatment is with bronchodilators to relax the bronchial muscles and thereby ease the breathing, and in severe cases by inhaled steroids that reduce inflammation of the bronchi.

Extrinsic asthma, which is triggered by exposure to irritants such as pollen and dust, is more common in children and young adults. In February 1997 Brazilian researchers reported two species of dust mite actually living on children's scalps. This explains why vacuuming of bedding sometimes fails to prevent asthma attacks. The use of antidandruff shampoo should keep numbers of mites down by reducing their food supply. Less common, intrinsic asthma tends to start in the middle years.

Approximately 5-10% of children suffer from asthma, but about a third of these will show no symptoms after adolescence, while another 5-10% of people develop the condition as adults. Growing evidence that the immune system is involved in both

ASTHMA - TUTORIAL FOR CHILDREN AND PARENTS

<http://sln.fi.edu/inquirer/warming.html>

Online tutorial for parents and children on asthma. It provides an explanation of what happens during an asthma attack, a description of the symptoms normally registered during an attack, and a discussion of the available medications. Movies and sound clips of asthmatic breathing are also included.

ASTHMA

Dust mites live in large numbers on the human scalp, feeding on skin flakes – an activity which causes allergic reactions in asthmatic children. This discovery was announced by Brazilian researchers in 1997, and may explain why repeated vacuuming of bedding does not get rid of dust mites.

forms of asthma has raised the possibility of a new approach to treatment.

Although the symptoms are similar to those of bronchial asthma, **cardiac asthma** is an unrelated condition and is a symptom of heart deterioration.

astigmatism aberration occurring in the lens of the eye. It results when the curvature of the lens differs in two perpendicular planes, so that rays in one plane may be in focus while rays in the other are not. With astigmatic eyesight, the vertical and horizontal cannot be in focus at the same time; correction is by the use of a cylindrical lens that reduces the overall focal length of one plane so that both planes are seen in sharp focus.

astrolabe ancient navigational instrument, forerunner of the sextant. Astrolabes usually consisted of a flat disc with a sighting rod that could be pivoted to point at the Sun or bright stars.

From the altitude of the Sun or star above the horizon, the local time could be estimated.

ASTROLABE – AN INSTRUMENT WITH A PAST AND A FUTURE

<http://myhouse.com/mc/planet/astrodir/astrolab.htm>

Good guide to this ancient astronomical computer. The long history of the instrument, and its importance in the history of astrology and astronomy, is explained with the help of good photographs. A section on the parts of the astrolabe explains how the instrument works and its uses.

astrometry measurement of the precise positions of stars, planets, and other bodies in space. Such information is needed for practical purposes including accurate timekeeping, surveying and navigation, and calculating orbits and measuring distances in space. Astrometry is not concerned with the surface features or the physical nature of the body under study.

Before telescopes, astronomical observations were simple astrometry. Precise astrometry has shown that stars are not fixed in position, but have a proper motion caused as they and the Sun orbit the Milky Way Galaxy. The nearest stars also show parallax (apparent change in position), from which their distances can be calculated. Above the distorting effects of the atmosphere, satellites such as Hipparcos can make even more precise measurements than ground telescopes, so refining the distance scale of space.

astronaut person making flights into space; the term **cosmonaut** is used in the West for any astronaut from the former Soviet Union.

ASTRONAUT

Astronauts in space cannot belch. It is gravity that causes bubbles to rise to the top of a liquid, so space shuttle crews were forced to request less gas in their fizzy drinks to avoid discomfort.

ASK AN ASTRONAUT

<http://www.nss.org/askastro/>

Apollo 17 multimedia archive with video and audio files, plus mission details and astronaut biographies. Sponsored by the National Space Society, this site includes numerous images, a list of questions and answers, and links to related sites.

astronautics science of space travel. See rocket; satellite; space probe.

Astronomer Royal honorary post in British astronomy. Originally it was held by the director of the Royal Greenwich Observatory; since 1972 the title of Astronomer Royal has been awarded separately as an honorary title to an outstanding British astronomer. The Astronomer Royal from 1995 is Martin Rees. There is a separate post of Astronomer Royal for Scotland.

Astronomical Almanac in astronomy, an international work of reference published jointly every year by the Royal Greenwich Observatory and the US Naval Observatory containing detailed tables of planetary motions, eclipses, and other astronomical phenomena.

astronomical unit unit (symbol AU) equal to the mean distance of the Earth from the Sun: 149,597,870 km/92,955,800 mi. It is used to describe planetary distances. Light travels this distance in approximately 8.3 minutes.

astronomy science of the celestial bodies; the Sun, the Moon, and the planets; the stars and galaxies; and all other objects in the universe. It is concerned with their positions, motions, distances, and physical conditions and with their origins and evolution. Astronomy thus divides into fields such as astrophysics, celestial mechanics, and cosmology. See also gamma-ray astronomy, infrared astronomy, radio astronomy, ultraviolet astronomy, and X-ray astronomy.

Greek astronomers Astronomy is perhaps the oldest recorded science; there are observational records from ancient Babylonia, China, Egypt, and Mexico. The first true astronomers, however, were the Greeks, who deduced the Earth to be a sphere and attempted to measure its size. Ancient Greek astronomers included Thales and Pythagoras. Eratosthenes of Cyrene measured the size of the Earth with considerable accuracy. Star catalogues were drawn up, the most celebrated being that of Hipparchus. The *Almagest*, by Ptolemy of Alexandria, summarized Greek astronomy and survived in its Arabic translation. The Greeks still regarded the Earth as the centre of the universe, although this was doubted by some philosophers, notably Aristarchus of Samos, who maintained that the Earth moves around the Sun.

Ptolemy, the last famous astronomer of the Greek school, died about AD 180, and little progress was made for some centuries.

Arab revival The Arabs revived the science, developing the astrolabe and producing good star catalogues. Unfortunately, a general belief in the pseudoscience of astrology continued until the end of the Middle Ages (and has been revived from time to time).

the Sun at the centre The dawn of a new era came in 1543, when a Polish canon, Copernicus, published a work entitled *De revolutionibus orbium coelestium/On the Revolutions of the Heavenly Spheres*, in which he demonstrated that the Sun, not the Earth, is the centre of our planetary system. (Copernicus was wrong in many respects – for instance, he still believed that all celestial orbits must be perfectly circular.) Tycho Brahe, a Dane, increased the accuracy of observations by means of improved instruments allied to his own personal skill, and his observations were used by German mathematician Johannes Kepler to prove the validity of the Copernican system. Considerable opposition existed, however, for removing the Earth from its central position in the universe; the Catholic church was openly hostile to the idea, and, ironically, Brahe never accepted the idea that the Earth could move around the Sun. Yet before the end of the 17th century, the theoretical work of Isaac Newton had established celestial mechanics.

Astronomy: chronology

| | | | |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2300 BC | Chinese astronomers made their earliest observations. | 1931 | Karl Jansky founded radio astronomy. |
| 2000 | Babylonian priests made their first observational records. | 1945 | Radar contact with the Moon was established by Z Bay of Hungary and the US Army Signal Corps Laboratory. |
| 1900 | Stonehenge was constructed: first phase. | 1948 | The 5-m/200-in Hale reflector telescope was installed at Mount Palomar, California, USA. |
| 434 | Anaxagoras claims the Sun is made up of hot rock. | 1957 | The Jodrell Bank telescope dish in England was completed. |
| 365 | The Chinese observed the satellites of Jupiter with the naked eye. | 1957 | The first Sputnik satellite (USSR) opened the age of space observation. |
| 3rd century | Aristarchus argued that the Sun is the centre of the Solar System. | 1962 | The first X-ray source was discovered in Scorpius. |
| 2nd century | Ptolemy's complicated Earth-centred system was promulgated, which dominated the astronomy of the Middle Ages. | 1963 | The first quasar was discovered. |
| AD | | 1967 | The first pulsar was discovered by Jocelyn Bell and Antony Hewish. |
| 1543 | Copernicus revived the ideas of Aristarchus in <i>De Revolutionibus</i> . | 1969 | The first crewed Moon landing was made by US astronauts. |
| 1608 | Hans Lippershey invented the telescope, which was first used by Galileo in 1609. | 1976 | A 6 m/240 in reflector telescope was installed at Mount Semirodki, USSR. |
| 1609 | Johannes Kepler's first two laws of planetary motion were published (the third appeared in 1619). | 1977 | Uranus was discovered to have rings. |
| 1632 | The world's first official observatory was established in Leiden in the Netherlands. | 1977 | The spacecraft Voyager 1 and 2 were launched, passing Jupiter and Saturn 1979-1981. |
| 1633 | Galileo's theories were condemned by the Inquisition. | 1978 | The spacecraft Pioneer Venus 1 and 2 reached Venus. |
| 1675 | The Royal Greenwich Observatory was founded in England. | 1978 | A satellite of Pluto, Charon, was discovered by James Christy of the US Naval Observatory. |
| 1687 | Isaac Newton's <i>Principia</i> was published, including his 'law of universal gravitation'. | 1986 | Halley's comet returned. Voyager 2 flew past Uranus and discovered six new moons. |
| 1705 | Edmond Halley correctly predicted that the comet that had passed the Earth in 1682 would return in 1758; the comet was later to be known by his name. | 1987 | Supernova SN1987A flared up, becoming the first supernova to be visible to the naked eye since 1604. The 4.2-m/165-in William Herschel Telescope on La Palma, Canary Islands, and the James Clerk Maxwell Telescope on Mauna Kea, Hawaii, began operation. |
| 1781 | William Herschel discovered Uranus and recognized stellar systems beyond our Galaxy. | 1988 | The most distant individual star was recorded - a supernova, 5 billion light years away, in the AC118 cluster of galaxies. |
| 1796 | Pierre Laplace elaborated his theory of the origin of the solar system. | 1989 | Voyager 2 flew by Neptune and discovered eight moons and three rings. |
| 1801 | Giuseppe Piazzi discovered the first asteroid, Ceres. | 1990 | Hubble Space Telescope was launched into orbit by the US space shuttle. |
| 1814 | Joseph von Fraunhofer first studied absorption lines in the solar spectrum. | 1991 | The space probe Galileo flew past the asteroid Gaspra, approaching it to within 26,000 km/16,200 mi. |
| 1846 | Neptune was identified by Johann Galle, following predictions by John Adams and Urbain Leverrier. | 1992 | COBE satellite detected ripples from the Big Bang that mark the first stage in the formation of galaxies. |
| 1859 | Gustav Kirchhoff explained dark lines in the Sun's spectrum. | 1994 | Fragments of comet Shoemaker-Levy struck Jupiter. |
| 1887 | The earliest photographic star charts were produced. | 1996 | US astronomers discovered the most distant galaxy so far detected. It is in the constellation Virgo and is 14 billion light years from Earth. |
| 1889 | Edward Barnard took the first photographs of the Milky Way. | 1997 | Data from the satellite Hipparcos improved estimates of the age of the universe, and the distances to many nearby stars. |
| 1908 | Fragment of comet fell at Tunguska, Siberia. | | |
| 1920 | Arthur Eddington began the study of interstellar matter. | | |
| 1923 | Edwin Hubble proved that the galaxies are systems independent of the Milky Way, and by 1930 had confirmed the concept of an expanding universe. | | |
| 1930 | The planet Pluto was discovered by Clyde Tombaugh at the Lowell Observatory, Arizona, USA. | | |

Galileo and the telescope The refracting telescope was invented about 1608, by Hans Lippershey in Holland, and was first applied to astronomy by Italian scientist Galileo in the winter of 1609-10. Immediately, Galileo made a series of spectacular discoveries. He found the four largest satellites of Jupiter, which gave strong support to the Copernican theory; he saw the craters of the Moon, the phases of Venus, and the myriad faint stars of our Galaxy, the Milky Way.

Galileo's most powerful telescope magnified only 30 times, but it was not long before larger telescopes were built and official observatories were established.

Galileo's telescope was a refractor; that is to say, it collected its light by means of a glass lens or object glass. Difficulties with his design led Newton, in 1671, to construct a reflector, in which the light is collected by means of a curved mirror.

further discoveries In the 17th and 18th centuries astronomy was mostly concerned with positional measurements. Uranus was discovered 1781 by William Herschel, and this was soon followed by the discovery of the first four asteroids, Ceres in 1801, Pallas in 1802, Juno in 1804, and Vesta in 1807. In 1846 Neptune was located by Johann Galle, following calculations by British astronomer John Couch Adams and French astronomer Urbain Jean Joseph Leverrier. Also significant was the first measurement of the dis-

tance of a star, when in 1838 the German astronomer Friedrich Bessel measured the parallax of the star 61 Cygni, and calculated that it lies at a distance of about 6 light years (about half the correct value).

Astronomical spectroscopy was developed, first by Fraunhofer in Germany and then by people such as Pietro Angelo Secchi and William Huggins, while Gustav Kirchhoff successfully interpreted the spectra of the Sun and stars. By the 1860s good photographs of the Moon had been obtained, and by the end of the century photographic methods had started to play a leading role in research.

galaxies William Herschel, probably the greatest observer in the history of astronomy, investigated the shape of our Galaxy during the latter part of the 18th century and concluded that its stars are arranged roughly in the form of a double-convex lens. Basically Herschel was correct, although he placed our Sun near the centre of the system; in fact, it is well out towards the edge, and lies 25,000 light years from the galactic nucleus. Herschel also studied the luminous 'clouds' or nebulae, and made the tentative suggestion that those nebulae capable of resolution into stars might be separate galaxies, far outside our own Galaxy.

It was not until 1923 that US astronomer Edwin Hubble, using the 2.5 m/100 in reflector at the Mount Wilson Observatory, was able to verify this suggestion. It is now known that the 'spiral neb-

ulae' are galaxies in their own right, and that they lie at immense distances. The most distant galaxy visible to the naked eye, the Great Spiral (Andromeda), is 2.2 million light years away; the most remote galaxy so far measured lies over 10 billion light years away. It was also found that galaxies tended to form groups, and that the groups were apparently receding from each other at speeds proportional to their distances.

a growing universe This concept of an expanding and evolving universe at first rested largely on Hubble's law, relating the distance of objects to the amount their spectra shift towards red – the λ red shift. Subsequent evidence derived from objects studied in other parts of the electromagnetic spectrum, at radio and X-ray wavelengths, has provided confirmation. Radio astronomy established its place in probing the structure of the universe by demonstrating in 1954 that an optically visible distant galaxy was identical with a powerful radio source known as Cygnus A. Later analysis of the comparative number, strength, and distance of radio sources suggested that in the distant past these, including the quasars discovered in 1963, had been much more powerful and numerous than today. This fact suggested that the universe has been evolving from an origin, and is not of infinite age as expected under a steady-state theory.

The discovery in 1965 of microwave background radiation was evidence for the enormous temperature of the giant explosion, or Big Bang, that brought the universe into existence.

further exploration Although the practical limit in size and efficiency of optical telescopes has apparently been reached, the siting of these and other types of telescope at new observatories in the previously neglected southern hemisphere has opened fresh areas of the sky to search. Australia has been in the forefront of these developments. The most remarkable recent extension of the powers of astronomy to explore the universe is in the use of rockets, satellites, space stations, and space probes. Even the range and accuracy of the conventional telescope may be greatly improved free from the Earth's atmosphere. When the USA launched the Hubble Space Telescope into permanent orbit in 1990, it was the most powerful optical telescope yet constructed, with a 2.4 m/94.5 in mirror. It detects celestial phenomena seven times more distant (up to 14 billion light years) than any Earth-based telescope.

See also black hole and infrared radiation.

We now have direct evidence of the birth of the Universe and its evolution ... ripples in space-time laid down earlier than the first billionth of a second. If you're religious it's like seeing God.

GEORGE SMOOT US astrophysicist.
Attributed remark 1992

astrophotography use of photography in astronomical research. The first successful photograph of a celestial object was the daguerreotype plate of the Moon taken by John W. Draper (1811–1882) of the USA in March 1840. The first photograph of a star, Vega, was taken by US astronomer William C. Bond (1789–1859) in 1850. Modern-day astrophotography uses techniques such as charge-coupled devices (CCDs).

astrophysics study of the physical nature of stars, galaxies, and the universe. It began with the development of spectroscopy in the 19th century, which allowed astronomers to analyse the composition of stars from their light. Astrophysicists view the universe as a vast natural laboratory in which they can study matter under conditions of temperature, pressure, and density that are unattainable on Earth.

asymmetric digital subscriber loop in computing, standard for transmitting video data; see ADSL.

asymptote in coordinate geometry, a straight line that a curve approaches progressively more closely but never reaches. The x and y axes are asymptotes to the graph of $xy = \text{constant}$ (a rectangular hyperbola).

If a point on a curve approaches a straight line such that its distance from the straight line is d , then the line is an asymptote to the

curve if limit d tends to zero as the point moves towards infinity. Among conic sections (curves obtained by the intersection of a plane and a double cone), a hyperbola has two asymptotes, which in the case of a rectangular hyperbola are at right angles to each other.

asynchronous irregular or not synchronized. In computer communications, the term is usually applied to data transmitted irregularly rather than as a steady stream. Asynchronous communications start bits and stop bits to indicate the beginning and end of each piece of data. Most personal computer communications are asynchronous, including connections across the Internet.

asynchronous transfer mode (ATM) in computing, high-speed computer networking standard suitable for all types of data, including voice and video, that can be used on both private and public networks. ATM is used mainly on the core 'backbones' of large communications networks and in wide-area networks.

The basic technology was developed as part of the Cambridge Ring in the late 1970s, and is now being adopted by companies such as IBM and AT&T.

ATAPI (abbreviation for *Advanced Technology Attachment Packet Interface*) in computing, enhancement to integrated drive electronics (IDE) that allows easier installation and support of CD-ROM drives and other devices. Part of the Enhanced IDE standard introduced by hard disc manufacturer Western Digital in 1994, ATAPI uses a standard software device driver and does away with the need for older, proprietary interfaces.

atavism (*Latin atavus 'ancestor'*) in genetics, the reappearance of a characteristic not apparent in the immediately preceding generations; in psychology, the manifestation of primitive forms of behaviour.

ataxia loss of muscular coordination due to neurological damage or disease.

AT command set (abbreviation for *attention command set*) set of standard commands allowing a modem to be controlled via software. These commands are used via special communications software to control a modem's actions from the computer console. The most common are ATZ to reset the modem and ATH to hang the modem up at the end of a call. The set was invented by Hayes Computer Products for its earliest modems.

Ateles genus of spider monkey.

atheroma furring-up of the interior of an artery by deposits, mainly of cholesterol, within its walls.

Associated with atherosclerosis, atheroma has the effect of narrowing the lumen (channel) of the artery, thus restricting blood flow. This predisposes to a number of conditions, including thrombosis, angina, and stroke.

atherosclerosis thickening and hardening of the walls of the arteries, associated with atheroma.

Atlas rocket US rocket, originally designed and built as an intercontinental missile, but subsequently adapted for space use. Atlas rockets launched astronauts in the Mercury series into orbit, as well as numerous other satellites and space probes.

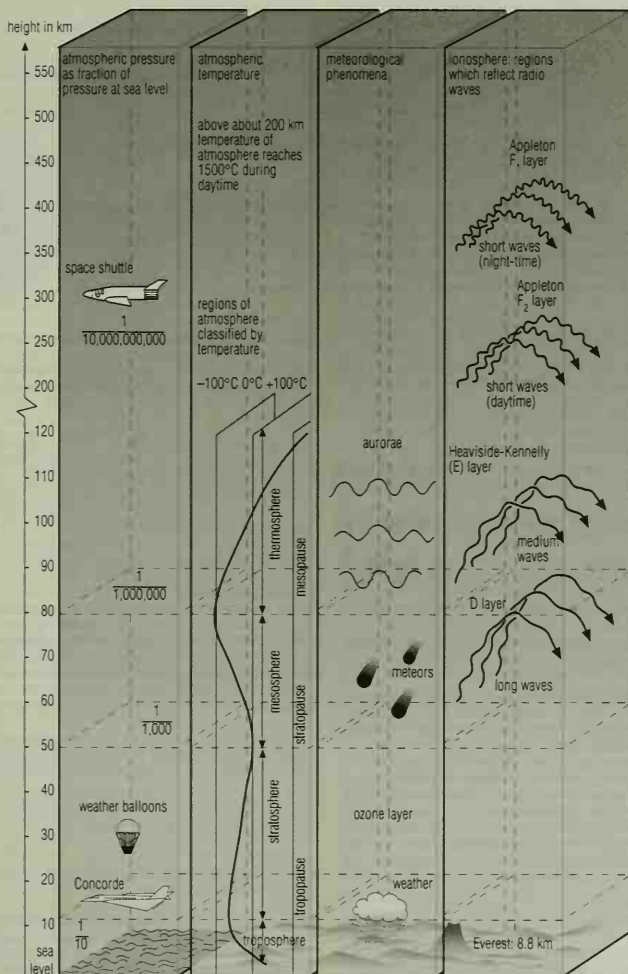

ATM in computing, abbreviation for asynchronous transfer mode, automated teller machine, or Adobe Type Manager, depending on context.

atmosphere mixture of gases surrounding a planet. Planetary atmospheres are prevented from escaping by the pull of gravity. On Earth, atmospheric pressure decreases with altitude. In its lowest layer, the atmosphere consists of 78% nitrogen and 21% oxygen, both in molecular form (two atoms bonded together), and 1% argon. Small quantities of other gases, including water and carbon dioxide, are important in the chemistry and physics of Earth's atmosphere. The atmosphere plays a major part in the various cycles of nature (the water cycle, the carbon cycle, and the nitrogen cycle). It is the principal industrial source of nitrogen, oxygen, and argon, which are obtained by the fractional distillation of liquid air.

The combination of gases, moisture, and dust particles in the Earth's atmosphere filter, reflect, refract, and scatter the rays of

light energy travelling from the Sun. Visible light varies in colour, the shorter wavelengths being blue and the longer wavelengths being red. Blue light waves are readily scattered by tiny particles of matter in the atmosphere, while the remaining light waves travel on uninterrupted unless they meet up with larger particles. Thus, the clearer and less polluted the atmosphere, the bluer the sky will appear; when there are smoke particles or other pollutants in the atmosphere, more of the colour rays are scattered and the sky will appear greyer and darker. Water droplets reflect the light

rays rather than scatter them, and so in a moist atmosphere the sky will appear a paler blue. Hence, the sky will appear deepest blue where the atmosphere is driest and least polluted, and when the sun is directly overhead. At sunrise or sunset, when sunlight has further to travel through the atmosphere, more of the light waves are scattered, and any undisturbed red light waves will give the sun and sky near the horizon a red or orange appearance. At higher altitudes, as the atmosphere thins, there are fewer particles to scatter the light rays and so more are absorbed, and the sky

atmosphere All but 1% of the Earth's atmosphere lies in a layer 30 km/19 mi above the ground. At a height of 5,500 m/18,000 ft, air pressure is half that at sea level. The temperature of the atmosphere varies greatly with height; this produces a series of layers, called the troposphere, stratosphere, mesosphere, and thermosphere.

Atmosphere: composition

| gas | symbol | volume (%) | role |
|----------------|-----------------|------------|-------------------------------------------------------------------------------------------------------------------------------|
| nitrogen | N ₂ | 78.08 | cycled through human activities and through the action of microorganisms on animal and plant waste |
| oxygen | O ₂ | 20.94 | cycled mainly through the respiration of animals and plants and through the action of photosynthesis |
| carbon dioxide | CO ₂ | 0.03 | cycled through respiration and photosynthesis in exchange reactions with oxygen. It is also a product of burning fossil fuels |
| argon | Ar | 0.093 | chemically inert and with only a few industrial uses |
| neon | Ne | 0.0018 | as argon |
| helium | He | 0.0005 | as argon |
| krypton | Kr | trace | as argon |
| xenon | Xe | trace | as argon |
| ozone | O ₃ | 0.00006 | a product of oxygen molecules split into single atoms by the Sun's radiation and unaltered oxygen molecules |
| hydrogen | H ₂ | 0.00005 | unimportant; it is so light it escapes into space |

tends to lose its colour and appear darker. The phenomenon of why the sky appears blue was first demonstrated by British physicist John Tyndall in the mid-19th century, and later explained theoretically by Lord Rayleigh.

atmosphere or **standard atmosphere** in physics, a unit (symbol atm) of pressure equal to 760 torr, 1013.25 millibars, or 1.01325 × 10⁵ newtons per square metre. The actual pressure exerted by the atmosphere fluctuates around this value, which is assumed to be standard at sea level and 0°C/32°F, and is used when dealing with very high pressures.

atmospheric pressure the pressure at any point on the Earth's surface that is due to the weight of the column of air above it; it therefore decreases as altitude increases. At sea level the average pressure is 101 kilopascals (1,013 millibars, 760 mmHg, or 14.7 lb per sq in).

Changes in atmospheric pressure, measured with a barometer, are used in weather forecasting. Areas of relatively high pressure are called anticyclones; areas of low pressure are called depressions.

To remember the effects of falling and rising atmospheric pressure:

**WHEN PRESSURE IS FALLING, STORMS MAY COME A'CALLING.
WHEN PRESSURE IS HIGH, EXPECT CLEAR BLUE SKY.**

atoll continuous or broken circle of coral reef and low coral islands surrounding a lagoon.

atom *Greek atomos 'undivided'* smallest unit of matter that can take part in a chemical reaction, and which cannot be broken down chemically into anything simpler. An atom is made up of protons and neutrons in a central nucleus surrounded by electrons (see atomic structure). The atoms of the various elements differ in atomic number, relative atomic mass, and chemical behaviour.

Atoms are much too small to be seen even by even the most powerful optical microscope (the largest, caesium, has a diameter of 0.0000005 mm/0.0000002 in), and they are in constant motion. However, modern electron microscopes, such as the scanning tunnelling microscope (STM) and the atomic force microscope (AFM), can produce images of individual atoms and molecules.

The unleashed power of the atom has changed everything save our modes of thinking and we thus drift toward unparalleled catastrophe.

ALBERT EINSTEIN German-born US physicist.

Telegram sent to prominent Americans 24 May 1946

atom, electronic structure The arrangement of electrons in a sodium atom and a sulphur atom. The number of electrons in a neutral atom gives that atom its atomic number: sodium has an atomic number of 11 and sulphur has an atomic number of 16.

atom, electronic structure of the arrangement of electrons around the nucleus of an atom, in distinct energy levels, also called orbitals or shells (see orbital, atomic). These shells can be regarded as a series of concentric spheres, each of which can contain a certain maximum number of electrons; the noble gases have an arrangement in which every shell contains this number (see noble gas structure). The energy levels are usually numbered beginning with the shell nearest to the nucleus. The outermost shell is known as the valency shell as it contains the valence electrons.

The lowest energy level, or innermost shell, can contain no more than two electrons. Outer shells are considered to be stable when they contain eight electrons but additional electrons can sometimes be accommodated provided that the outermost shell has a stable configuration. Electrons in unfilled shells are available to take part in chemical bonding, giving rise to the concept of valency. In ions, the electron shells contain more or fewer electrons than are required for a neutral atom, generating negative or positive charges.

The atomic number of an element indicates the number of electrons in a neutral atom. From this it is possible to deduce its electronic structure. For example, sodium has atomic number 11 ($Z = 11$) and its electronic arrangement (configuration) is two electrons in the first energy level, eight electrons in the second energy level and one electron in the third energy level – generally written as 2.8.1. Similarly for sulphur ($Z = 16$), the electron arrangement will be 2.8.6. The electronic structure dictates whether two elements will combine by ionic or covalent bonding (see bond) or not at all.

atomic absorption spectrometry technique used in archaeology to determine quantitatively the chemical composition of artefactual metals, minerals, and rocks, in order to identify raw material sources, to relate artefacts of the same material, or to trace trade routes. A sample of the material is atomized in a flame, and its light intensity measured. The method is slow and destroys the sample.

atomic clock timekeeping device regulated by various periodic processes occurring in atoms and molecules, such as atomic vibra-

tion or the frequency of absorbed or emitted radiation.

The first atomic clock was the **ammonia clock**, invented at the US National Bureau of Standards in 1948. It was regulated by measuring the speed at which the nitrogen atom in an ammonia molecule vibrated back and forth. The rate of molecular vibration is not affected by temperature, pressure, or other external influences, and can be used to regulate an electronic clock.

A more accurate atomic clock is the **caesium clock**. Because of its internal structure, a caesium atom produces or absorbs radiation of a very precise frequency (9,192,631,770 Hz) that varies by less than one part in 10 billion. This frequency has been used to define the second, and is the basis of atomic clocks used in international timekeeping.

Hydrogen maser clocks, based on the radiation from hydrogen atoms, are the most accurate. The hydrogen maser clock at the US Naval Research Laboratory, Washington DC, is estimated to lose one second in 1,700,000 years. Cooled hydrogen maser clocks could theoretically be accurate to within one second in 300 million years.

Atomic clocks are so accurate that minute adjustments must be made periodically to the length of the year to keep the calendar exactly synchronized with the Earth's rotation, which has a tendency to slow down. There have been 17 adjustments made since 1972 adding a total of 20 seconds to the calendar. In 1997 the northern hemisphere's summer was longer than usual – by one second. An extra second was added to the world's time at precisely 23 hours, 59 minutes, and 60 seconds on 30 June 1997. The adjustment was called for by the International Earth Rotation Service in Paris, which monitors the difference between Earth time and atomic time.

atomic energy another name for ψ nuclear energy.

atomic force microscope (AFM) microscope developed in the late 1980s that produces a magnified image using a diamond probe, with a tip so fine that it may consist of a single atom, dragged over the surface of a specimen to 'feel' the contours of the surface. In effect, the tip acts like the stylus of a record player, reading the surface. The tiny up-and-down movements of the probe are converted to an image of the surface by computer and displayed on a screen. The AFM is useful for examination of biological specimens since, unlike the ψ scanning tunnelling microscope, the specimen does not have to be electrically conducting.

atomicity number of atoms of an element that combine together to form a molecule. A molecule of oxygen (O_2) has atomicity 2; sulphur (S_8) has atomicity 8.

atomic mass see ψ relative atomic mass.

atomic mass unit or **dalton unit** (symbol amu or u) unit of mass that is used to measure the relative mass of atoms and molecules. It is equal to one-twelfth of the mass of a carbon-12 atom, which is equivalent to the mass of a proton or 1.66×10^{-27} kg. The relative atomic mass of an atom has no units; thus oxygen-16 has an atomic mass of 16 daltons but a relative atomic mass of 16.

atomic number or **proton number** the number (symbol Z) of protons in the nucleus of an atom. It is equal to the positive charge on the nucleus.

In a neutral atom, it is also equal to the number of electrons surrounding the nucleus. The chemical elements are arranged in the ψ periodic table of the elements according to their atomic number. See also ψ nuclear notation.

atomic radiation energy given out by disintegrating atoms during ψ radioactive decay, whether natural or synthesized. The energy may be in the form of fast-moving particles, known as ψ alpha particles and ψ beta particles, or in the form of high-energy electromagnetic waves known as ψ gamma radiation. Overlong exposure to atomic radiation can lead to ψ radiation sickness.

Radiation biology studies the effect of radiation on living organisms. Exposure to atomic radiation is linked to chromosomal damage, cancer, and, in laboratory animals at least, hereditary disease.

atomic size or **atomic radius** size of an atom expressed as the radius in ψ angstroms or other units of length.

The sodium atom has an atomic radius of 1.57 angstroms (1.57×10^{-8} cm). For metals, the size of the atom is always greater than the size of its ion. For non-metals the reverse is true.

atomic structure internal structure of an atom.

the nucleus The core of the atom is the **nucleus**, a dense body only one ten-thousandth the diameter of the atom itself. The simplest nucleus, that of hydrogen, comprises a single stable positively charged particle, the **proton**. Nuclei of other elements contain more protons and additional particles, called **neutrons**, of about the same mass as the proton but with no electrical charge. Each element has its own characteristic nucleus with a unique number of protons, the **atomic number**. The number of neutrons may vary. Where atoms of a single element have different numbers of neutrons, they are called ψ isotopes. Although some isotopes tend to be unstable and exhibit ψ radioactivity, they all have identical chemical properties.

electrons The nucleus is surrounded by a number of moving electrons, each of which has a negative charge equal to the positive charge on a proton, but which weighs only $\frac{1}{1836}$ times as much. In a neutral atom, the nucleus is surrounded by the same number of electrons as it contains protons. According to quantum theory, the position of an electron is uncertain; it may be found at any point. However, it is more likely to be found in some places than others. The region of space in which an electron is most likely to be found is called an **orbital** (see ψ orbital, atomic). The chemical properties of an element are determined by the ease with which its atoms can gain or lose electrons from its outer orbitals.

attraction and repulsion Atoms are held together by the electrical forces of attraction between each negative electron and the positive protons within the nucleus. The latter repel one another with enormous forces; a nucleus holds together only because an even stronger force, called the **strong nuclear force**, attracts the protons and neutrons to one another. The strong force acts over a very short range – the protons and neutrons must be in virtual contact with one another (see ψ forces, fundamental). If, therefore, a fragment of a complex nucleus, containing some protons, becomes only slightly loosened from the main group of neutrons and protons, the natural repulsion between the protons will cause this fragment to fly apart from the rest of the nucleus at high speed. It is by such fragmentation of atomic nuclei (nuclear ψ fission) that nuclear energy is released.

atomic time time as given by ψ atomic clocks, which are regulated by natural resonance frequencies of particular atoms, and display a continuous count of seconds.

In 1967 a new definition of the second was adopted in the SI system of units: the duration of 9,192,631,770 periods of the radiation corresponding to the transition between two hyperfine levels of the ground state of the caesium-133 atom. The International Atomic Time Scale is based on clock data from a number of countries; it is a continuous scale in days, hours, minutes, and seconds from the origin on 1 January 1958, when the Atomic Time Scale was made 0 h 0 min 0 sec when Greenwich Mean Time was at 0 h 0 min 0 sec.

atomic weight another name for ψ relative atomic mass.

atomizer device that produces a spray of fine droplets of liquid. A vertical tube connected with a horizontal tube dips into a bottle of liquid, and at one end of the horizontal tube is a nozzle, at the other a rubber bulb. When the bulb is squeezed, air rushes over the top of the vertical tube and out through the nozzle. Following ψ Bernoulli's principle, the pressure at the top of the vertical tube is reduced, allowing the liquid to rise. The air stream picks up the liquid, breaks it up into tiny drops, and carries it out of the nozzle as a spray. Scent spray, paint spray guns, and carburettors all use the principle of the atomizer.

ATP (abbreviation for **adenosine triphosphate**), a nucleotide molecule found in all cells. It can yield large amounts of energy, and is used to drive the thousands of biological processes needed to sustain life, growth, movement, and reproduction. Green plants use light energy to manufacture ATP as part of the process of ψ photosynthesis. In animals, ATP is formed by the breakdown of glucose molecules, usually obtained from the carbohydrate component of a diet, in a series of reactions termed ψ respiration. It is the driving force behind muscle contraction and the synthesis of complex molecules needed by individual cells.

atrium either of the two upper chambers of the heart. The left atrium receives freshly oxygenated blood from the lungs via the pulmonary vein; the right atrium receives deoxygenated blood from the vena cava. Atrium walls are thin and stretch easily to allow blood into the heart. On contraction, the atria force blood into the thick-walled ventricles, which then give a second, more powerful beat.

atrophy in medicine, a diminution in size and function, or output, of a body tissue or organ. It is usually due to nutritional impairment, disease, or disuse (muscle).

atropine alkaloid derived from *belladonna*, a plant with toxic properties. It acts as an anticholinergic, inhibiting the passage of certain nerve impulses. It is used in premedication, to reduce bronchial and gastric secretions. It is also administered as a mild antispasmodic drug, and to dilate the pupil of the eye.

attachment way of incorporating a file into an e-mail message for transmission. Within a single system, such as a corporate local area network (LAN) or a commercial online service, binary files can be sent intact. Over the Internet, attached files must be encoded into ASCII characters and then decoded by the receiver. See MIME.

attar of roses perfume derived from the essential oil of roses (usually damask roses), obtained by crushing and distilling the petals of the flowers.

attention-deficit hyperactivity disorder (ADHD) psychiatric condition occurring in young children characterized by impaired attention and hyperactivity. The disorder, associated with disruptive behaviour, learning difficulties, and under-achievement, is more common in boys. It is treated with methylphenidate (Ritalin). There was a 50% increase in the use of the drug in the USA 1994-96, with an estimated 5% of school-age boys diagnosed as suffering from ADHD.

In 1996, US researchers found that 50% of children diagnosed as ADHD sufferers carry a gene that affects brain cell response to the neurotransmitter dopamine. The same gene has also been linked to impulsiveness in adults. Diagnosis requires the presence, for at least six months, of eight behavioural problems, first developing before the age of seven. In addition to their hyperactivity, such children are found to be reckless, impulsive, and accident prone; they are often aggressive and tend to be unpopular with other children. The outlook for ADHD sufferers varies, with up to a quarter being diagnosed with antisocial personality disorder as adults.

aubergine or **eggplant** plant belonging to the nightshade family, native to tropical Asia. Its purple-skinned, sometimes white, fruits are eaten as a vegetable. (*Solanum melongena*, family Solanaceae.)

aubrieta any of a group of spring-flowering dwarf perennial plants native to the Middle East. All are trailing plants with showy, purple flowers. They are widely cultivated in rock gardens. (Genus *Aubrieta*, family Cruciferae.)

audio file computer file that encodes sounds which can be played back using the appropriate software and hardware. On the World Wide Web, the latest types of audio files can be played on the user's computer system in real time while they are being downloaded. Apple Macintosh computers have sound capabilities built in, as do multimedia personal computers (MPCs). Older PCs need to have a sound card installed in order to achieve good playback quality.

audio-video interleave in computing, file format for video clips.

auditory canal tube leading from the outer ear opening to the eardrum. It is found only in animals whose eardrums are located inside the skull, principally mammals and birds.

audit trail record of computer operations, showing what has been done and, if available, who has done it. The term is taken from accountancy, but audit trails are now widely used to check many aspects of computer security, in addition to use in accounts programs.

auger tool for boring holes. Originally, a carpenter's tool, with a cutting edge and a screw point, manipulated by means of a handle at right angles to the shank. In archaeology a large auger is used to collect sediment and soil samples below ground without hand

auk *The Atlantic, or common, puffin* *Fratercula arctica* lives in the open seas and breeds on the rocky coasts of the N Atlantic. With its short tail and narrow wings, which beat rapidly in flight, the puffin is a typical auk. Like all of the auks, the puffin spends most of its life at sea, coming ashore only during the breeding season. Its colourful striped beak has serrated edges to allow it to catch and grip many small fish before flying back to the nest. Premaphotos Wildlife

excavation, or to determine the depth and type of archaeological deposits. The auger may be hand- or machine-powered.

augmented reality use of computer systems and data to overlay video or other real-life representations. For example, a video of a car engine with the mechanical drawings overlaid.

auk oceanic bird belonging to the family Alcidae, order Charadriiformes, consisting of 22 species of marine diving birds including razorbills, puffins, murres, and guillemots. Confined to the northern hemisphere, their range extends from well inside the Arctic Circle to the lower temperate regions. They feed on fish, and use their wings to 'fly' underwater in pursuit.

Most auks are colonial, breeding on stack tops or cliff edges, although some nest in crevices or holes. With the exception of one species they all lay a single large, very pointed egg.

AUP abbreviation for acceptable use policy; see acceptable use.

auricula species of primrose, a plant whose leaves are said to resemble a bear's ears. It grows wild in the Alps but is popular in cool-climate areas and often cultivated in gardens. (*Primula auricula*.)

Auriga constellation of the northern hemisphere, represented as a charioteer. Its brightest star is the first-magnitude α Capella, about 45 light years from Earth; Epsilon Aurigae is an eclipsing binary star with a period of 27 years, the longest of its kind (last eclipse 1983).

auroids (plural **auroids**) extinct species of long-horned wild cattle *Bos primigenius* that formerly roamed Europe, SW Asia, and N Africa. It survived in Poland until 1627. Black to reddish or grey, it was up to 1.8 m/6 ft at the shoulder. It is depicted in many cave paintings, and is considered the ancestor of domestic cattle.

aurora coloured light in the night sky near the Earth's magnetic poles, called *aurora borealis* ('northern lights') in the northern

hemisphere and *aurora australis* in the southern hemisphere. Although auroras are usually restricted to the polar skies, fluctuations in the ζ olar wind occasionally cause them to be visible at lower latitudes. An aurora is usually in the form of a luminous arch with its apex towards the magnetic pole followed by arcs, bands, rays, curtains, and coronas, usually green but often showing shades of blue and red, and sometimes yellow or white. Aurorae are caused at heights of over 100 km/60 mi by a fast stream of charged particles from solar flares and low-density 'holes' in the Sun's corona.

These are guided by the Earth's magnetic field towards the north and south magnetic poles, where they enter the upper atmosphere and bombard the gases in the atmosphere, causing them to emit visible light.

auscultation evaluation of internal organs by listening, usually with the aid of a stethoscope.

AUSSAT organization formed in 1981 by the federal government of Australia and Telecom Australia to own and operate Australia's domestic satellite system. The first stage, *Aussat 1*, was launched by the US space shuttle *Discovery* in 1985 and the third and final stage was launched from French Guiana, South America, in 1987. The AUSSAT satellite system enables people in remote outback areas of Australia to receive television broadcasts.

Australian cattle dog breed of herding dog known also as a 'heeler' from its technique of controlling cattle by nipping their heels. It has a short coat flecked with red or blue, pricked ears, and a long tail, and stands about 51 cm/20 in tall.

Bred from imported collies, Australian cattle dogs are also claimed to have ζ dingo blood.

Australian Museum the original museum of Australia, which dates from 1827, when it was known as the Colonial Museum. Housed in Sydney, New South Wales, its collection covers anthropology, geology, palaeontology, and the natural sciences (with the exception of botany). It is rated as one of the major natural history museums in the world.

Australian sheepdog breed of dog. See ζ heepie.

Australian terrier small long-set dog with a long body and straight back. Its straight, rough coat is about 5-6.5 cm/2-2.5 in long, and blue or silver-grey, and tan or clear red or sandy in colour. It has a long head with a topknot of soft hair and ears either pricked or dropped forwards towards the front. Australian terriers are about 25 cm/10 in high and weigh 4.5-5 kg/10-11 lb.

The Australian terrier traces its ancestry to the Cairn, Norwich, and Yorkshire terriers.

Australia Prize annual award for achievement internationally in science and technology, established 1990 and worth £115,000.

The first winners were Allan Kerr of Adelaide University, Australia; Eugene Nester of Washington University, USA; and Jeff Schell of the Max Planck Institute in Cologne, Germany. Their studies of the genetic systems of the crown-gall bacterium *Agrobacterium tumefaciens* led to the creation of genetically engineered plants resistant to herbicides, pests, and viruses.

Australia Telescope giant radio telescope in New South Wales, Australia, operated by the Commonwealth Scientific and Industrial Research Organization (CSIRO). It consists of six 22-m/72-ft antennae at Culgoora, a similar antenna at Siding Spring Mountain, and the 64-m/210-ft ζ Parkes radio telescope - the whole simulating a dish 300 m/186 mi across.

Australopithecus the first hominid, living 3.5-4 million years ago; see ζ human species, ζ origins of.

authentication system for certifying the origin of an electronic communication. In the real world, a handwritten signature authenticates a document, for example a contract, as coming from a particular person. In the electronic world, encryption systems provide the same function via ζ igital signatures and other techniques.

In public-key cryptography, for example, the ability to decrypt a message with a particular user's public key authenticates the message as coming from that user and no one else. Authentication is an essential requirement for electronic commerce.

authoring development of multimedia presentations. Authoring includes pulling together the necessary audio, video, graphics, and text files and formatting them for display.

authoring tool software that allows developers to create multimedia presentations or World Wide Web pages. Typically, these tools automate some of the more difficult parts of generating program source codes so that developers can work on a higher, more abstract level. Popular authoring tools for the World Wide Web include Hot Metal and HTML Assistant, both available in ζ shareware versions.

authorization permission to access a particular system. Unauthorized access to private computer systems was made illegal in many countries during the late 1980s.

autism, infantile rare disorder, generally present from birth, characterized by a withdrawn state and a failure to develop normally in language or social behaviour. Although the autistic child may, rarely, show signs of high intelligence (in music or with numbers, for example), many have impaired intellect. The cause is unknown, but is thought to involve a number of factors, possibly including an inherent abnormality of the child's brain. Special education may bring about some improvement.

Autism was initially defined by four common traits - preference for aloneness; insistence on sameness; need for elaborate routines; and the possession of some abilities that seem exceptional compared with other deficits - but current clinical diagnosis involves wider criteria.

AutoCAD the leading computer-aided design (CAD) software package. It is published by the specialist US company Autodesk (founded 1982). Users include engineers, architects, and designers.

autochrome in photography, a single-plate additive colour process devised by the ζ umiere brothers in 1903. It was the first commercially available process, in use 1907-35.

autoclave pressurized vessel that uses superheated steam to sterilize materials and equipment such as surgical instruments. It is similar in principle to a pressure cooker.

autoexec.bat in computing, a file in the ζ MS-DOS operating system that is automatically run when the computer is ζ booted.

autogiro or *autogyro* heavier-than-air craft that supports itself in the air with a rotary wing, or rotor. The Spanish aviator Juan de la Cierva designed the first successful autogiro in 1923. The autogiro's rotor provides only lift and not propulsion; it has been superseded by the helicopter, in which the rotor provides both. The autogiro is propelled by an orthodox propeller.

The three- or four-bladed rotor on an autogiro spins in a horizontal plane on top of the craft, and is not driven by the engine. The blades have an aerofoil cross section, as a plane's wings. When the autogiro moves forward, the rotor starts to rotate by itself, a state known as autorotation. When travelling fast enough, the rotor develops enough lift from its aerofoil blades to support the craft.

autoimmunity in medicine, condition where the body's immune responses are mobilized not against 'foreign' matter, such as invading germs, but against the body itself. Diseases considered to be of autoimmune origin include ζ myasthenia gravis, ζ heumatoid arthritis, and ζ lupus erythematosus.

In autoimmune diseases T-lymphocytes reproduce to excess to home in on a target (properly a foreign disease-causing molecule); however, molecules of the body's own tissue that resemble the target may also be attacked, for example insulin-producing cells, resulting in insulin-dependent diabetes; if certain joint membrane cells are attacked, then rheumatoid arthritis may result; and if myelin, the basic protein of the nervous system, then multiple sclerosis results. In 1990 in Israel a T-cell vaccine was produced that arrests the excessive reproduction of T-lymphocytes attacking healthy target tissues.

autolysis in biology, the destruction of a cell after its death by the action of its own ζ enzymes, which break down its structural molecules.

automatic fallback in computing, feature allowing modems to drop to a slower speed if conditions such as line noise make it necessary. Modem speeds are typically rated according to one or another CCITT standard (known as a V number). All modems rated for a specific standard are backwards compatible.

automatic pilot control device that keeps an aeroplane flying automatically on a given course at a given height and speed.

The automatic pilot contains a set of gyroscopes that provide references for the plane's course. Sensors detect when the plane deviates from this course and send signals to the control surfaces – the ailerons, elevators, and rudder – to take the appropriate action. Autopilot is also used in missiles. Most airliners cruise on automatic pilot, also called autopilot and gyropilot, for much of the time.

US business executive Lawrence Sperry first used a gyroscope in 1912 to create an artificial horizon. This entered production in 1924 and was soon linked to aircraft controls to increase stability. More gyroscopes were added later to control altitude and course. The first automatic pilot was introduced in the 1930s using pneumatic power.

automation widespread use of self-regulating machines in industry. Automation involves the addition of control devices, using electronic sensing and computing techniques, which often follow the pattern of human nervous and brain functions, to already mechanized physical processes of production and distribution; for example, steel processing, mining, chemical production, and road, rail, and air control.

automation Industrial automation has led to greater productivity and improved quality control. On this production line at a Rover car plant in England car bodies are welded by computer-controlled robots, a task that is complex yet boring and potentially hazardous for human workers. Rover Group

Civilization advances by extending the number of important operations which we can perform without thinking about them.

ALFRED NORTH WHITEHEAD English philosopher and mathematician.
An Introduction to Mathematics

automatism performance of actions without awareness or conscious intent. It is seen in sleepwalking and in some (relatively rare) psychotic states.

automaton mechanical figure imitating human or animal performance. Automata are usually designed for aesthetic appeal as opposed to purely functional robots. The earliest recorded automaton is an Egyptian wooden pigeon of 400 BC.

autonomic nervous system in mammals, the part of the nervous system that controls those functions not controlled voluntarily, including the heart rate, activity of the intestines, and the production of sweat.

There are two divisions of the autonomic nervous system. The sympathetic system responds to stress, when it speeds the heart rate, increases blood pressure, and generally prepares the body for action. The parasympathetic system is more important when the body is at rest, since it slows the heart rate, decreases blood pressure, and stimulates the digestive system.

At all times, both types of autonomic nerves carry signals that bring about adjustments in visceral organs. The actual rate of heartbeat is the net outcome of opposing signals. Today, it is known that the word 'autonomic' is misleading – the reflexes managed by this system are actually integrated by commands from the brain and spinal cord (the central nervous system).

autopsy or *postmortem* examination of the internal organs and tissues of a dead body, performed to try to establish the cause of death.

autoradiography in biology, a technique for following the movement of molecules within an organism, especially a plant, by labelling with a radioactive isotope that can be traced on photographs. It is used to study photosynthesis, where the pathway of radioactive carbon dioxide can be traced as it moves through the various chemical stages.

autoresponder on the Internet, a server that responds automatically to specific messages or input. A common use for autoresponders is to automate the dispatch of sales information via e-mail. A user requesting such information typically sends a message with specified words such as 'send info' in the subject line or the body of the message. The words trigger the autoresponder to send the prepared information file.

Autoresponders are also used in e-mail systems which can be configured to notify correspondents that the user is on holiday.

autosome any chromosome in the cell other than a sex chromosome. Autosomes are of the same number and kind in both males and females of a given species.

autosuggestion conscious or unconscious acceptance of an idea as true, without demanding rational proof, but with potential subsequent effect for good or ill. Pioneered by French psychotherapist Emile Coué (1857–1926) in healing, it is sometimes used in modern psychotherapy to conquer nervous habits and dependence on addictive substances such as tobacco and alcohol.

autotroph any living organism that synthesizes organic substances from inorganic molecules by using light or chemical energy. Autotrophs are the primary producers in all food chains since the materials they synthesize and store are the energy sources of all other organisms. All green plants and many planktonic organisms are autotrophs, using sunlight to convert carbon dioxide and water into sugars by photosynthesis.

The total biomass of autotrophs is far greater than that of animals, reflecting the dependence of animals on plants, and the ultimate dependence of all life on energy from the Sun – green plants convert light energy into a form of chemical energy (food) that

animals can exploit. Some bacteria use the chemical energy of sulphur compounds to synthesize organic substances. It is estimated that 10% of the energy in autotrophs can pass into the next stage of the food chain, the rest being lost as heat or indigestible matter. See also *heterotroph*.

autumnal equinox see *equinox*.

autumn crocus any of a group of late-flowering plants belonging to the lily family. The mauve headed saffron (*Colchicum autumnale*) yields colchicine, which is used in treating gout and in plant breeding. (Genus *Colchicum*, family Liliaceae.)

Colchicine causes plants to double the numbers of their chromosomes, forming *polyploids*

auxin plant hormone that promotes stem and root growth in plants. Auxins influence many aspects of plant growth and development, including cell enlargement, inhibition of development of axillary buds, *tropisms*, and the initiation of roots. Synthetic auxins are used in rooting powders for cuttings, and in some weed-killers, where high auxin concentrations cause such rapid growth that the plants die. They are also used to prevent premature fruit-drop in orchards. The most common naturally occurring auxin is known as indoleacetic acid, or IAA. It is produced in the shoot apex and transported to other parts of the plant.

avalanche from French *avalier* 'to swallow' fall or flow of a mass of snow and ice down a steep slope under the force of gravity. Avalanches occur because of the unstable nature of snow masses in mountain areas.

Changes of temperature, sudden sound, or earth-borne vibrations may trigger an avalanche, particularly on slopes of more than 35°. The snow compacts into ice as it moves, and rocks may be carried along, adding to the damage caused.

Avalanches leave slide tracks, long gouges down the mountain-side that can be up to 1 km/0.6 mi long and 100 m/330 ft wide. These slides have a similar beneficial effect on biodiversity as do forest fires, clearing the land of snow and mature mountain forest enabling plants and shrubs that cannot grow in shade, to recolonize and creating wildlife corridors.

AVAILANCE AWARENESS

<http://www-nsidc.colorado.edu/NSIDC/EDUCATION/AVALANCHE/>

Excellent description of avalanches, what causes them, and how to minimize dangers if caught in one. There is advice on how to determine the stability of a snowpack, what to do if caught out, and how to locate people trapped under snow. Nobody skiing off piste should set off without reading this.

avatar computer-generated character that represents a human in on-screen interaction. In the mid-1990s, avatars were primarily used in computer games, but because they take up much less memory or bandwidth than full video, companies such as British Telecom were researching the possibility of building multiparty videoconferencing systems using this technology.

Avebury Europe's largest stone circle (diameter 412 m/1,350 ft), in Wiltshire, England. This megalithic henge monument, probably a ritual complex, contains 650 massive blocks of stone, arranged in circles and avenues. It was probably constructed around 3,500 years ago, and is linked with nearby *Silbury Hill*.

The henge, an earthen bank and interior ditch with opposed entrances, originally rose 15 m/49 ft above the bottom of the ditch. This earthwork and an outer ring of stones surround the inner circles. The stones vary in size from 1.5 m/5 ft to 5.5 m/18 ft high and 1 m/3 ft to 3.65 m/12 ft broad. They were erected by a late Neolithic or early Bronze Age culture. Visible remains seen today may cover an earlier existing site – a theory applicable to a number of prehistoric sites.

avens any of several low-growing plants found throughout Europe, Asia, and N Africa. (Genus *Geum*, family Rosaceae.)

Mountain avens (*Dryas octopetala*) belongs to a different genus and grows in mountain and arctic areas of Europe, Asia, and North America. A creeping perennial, it has white flowers with yellow stamens.

average in statistics, a term used inexactly to indicate the typical member of a set of data. It usually refers to the *arithmetical mean*. The term is also used to refer to the middle member of the set when it is sorted in ascending or descending order (the *Gmedian*), and the most commonly occurring item of data (the *mode*), as in 'the average family'.

AVI (abbreviation for *Audio-Visual Interleave*) file format capable of storing moving images (such as video) with accompanying sound. AVI files can be replayed by any multimedia PC with Microsoft *Windows* and a *sound card*. AVI files are frequently very large (around 50 Mbyte for a five-minute rock video, for example), so they are usually stored on *CD-ROM*.

aviation term used to describe the science of powered flight.

AVIATION ENTHUSIASTS' CORNER

<http://www.brooklyn.cuny.edu/rec/air/air.html>

Forum dedicated to furthering interest in aviation-related hobbies. It includes links to museums and displays, features on key events in aviation history, and indexes of aircraft by type and manufacturer.

avocado tree belonging to the laurel family, native to Central America. Its dark-green, thick-skinned, pear-shaped fruit has bumpy-textured flesh and is used in salads. (*Persea americana*, family Lauraceae.)

avocet wading bird, with a characteristic long, narrow, upturned bill, which it uses to sift water as it feeds in the shallows. It is about 45 cm/18 in long, has long legs, partly webbed feet, and black and white plumage. There are four species of avocet, genus *Recurvirostra*, family *Recurvirostridae*, order *Charadriiformes*. They are found in Europe, Africa, and central and southern Asia. Stilts belong to the same family.

Avogadro, Amedeo, Conte di Quaregna (1776–1856) Italian physicist, one of the founders of physical chemistry, who proposed *Avogadro's hypothesis* on gases in 1811. His work enabled scientists to calculate *Avogadro's number*, and still has relevance for atomic studies.

Avogadro made it clear that the gas particles need not be individual atoms but might consist of molecules, the term he introduced to describe combinations of atoms. No previous scientist had made this fundamental distinction between the atoms of a substance and its molecules.

Avogadro's hypothesis in chemistry, the law stating that equal volumes of all gases, when at the same temperature and pressure,

AVOGADRO'S HYPOTHESIS OF 1811

<http://dbhs.wvusd.k12.ca.us/Chem-History/Avogadro.html>

Avogadro's hypothesis was contained in the *Essay on a Manner of Determining the Relative Masses of the Elementary Molecules of Bodies, and the Proportions in Which They Enter Into These Compounds from the Journal de physique*, 73: 58-76 (1811). This Web site is a transcript of a translation of that essay taken from *Alemic Club Reprints*, No. 4, *Foundations of the Molecular Theory: Comprising Papers and Extracts by John Dalton, Joseph Louis Gay-Lussac, and Amadeo Avogadro (1808-11)*.

have the same numbers of molecules. It was first propounded by Amedeo Avogadro.

Avogadro's number or *Avogadro's constant* the number of carbon atoms in 12 g of the carbon-12 isotope (6.022045×10^{23}). The relative atomic mass of any element, expressed in grams, contains this number of atoms. It is named after Amedeo Avogadro.

avoirdupois system of units of mass based on the pound (0.45 kg), which consists of 16 ounces (each of 16 drams) or 7,000 grains (each equal to 65 mg).

axil upper angle between a leaf (or bract) and the stem from which it grows. Organs developing in the axil, such as shoots and buds, are termed axillary, or lateral.

axiom in mathematics, a statement that is assumed to be true and upon which theorems are proved by using logical deduction; for example, two straight lines cannot enclose a space. The Greek mathematician Euclid used a series of axioms that he considered could not be demonstrated in terms of simpler concepts to prove his geometrical theorems.

axis (plural *axes*) in geometry, one of the reference lines by which a point on a graph may be located. The horizontal axis is usually referred to as the *x*-axis, and the vertical axis as the *y*-axis. The term is also used to refer to the imaginary line about which an object may be said to be symmetrical (*axis of symmetry*) – for example, the diagonal of a square – or the line about which an object may revolve (*axis of rotation*).

axis deer or *chital* species of deer found in India and the East Indies. It is profusely spotted with white on a fawn background, shading from almost black on the back to white on the underparts.

classification The axis deer *Axis axis* is in family Cervidae, order Artiodactyla.

axolotl *Aztec* 'water monster' aquatic larval form ('tadpole') of the Mexican salamander *Ambystoma mexicanum*, belonging to the family Ambystomatidae. Axolotls may be up to 30 cm/12 in long. They are remarkable because they can breed without changing to the adult form, and will metamorphose into adults only in response to the drying-up of their ponds. The adults then migrate to another pond.

Axolotls resemble a newt in shape, having a powerful tail, two pairs of weak limbs, and three pairs of simple external gills. They lay eggs like a frog's in strings attached to water plants by a viscous substance, and the young, hatched in two to three weeks, resemble the parents. See also *çneotený*.

axon long threadlike extension of a çnerve cell that conducts electrochemical impulses away from the cell body towards other nerve cells, or towards an effector organ such as a muscle. Axons terminate in çsynapses, junctions with other nerve cells, muscles, or glands.

aye-aye nocturnal tree-climbing prosimian *Daubentonia madagascariensis* of Madagascar, related to the lemurs. It is just over 1 m/3 ft long, including a tail 50 cm/20 in long.

It has an exceptionally long middle finger with which it probes for insects and their larvae under the bark of trees, and gnawing, rodentlike front teeth, with which it tears off the bark to get at its prey. The aye-aye has become rare through loss of its forest habitat, and is now classified as an endangered species.

Ayurveda basically naturopathic system of medicine widely practised in India and based on principles derived from the ancient Hindu scriptures, the Vedas. Hospital treatments and remedial prescriptions tend to be nonspecific and to coordinate holistic therapies for body, mind, and spirit.

azalea any of a group of deciduous flowering shrubs belonging to the heath family. Several species are native to Asia and North America, and many cultivated varieties have been derived from these. Azaleas are closely related to the mostly evergreen çrhododendrons. (Genus *Rhododendron*, family Ericaceae.)

Azaleas, particularly the Japanese varieties, make fine ornamental shrubs. Several species are highly poisonous.

Azilian archaeological period following the close of the Old Stone (Palaeolithic) Age and regarded as the earliest culture of the Mesolithic Age in W Europe. It was first recognized at Le Mas d'Azil, a cave in Ariège, France.

azimuth in astronomy, the angular distance of an object eastwards along the horizon, measured from due north, between the astronomical çmeridian (the vertical circle passing through the centre of the sky and the north and south points on the horizon) and the vertical circle containing the celestial body whose position is to be measured.

azo dye synthetic dye containing the azo group of two nitrogen atoms (N=N) connecting aromatic ring compounds. Azo dyes are usually red, brown, or yellow, and make up about half the dyes produced. They are manufactured from aromatic çamines.

AZT drug used in the treatment of AIDS; see çzidovudine.

B

Babbage, Charles (1792-1871)

English mathematician who devised a precursor of the computer. He designed an analytical engine, a general-purpose mechanical computing device for performing different calculations according to a program input on punched cards (an idea borrowed from the Jacquard loom). This device was never built, but it embodied many of the principles on which digital computers are based.

Mary Evans Picture Library

BABBAGE, CHARLES

Charles Babbage, who was perhaps the first person to conceive the idea of a mechanical computer, was a stickler for accuracy. He once wrote to the poet Tennyson to object to the poet's lines 'Every moment dies a man, every moment one is born'. According to Babbage, Tennyson's recipe gave zero population growth, and should be corrected to: 'Every moment one and one-sixteenth is born'.

Babbitt metal soft, white metal, an alloy of tin, lead, copper, and antimony, used to reduce friction in bearings, developed by the US inventor Isaac Babbitt in 1839.

babbler bird of the thrush family Muscicapidae with a loud babbling cry. Babblers, subfamily Timaliinae, are found in the Old World, and there are some 250 species in the group.

babirusa wild pig *Babirusa babirusa*, becoming increasingly rare, found in the moist forests and by the water of Sulawesi, Buru, and nearby Indonesian islands. The male has large upper tusks which grow upwards through the skin of the snout and curve back towards the forehead. The babirusa is up to 80 cm/2.5 ft at the shoulder. It is nocturnal, and swims well.

baboon large monkey of the genus *Papio*, with a long doglike muzzle and large canine teeth, spending much of its time on the ground in open country. Males, with head and body up to 1.1 m/3.5 ft long, are larger than females, and dominant males rule the 'troops' in which baboons live. They inhabit Africa and SW Arabia.

Species include the olive baboon *P. anubis* from W Africa to Kenya, the chacma *P. ursinus* from S Africa, and the sacred

baboon *P. hamadryas* from NE Africa and SW Arabia. The male sacred baboon has a 'cape' of long hair.

bacille Calmette-Guérin tuberculosis vaccine ζ BCG.

bacillus member of a group of rodlike bacteria that occur everywhere in the soil and air. Some are responsible for diseases such as anthrax or for causing food spoilage.

backbone in networking, a high-bandwidth trunk to which smaller networks connect. The original backbone of the Internet was NSFnet, funded by the US National Science Foundation, which linked together the five regional supercomputing centres.

backcross breeding technique used to determine the genetic makeup of an individual organism.

background radiation radiation that is always present in the environment. By far the greater proportion (87%) of it is emitted from natural sources. Alpha and beta particles, and gamma radiation are radiated by the traces of radioactive minerals that occur naturally in the environment and even in the human body, and by radioactive gases such as radon and thoron, which are found in soil and may seep upwards into buildings. Radiation from space (ζ cosmic radiation) also contributes to the background level.

backing storage in computing, memory outside the central processing unit used to store programs and data that are not in current use. Backing storage must be nonvolatile - that is, its contents must not be lost when the power supply to the computer system is disconnected.

back pain aches in the region of the spine. Low back pain can be caused by a very wide range of medical conditions. About half of all episodes of back pain will resolve within a week, but severe back pain can be chronic and disabling. The causes include muscle strain, a prolapsed intervertebral disc, and vertebral collapse due to osteoporosis or cancer. Treatment methods include rest, analgesics, physiotherapy, osteopathy, and exercises.

backswimmer or **water boatman** aquatic predatory bug living mostly in fresh water. The adults are about 15 mm/0.5 in long and rest upside down at the water surface to breathe. When disturbed they dive, carrying with them a supply of air trapped under the wings. They have piercing beaks, used in feeding on tadpoles and small fish.

classification Backswimmers belong to the genus *Notonecta*, family Notonectidae in suborder Heteroptera, order Hemiptera (true bugs), class Insecta, phylum Arthropoda.

Females have a sharp ovipositor to pierce the stems of aquatic plants. In each notch one egg is laid; each female lays a total of approximately 60 eggs over a period of a few weeks. Backswimmers fly readily from pond to pond.

backup in computing, a copy file that is transferred to another medium, usually a floppy disc or tape. The purpose of this is to have available a copy of a file that can be restored in case of a fault in the system or the file itself. Backup files are also created by many applications (with the extension .BAC or .BAK); a version is therefore available of the original file before it was modified by the current application.

backup system in computing, a duplicate computer system that can take over the operation of a main computer system in the event of equipment failure. A large interactive system, such as an airline's ticket-booking system, cannot be out of action for even a few hours without causing considerable disruption. In such cases a complete duplicate computer system may be provided to take over and run the system should the main computer develop a fault or need maintenance.

Backup systems include incremental backup and full backup.

backwards compatible in computing, term describing a product that is designed to be compatible with its predecessors. In software, a word processor is backwards compatible if it can read and write the files of earlier versions of the same software, and an operating system is backwards compatible if it can run programs designed for earlier versions of the operating system. Similarly, all modems

are compatible with all the standards (V numbers) which precede the fastest one they can handle.

bacon beetle destructive species of beetle that attacks bacon, dried foods, and hides. It is related to the carpet beetles.

classification The bacon beetle *Dermestes lardarius* is in the family Dermestidae, order Coleoptera, class Insecta, phylum Arthropoda.

bacteria (singular *bacterium*) microscopic single-celled organisms lacking a nucleus. Bacteria are widespread, present in soil, air, and water, and as parasites on and in other living things. Some parasitic bacteria cause disease by producing toxins, but others are harmless and may even benefit their hosts. Bacteria usually reproduce by binary fission (dividing into two equal parts), and this may occur approximately every 20 minutes. It is thought that 1–10% of the world's bacteria have been identified.

classification Bacteria are now classified biochemically, but their varying shapes provide a rough classification; for example, cocci are round or oval, bacilli are rodlike, spirilla are spiral, and vibrios are shaped like commas. Exceptionally, one bacterium has been found, *Gemmata obscuriglobus*, that does have a nucleus. Unlike viruses, bacteria do not necessarily need contact with a live cell to become active.

Bacteria can be classified into two broad classes (called Gram

positive and negative) according to their reactions to certain stains, or dyes, used in microscopy. The staining technique, called the Gram test after Danish bacteriologist Hans Gram, allows doctors to identify many bacteria quickly.

Bacteria have a large loop of ϕ DNA, sometimes called a bacterial chromosome. In addition there are often small, circular pieces of DNA known as plasmids that carry spare genetic information. These plasmids can readily move from one bacterium to another, even though the bacteria may be of different species. In a sense, they are parasites within the bacterial cell, but they survive by coding characteristics that promote the survival of their hosts. For example, some plasmids confer antibiotic resistance on the bacteria they inhabit. The rapid and problematic spread of antibiotic resistance among bacteria is due to plasmids, but they are also useful to humans in genetic engineering. There are ten times more bacterial cells than human cells in the human body.

functions Certain types of bacteria are vital in many food and industrial processes, while others play an essential role in the nitrogen cycle, which maintains soil fertility. For example, bacteria are used to break down waste products, such as sewage; make butter, cheese, and yoghurt; cure tobacco; tan leather; and (by virtue of the ability of certain bacteria to attack metal) clean ships' hulls and derest their tanks, and even extract minerals from mines. Several species of bacteria in the stomach of a bowhead whale are

Phages

BY DAVID EVANS

Introduction

Phages, or bacteriophages (literally 'bacteria eaters'), are viruses that infect bacteria. They were first identified by F.W. Twort in 1905 and, independently, by F d'Herelle in 1917 as filterable infectious agents that caused the lysis (disintegration) of *Shigella dysenteriae*, the bacterium that causes dysentery. They were initially of interest for their specificity, they would not infect other bacteria, and potential therapeutic use, and have become some of the best characterized viruses.

Life cycle of phages

Phages, like other viruses, are obligate intracellular parasites. They cannot reproduce independently and must instead infect a host bacterium within which they replicate, usually resulting in the lysis of the bacteria and release of progeny phage particles. The phage particle is a metabolically inert entity consisting of a protein coat (capsid) surrounding the genome which consists of single- or double-stranded DNA or RNA. Two distinct replication patterns exist: lytic, in which genome replication, transcription and translation of phage genes and the subsequent assembly of progeny phage particles occurs immediately (so called virulent phages) and lysogenic, in which the phage genome becomes integrated into the host chromosome (the temperate phages). In the latter case the phage genome is replicated as part of the bacterial chromosome, remaining latent as a prophage until induction at which point the phage enters a normal lytic cycle.

Phage structure and classification

The diverse range of phages are primarily classified according to their capsid structure (filamentous – e.g. M13, tailless icosahedral – e.g. [phg] X174, phages with noncontractile tails – e.g. [lambda] and phages with contractile tails – e.g. T2) and the type of genetic material. The T-even phages of *Escherichia coli* (T2, T4, T6) possess large double-stranded DNA genomes within an icosahedral capsid bearing a contractile tail, and are some of the most complex of all viruses.

Phages in research

The short replication cycle (as little as 15 min) and ease of

manipulation in the laboratory have meant that phages have been used for some of the most significant biological, and in particular genetic, experiments of the last 50 years. The identification of DNA as the genetic material was based on a study of phage T2 infection of *E. coli* by Alfred Hershey and Martha Chase in 1952. Phage [phg] X174, a single-stranded DNA phage was the first complete genome to be sequenced (1977), leading to the discovery of overlapping genes, and the switch between lytic and lysogenic life cycles by phage lambda ([lambda]) is the paradigm for a 'genetic switch', which has broad similarities with similar controlling events in many other organisms (including humans). The natural ability of phages to exchange genetic material between bacteria has led to them being exploited for experiments in molecular genetics – both phage M13 and [lambda] are widely used DNA cloning vectors.

Phages and human disease

The specificity of bacterial infection by phages means that they can be used to distinguish between different strains of bacteria (particularly *Salmonella* sp.), a technique called 'phage typing' widely used in reference laboratories. Furthermore, phages may have a role in causing human disease as well as diagnosing it. *Vibrio cholerae*, the bacterium that causes cholera, requires two factors for full virulence; the cholera toxin (CT) and a toxin-coregulated pilin (TCP) required for intestinal colonization. Recent research has shown that the genes encoding both CT and TCP are carried by the filamentous phage CTX ϕ , which can transfer them to apathogenic strains of *V. cholerae* and so lead to the formation of novel virulent strains capable of causing cholera.

d'Herelle suggested that the specific lysis of bacteria by phages could be exploited in the development of therapeutic treatments for bacterial infections. The intervening 80 years have seen the discovery and widespread use of antibiotics for treating bacterial infection. Although very effective, there are an increasing number of multiply drug-resistant bacteria, e.g. *Mycobacterium tuberculosis* (TB) and *Staphylococcus aureus* (septicaemia) as a direct consequence of the widespread use of antibiotics, and there has been a resurgence in the interest in the use of phages for treating bacterial infection.

capable of digesting pollutants (naphthalene and anthracene, two carcinogenic fractions of oil difficult to break down, and PCBs, also carcinogenic).

Bacteria cannot normally survive temperatures above 100°C/212°F, such as those produced in pasteurization, but those in deep-sea hot vents in the eastern Pacific are believed to withstand temperatures of 350°C/662°F. *Thermus aquaticus*, or taq, grows freely in the boiling waters of hot springs, and an enzyme derived from it is used in genetic engineering to speed up the production of millions of copies of any DNA sequence, a reaction requiring very high temperatures.

interaction Certain bacteria can influence the growth of others; for example, lactic acid bacteria will make conditions unfavourable for salmonella bacteria. Other strains produce nisin, which inhibits growth of listeria and botulism organisms. Plans in the food industry are underway to produce super strains of lactic acid bacteria to avoid food poisoning.

An estimated 99% of bacteria live in biofilms rather than in single-species colonies. These are complex colonies made up of a number of different species of bacteria structured on a layer of slime produced by the bacteria. Fungi, algae, and protozoa may also inhabit the biofilms.

prehistoric bacteria Bacterial spores 40 million years old were extracted from a fossilized bee and successfully germinated by US scientists in 1995. It is hoped that prehistoric bacteria can be tapped as a source of new chemicals for use in the drugs industry. Any bacteria resembling extant harmful pathogens will be destroyed, and all efforts are being made to ensure no bacteria escape the laboratory.

bacteriology the study of ϕ bacteria.

bacteriophage virus that attacks ϕ bacteria. Such viruses are now of use in genetic engineering.

Bactrian species of camel *Camelus bactrianus* found in the Gobi Desert in Central Asia. Body fat is stored in two humps on the back. It has very long winter fur which is shed in ragged lumps. The head and body length is about 3 m/10 ft, and the camel is up to 2.1 m/6.8 ft tall at the shoulder. Most Bactrian camels are domesticated and are used as beasts of burden in W Asia.

badger large mammal of the weasel family with molar teeth of a crushing type adapted to a partly vegetable diet, and short strong legs with long claws suitable for digging. The Eurasian common badger *Meles meles* is about 1 m/3 ft long, with long, coarse, greyish hair on the back, and a white face with a broad black stripe along each side. Mainly a woodland animal, it is harmless and nocturnal, and spends the day in a system of burrows called a 'sett'. It feeds on roots, a variety of fruits and nuts, insects, worms, mice, and young rabbits.

The Eurasian badger lives for up to 15 years. It mates February to March, and again July to September if the earlier mating has not resulted in fertilization. Implantation of the ϕ blastocyst (early embryo) is however delayed until December. Cubs are born January to March, and remain below ground for eight weeks. They remain with the sow at least until autumn.

The American badger *Taxidea taxus* is slightly smaller than the Eurasian badger, and lives in open country in North America. Various species of hog badger, ferret badger, and stink badger occur in S and E Asia, the last having the well-developed anal scent glands characteristic of the weasel family.

badlands barren landscape cut by erosion into a maze of ravines, pinnacles, gullies and sharp-edged ridges. Areas in South Dakota and Nebraska, USA, are examples.

Baikunur launch site for spacecraft, located at Tyuratam, Kazakhstan, near the Aral Sea: the first satellites and all Soviet space probes and crewed Soyuz missions were launched from here. It covers an area of 12,200 sq km/4,675 sq mi, much larger than its US equivalent, the ϕ Kennedy Space Center in Florida.

Bailey bridge prefabricated bridge developed by the British Army in World War II; made from a set of standardized components so that bridges of varying lengths and load-carrying ability could be assembled to order.

Baird, John Logie (1888–1946)

Scottish electrical engineer who pioneered television. In 1925 he gave the first public demonstration of television, transmitting an image of a recognizable human face. The following year, he gave the world's first demonstration of true television before an audience of about 50 scientists at the Royal Institution, London. By 1928 Baird had succeeded in demonstrating colour television.

Baird used a mechanical scanner which temporarily changed an image into a sequence of electronic signals that could then be reconstructed on a screen as a pattern of half-tones. The neon discharge lamp Baird used offered a simple means for the electrical modulation of light at the receiver. His first pictures were formed of only 30 lines repeated approximately 10 times a second. The results were crude but it was the start of television as a practical technology.

By 1927, Baird had transmitted television over 700 km/435 mi of telephone line between London and Glasgow and soon after made the first television broadcast using radio, between London and the SS Berengaria, halfway across the Atlantic Ocean. He also made the first transatlantic television broadcast between Britain and the United States when signals transmitted from the

Baird station in Coulson, Kent, were picked up by a receiver in Hartsdale, New York.

Baird's black-and-white system was used by the BBC in an experimental television service in 1929. In 1936, when the public television service was started, his system was threatened by one promoted by Marconi-EMI. The following year the Baird system was dropped in favour of the Marconi electronic system, which gave a better definition.

Mary Evans Picture Library

They were used in every theatre of the war and many remained in place for several years after the war until the civil authorities could replace them with more permanent structures.

Baily's beads bright spots of sunlight seen around the edge of the Moon for a few seconds immediately before and after a total eclipse of the Sun, caused by sunlight shining between mountains at the Moon's edge. Sometimes one bead is much brighter than the others, producing the so-called diamond ring effect. The effect was described in 1836 by the English astronomer Francis Baily (1774–1844), a wealthy stockbroker who retired in 1825 to devote himself to astronomy.

Bakelite first synthetic ϕ lastic, created by Leo Baekeland in 1909. Bakelite is hard, tough, and heatproof, and is used as an

BADLANDS NATIONAL PARK

<http://www.nps.gov/badl/htmlfiles/expanded.htm>

Impressive US National Park Service guide to the Badlands National Park. There is comprehensive information on the geology, flora and fauna, and history of the Badlands. Hikers are provided with detailed guidance on routes and there is a listing of the park's educational activities.

electrical insulator. It is made by the reaction of phenol with formaldehyde, producing a powdery resin that sets solid when heated. Objects are made by subjecting the resin to compression moulding (simultaneous heat and pressure in a mould).

It is one of the thermosetting plastics, which do not remelt when heated, and is often used for electrical fittings.

baking powder mixture of bicarbonate of soda, an acidic compound, and a nonreactive filler (usually starch or calcium sulphate), used in baking as a raising agent. It gives a light open texture to cakes and scones, and is used as a substitute for yeast in making soda bread.

Several different acidic compounds (for example, tartaric acid, cream of tartar, sodium or calcium acid phosphates, and gluconolactone) may be used, any of which will react with the sodium hydrogen carbonate, in the presence of water and heat, to release the carbon dioxide that causes the cake mix or dough to rise.

balance apparatus for weighing or measuring mass. The various types include the **beam balance**, consisting of a centrally pivoted lever with pans hanging from each end, and the **spring balance**, in which the object to be weighed stretches (or compresses) a vertical coil spring fitted with a pointer that indicates the weight on a scale. Kitchen and bathroom scales are balances.

balanced diet diet that includes carbohydrate, protein, fat, vitamins, water, minerals, and fibre (roughage). Although all these substances are needed if a person is to be healthy, there is disagreement over how much of each type a person needs.

balance of nature in ecology, the idea that there is an inherent equilibrium in most ecosystems, with plants and animals interacting so as to produce a stable, continuing system of life on Earth. The activities of human beings can, and frequently do, disrupt the balance of nature.

Organisms in the ecosystem are adapted to each other – for example, waste products produced by one species are used by another and resources used by some are replenished by others; the oxygen needed by animals is produced by plants while the waste product of animal respiration, carbon dioxide, is used by plants as a raw material in photosynthesis. The nitrogen cycle, the water cycle, and the control of animal populations by natural predators are other examples.

BALDNESS

The best way for a man to know whether he will go bald is to look at his mother's father. Baldness is hereditary, but the gene controlling it is on the sex-linked chromosome and skips one generation.

baldness loss of hair from the scalp, common in older men. Its onset and extent are influenced by genetic make-up and the level of male sex hormones. There is no cure, and expedients such as hair implants may have no lasting effect. Hair loss in both sexes may also occur as a result of ill health or radiation treatment, such as for cancer. Alopecia, a condition in which the hair falls out, is different from the 'male-pattern baldness' described above.

Experience is a comb which nature gives to men when they are bald.

ANONYMOUS Eastern proverb

Balistidae family of fish containing the triggerfish.

ball-and-socket joint joint allowing considerable movement in three dimensions, for instance the joint between the pelvis and the femur. To facilitate movement, such joints are rimmed with cartilage and lubricated by synovial fluid. The bones are kept in place by ligaments and moved by muscles.

ballistics study of the motion and impact of projectiles such as bullets, bombs, and missiles. For projectiles from a gun, relevant exterior factors include temperature, barometric pressure, and wind strength; and for nuclear missiles these extend to such factors as the speed at which the Earth turns.

balloon lighter-than-air craft that consists of a gasbag filled with gas lighter than the surrounding air and an attached basket, or gondola, for carrying passengers and/or instruments. In 1783, the first successful human ascent was in Paris, in a hot-air balloon designed by the Montgolfier brothers Joseph Michel and Jacques Etienne. In 1785, a hydrogen-filled balloon designed by French physicist Jacques Charles travelled across the English Channel.

balloon help small cartoon-style bubble which pops up in a graphical computer system to convey online help. In many new products, balloon help is activated by holding the mouse over an icon or other type of control for a few seconds. Such help is context-sensitive.

ball valve valve that works by the action of external pressure raising a ball and thereby opening a hole.

balm, lemon garden herb, see *lemon balm*.

balsam any of various garden plants belonging to the balsam family. They are usually annuals with spurred red or white flowers and pods that burst and scatter their seeds when ripe. (Genus *Impatiens*, family Balsaminaceae.)

In medicine and perfumery, balsam refers to various oily or gummy aromatic plant resins, such as balsam of Peru from the Central American tree *Myroxylon pereirae*.

bamboo any of a large group of giant grass plants, found mainly in tropical and subtropical regions. Some species grow as tall as 36 m/

bamboo The tall, closely packed stems of many bamboos, such as this example from the tropical rainforest of Brazil, frequently form dense clumps in the forest understorey. Bamboo grows rapidly and has a wide variety of uses. Premaphotos Wildlife

120 ft. The stems are hollow and jointed and can be used in furniture, house, and boat construction. The young shoots are edible; paper is made from the stems. (Genus *Bambusa*, family Gramineae.)

Bamboos flower and seed only once before the plant dies, sometimes after growing for as long as 120 years.

banana any of several tree-like tropical plants which grow up to 8 m/25 ft high. The edible banana is the fruit of a sterile hybrid form. (Genus *Musa*, family Musaceae.)

The curved yellow fruits of the commercial banana, arranged in clusters known as 'hands', form cylindrical masses of a hundred or more fruits.

They are picked and exported green and ripened aboard refrigerated ships. The plant is destroyed after cropping. The plantain, a larger, coarser hybrid variety that is used green as a cooked vegetable, is a dietary staple in many countries. In the wild, bananas depend on bats for pollination.

banded brush beetle type of rose chafer.

classification The banded brush beetle *Trichius fasciatus*, in the subfamily Trichinae, family Scarabaeidae, order Coleoptera, class Insecta, phylum Arthropoda.

bandfish marine bony fish. It is elongated with very long dorsal fins that run the length of its body. Bandfish spend most of their time on the sea bed, occasionally swimming to midwater to feed on small planktonic crustacea.

bandicoot small marsupial mammal inhabiting Australia and New Guinea. There are about 11 species, family Peramelidae, rat- or rabbit-sized, and living in burrows. They have long snouts, eat insects, and are nocturnal. A related group, the rabbit bandicoots or bilbies, is reduced to a single species that is now endangered and protected by law.

bandwidth in computing and communications, the rate of data transmission, measured in bits per second (bps).

bandy-bandy venomous Australian snake *Vermicella annulata* of the cobra family, which grows to about 75 cm/2.5 ft. It is banded in black and white. It is not aggressive toward humans.

bang in UNIX, an exclamation mark (!). It appears in some older types of Internet addresses and is used in dictating the commands necessary to run UNIX systems.

bang path list of routing that appears in the header of a message sent across the Internet, showing how it travelled from the sender to its destination. It is named after the ϕ bangs separating the sites in the list.

banksia any shrub or tree of a group native to Australia, including the honeysuckle tree. They are named after the British naturalist and explorer Joseph Banks. (Genus *Banksia*, family Proteaceae.)

Banksias have spiny evergreen leaves and large flower spikes, made up of about 1,000 individual flowers formed around a central axis. The colours of the flower spikes can be gold, red, brown, purple, greenish-yellow, and grey.

banner in computing, advertisement on a World Wide Web page, usually but not always in the form of a horizontal rectangle. Clicking on a banner usually takes the user to the advertised Web site. Noncommercial sites display one another's banners via organizations like LinkExchange and BannerExchange.

bantam small ornamental variety of domestic chicken weighing about 0.5–1 kg/1–2 lb. Bantams can either be a small version of one of the larger breeds, or a separate type. Some are prolific egg layers. Bantam cocks have a reputation as spirited fighters.

banteng wild species of cattle *Bos banteng*, now scarce, but formerly ranging from Myanmar (Burma) through SE Asia to Malaysia and Java, inhabiting hilly forests. Its colour varies from pale brown to blue-black, usually with white stockings and rump patch, and it is up to 1.5 m/5 ft at the shoulder.

banyan tropical Asian fig tree. It produces aerial roots that grow down from its spreading branches, forming supporting pillars that look like separate trunks. (*Ficus benghalensis*, family Moraceae.)

baobab tree with rootlike branches, hence the nickname 'upside-down tree', and a disproportionately thick girth, up to 9 m/30 ft in diameter. The pulp of its fruit is edible and is known as monkey bread. (Genus *Adansonia*, family Bombacaceae.)

bar unit of pressure equal to 10^5 pascals or 10^6 dynes/cm², approximately 750 mmHg or 0.987 atm. Its diminutive, the millibar (one-thousandth of a bar), is commonly used by meteorologists.

barb general name for fish of the genus *Barbus* and some related genera of the family Cyprinidae. As well as the barbel, barbs include many small tropical Old World species, some of which are familiar aquarium species. They are active egg-laying species, usually of 'typical' fish shape and with barbels at the corner of the mouth.

Barbary ape tailless, yellowish-brown macaque monkey *Macaca sylvanus*, 55–75 cm/20–30 in long. Barbary apes are found in the mountains and wilds of Algeria and Morocco, especially in the forests of the Atlas Mountains. They were introduced to Gibraltar, where legend has it that the British will leave if the ape colony dies out.

The macaque is threatened by illegal logging, which is devastating some of the ancient forests in the area. Although it is breeding well in captivity, forest loss may confound attempts to reintroduce this species into the wild.

Barbary sheep or *oudad* or *udad* species of bovid related to the goat and sheep. It has powerful horns and a goatlike odour, but is distinguished from goats by its longer tail and the mane of long hair on the throat and upper parts of the forelegs. It is found in North Africa and parts of the Sudan. **classification** The Barbary sheep *Ammotragus lervia* is in family Bovidae, order Artiodactyla

barbastelle insect-eating bat *Barbastella barbastellus* with hairy cheeks and lips, 'frosted'

banyan This banyan tree in the Ranthambore National Park in N India is reputed to be the second largest specimen in the country. Its shade provides a midday resting place for many people and animals. As a result, banyans are planted along roadsides over much of India. Premaphotos Wildlife

black fur, and a wingspan of about 25 cm/10 in. It lives in hollow trees and under roofs, and is occasionally found in the UK but more commonly in Europe.

barbed wire cheap fencing material made of strands of galvanized wire (see *galvanizing*), twisted together with sharp barbs at close intervals. In 1873 an American, Joseph Glidden, devised a machine to mass-produce barbed wire. Its use on the open grasslands of 19th-century America led to range warfare between farmers and cattle ranchers; the latter used to drive their herds cross-country.

barbel freshwater fish *Barbus barbus* found in fast-flowing rivers with sand or gravel bottoms in Britain and Europe. Long-bodied, and up to 1 m/3 ft long in total, the barbel has four barbels ('little beards' - sensory fleshy filaments) near the mouth.

barberry any spiny shrub belonging to the barberry family, with sour red berries and yellow flowers. These shrubs are often used as hedges. (Genus *Berberis*, family Berberidaceae.)

barbet Latin *barbatus*, 'bearded' small, tropical bird, often brightly coloured. There are about 78 species of barbet in the family Capitonidae, order Piciformes, common to tropical Africa, Asia, and America. Barbets eat insects and fruit and, being distant relations of woodpeckers, drill nest holes with their beaks. The name comes from the 'little beard' of bristles about the mouth that assists them in catching insects.

barbiturate hypnosedative drug, commonly known as a 'sleeping pill', consisting of any salt or ester of barbituric acid $C_4H_4O_2N_2$. It works by depressing brain activity. Most barbiturates, being highly addictive, are no longer prescribed and are listed as controlled substances.

Tolerance develops quickly in the user so that increasingly large doses are required to induce sleep. A barbiturate's action persists for hours or days, causing confused, aggressive behaviour or disorientation. Overdosage causes death by inhibiting the breathing centre in the brain. Short-acting barbiturates are used as anaesthetics to induce general anaesthesia; slow-acting ones may be prescribed for epilepsy.

bar chart in statistics, a way of displaying data, using horizontal or vertical bars. The heights or lengths of the bars are proportional to the quantities they represent.

bar code pattern of bars and spaces that can be read by a computer. Bar codes are widely used in retailing, industrial distribution, and public libraries. The code is read by a scanning device; the computer determines the code from the widths of the bars and spaces.

bar code The bars of varying thicknesses and spacings represent two series of numbers, identifying the manufacturer and the product. Two longer, thinner bars mark the beginning and end of the manufacturer and product codes. The bar code is used on most articles for sale in shops.

The technique was patented in 1949 but became popular only in 1973, when the food industry in North America adopted the Universal Product Code system.

barium Greek *barytes* 'heavy' soft, silver-white, metallic element, symbol Ba, atomic number 56, relative atomic mass 137.33. It is one of the alkaline-earth metals, found in nature as barium carbonate and barium sulphate. As the sulphate it is used in medicine: taken as a suspension (a 'barium meal'), its movement along the gut is followed using X-rays. The barium sulphate, which is opaque to X-rays, shows the shape of the gut, revealing any abnormalities of the alimentary canal. Barium is also used in alloys, pigments, and safety matches and, with strontium, forms the emissive surface in cathode-ray tubes. It was first discovered in barytes or heavy spar.

bark protective outer layer on the stems and roots of woody plants, composed mainly of dead cells. To allow for expansion of the stem, the bark is continually added to from within, and the outer surface often becomes cracked or is shed as scales. Trees deposit a variety of chemicals in their bark, including poisons. Many of these chemical substances have economic value because they can be used in the manufacture of drugs. Quinine, derived from the bark of the *Cinchona* tree, is used to fight malarial infections; curare, an anaesthetic used in medicine, comes from the *Strychnos toxifera* tree in the Amazonian rainforest.

Bark technically includes all the tissues external to the vascular cambium (the phloem, cortex, and periderm), and its thickness may vary from 2.5 mm/0.1 in to 30 cm/12 in or more, as in the giant redwood *Sequoia* where it forms a thick, spongy layer.

bark beetle any one of a number of species of mainly wood-boring beetles. Bark beetles are cylindrical, brown or black, and 1-9 mm/0.04-0.4 in long. Some live just under the bark and others bore deeper into the hardwood. The detailed tunnelling pattern that they make within the trunk varies with the species concerned, and is used for identification.

Most bark beetles live in forest trees; some, however, attack fruit trees. Generally, but not always, dead or dying timber is attacked. Some species transmit pathogens, for example, the fungus that causes Dutch elm disease.

Examples include the birch bark beetle *Scolytus ratzeburgi* and the greater fruit-tree bark beetle *S. mali*.

classification Bark beetles are in the families Curculionidae or Scolytidae, order Coleoptera, class Insecta, phylum Arthropoda.

barking deer another name for the chamois.

barley cereal belonging to a family of grasses. It resembles wheat but is more tolerant of cold and draughts. Cultivated barley (*Hordeum vulgare*) comes in three main varieties - six-rowed, four-rowed, and two-rowed. (Family Gramineae.)

Barley was one of the earliest cereals to be cultivated, about 5000 BC in Egypt, and no other cereal can thrive in so wide a range of climatic conditions; polar barley is sown and reaped well within the Arctic Circle in Europe. Barley is no longer much used in bread making, but it is used in soups and stews and as a starch. Its high-protein form is widely used as animal feed, and its low-protein form is used in brewing and distilling alcoholic drinks.

barley midge another name for the chironomid fly.

barn farm building traditionally used for the storage and processing of cereal crops and hay. On older farmsteads, the barn is usually the largest building. It is often characterized by ventilation openings rather than windows and has at least one set of big double doors for access. Before mechanization, wheat was threshed by hand on a specially prepared floor inside these doors.

barnacle marine crustacean of the subclass Cirripedia. The larval form is free-swimming, but when mature, it fixes itself by the head to rock or floating wood. The animal then remains attached, enclosed in a shell through which the cirri (modified legs) protrude to sweep food into the mouth. Barnacles include the stalked goose barnacle *Lepas anatifera* found on ships' bottoms, and the acorn barnacles, such as *Balanus balanoides*, common on rocks.

barnacle Acorn barnacles, such as *Chthamalus stellatus*, are a familiar sight on rocky seashores between the tidemarks, where they are the most abundant life form. Identification of the various species is based on the arrangement of the calcareous plates and requires the use of a powerful hand lens or microscope. Premaphotos Wildlife

Barnard's star second-closest star to the Sun, six light years away in the constellation Ophiuchus. It is a faint red dwarf of 10th magnitude, visible only through a telescope. It is named after the US astronomer Edward E Barnard (1857-1923), who discovered in 1916 that it has the fastest proper motion of any star, crossing 1 degree of sky every 350 years.

Some observations suggest that Barnard's star may be accompanied by planets.

BARNACLE

The parasitic barnacle *Loxothylacus panopaei* uses a crab as its host. The barnacle larva attaches itself to a crab and injects it with a squirming worm-shaped bag of cells. One of these cells develops into the adult barnacle that spends its life as a lump on the crab's carapace.

Barnard, Christiaan Neethling (1922-)

South African surgeon who performed the first human heart transplant 1967 at Groote Schuur Hospital in Cape Town. The 54-year-old patient lived for 18 days.

Barnard also discovered that intestinal atresia – a congenital deformity in the form of a hole in the small intestine – is the result of an insufficient supply of blood to the fetus during pregnancy. It was a fatal defect before he developed the corrective surgery.

barograph device for recording variations in atmospheric pressure. A pen, governed by the movements of an aneroid barometer, makes a continuous line on a paper strip on a cylinder that rotates over a day or week to create a **barogram**, or permanent record of variations in atmospheric pressure.

barometer instrument that measures atmospheric pressure as an indication of weather. Most often used are the **mercury barometer** and the **aneroid barometer**.

barometer (left) The mercury barometer and (right) the aneroid barometer. In the mercury barometer, the weight of the column of mercury is balanced by the pressure of the atmosphere on the lower end. A change in height of the column indicates a change in atmospheric pressure. In the aneroid barometer, any change of atmospheric pressure causes the metal box which contains the vacuum to be squeezed or to expand slightly. The movements of the box sides are transferred to a pointer and scale via a chain of levers.

In a mercury barometer a column of mercury in a glass tube, roughly 0.75 m/2.5 ft high (closed at one end, curved upwards at the other), is balanced by the pressure of the atmosphere on the open end; any change in the height of the column reflects a change in pressure. In an aneroid barometer, a shallow cylindrical metal box containing a partial vacuum expands or contracts in response to changes in pressure.

baroreceptor in biology, a specialized nerve ending that is sensitive to pressure. There are baroreceptors in various regions of the heart and circulatory system (carotid sinus, aortic arch, atria, pulmonary veins, and left ventricle). Increased pressure in these structures stimulates the baroreceptors, which relay information to the medulla providing an important mechanism in the control of blood pressure.

barracuda large predatory fish *Sphyrna barracuda* found in the warmer seas of the world. It can grow over 2 m/6 ft long and has a superficial resemblance to a pike. Young fish shoal, but the older ones are solitary. The barracuda has very sharp shearing teeth and may attack people.

BARRACUDA

Barracudas are mysteriously attracted to all things yellow. This means that they may be caught by the use of yellow-feathered lines.

barrel cylindrical container, tapering at each end, made of thick strips of wood bound together by metal hoops. Barrels are used for the bulk storage of fine wines and spirits.

Barrels were made by craftsmen known as coopers, whose main skill was the shaping and bending of the wooden staves (staves) so that they fitted together without gaps when secured by the hoops. Barrels were widely used for storing liquids and dry goods until the development of plastic containers.

barrel unit of liquid capacity, the value of which depends on the liquid being measured. It is used for petroleum, a barrel of which contains 159 litres/35 imperial gallons; a barrel of alcohol contains 189 litres/41.5 imperial gallons.

barrier island long island of sand, lying offshore and parallel to the coast.

Some are over 100 km/60 mi in length. Most barrier islands are derived from marine sands piled up by shallow longshore currents that sweep sand parallel to the seashore. Others are derived from former spits, connected to land and built up by drifted sand, that were later severed from the mainland.

Often several islands lie in a continuous row offshore. Coney Island and Jones Beach near New York City are well-known examples, as is Padre Island, Texas. The Frisian Islands are barrier islands along the coast of the Netherlands.

barrier reef coral reef that lies offshore, separated from the mainland by a shallow lagoon.

Barringer Crater or *Arizona Meteor Crater* or *Coon Butte* impact crater near Winslow in Arizona caused by the impact of a 50 m/165 ft iron meteorite some 25,000 years ago. It is 1.2 km/0.7 mi in diameter, 200 m/660 ft deep and the walls are raised 50–60 m/165–198 ft above the surrounding desert.

It is named after the US mining engineer Daniel Barringer who proposed in 1902 that it was an impact crater rather than a volcanic feature, an idea confirmed in the 1960s by US geologist Eugene Shoemaker.

barrow *Old English beorh 'hill or mound'* burial mound, usually composed of earth but sometimes of stones. Examples are found in many parts of the world. The two main types are *long*, dating from the Neolithic (New Stone Age), and *round*, dating from the early Bronze Age. Barrows made entirely of stones are known as cairns.

long barrow Long barrows may be mere mounds, typically higher and wider at one end. They usually contain a chamber of wood or stone slabs, or a turf-lined cavity, in which the body or bodies of the deceased were placed. Secondary chambers may be added in the sides of the mound. They are common in South England from Sussex to Dorset. Earthen (or unchambered) long barrows belong to the early and middle Neolithic, whereas others were constructed over megalithic (great stone) tombs which generally served as collective burial chambers. The stones are arranged to form one, often large, chamber with a single entrance, and are buried under a mound of earth. The remains of these stone chambers, once their earth covering has disappeared, are known as *dolmens*, and in Wales as *cromlechs*.

round barrow Round barrows belong mainly to the Bronze Age, although in historic times there are examples from the Roman period, and some of the Saxon and most of the Danish invaders were barrow-builders. In northern Europe, round barrows were sometimes built above a tree-trunk coffin in which waterlogged conditions have preserved non-skeletal material, such as those found in Denmark dating from around 1000 BC.

In Britain the most common type is the bell barrow, consisting of a circular mound enclosed by a ditch and an outside bank of earth. Other types include the bowl barrow, pond barrow, saucer barrow, ring barrow, and disc barrow, all of which are associated with the Wessex culture (early Bronze Age culture of S England dating from approximately 2000–1500 BC).

Barrows from the Roman era have a distinctive steep and conical outline, and in SE Britain usually cover the graves of wealthy merchant traders. They are also found in Belgic Gaul, where the traders had commercial links. Not all burials in the Roman era were in barrows; cemeteries were also used.

In eastern European and Asiatic areas where mobility was afforded by the horse and wagon, a new culture developed of pit graves marked by a *kurgan*, or round mound, in which a single body lay, often accompanied by grave goods which might include a wagon. These date from around 3000 BC.

boat burial The placing of a great person's body in a ship is seen in Viking burials, such as the Oseberg ship in Norway, which was buried and sealed around AD 800. Barrows were erected over boat burials during the Saxon period, and the Sutton Hoo boat burial excavated in Suffolk, England during 1938–39 was that of an East Anglian king of Saxon times.

baryon in nuclear physics, a heavy subatomic particle made up of three indivisible elementary particles called quarks. The baryons form a subclass of the hadrons and comprise the nucleons (protons and neutrons) and hyperons.

basal metabolic rate (BMR) minimum amount of energy needed by the body to maintain life. It is measured when the subject is awake but resting, and includes the energy required to keep the heart beating, sustain breathing, repair tissues, and keep the brain and nerves functioning. Measuring the subject's consumption of oxygen gives an accurate value for BMR, because oxygen is needed to release energy from food.

A cruder measure of BMR estimates the amount of heat given off, some heat being released when food is used up. BMR varies from one species to another, and from males to females. In humans, it is highest in children and declines with age. Disease, including mental illness, can make it rise or fall. Hormones from the thyroid gland control the BMR.

basalt commonest volcanic igneous rock in the solar system. Much of the surfaces of the terrestrial planets Mercury, Venus, Earth, and Mars, as well as the Moon, are composed of basalt. Earth's ocean floor is virtually entirely made of basalt. Basalt is mafic, that is, it contains relatively little silica: about 50% by weight. It is usually dark grey but can also be green, brown, or black. Its essential constituent minerals are calcium-rich feldspar and calcium and magnesium-rich pyroxene.

The groundmass may be glassy or finely crystalline, sometimes with large crystals embedded. Basaltic lava tends to be runny and flows for great distances before solidifying. Successive eruptions of basalt have formed the great plateaus of Colorado and the Deccan plateau region of southwest India. In some places, such as Fingal's

Cave in the Inner Hebrides of Scotland and the Giant's Causeway in Antrim, Northern Ireland, shrinkage during the solidification of the molten lava caused the formation of hexagonal columns.

The dark-coloured lowland maria regions (see ☾mare) of the Moon are underlain by basalt. Lunar mare basalts have higher concentrations of titanium and zirconium and lower concentrations of volatile elements like potassium and sodium relative to terrestrial basalts. Martian basalts are characterized by low ratios of iron to manganese relative to terrestrial basalts, as judged from some martian meteorites (shergottites, a class of the SNC meteorites) and spacecraft analyses of rocks and soils on the Martian surface.

bascul bridge type of drawbridge in which one or two counter-weighted deck members pivot upwards to allow shipping to pass underneath. One example is the double bascule Tower Bridge, London.

base in chemistry, a substance that accepts protons, such as the hydroxide ion (OH^-) and ammonia (NH_3). Bases react with acids to give a salt. Those that dissolve in water are called alkalis.

Inorganic bases are usually oxides or hydroxides of metals, which react with dilute acids to form a salt and water. A number of carbonates also react with dilute acids, additionally giving off carbon dioxide. Many organic compounds that contain nitrogen are bases.

base in mathematics, the number of different single-digit symbols used in a particular number system. In our usual (decimal) counting system of numbers (with symbols 0, 1, 2, 3, 4, 5, 6, 7, 8, 9) the base is 10. In the binary number system, which has only the symbols 1 and 0, the base is two. A base is also a number that, when raised to a particular power (that is, when multiplied by itself a particular number of times as in $10^2 = 10 \times 10 = 100$), has a logarithm equal to the power. For example, the logarithm of 100 to the base ten is 2.

In geometry, the term is used to denote the line or area on which a polygon or solid stands.

Science is an essentially anarchistic enterprise: theoretical anarchism is more humanitarian and more likely to encourage progress than its law-and-order alternatives.

PAUL K FEYERABEND Austrian-born US philosopher of science.
Against Method 1975

base Four different numerical systems showing the numbers 1–16, with some examples of greater numbers. In the hexadecimal (base 16) system, all numbers up to 15 must be represented by a single character. To achieve this the decimal values 10–15 are represented by the letters A–F.

baseband in computing, type of ☾network that transmits a computer signal without modulation (conversion of ☾digital signals to ☾analogue). To be able to send a computer's signal over the analogue telephone network, a ☾modem is required to convert – or modulate – the signal. On baseband networks, which include the most popular standards such as ☾Ethernet, the signal can be sent directly, without such processing.

basenji breed of dog originating in Central Africa, where it is used for hunting. About 41 cm/16 in tall, it has pointed ears, curled tail, and short glossy coat of black or red, often with white markings. It is remarkable because it has no true bark.

base pair in biochemistry, the linkage of two base (purine or pyrimidine) molecules in ☾DNA. They are found in nucleotides, and form the basis of the genetic code.

One base lies on one strand of the DNA double helix, and one on the other, so that the base pairs link the two strands like the rungs of a ladder. In DNA, there are four bases: adenine and guanine (purines) and cytosine and thymine (pyrimidines). Adenine always pairs with thymine, and cytosine with guanine.

BASIC (acronym for *beginner's all-purpose symbolic instruction code*) high-level computer-programming language, developed 1964, originally designed to take advantage of ☾multiuser systems (which can be used by many people at the same time). The language is relatively easy to learn and is popular among microcomputer users.

Most versions make use of an ☾interpreter, which translates BASIC into ☾machine code and allows programs to be entered and run with no intermediate translation. Some more recent versions of BASIC allow a ☾compiler to be used for this process.

basicity number of replaceable hydrogen atoms in an acid. Nitric acid (HNO_3) is monobasic, sulphuric acid (H_2SO_4) is dibasic, and phosphoric acid (H_3PO_4) is tribasic.

basic-oxygen process most widely used method of steelmaking, involving the blasting of oxygen at supersonic speed into molten pig iron.

Pig iron from a blast furnace, together with steel scrap, is poured into a converter, and a jet of oxygen is then projected into the mixture. The excess carbon in the mix and other impurities

basic-oxygen process The basic-oxygen process is the primary method used to produce steel. Oxygen is blown at high pressure through molten pig iron and scrap steel in a converter lined with basic refractory materials. The impurities, principally carbon, quickly burn out, producing steel.

quickly burn out or form a slag, and the converter is emptied by tilting. It takes only about 45 minutes to refine 350 tonnes/400 tons of steel. The basic-oxygen process was developed 1948 at a steel-works near the Austrian towns of Linz and Donawitz. It is a version of the Bessemer process.

basidiocarp spore-bearing body, or 'fruiting body', of all basidiomycete fungi (see fungus), except the rusts and smuts. A well known example is the edible mushroom *Agaricus brunneus*. Other types include globular basidiocarps (puffballs) or flat ones that project from tree trunks (brackets). They are made up of a mass of tightly packed, intermeshed hyphae.

The tips of these hyphae develop into the reproductive cells, or basidia, that form a fertile layer known as the hymenium, or gills, of the basidiocarp. Four spores are budded off from the surface of each basidium.

basil or *sweet basil* plant with aromatic leaves, belonging to the mint family. A native of the tropics, it is cultivated in Europe as a herb and used to flavour food. Its small white flowers appear on spikes. (Genus *Ocimum basilicum*, family Labiatae.)

basilisk Central and South American lizard, genus *Basiliscus*. It is about 50 cm/20 in long and weighs about 90 g/0.2 lb. Its rapid speed (more than 2 m/6.6 ft per second) and the formation of air pockets around the feet enable it to run short distances across the surface of water. The male has a well-developed crest on the head, body, and tail.

basket-star any brittle-star of the order Phrynaphiurida, whose spiny arms branch repeatedly to form a coiled mass. Unlike other brittle-stars, which tend to be carnivorous, the hundred or so species of basket-star are suspension feeders, trapping large particles in their extended arms.

bass long-bodied scaly sea fish *Morone labrax* found in the N Atlantic and Mediterranean. They grow to 1 m/3 ft, and are often seen in shoals.

Other fish of the same family (Serranidae) are also called bass, as are North American freshwater fishes of the family Centrarchidae, such as black bass and small-mouthed bass.

basset any of several breeds of hound with a long low body and long pendulous ears, of a type originally bred in France for hunting hares by scent.

BAT CONSERVATION INTERNATIONAL

<http://www.batcon.org/>

Articles, photographs, and miscellaneous bat trivia, plus sound files of bat echolocation signals. As well as promoting membership of their bat society, this page contains plenty of bat-related information, including US and European species' lists and tips on photographing these elusive animals.

bat any mammal of the order Chiroptera, related to the Insectivora (hedgehogs and shrews), but differing from them in being able to fly. Bats are the only true flying mammals. Their forelimbs are developed as wings capable of rapid and sustained flight. There are two main groups of bats: **megabats**, which eat fruit, and **microbats**, which mainly eat insects. Although by no means blind, many microbats rely largely on echolocation for navigation and finding prey, sending out pulses of high-pitched sound and listening for the echo. Bats are nocturnal, and those native to temperate countries hibernate in winter. There are about 977 species forming the order Chiroptera, making this the second-largest mammalian order; bats make up nearly one-quarter of the world's mammals. Although bats are widely distributed, populations have declined alarmingly and many species are now endangered.

megabats The Megachiroptera live in the tropical regions of the Old World, Australia, and the Pacific, and feed on fruit, nectar, and pollen. The hind feet have five toes with sharp hooked claws which suspend the animal head downwards when resting. There are 162 species of Megachiroptera. Relatively large, weighing up to 900 g/2 lb and with a wingspan as great as 1.5 m/5 ft, they have large eyes and a long face, earning them the name 'flying fox'. Most orient by sight.

Many rainforest trees depend on bats for pollination and seed dispersal, and around 300 bat-dependent plant species yield more than 450 economically valuable products. Some bats are keystone species on whose survival whole ecosystems may depend. Bat-pollinated flowers tend to smell of garlic, rotting vegetation, or fungus.

microbats Most bats are Microchiroptera, mainly small and insect-eating. Some eat fish as well as insects; others consume small rodents, frogs, lizards, or birds; a few feed on the blood of mammals (vampire bats). There are about 750 species. They roost in caves, crevices, and hollow trees. A single bat may eat 3,000

bat The Gambian epauletted bat *Epomophorus gambianus* is a common species in W Africa. It often roosts quite low in trees during the day, undisturbed by the presence of people. Like many tropical bats, it feeds on fruit. A young bat is visible tucked under the wing of one of the females pictured. Premaphotos Wildlife

insects in one night. The bumblebee bat, inhabiting SE Asian rainforests, is the smallest mammal in the world.

Many microbats have poor sight and orientation and hunt their prey principally by echolocation. They have relatively large ears and many have nose-leaves, fleshy appendages around the nose and mouth, that probably help in sending or receiving the signals, which are squeaks pitched so high as to be inaudible to the human ear. **ancestors** The difference in the two bat groups is so marked that many biologists believe that they must have had different ancestors: microbats descending from insectivores and megabats descending from primates. Analysis of the proteins in blood serum from megabats and primates by German biologists in 1994 showed enough similarities to suggest a close taxonomic relationship between the two groups.

biology A bat's wings consist of a thin hairless skin expansion, stretched between the four fingers of the hand, from the last finger down to the hindlimb, and from the hindlimb to the tail. The thumb is free and has a sharp claw to help in climbing. The shoulder girdle and breastbone are large, the latter being keeled, and the pelvic girdle is small. The bones of the limbs are hollow, other bones are slight, and the ribs are flattened.

An adult female bat usually rears only one pup a year, which she carries with her during flight. In species that hibernate, mating may take place before hibernation, the female storing the sperm in the genital tract throughout the winter and using it to fertilize her egg on awakening in spring.

batch file file that runs a group (batch) of commands. The most commonly used batch file is the DOS start-up file AUTOEXEC.BAT.

batch processing in computing, a system for processing data with little or no operator intervention. Batches of data are prepared in advance to be processed during regular 'runs' (for example, each night). This allows efficient use of the computer and is well suited to applications of a repetitive nature, such as a company payroll.

In interactive computing, by contrast, data and instructions are entered while the processing program is running.

bat-eared fox small African fox *Otocorys megalotis*, with huge ears, sandy or greyish coat, black legs, and black-tipped bushy tail. They measure about 80 cm/31.5 in in length, including tail, and are 30 cm/12 in at the shoulder; weight 3.5 kg/6.5–11 lb. Bat-eared foxes feed on insects, particularly termites. There are East African and South African subspecies.

Litters of two to five cubs are born after a gestation period of 60 days. Both parents help to raise the young, sometimes aided by a cub from the previous year, but cub mortality is high as they are vulnerable to predators and disease. Cubs are fully grown at four months.

Bates eyesight training method developed by US ophthalmologist William Bates (1860–1931) to enable people to correct problems of vision without wearing glasses. The method is of proven effectiveness in relieving all refractive conditions, correcting squints, lazy eyes, and similar problems, but does not claim to treat eye disease.

bat fly wingless parasitic fly. Bat flies are tiny, bloodsucking, external parasites of bats and look rather spiderlike.

Penicillidia dufouri measures about 5 mm/0.2 in in length, is rust-brown in colour and parasitizes mouse-eared bats.

classification Bat flies are in the families Nycteribiidae and Streblidae, order Diptera, class Insecta, phylum Arthropoda.

batolith large, irregular, deep-seated mass of intrusive igneous rock, usually granite, with an exposed surface of more than 100 sq km/40 sq mi. The mass forms by the intrusion or upswelling of magma (molten rock) through the surrounding rock. Batoliths form the core of some large mountain ranges like the Sierra Nevada of western North America.

According to plate tectonic theory, magma rises in subduction zones along continental margins where one plate sinks beneath another. The solidified magma becomes the central axis of a rising mountain range, resulting in the deformation (folding and overthrusting) of rocks on either side. Gravity measurements indicate

Bates, H(enry) W(alter) (1825–1892)

English naturalist and explorer. He spent 11 years collecting animals and plants in South America and identified 8,000 new species of insects. He made a special study of camouflage in animals, and his observation of insect imitation of species that are unpleasant to predators is known as 'Batesian mimicry'.

Mary Evans Picture Library

that the downward extent or thickness of many batholiths is some 6–9 mi/10–15 km.

bathyal zone upper part of the ocean, which lies on the continental shelf at a depth of between 200 m/650 ft and 2,000 m/6,500 ft.

Bathyal zones (both temperate and tropical) have greater biodiversity than coral reefs, according to a 1995 study by the Natural History Museum in London. Maximum biodiversity occurs between 1,000 m/3,280 ft and 3,000 m/9,800 ft.

bathyscaph or **bathyscaphe** or **bathyscape** deep-sea diving apparatus used for exploration at great depths in the ocean. In 1960, Jacques Piccard and Don Walsh took the bathyscaph *Trieste* to a depth of 10,917 m/35,820 ft in the Challenger Deep in the Mariana Trench off the island of Guam in the Pacific Ocean.

battery any energy-storage device allowing release of electricity on demand. It is made up of one or more electrical cells. Primary-cell batteries are disposable; secondary-cell batteries, or accumulators, are rechargeable. Primary-cell batteries are an extremely uneconomical form of energy, since they produce only 2% of the power used in their manufacture. It is dangerous to try to recharge a primary-cell battery.

The common dry cell is a primary-cell battery based on the Leclanché cell and consists of a central carbon electrode immersed

battery The common dry cell relies on chemical changes occurring between the electrodes – the central carbon rod and the outer zinc casing – and the ammonium chloride electrolyte to produce electricity. The mixture of carbon and manganese is used to increase the life of the cell.

in a paste of manganese dioxide and ammonium chloride as the electrolyte. The zinc casing forms the other electrode.

The lead-acid car battery is a secondary-cell battery. The car's generator continually recharges the battery when the engine is running. It consists of sets of lead (positive) and lead peroxide (negative) plates in an electrolyte of sulphuric acid (battery acid). Hydrogen cells and sodium-sulphur batteries were developed in 1996 to allow cars to run entirely on battery power for up to 60 km/100 mi.

The introduction of rechargeable nickel-cadmium batteries has revolutionized portable electronic news gathering (sound recording, video) and information processing (computing). These batteries offer a stable, short-term source of power free of noise and other electrical hazards.

battery acid ϕ sulphuric acid of approximately 70% concentration used in lead-acid cells (as found in car batteries).

The chemical reaction within the battery that is responsible for generating electricity also causes a change in the acid's composition. This can be detected as a change in its specific gravity: in a fully charged battery the acid's specific gravity is 1.270–1.290; in a half-charged battery it is 1.190–1.210; in a flat battery it is 1.110–1.130.

baud in engineering, a unit of electrical signalling speed equal to one pulse per second, measuring the rate at which signals are sent between electronic devices such as telegraphs and computers; 300 baud is about 300 words a minute.

Bauds were used as a measure to identify the speed of ϕ modems until the early 1990s because at the lower modem speeds available then the baud rate generally equalled the rate of transmission measured in ϕ bps (bits per second). At higher speeds, this is not the case, and modem speeds now are generally quoted in bps.

Baudot code five-bit code developed in France by engineer Emil Baudot (1845–1903) in the 1870s. It is still in use for telex.

bauxite principal ore of ϕ aluminium, consisting of a mixture of hydrated aluminium oxides and hydroxides, generally contaminated with compounds of iron, which give it a red colour. It is formed by the chemical weathering of rocks in tropical climates. Chief producers of bauxite are Australia, Guinea, Jamaica, Russia, Kazakhstan, Surinam, and Brazil.

To extract aluminium from bauxite, high temperatures (about 800°C/1,470°F) are needed to make the ore molten. Strong electric currents are then passed through the molten ore. The process is only economical if cheap electricity is readily available, usually from a hydroelectric plant.

bay any of various species of ϕ laurel tree. The aromatic evergreen leaves are used for flavouring in cookery. There is also a golden-leaved variety. (Genus *Laurus*, family Lauraceae.)

Bayesian statistics form of statistics that uses the knowledge of prior probability together with the probability of actual data to determine posterior probabilities, using Bayes' theorem.

Bayes' theorem in statistics, a theorem relating the ϕ probability of particular events taking place to the probability that events conditional upon them have occurred.

For example, the probability of picking an ace at random out of a pack of cards is $\frac{4}{52}$. If two cards are picked out, the probability of the second card being an ace is conditional on the first card: if the first card is an ace the probability of drawing a second ace will be $\frac{3}{51}$; if not it will be $\frac{4}{51}$. Bayes' theorem gives the probability that given that the second card is an ace, the first card is also.

BCE abbreviation for before the Common Era, used with dates instead of BC.

B cell or *B lymphocyte* immune cell that produces antibodies. Each B cell produces just one type of antibody, specific to a single ϕ antigen. Lymphocytes are related to ϕ T cells.

BCG (abbreviation for *bacille Calmette-Guérin*), bacillus injected as a vaccine to confer active immunity to ϕ tuberculosis (TB).

BCG was developed by Albert Calmette and Camille Guérin in France in 1921 from live bovine TB bacilli. These bacteria were bred in the laboratory over many generations until they became attenuated (weakened). Each inoculation contains just enough live, attenuated bacilli to provoke an immune response: the formation of specific antibodies. The vaccine provides protection for 50–80% of infants vaccinated.

beach strip of land bordering the sea, normally consisting of boulders and pebbles on exposed coasts or sand on sheltered coasts. It is usually defined by the high- and low-water marks. A berm, a ridge of sand and pebbles, may be found at the farthest point that the water reaches.

The material of the beach consists of a rocky debris eroded from exposed rocks and headlands, or carried in by rivers. The material is transported to the beach, and along the beach, by waves that hit the coastline at an angle, resulting in a net movement of the material in one particular direction. This movement is known as longshore drift. Attempts are often made to halt longshore drift by erecting barriers (groynes), at right angles to the movement. Pebbles are worn into round shapes by being battered against one another by wave action and the result is called shingle. The finer material, the sand, may be subsequently moved about by the wind, forming sand dunes.

Apart from the natural process of longshore drift, a beach may be threatened by the commercial use of sand and aggregate, by the mineral industry – since particles of metal ore are often concentrated into workable deposits by the wave action – and by pollution (for example, by oil spilled or dumped at sea).

beagle short-haired hound with pendant ears, sickle tail, and a bell-like voice, bred for hunting hares on foot ('beagling').

beak horn-covered projecting jaws of a bird (see ϕ bill), or other horny jaws such as those of the octopus, platypus, or tortoise.

Beaker people prehistoric people thought to have been of Iberian origin, who spread out over Europe from the 3rd millennium BC. They were skilled in metalworking, and are identified by their use of distinctive earthenware drinking vessels with various designs.

A type of beaker with an inverted bell-shaped profile was widely distributed throughout Europe. These bell beakers are associated with the spread of alcohol consumption, probably mead. The Beaker people favoured individual inhumation (burial of the intact body), often in round ϕ barrows, with an associated set of small stone and metal artefacts, or secondary burials in some form of chamber tomb. A beaker typically accompanied male burials, possibly to hold a drink for the deceased on their final journey. The inclusion of flint, later metal, daggers in grave goods may signify a warrior, and suggests that the incursion of Bell Beaker culture may have come as an intrusion into traditional pre-existing cultures.

beam balance instrument for measuring mass (or weight). A simple form consists of a beam pivoted at its midpoint with a pan hanging at each end. The mass to be measured, in one pan, is compared with a variety of standard masses placed in the other. When the beam is balanced, the masses' turning effects or moments under gravity, and hence the masses themselves, are equal.

beam engine engine that works by providing an up and down motion to one end of a beam, which is translated into working machinery at the other end. Beam machines may be powered by a number of sources, including steam and water.

beam weapon weapon capable of destroying a target by means of a high-energy beam. Beam weapons similar to the 'death ray' of science fiction have been explored, most notably during Ronald Reagan's presidential term in the 1980s in the USA.

The high-energy laser (HEL) produces a beam of high accuracy that burns through the surface of its target. The charged particle beam uses either electrons or protons, which have been accelerated almost to the speed of light, to slice through its target.

bean seed of a large number of leguminous plants (see ϕ legume). Beans are rich in nitrogen compounds and proteins and are grown

both for human consumption and as food for cattle and horses. Varieties of bean are grown throughout Europe, the USA, South America, China, Japan, SE Asia, and Australia.

The broad bean (*Vicia faba*) has been cultivated in Europe since prehistoric times. The French bean, kidney bean, or haricot (*Phaseolus vulgaris*) is probably of South American origin; the runner bean (*P. coccineus*) is closely related to it, but differs in its climbing habit. Among beans of warmer countries are the lima or butter bean (*P. lunatus*) of South America; the soya bean (*Glycine max*), extensively used in China and Japan; and the winged bean (*Psophocarpus tetragonolobus*) of SE Asia. The tuberous root of the winged bean has potential as a main crop in tropical areas where protein deficiency is common. The Asian mung bean (*Phaseolus mungo*) yields the bean sprouts used in Chinese cookery. Canned haked beans are usually a variety of (*P. vulgaris*), which grows well in the USA.

BEAR DEN

<http://www.nature-net.com/bears/index.html>

Invaluable resource for information on all types of bears. As well as general information on the evolution and history of bears in general, there are more specific details on each of the eight species of bear, including habitat, reproduction, food, and much more. The site also has photographs and sound effects.

bear large mammal with a heavily built body, short powerful limbs, and a very short tail. Bears breed once a year, producing one to four cubs. In northern regions they hibernate, and the young are born in the winter den. They are found mainly in North America and N Asia. The skin of the polar bear is black to conserve 80–90% of the solar energy trapped and channelled down the hollow hairs of its fur.

Bears walk on the soles of the feet and have long, nonretractable claws. The bear family, Ursidae, is related to carnivores such as dogs and weasels, and all are capable of killing prey. (The panda is probably related to both bears and raccoons.)

species There are seven species of bear. The brown bear *Ursus arctos* formerly ranged across most of Europe, N Asia, and North America, but is now reduced in number. It varies in size from under 2 m/7 ft long in parts of the Old World to 2.8 m/9 ft long and 780 kg/1,700 lb in Alaska. The **grizzly bear** is a North American variety of this species, and another subspecies, the **Kodiak bear** of

Alaska, is the largest living land carnivore. The white polar bear *Thalarchos maritimus* is up to 2.5 m/8 ft long, has furry undersides to the feet, and feeds mainly on seals. It is found in the north polar region. The North American black bear *Euarctos americanus* and the Asian black bear *Selenarctos thibetanus* are smaller, only about 1.6 m/5 ft long. The latter has a white V-mark on its chest. The spectacled bear *Tremarctos ornatus* of the Andes is similarly sized, as is the sloth bear *Melursus ursinus* of India and Sri Lanka, which has a shaggy coat and uses its claws and protrusile lips to obtain termites, one of its preferred foods. The smallest bear is the Malaysian sun bear *Helarctos malayanus*, rarely more than 1.2 m/4 ft long, a good climber, whose favourite food is honey.

threat of extinction Of the seven species of bear, five are currently reckoned to be endangered and all apart from the polar bear and the American black bear are in decline. The population of brown bears in the Pyrenees was estimated at eight in 1994, and it is feared they will be extinct in 20 years unless new bears are introduced. In May 1996 two female Slovenian brown bears were released into the central Pyrenees; the Slovenian brown bear is closest genetically to the Pyrenean one.

In 1992, American black bears were upgraded to Appendix 2 of CITES (Convention on International Trade in Endangered Species) to stem the trade in their gall bladders, which are used in Asian traditional medicine to treat liver disease. The gall bladders contain an active substance, ursodiol, which is tapped through surgically-implanted tubes. Although an inexpensive synthetic version of ursodiol is available, in 1995 there were at least 10,000 bears being kept in farms in China for their gall bladders, for which many people still prefer to pay thousands of dollars. Trade in Asian black bears and their parts is illegal.

bearberry any of a group of evergreen trailing shrubs belonging to the heath family, found in high and rocky places. Most bearberries are North American but *Arctostaphylos uva-ursi* is also found in Asia and Europe in northern mountainous regions. It has small pink flowers in spring, followed by red berries that are dry but edible. (Genus *Arctostaphylos*, family Ericaceae.)

bearded collie breed of British (sheepdog with shaggy hair on its muzzle. Standing about 53 cm/21 in tall, it has a long coat, which is often grey, or sometimes sandy, with white on the head, chest, and feet.

Bear, Great and Little common names (and translations of the Latin) for the constellations ♀Ursa Major and ♀Ursa Minor respectively.

bearing device used in a machine to allow free movement between two parts, typically the rotation of a shaft in a housing.

roller bearing

ball bearing

journal bearing

bearing Three types of bearing. The roller and the ball bearing are similar, differing only in the shape of the parts that roll when the middle shaft turns. The simpler journal bearing consists of a sleeve, or journal, lining the surface of the rotating shaft. The bearing is lubricated to reduce friction and wear.

Ball bearings consist of two rings, one fixed to a housing, one to the rotating shaft. Between them is a set, or race, of steel balls. They are widely used to support shafts, as in the spindle in the hub of a bicycle wheel.

The sleeve, or **journal bearing**, is the simplest bearing. It is a hollow cylinder, split into two halves. It is used for the big-end and main bearings on a car crankshaft.

In some machinery the balls of ball bearings are replaced by cylindrical rollers or thinner **needle bearings**.

In precision equipment such as watches and aircraft instruments, bearings may be made from material such as ruby and are known as **jewel bearings**.

For some applications bearings made from nylon and other plastics are used. They need no lubrication because their surfaces are naturally waxy.

the bearing of B from A is 065°
the backbearing, or bearing of A from B, is 245°

bearing A bearing is the direction of a fixed point, or the path of a moving object, from a point of observation on the Earth's surface, expressed as an angle from the north. In the diagram, the bearing of a point A from an observer at B is the angle between the line BA and the north line through B, measured in a clockwise direction from the north line.

bearing the direction of a fixed point, or the path of a moving object, from a point of observation on the Earth's surface, expressed as an angle from the north. Bearings are taken by compass and are measured in degrees ($^\circ$), given as three-digit numbers increasing clockwise. For instance, north is 000° , north-

east is 045° , south is 180° , and southwest is 225° .

True north differs slightly from magnetic north (the direction in which a compass needle points), hence NE may be denoted as $045M$ or $045T$, depending on whether the reference line is magnetic (M) or true (T) north. True north also differs slightly from grid north since it is impossible to show a spherical Earth on a flat map.

beat frequency in musical acoustics, fluctuation produced when two notes of nearly equal pitch or frequency are heard together. Beats result from the interference between the sound waves of the notes. The frequency of the beats equals the difference in frequency of the notes.

Beaufort scale system of recording wind velocity (speed), devised by Francis Beaufort in 1806. It is a numerical scale ranging from 0 to 17, calm being indicated by 0 and a hurricane by 12; 13–17 indicate degrees of hurricane force.

In 1874 the scale received international recognition; it was modified in 1926. Measurements are made at 10 m/33 ft above ground level.

BEAVER

By building dams, beavers create extremely fertile living conditions for other animals. The ponds formed by the dams trap a wealth of nourishing minerals. They are also full of zooplankton, the combined mass of which is a thousand times greater than that found elsewhere.

beaver aquatic rodent with webbed hind feet, a broad flat scaly tail, and thick waterproof fur. It has very large incisor teeth and fells trees to feed on the bark and to use the logs to construct the 'lodge', in which the young are reared, food is stored, and much of the winter is spent. There are two species, the Canadian *Castor canadensis* and the European *C. fiber*. They grow up to 1.4 m/4.6 ft in length and weigh about 20 kg/44 lb.

Beavers are monogamous and a pair will produce a litter of twins each year. Their territory consists of about 3 km² mi of river. Beavers can construct dams on streams, and thus modify the environment considerably; beaver ponds act as traps for minerals and provide fertile living conditions for other species – zooplankton biomass may be 1,000 times greater within a beaver pond than elsewhere. Beavers once ranged across Europe, N Asia, and North America, but in Europe now only survive where they are protected, and are reduced elsewhere, partly through trapping for their fur.

becquerel SI unit (symbol Bq) of radioactivity, equal to one radioactive disintegration (change in the nucleus of an atom when a particle or ray is given off) per second.

Beaufort Scale

| Number and description | Features | Air speed | |
|------------------------|----------------------------------------------------|-----------|----------|
| | | kph | mph |
| 0 calm | smoke rises vertically; water smooth | 0–2 | 0–1 |
| 1 light air | smoke shows wind direction; water ruffled | 2–5 | 1–3 |
| 2 light breeze | leaves rustle; wind felt on face | 6–11 | 4–7 |
| 3 gentle breeze | loose paper blows around | 12–19 | 8–12 |
| 4 moderate breeze | branches sway | 20–29 | 13–18 |
| 5 fresh breeze | small trees sway, leaves blown off | 30–39 | 19–24 |
| 6 strong breeze | whistling in telephone wires; sea spray from waves | 40–50 | 25–31 |
| 7 near gale | large trees sway | 51–61 | 32–38 |
| 8 gale | twigs break from trees | 62–74 | 39–46 |
| 9 strong gale | branches break from trees | 75–87 | 47–54 |
| 10 storm | trees uprooted, weak buildings collapse | 88–101 | 55–63 |
| 11 violent storm | widespread damage | 102–117 | 64–73 |
| 12 hurricane | widespread structural damage | above 118 | above 74 |

Becquerel, (Antoine) Henri (1852-1908)

French physicist. He discovered penetrating radiation coming from uranium salts, the first indication of radioactivity, and shared a Nobel prize with Marie and Pierre Curie in 1903.

Mary Evans Picture Library

The becquerel is much smaller than the previous standard unit, the curie (3.7×10^{10} Bq). It is named after French physicist Henri Becquerel.

bed in geology, a single sedimentary rock unit with a distinct set of physical characteristics or contained fossils, readily distinguishable from those of beds above and below. Well-defined partings called bedding planes separate successive beds or strata.

The depth of a bed can vary from a fraction of a centimetre to several metres or yards, and can extend over any area. The term is also used to indicate the floor beneath a body of water (lake bed) and a layer formed by a fall of particles (ash bed).

bedbug flattened wingless red-brown insect *Cimex lectularius* with piercing mouthparts. It hides by day in crevices or bedclothes and emerges at night to suck human blood.

Bedlington breed of terrier with a short body, long legs, and curly hair, usually grey, named after a district of Northumberland, England.

bee four-winged insect of the superfamily Apoidea in the order Hymenoptera, usually with a sting. There are over 12,000 species, of which fewer than 1 in 20 are social in habit. The hive bee or honeybee *Apis mellifera* establishes perennial colonies of about 80,000, the majority being infertile females (workers), with a few larger fertile males (drones), and a single very large fertile female (the queen). Worker bees live for no more than a few weeks, while a drone may live a few months, and a queen several years. Queen honeybees lay two kinds of eggs: fertilized, female eggs, which have two sets of chromosomes and develop into workers or queens, and unfertilized, male eggs, which have only one set of chromosomes and develop into drones.

Bees transmit information to each other about food sources by 'dances', each movement giving rise to sound impulses which are picked up by tiny hairs on the back of the bee's head, the orientation of the dance also having significance. They use the Sun in navigation (see migration). Besides their use in crop pollination and production of honey and wax, bees (by a measure of contaminants brought back to their hives) can provide an inexpensive and effective monitor of industrial and other pollution of the atmosphere and soil.

The most familiar species is the bumblebee, genus *Bombus*, which is larger and stronger than the hive bee and so is adapted to fertilize plants in which the pollen and nectar lie deep, as in red clover; they can work in colder weather than the hive bee.

Social bees, apart from the bumblebee and the hive bee, include

BEEKEEPING

<http://weber.u.washington.edu/~jlsks/bee.html>

Everything you could possibly wish to know about beekeeping is here. There are, for example, sections on the diseases afflicting bees, as well as advice on honey and mead-making. The site also includes an archived list of articles and some multimedia items.

the stingless South American vulture bee *Trigona hypogaea*, discovered in 1982, which is solely carnivorous.

Solitary bees include species useful in pollinating orchards in spring, and may make their nests in tunnels under the ground or in hollow plant stems; 'cuckoo' bees lay their eggs in the nests of bumblebees, which they closely resemble.

The killer bees of South America are a hybrid type, created when an African subspecies of honeybee escaped from a research establishment in Brazil in 1957. They mated with, and supplanted, the honeybees of European origin in most of South and Central America, and by 1990 had spread as far north as Texas, USA. As well as being more productive and resistant to disease than European honeybees, they also defend their hives more aggressively, in larger numbers, and for a greater length of time than other honeybees. However, their stings are no more venomous, and although they have killed hundreds of thousands of animals and probably more than 1,000 people, most individuals survive an attack, and almost all deaths have occurred where the victim has somehow been prevented from fleeing.

Most bees are passive unless disturbed, but some species are aggressive. One bee sting may be fatal to a person who is allergic to them, but this is comparatively rare (about 1.5% of the population), and most adults can survive 300-500 stings without treatment. A vaccine treatment against bee stings, which uses concentrated venom, has been developed.

beech one of several European hardwood trees or related trees growing in Australasia and South America. The common beech (*Fagus sylvatica*), found in European forests, has a smooth grey trunk and edible nuts, or 'mast', which are used as animal feed or processed for oil. The timber is used in furniture. (Genus *Fagus* and *Nothofagus*, family Fagaceae.)

bee-eater brightly-coloured bird *Merops apiaster*, family Meropidae, order Coraciiformes, found in Africa, S Europe, and Asia. Bee-eaters are slender, with chestnut, yellow, and blue-green plumage, a long bill and pointed wings, and a flight like that of the swallow, which they resemble in shape. They feed on bees, wasps, and other insects, and nest in colonies in holes dug out with their long bills in sandy river banks.

bee louse any of a number of species of wingless flies parasitic on bees. They look more like lice than flies. Most have claws at the ends of their legs.

classification Bee lice are in the family Braulidae, order Diptera (suborder Cyclorrhapha), class Insecta, phylum Arthropoda.

Bee lice lay their eggs on the walls or under the cappings of honey cells. The larvae work their way from one cell to the next, feeding on the honey. In small numbers the bee louse is insignificant; if many are present however, they can be serious pests to bees and beekeepers.

Braula caeca is rust-brown and about 1.5 mm/0.06 in long. It is a parasite of honeybees.

beet any of several plants belonging to the goosefoot family, used as food crops. One variety of the common beet (*Beta vulgaris*) is used in to produce sugar and another, the mangelwurzel, is grown as a cattle feed. The beetroot, or red beet (*B. rubra*), is a salad plant. (Genus *Beta*, family Chenopodiaceae.)

beetfly small grey fly with black hairs. Its maggots feed on beet leaves. As soon as the maggots hatch they begin to feed, continuing for one month, when they turn into chestnut-brown pupae. The flies emerge a fortnight later.

classification The beet fly *Anthomyia betae* is in the family Anthomyiidae, order Diptera, class Insecta, phylum Arthropoda.

beetle common name of insects in the order Coleoptera (Greek 'sheath-winged') with leathery forewings folding down in a protective sheath over the membranous hindwings, which are those used for flight. They pass through a complete metamorphosis. They include some of the largest and smallest of all insects: the largest is the Hercules beetle *Dynastes hercules* of the South American rainforests, 15 cm/6 in long; the smallest is only 0.03 cm/0.02 in long. Comprising more than 50% of the animal kingdom, beetles number some 370,000 named species, with many not yet described.

BEETLE

When it jumps, the flea beetle accelerates at 260 times more than gravity while spinning head over heels about 70 times per second. Flea beetles always land the right way up.

Beetles are found in almost every land and freshwater habitat, and feed on almost anything edible. Examples include click beetle or skipjack species of the family Elateridae, so called because if they fall on their backs they right themselves with a jump and a loud click; the larvae, known as wireworms, feed on the roots of crops. In some tropical species of Elateridae the beetles have luminous organs between the head and abdomen and are known as fireflies. The potato pest Colorado beetle *Leptinotarsa decemlineata* is striped in black and yellow. The blister beetle *Lytta vesicatoria*, a shiny green species from S Europe, was once sold pulverized as an aphrodisiac and contains the toxin cantharidin. The larvae of the furniture beetle *Anobium punctatum* and the death-watch beetle *Xestobium rufovillosum* and their relatives are serious pests of structural timbers and furniture (see woodworm).

begonia any of a group of tropical and subtropical plants. They have fleshy and succulent leaves, and some have large, brilliant flowers. There are numerous species in the tropics, especially in South America and India. (Genus *Begonia*, family Begoniaceae.)

behaviourism school of psychology originating in the USA, of which the leading exponent was John B Watson.

Behaviourists maintain that all human activity can ultimately be explained in terms of conditioned reactions or reflexes and habits formed in consequence. Leading behaviourists include Ivan P Pavlov and B F Skinner.

It is a good morning exercise for a research scientist to discard a pet hypothesis every day before breakfast. It keeps him young.

KONRAD LORENZ Austrian zoologist.
The So-Called Evil

behaviour therapy in psychology, the application of behavioural principles, derived from learning theories, to the treatment of clinical conditions such as phobias, obsessions, and sexual and interpersonal problems.

The symptoms of these disorders are regarded as learned patterns of behaviour that therapy can enable the patient to unlearn. For example, in treating a phobia, the patient is taken gradually into the feared situation in about 20 sessions until the fear noticeably reduces.

bel unit of sound measurement equal to ten decibels. It is named after Scottish scientist Alexander Graham Bell.

belemnite extinct relative of the squid, with rows of little hooks rather than suckers on the arms. The parts of belemnites most frequently found as fossils are the bullet-shaped shells that were within the body. Like squid, these animals had an ink sac which could be used to produce a smokescreen when attacked.

Belgian sheepdog any of four varieties of herding and guarding dog developed in Belgium: the Groenendael, Tervuren, Malinois, and Lakenois. Similar in build and size, they stand about 62 cm/24 in tall, the main difference between them being the variations in colour and type of coat.

The Groenendael has a long all-black coat; the Tervuren has a long tawny coat with black markings on the face; the Malinois is similar to the Tervuren in colour, but with a short coat; the Lakenois also shares the Tervuren's colouring, but with a short, coarse, wavy coat.

Bell, Alexander Graham (1847-1922)

Scottish-born US scientist and inventor. He was the first person ever to transmit speech from one point to another by electrical means. This invention - the telephone - was made in 1876. Later Bell experimented with a type of phonograph and, in aeronautics, invented the tricycle undercarriage.

Bell also invented a photophone, which used selenium crystals to apply the telephone principle to transmitting words in a beam of light. He thus achieved the first wireless transmission of speech.

Mary Evans Picture Library

BELL, ALEXANDER GRAHAM

Alexander Graham Bell's invention of the telephone stemmed from his interest in hearing defects. His wife was profoundly deaf. On the day that Bell was buried in 1922, the entire telephone network in the USA was closed down for one minute in tribute.

belladonna or **deadly nightshade** poisonous plant belonging to the nightshade family, found in Europe and Asia. It grows to 1.5 m/5 ft in height, with dull green leaves growing in unequal pairs, up to 20 cm/8 in long, and single purplish flowers that produce deadly black berries. Drugs are made from the leaves. (*Atropa belladonna*, family Solanaceae.)

The dried powdered leaves are used to produce the drugs atropine and hyoscine. Belladonna extract acts medicinally as an anticholinergic (blocking the passage of certain nerve impulses), and is highly poisonous in large doses.

Bell Burnell, (Susan) Jocelyn (1943-) British astronomer. In 1967 she discovered the first pulsar (rapidly flashing star) with Antony Hewish and colleagues at Cambridge University, England.

bellflower general name for many plants with bell-shaped flowers. The harebell (*Campanula rotundifolia*) is a wild bellflower. The Canterbury bell (*C. medium*) is the garden variety, originally from S Europe. (Genus *Campanula*, family Campanulaceae.)

bells nautical term applied to half-hours of watch. A day is divided into seven watches, five of four hours each and two, called dog-watches, of two hours. Each half-hour of each watch is indicated by the striking of a bell, eight bells signalling the end of the watch.

benchmark in computing, a measure of the performance of a piece of equipment or software, usually consisting of a standard program or suite of programs. Benchmarks can indicate whether a computer is powerful enough to perform a particular task, and so enable machines to be compared. However, they provide only a very rough guide to practical performance, and may lead manufacturers to design systems that get high scores with the artificial benchmark programs but do not necessarily perform well with day-to-day programs or data.

bends or **compressed-air sickness** or **caisson disease** popular name for a syndrome seen in deep-sea divers, arising from too

rapid a release of nitrogen from solution in their blood. If a diver surfaces too quickly, nitrogen that had dissolved in the blood under increasing water pressure is suddenly released, forming bubbles in the bloodstream and causing pain (the 'bends') and paralysis. Immediate treatment is gradual decompression in a decompression chamber, whilst breathing pure oxygen.

Beniöff zone seismically active zone inclined from a deep sea trench beneath a continent or continental margin. Earthquakes along Beniöff zones define the top surfaces of plates of lithosphere that descend in to the mantle beneath another, overlying plate. The zone is named after Hugo Beniöff, a US seismologist who first described this feature.

bent or **bent grass** any of a group of grasses. Creeping bent grass (*Agrostis stolonifera*), also known as florin, is common in N North America, Europe, and Asia, including lowland Britain. It spreads by runners and has large attractive clusters (panicles) of yellow or purple flowers on thin stalks, like oats. It is often used on lawns and golf courses. (Genus *Agrostis*, family Gramineae.)

benzaldehyde C_6H_5CHO colourless liquid with the characteristic odour of almonds. It is used as a solvent and in the making of perfumes and dyes. It occurs in certain leaves, such as the cherry, laurel, and peach, and in a combined form in certain nuts and kernels. It can be extracted from such natural sources, but is usually made from toluene.

Benzedrine trade name for α -amphetamine, a stimulant drug.

benzene C_6H_6 clear liquid hydrocarbon of characteristic odour, occurring in coal tar. It is used as a solvent and in the synthesis of many chemicals.

The benzene molecule consists of a ring of six carbon atoms, all of which are in a single plane, and it is one of the simplest cyclic compounds. Benzene is the simplest of a class of compounds collectively known as **aromatic compounds**. Some are considered carcinogenic (cancer-inducing).

benzene The molecule of benzene consists of six carbon atoms arranged in a ring, with six hydrogen atoms attached. The benzene ring structure is found in many naturally occurring organic compounds.

benzodiazepine any of a group of mood-altering drugs (tranquillizers), for example Librium and Valium. They are addictive and interfere with the process by which information is transmitted between brain cells, and various side effects arise from continued use. They were originally developed as muscle relaxants, and then excessively prescribed in the West as anxiety-relieving drugs.

Today the benzodiazepines are recommended only for short-term use in alleviating severe anxiety or insomnia.

benzoic acid C_6H_5COOH white crystalline solid, sparingly soluble in water, that is used as a preservative for certain foods and as an antiseptic. It is obtained chemically by the direct oxidation of ben-

zaldehyde and occurs in certain natural resins, some essential oils, and as hippuric acid.

benzoin resin (thick liquid that hardens in the air) obtained by making cuts in the bark of the tree *Styrax benzoin*, which grows in the East Indies. Benzoin is used in cosmetics, perfumes, and incense.

benzopyrene one of a number of organic compounds associated with a particular polycyclic ring structure. Benzopyrenes are present in coal tar at low levels and are considered carcinogenic (cancer-inducing). Traces of benzopyrenes are present in wood smoke, and this has given rise to some concern about the safety of naturally smoked foods.

bergamot small evergreen tree belonging to the rue family. A fragrant citrus-scented essence is obtained from the rind of its fruit and used as a perfume and food flavouring, for example in Earl Grey tea. The sole source of supply is S Calabria, Italy, but the name comes from the town of Bergamo, in Lombardy. (*Citrus bergamia*, family Rutaceae.)

Bergmann musquete Machine Pistol 18 German automatic weapon of World War I, the forerunner of the modern submachine gun. A simple automatic weapon with a short barrel and wooden stock, it fired the standard 9 mm pistol cartridge at 400 rounds per minute.

It was first issued in 1916 for trench defence, but the adoption of the infiltration tactic by General von Hutier led to the weapon being issued to 'Storm Troops' since it provided the ideal combination of firepower and portability demanded in this role.

beriberi nutritional disorder occurring mostly in the tropics and resulting from a deficiency of vitamin B_1 (thiamine). The disease takes two forms: in one α -oedema (waterlogging of the tissues) occurs; in the other there is severe emaciation. There is nerve degeneration in both forms and many victims succumb to heart failure.

Beringia or **Bering Land Bridge** former land bridge 1,600 km/1,000 mi wide between Asia and North America; it existed during the ice ages that occurred before 35,000 BC and during the period 24,000–9,000 BC. It is now covered by the Bering Strait and Chukchi Sea.

berkelium synthesized, radioactive, metallic element of the actinide series, symbol Bk, atomic number 97, relative atomic mass 247.

It was first produced in 1949 by Glenn Seaborg and his team, at the University of California at Berkeley, USA, after which it is named.

Bernoulli's principle law stating that the pressure of a fluid varies inversely with speed, an increase in speed producing a decrease in pressure (such as a drop in hydraulic pressure as the fluid speeds up flowing through a constriction in a pipe) and vice versa. The principle also explains the pressure differences on each surface of an aerofoil, which gives lift to the wing of an aircraft. The principle was named after Swiss mathematician and physicist Daniel Bernoulli.

berry fleshy, many-seeded fruit that does not split open to release the seeds. The outer layer of tissue, the exocarp, forms an outer skin that is often brightly coloured to attract birds to eat the fruit and thus disperse the seeds. Examples of berries are the tomato and the grape.

A **pepo** is a type of berry that has developed a hard exterior, such as the cucumber fruit. Another is the hesperidium, which has a thick, leathery outer layer, such as that found in citrus fruits, and fluid-containing vesicles within, which form the segments.

beryl mineral, beryllium aluminium silicate, $Be_3Al_2Si_6O_{18}$, which forms crystals chiefly in granite. It is the chief ore of beryllium. Two of its gem forms are aquamarine (light-blue crystals) and emerald (dark-green crystals).

beryllium hard, light-weight, silver-white, metallic element, symbol Be, atomic number 4, relative atomic mass 9.012. It is one of

the alkaline-earth metals, with chemical properties similar to those of magnesium. In nature it is found only in combination with other elements and occurs mainly as beryl ($3\text{BeO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2$). It is used to make sturdy, light alloys and to control the speed of neutrons in nuclear reactors. Beryllium oxide was discovered in 1798 by French chemist Louis-Nicolas Vauquelin (1763–1829), but the element was not isolated until 1828, by Friedrich Wöhler and Antoine-Alexandre-Brutus Bussy independently.

In 1992 large amounts of beryllium were unexpectedly discovered in six old stars in the Milky Way.

Berzelius, Jöns Jakob (1779–1848)

Swedish chemist. He accurately determined more than 2,000 relative atomic and molecular masses. In 1813–14, he devised the system of chemical symbols and formulae now in use and proposed oxygen as a reference standard for atomic masses. His discoveries include the elements cerium 1804, selenium 1817, and thorium 1828; he was the first to prepare silicon in its amorphous form and to isolate zirconium. The words 'isomerism', 'allotropy', and 'protein' were coined by him.

Berzelius noted that some reactions appeared to work faster in the presence of another substance which itself did not appear to change, and postulated that such a substance contained a catalytic force. Platinum, for example, was capable of speeding up reactions between gases. Although he appreciated the nature of catalysis, he was unable to give any real explanation of the mechanism.

Mary Evans Picture Library

Bessemer process the first cheap method of making steel, invented by Henry Bessemer in England 1856. It has since been superseded by more efficient steel-making processes, such as the basic-oxygen process. In the Bessemer process compressed air is

Bessemer process In a Bessemer converter, a blast of high-pressure air oxidizes impurities in molten iron and converts it to steel.

Bessemer, Henry (1813–1898)

British engineer and inventor who developed a method of converting molten pig iron into steel (the Bessemer process) in 1856. Knighted in 1879.

Mary Evans Picture Library

blown into the bottom of a converter, a furnace shaped like a cement mixer, containing molten pig iron. The excess carbon in the iron burns out, other impurities form a slag, and the furnace is emptied by tilting.

beta pre-release version of a new software program still in development, which is handed out to users for testing. The worst bugs are usually eliminated at the earlier alpha stage of development. Beta testers use the software to do real work and report any bugs or badly implemented features they find to the developers, who incorporate this information in refining the product for release. Companies that assist with such testing are known as beta sites.

beta-blocker any of a class of drugs that block impulses that stimulate certain nerve endings (beta receptors) serving the heart muscle. This reduces the heart rate and the force of contraction, which in turn reduces the amount of oxygen (and therefore the blood supply) required by the heart. Beta-blockers may be useful in the treatment of angina, arrhythmia (abnormal heart rhythms), and raised blood pressure, and following heart attacks. They must be withdrawn from use gradually.

beta decay the disintegration of the nucleus of an atom to produce a beta particle, or high-speed electron, and an electron-anti-neutrino. During beta decay, a neutron in the nucleus changes into a proton, thereby increasing the atomic number by one while the mass number stays the same. The mass lost in the change is converted into kinetic (movement) energy of the beta particle.

Beta decay is caused by the weak nuclear force, one of the fundamental forces of nature operating inside the nucleus.

beta index mathematical measurement of the connectivity of a transport network. If the network is represented as a simplified topological map, made up of nodes (junctions or places) and edges (links), the beta index may be calculated by dividing the number of nodes by the number of edges. If the number of nodes is n and the number of edges is e , then the beta index B is given by the formula:

$$B = n/e$$

The higher the index number, the better connected the network is. If B is greater than 1, then a complete circuit exists.

beta particle electron ejected with great velocity from a radioactive atom that is undergoing spontaneous disintegration. Beta particles do not exist in the nucleus but are created on disintegration, beta decay, when a neutron converts to a proton to emit an electron.

Beta particles are more penetrating than alpha particles, but less so than gamma radiation; they can travel several metres in air, but are stopped by 2–3 mm of aluminium. They are less strongly ionizing than alpha particles and, like cathode rays, are easily deflected by magnetic and electric fields.

beta version in computing, a pre-release version of software or an application program, usually distributed to a limited number of expert users (and often reviewers). Distribution of beta versions allows user testing and feedback to the developer, so that any necessary modifications can be made before release.

Betelgeuse or **Alpha Orionis** red supergiant star in the constellation of Orion. It is the tenth brightest star in the night sky, although its brightness varies. It is 1,100 million km/700 million mi

across, about 800 times larger than the Sun, roughly the same size as the orbit of Mars. It is over 10,000 times as luminous as the Sun, and lies 650 light years from Earth. Light takes 60 minutes to travel across the giant star.

Its magnitude varies irregularly between 0.4 and 1.3 in a period of 5.8 years. It was the first star whose angular diameter was measured with the Mount Wilson interferometer in 1920. The name is a corruption of the Arabic, describing its position in the shoulder of Orion.

betel nut fruit of the areca palm (*Areca catechu*), which is chewed together with lime and betel pepper as a stimulant by peoples of the East and Papua New Guinea. Chewing it blackens the teeth and stains the mouth deep red.

betony plant belonging to the mint family, formerly used in medicine and dyeing. It has a hairy stem and leaves, and dense heads of reddish-purple flowers. (*Stachys* (formerly *Betonica*) *officinalis*, family Labiateae.)

Bezier curve curved line invented by Pierre Bézier that connects a series of points (or 'nodes') in the smoothest possible way. The shape of the curve is governed by a series of complex mathematical formulae. They are used in computer graphics and CAD.

bezoar or **bezoar stone** hardened mass occasionally found in the stomach or intestines of ruminating animals, such as goats, llamas, antelopes, and cows. They appear to be formed through the presence of some irritating substance in the alimentary tract.

bhang name for a weak form of the drug cannabis used in India.

bhp abbreviation for brake horsepower.

bicarbonate common name for hydrogenocarbonate

bicarbonate indicator pH indicator sensitive enough to show a colour change as the concentration of the gas carbon dioxide increases. The indicator is used in photosynthesis and respiration experiments to find out whether carbon dioxide is being liberated. The initial red colour changes to yellow as the pH becomes more acidic.

Carbon dioxide, even in the concentrations found in exhaled air, will dissolve in the indicator to form a weak solution of carbonic acid, which will lower the pH and therefore give the characteristic colour change.

bicarbonate of soda or **baking soda** (technical name **sodium hydrogenocarbonate**) NaHCO_3 white crystalline solid that neutralizes acids and is used in medicine to treat acid indigestion. It is also used in baking powders and effervescent drinks.

bichir African fish, genus *Polypterus*, found in tropical swamps and rivers. Cylindrical in shape, some species grow to 70 cm/2.3 ft or more. They show many 'primitive' features, such as breathing air by using the swimbladder, having a spiral valve in the intestine, having heavy bony scales, and having larvae with external gills. These, and the fleshy fins, lead some scientists to think they are related to lungfish and coelacanths.

bichon frise breed of small dog probably originating in France or Spain and characterized by its pure white, softly curling coat. Compactly built, it carries its tail curved over its back and stands 23–8 cm/9–11 in at the shoulder.

bicuspid valve or **mitral valve** in the left side of the heart, a flap of tissue that prevents blood flowing back into the atrium when the ventricle contracts.

bicycle pedal-driven two-wheeled vehicle used in cycling. It consists of a metal frame mounted on two large wire-spoked wheels, with handlebars in front and a seat between the front and back wheels. The bicycle is an energy-efficient, nonpolluting form of transport, and it is estimated that 800 million bicycles are in use throughout the world – outnumbering cars three to one. China, India, Denmark, and the Netherlands are countries with a high use of bicycles. More than 10% of road spending in the Netherlands is on cycleways and bicycle parking.

history The first bicycle was invented in Paris in 1791 and was a form

of hobby-horse (though there are versions of the hobby-horse that date back even earlier) that had to be propelled by pushing the feet against the ground. The first treadle-propelled cycle was designed by the Scottish blacksmith Kirkpatrick Macmillan in 1839. The Rover 'safety bike' of 1885 may be considered the forerunner of the modern bicycle, with a chain and sprocket drive on the rear wheel. By the end of the 19th century wire wheels, metal frames (replacing wood), and pneumatic tyres (invented by the Scottish veterinary surgeon John B Dunlop 1888) had been added. Among the bicycles of that time was the front-wheel-driven penny farthing with a large front wheel.

technology Recent technological developments have been related to reducing wind resistance caused by the frontal area and the turbulent drag of the bicycle. Most of an Olympic cyclist's energy is taken up in fighting wind resistance in a sprint. The first major innovation was the solid wheel, first used in competitive cycling 1984, but originally patented as long ago as 1875. Further developments include handlebars that allow the cyclist to crouch and use the shape of the hands and forearms to divert air away from the chest. Modern racing bicycles now have a monocoque structure produced by laying carbon fibre around an internal mould and then baking them in an oven. Using all these developments, Chris Boardman set a speed record of 54.4 kph (34 mph) on his way to winning a gold medal at the 1992 Barcelona Olympics. To manufacture a bicycle requires only 1% of the energy and materials used to build a car.

When I see an adult on a bicycle, I have hope for the human race.

H G WELLS English writer.
Attributed remark

biennial plant plant that completes its life cycle in two years. During the first year it grows vegetatively and the surplus food produced is stored in its perennating organ, usually the root. In the following year these food reserves are used for the production of leaves, flowers, and seeds, after which the plant dies. Many root vegetables are biennials, including the carrot *Daucus carota* and parsnip *Pastinaca sativa*. Some garden plants that are grown as biennials are actually perennials, for example, the wallflower *Cheiranthus cheiri*.

Big Bang in astronomy, the hypothetical 'explosive' event that marked the origin of the universe as we know it. At the time of the Big Bang, the entire universe was squeezed into a hot, superdense state. The Big Bang explosion threw this compact material outwards, producing the expanding universe (see red shift). The cause of the Big Bang is unknown; observations of the current rate of expansion of the universe suggest that it took place about 10–20 billion years ago. The Big Bang theory began modern cosmology.

According to a modified version of the Big Bang, called the **inflationary theory**, the universe underwent a rapid period of expansion shortly after the Big Bang, which accounts for its current large size and uniform nature. The inflationary theory is supported by the most recent observations of the cosmic background radiation.

Scientists have calculated that one 10^{-36} second (equivalent to one million-million-million-million-million-millionth of a second) after the Big Bang, the universe was the size of a pea, and the temperature was 10 billion million million million°C (18 billion million million million°F). One second after the Big Bang, the temperature was about 10 billion°C (18 billion°F).

Big Blue popular name for IBM, derived from the company's size and its blue logo.

Big Crunch in cosmology, a possible fate of the universe in which it ultimately collapses to a point following the halting and reversal of the present expansion. See also Big Bang and critical density.

Big Dipper North American name for the Plough, the seven brightest and most prominent stars in the constellation Ursa Major.

big horn sheep or *Rocky Mountain sheep* species of large North American sheep with a brown coat, which turns to bluish-grey in winter. It is so named from the size of the horns of the ram, which often measure over 1 m/3.3 ft round the curve.

classification The big horn sheep *Ovis canadensis* is in family Bovidae, order Artiodactyla

bight coastal indentation, crescent-shaped or gently curving, such as the Bight of Biafra in W Africa and the Great Australian Bight.

Big Seven hierarchies on UseNet, the original seven hierarchies of newsgroups. They are: comp (computing), misc (miscellaneous), news, rec (recreation), sci (science), soc (social issues), and talk (debate). These categories of newsgroups are managed according to specific rules which govern the creation of new groups, in contrast to the alt hierarchy.

bilberry any of several shrubs belonging to the heath family, closely related to North American blueberries. They have blue or black edible berries. (Genus *Vaccinium*, family Ericaceae.)

bilby rabbit-eared bandicoot *Macrotis lagotis*, a lightly built marsupial with big ears and long nose. This burrowing animal is mainly carnivorous, and its pouch opens backwards.

bile brownish alkaline fluid produced by the liver. Bile is stored in the gall bladder and is intermittently released into the duodenum (small intestine) to aid digestion. Bile consists of bile salts, bile pigments, cholesterol, and lecithin. Bile salts assist in the breakdown and absorption of fats; bile pigments are the breakdown products of old red blood cells that are passed into the gut to be eliminated with the faeces.

To remember the properties of bile:

BILE FROM THE LIVER EMULSIFIES GREASES
TINGES THE URINE AND COLOURS THE FAECES
AIDS PERISTALSIS, PREVENTS PUTREFACTION

IF YOU REMEMBER ALL THIS YOU'LL GIVE SATISFACTION.

bilharzia or *schistosomiasis* disease that causes anaemia, inflammation, formation of scar tissue, dysentery, enlargement of the spleen and liver, cancer of the bladder, and cirrhosis of the liver. It is contracted by bathing in water contaminated with human sewage. Some 200 million people are thought to suffer from this disease in the tropics, and 750,000 people a year die.

Freshwater snails act as host to the first larval stage of blood flukes of the genus *Schistosoma*; when these larvae leave the snail in their second stage of development, they are able to pass through human skin, become sexually mature, and produce quantities of eggs, which pass to the intestine or bladder. Numerous eggs are excreted from the body in urine or faeces to continue the cycle. Treatment is by means of drugs, usually containing antimony, to kill the parasites.

bill in birds, the projection of the skull bones covered with a horny sheath. It is not normally sensitive, except in some aquatic birds, rooks, and woodpeckers, where the bill is used to locate food that is not visible. The bills of birds are adapted by shape and size to specific diets, for example, shovellers use their bills to sieve mud in order to extract food; birds of prey have hooked bills adapted to tearing flesh; the bills of the avocet, and the curlew are long and narrow for picking tiny invertebrates out of the mud; and those of woodpeckers are sharp for pecking holes in trees and plucking out insects. The bill is also used by birds for preening, fighting, display, and nest-building.

billion the cardinal number represented by a 1 followed by nine zeros (1,000,000,000 or 10^9), equivalent to a thousand million.

bimetallic strip strip made from two metals each having a different coefficient of thermal expansion; it therefore bends when subjected to a change in temperature. Such strips are used widely for

temperature measurement and control, for instance in the domestic thermostat.

bimodal in statistics, having two distinct peaks of frequency distribution.

binary file any file that is not plain text. Program (.EXE or .COM), sound, video, and graphics files are all types of binary files. Such files require special treatment for inclusion in e-mail sent across the Internet, which can transmit only ASCII text and imposes a size limit of 64Kb per message. Several programs have been developed to code binary files into ASCII for transmission, splitting them into smaller parts as necessary. The most commonly used such program is UUencode, but there are others including base64 and BinHex. See also MIME.

binary fission in biology, a form of asexual reproduction, whereby a single-celled organism, such as the amoeba, divides into two smaller 'daughter' cells. It can also occur in a few simple multicellular organisms, such as sea anemones, producing two smaller sea anemones of equal size.

binary large object (contracted to *BLOB*) in computing, any large single block of data stored in a database, such as a picture or sound file. A BLOB does not include record fields, and so cannot be directly searched by the database's search engine.

binary newsgroup any UseNet newsgroup set up for the transmission of picture and other nontext files. The binary newsgroups have their own sub-hierarchy, alt.binaries, and include groups such as alt.binaries.pictures.fine-art.digitized and alt.binaries.pictures.erotic.

Because newsgroups are subject to the same restrictions as Internet e-mail for the transmission of binary files, pictures, programs, and other files posted to these newsgroups are UUencoded and split into sections. To view the pictures, all the parts must be downloaded and then UDecoded and stitched back together to form the original file, which can then be viewed using the appropriate graphics program.

Other binary newsgroups distribute sound files (alt.binaries.sound.*) or user-contributed new levels for games such as *Doom* (alt.binaries.doom). These newsgroups take up a lot of bandwidth and therefore not all sites elect to carry them; blocking software typically bars access to many of these groups. It is considered a breach of netiquette to post binary files to nonbinary newsgroups.

binary number system system of numbers to base two, using combinations of the digits 1 and 0. Codes based on binary numbers are used to represent instructions and data in all modern digital computers, the values of the binary digits (contracted to 'bits') being stored or transmitted as, for example, open/closed switches, magnetized/unmagnetized discs and tapes, and high/low voltages in circuits.

The value of any position in a binary number increases by powers of 2 (doubles) with each move from right to left (1, 2, 4, 8, 16, and so on). For example, 1011 in the binary number system means $(1 \times 8) + (0 \times 4) + (1 \times 2) + (1 \times 1)$, which adds up to 11 in the decimal system.

binary number system The capital letter A represented in binary form.

binary search in computing, a rapid technique used to find any particular record in a list of records held in sequential order. The computer is programmed to compare the record sought with the record in the middle of the ordered list. This being done, the computer discards the half of the list in which the record does not

appear, thereby reducing the number of records left to search by half. This process of selecting the middle record and discarding the unwanted half of the list is repeated until the required record is found.

binary star pair of stars moving in orbit around their common centre of mass. Observations show that most stars are binary, or even multiple – for example, the nearest star system to the Sun, α Centauri.

One of the stars in the binary system Epsilon Aurigae may be the largest star known. Its diameter is 2,800 times that of the Sun. If it were in the position of the Sun, it would engulf Mercury, Venus, Earth, Mars, Jupiter, and Saturn. A spectroscopic binary is a binary in which two stars are so close together that they cannot be seen separately, but their separate light spectra can be distinguished by a spectroscope.

Another type is the δ eclipsing binary.

binding energy in physics, the amount of energy needed to break the nucleus of an atom into the neutrons and protons of which it is made.

BinHex program for coding δ binary files into δ ASCII for transmission over the Internet via e-mail.

binoculars optical instrument for viewing an object in magnification with both eyes; for example, field glasses and opera glasses. Binoculars consist of two telescopes containing lenses and prisms, which produce a stereoscopic effect as well as magnifying the image.

Use of prisms has the effect of 'folding' the light path, allowing for a compact design.

The first binocular telescope was constructed by the Dutch inventor Hans Lippershey in 1608. Later development was largely due to the German Ernst Abbe of Jena, who at the end of the 19th century designed prism binoculars that foreshadowed the instruments of today, in which not only magnification but also stereoscopic effect is obtained.

binomial in mathematics, an expression consisting of two terms, such as $a + b$ or $a - b$.

binomial system of nomenclature in biology, the system in which all organisms are identified by a two-part Latinized name. Devised by the biologist δ Linnaeus, it is also known as the Linnaean system. The first name is capitalized and identifies the δ genus; the second identifies the δ species within that genus.

binomial theorem formula whereby any power of a binomial quantity may be found without performing the progressive multiplications.

It was discovered by Isaac δ Newton and first published in 1676.

binturong shaggy-coated mammal *Arctitis binturong*, the largest member of the mongoose family, nearly 1 m/3 ft long excluding a long muscular tail with a prehensile tip. Mainly nocturnal and tree-dwelling, the binturong is found in the forests of SE Asia, feeding on fruit, eggs, and small animals.

biochemistry science concerned with the chemistry of living organisms: the structure and reactions of proteins (such as enzymes), nucleic acids, carbohydrates, and lipids.

Its study has led to an increased understanding of life processes, such as those by which organisms synthesize essential chemicals from food materials, store and generate energy, and pass on their characteristics through their genetic material. A great deal of medical research is concerned with the ways in which these processes are disrupted. Biochemistry also has applications in agriculture and in the food industry (for instance, in the use of enzymes).

biodegradable capable of being broken down by living organisms, principally bacteria and fungi. In biodegradable substances, such as food and sewage, the natural processes of decay lead to compaction and liquefaction, and to the release of nutrients that are then recycled by the ecosystem.

This process can have some disadvantageous side effects, such as the release of methane, an explosive greenhouse gas. However, the technology now exists for waste tips to collect methane in

binoculars An optical instrument that allows the user to focus both eyes on the magnified image at the same time. The essential components of binoculars are objective lenses, eyepieces, and a system of prisms to invert and reverse the image. A focusing system provides a sharp image by adjusting the relative positions of these components.

underground pipes, drawing it off and using it as a cheap source of energy. Nonbiodegradable substances, such as glass, heavy metals, and most types of plastic, present serious problems of disposal.

biodiversity (contraction of *biological diversity*) measure of the variety of the Earth's animal, plant, and microbial species; of genetic differences within species; and of the ecosystems that support those species. Its maintenance is important for ecological stability and as a resource for research into, for example, new drugs and crops. In the 20th century, the destruction of habitats is believed to have resulted in the most severe and rapid loss of biodiversity in the history of the planet.

Estimates of the number of species vary widely because many species-rich ecosystems, such as tropical forests, contain unexplored and unstudied habitats. Especially among small organisms, many are unknown; for instance, it is thought that only 1–10% of the world's bacterial species have been identified.

The most significant threat to biodiversity comes from the destruction of rainforests and other habitats in the southern hemisphere. It is estimated that 7% of the Earth's surface hosts 50–75% of the world's biological diversity. Costa Rica, for example, has an area less than 10% of the size of France but possesses three times as many vertebrate species.

biodynamic farming agricultural practice based on the principle of homeopathy: tiny quantities of a substance are applied to transmit vital qualities to the soil. It is a form of organic farming, and was developed by the Austrian holistic mystic Rudolf Steiner and Ehrenfried Pfeiffer.

bioengineering the application of engineering to biology and medicine. Common applications include the design and use of artificial limbs, joints, and organs, including hip joints and heart valves.

biofeedback in medicine, the use of electrophysiological monitoring devices to 'feed back' information about internal processes and thus facilitate conscious control. Developed in the USA in the 1960s, independently by neurophysiologist Barbara Brown and neuropsychiatrist Joseph Kamiya, the technique is effective in alleviating hypertension and preventing associated organic and physiological dysfunction.

biofuel any solid, liquid, or gaseous fuel produced from organic (once living) matter, either directly from plants or indirectly from industrial, commercial, domestic, or agricultural wastes. There are three main methods for the development of biofuels: the burning of dry organic wastes (such as household refuse, industrial and agricultural wastes, straw, wood, and peat); the fermentation of wet wastes (such as animal dung) in the absence of oxygen to produce biogas (containing up to 60% methane), or the fermentation of sugar cane or corn to produce alcohol and esters; and energy forestry (producing fast-growing wood for fuel).

Fermentation produces two main types of biofuels: alcohols and esters. These could theoretically be used in place of fossil fuels but, because major alterations to engines would be required, biofuels are usually mixed with fossil fuels. The EU allows 5% ethanol, derived from wheat, beet, potatoes, or maize, to be added to fossil fuels. A quarter of Brazil's transportation fuel in 1994 was ethanol.

biogenesis biological term coined in 1870 by English scientist Thomas Henry Huxley to express the hypothesis that living matter always arises out of other similar forms of living matter. It superseded the opposite idea of spontaneous generation or abiogenesis (that is, that living things may arise out of nonliving matter).

biogeography study of how and why plants and animals are distributed around the world, in the past as well as in the present; more specifically, a theory describing the geographical distribution of species developed by Robert MacArthur and US zoologist Edward O. Wilson. The theory argues that for many species, ecological specializations mean that suitable habitats are patchy in their occurrence. Thus for a dragonfly, ponds in which to breed are separated by large tracts of land, and for edelweiss adapted to alpine peaks the deep valleys between cannot be colonized.

biological clock regular internal rhythm of activity, produced by unknown mechanisms, and not dependent on external time signals. Such clocks are known to exist in almost all animals, and also in many plants, fungi, and unicellular organisms; the first biological clock gene in plants was isolated in 1995 by a US team of researchers. In higher organisms, there appears to be a series of clocks of graded importance. For example, although body temperature and activity cycles in human beings are normally 'set' to 24 hours, the two cycles may vary independently, showing that two clock mechanisms are involved.

biological control The beetle *Cryptolaemus montrouzieri* being released on to a mealybug-infested passion flower. Because mealybugs, which are a serious pest, have a waxy coating and so are resistant to insecticides, biological control agents are used against them. Premaphotos Wildlife

biological control control of pests such as insects and fungi through biological means, rather than the use of chemicals. This can include breeding resistant crop strains; inducing sterility in the pest; infecting the pest species with disease organisms; or introducing the pest's natural predator. Biological control tends to be naturally self-regulating, but as ecosystems are so complex, it is difficult to predict all the consequences of introducing a biological controlling agent.

The introduction of the cane toad to Australia 50 years ago to eradicate a beetle that was destroying sugar beet provides an example of the unpredictability of biological control. Since the cane toad is poisonous it has few Australian predators and it is now a pest, spreading throughout eastern and northern Australia at a rate of 35 km/22 mi a year.

BIOLOGICAL CONTROL

<http://www.nysaes.cornell.edu/80/ent/biocontrol/>

University-based site on the various methods of biological control used by farmers in the USA. This includes sections on parasitoids, predators, pathogens, and weed feeders. Each section contains images and sections on 'relative effectiveness' and 'pesticide susceptibility'.

biological oxygen demand (BOD) the amount of dissolved oxygen taken up by microorganisms in a sample of water. Since these microorganisms live by decomposing organic matter, and the amount of oxygen used is proportional to their number and meta-

biotic rate, BOD can be used as a measure of the extent to which the water is polluted with organic compounds.

biological shield shield around a nuclear reactor that is intended to protect personnel from the effects of radiation. It usually consists of a thick wall of steel and concrete.

biology *Greek bios 'life', logos 'discourse'* science of life. Biology includes all the life sciences – for example, anatomy and physiology (the study of the structure of living things), cytology (the study of cells), zoology (the study of animals) and botany (the study of plants), ecology (the study of habitats and the interaction of living species), animal behaviour, embryology, and taxonomy, and plant breeding. Increasingly in the 20th century biologists have concentrated on molecular structures: biochemistry, biophysics, and genetics (the study of inheritance and variation).

Biological research has come a long way towards understanding the nature of life, and during the 1990s our knowledge will be further extended as the international Human Genome Project attempts to map the entire genetic code contained in the 23 pairs of human chromosomes.

The greatest stride in biology, in our century, was its shift to the molecular dimension. The next will be its shift toward the sub-molecular, electronic dimension.

ALBERT SZENT-GYORGYI Hungarian-born US biochemist.
Bioelectronics 1968

bioluminescence production of light by living organisms. It is a feature of many deep-sea fishes, crustaceans, and other marine animals. On land, bioluminescence is seen in some nocturnal insects such as glow-worms and fireflies, and in certain bacteria and fungi. Light is usually produced by the oxidation of luciferin, a reaction catalysed by the enzyme luciferase. This reaction is unique, being the only known biological oxidation that does not produce heat. Animal luminescence is involved in communication, camouflage, or the luring of prey, but its function in other organisms is unclear.

biomass the total mass of living organisms present in a given area. It may be specified for a particular species (such as earthworm biomass) or for a general category (such as herbivore biomass). Estimates also exist for the entire global plant biomass. Measurements of biomass can be used to study interactions between organisms, the stability of those interactions, and variations in population numbers. Where dry biomass is measured, the material is dried to remove all water before weighing.

Some two-thirds of the world's population cooks and heats water by burning biomass, usually wood. Plant biomass can be a renewable source of energy as replacement supplies can be grown relatively quickly. Fossil fuels however, originally formed from biomass, accumulate so slowly that they cannot be considered renewable. The burning of biomass (defined either as natural areas of the ecosystem or as forest, grasslands, and fuelwoods) produces 3.5 million tonnes of carbon in the form of carbon dioxide each year, accounting for up to 40% of the world's annual carbon dioxide production.

BIOMASS

http://www.nrel.gov/research/industrial_tech/biomass.html

Well-presented information on biomass from the US Department of Energy. A graph supports the textual explanation of the fact that the world is only using 7% of annual biomass production. There is a clear explanation of the chemical composition of biomass and development of technologies to transform it into usable fuel sources.

biome broad natural assemblage of plants and animals shaped by common patterns of vegetation and climate. Examples include the tundra biome and the desert biome.

biomechanics application of mechanical engineering principles and techniques in the field of medicine and surgery, studying natural structures to improve those produced by humans. For example, mother-of-pearl is structurally superior to glass fibre, and deer antlers have outstanding durability because they are composed of microscopic fibres. Such natural structures may form the basis of high-tech composites. Biomechanics has been responsible for many recent advances in orthopaedics, anaesthesia, and intensive care. Biomechanical assessment of the requirements for replacement of joints, including evaluation of the stresses and strains between parts, and their reliability, has allowed development of implants with very low friction and long life.

biometrics in computing, biometrics is applied loosely to the measurement of biological (human) data, usually for security purposes, rather than the statistical analysis of biological data. For example, when someone wants to enter a building or cash a cheque, their finger or eyeball may be scanned and compared with a fingerprint or eyeball scan stored earlier. Biometrics saves people from having to remember PINs (personal identification numbers) and passwords.

biometry literally, the measurement of living things, but generally used to mean the application of mathematics to biology. The term is now largely obsolete, since mathematical or statistical work is an integral part of most biological disciplines.

bionics from 'biological electronics' design and development of electronic or mechanical artificial systems that imitate those of living things. The bionic arm, for example, is an artificial limb (prosthesis) that uses electronics to amplify minute electrical signals generated in body muscles to power electric motors, which operate the joints of the fingers and wrist.

The first person to receive two bionic ears was Peter Stewart, an Australian journalist, 1989. His left ear was fitted with an array of 22 electrodes, replacing the hairs that naturally convert sounds into electrical impulses. Five years previously he had been fitted with a similar device in his right ear.

biophysics application of physical laws to the properties of living organisms. Examples include using the principles of mechanics to calculate the strength of bones and muscles, and thermodynamics to study plant and animal energetics.

biopsy removal of a living tissue sample from the body for diagnostic examination.

biorhythm rhythmic change, mediated by hormones, in the physical state and activity patterns of certain plants and animals that have seasonal activities. Examples include winter hibernation, spring flowering or breeding, and periodic migration. The hormonal changes themselves are often a response to changes in day length (photoperiodism); they signal the time of year to the animal or plant. Other biorhythms are innate and continue even if external stimuli such as day length are removed. These include a 24-hour or circadian rhythm, a 28-day or circalunar rhythm (corresponding to the phases of the Moon), and even a year-long rhythm in some organisms.

Such innate biorhythms are linked to an internal or biological clock, whose mechanism is still poorly understood.

Often both types of rhythm operate; thus many birds have a circalunar rhythm that prepares them for the breeding season, and a photoperiodic response. There is also a nonscientific and unproven theory that human activity is governed by three biorhythms: the intellectual (33 days), the emotional (28 days), and the physical (23 days). Certain days in each cycle are regarded as 'critical', even more so if one such day coincides with that of another cycle.

BIOS (acronym for *basic input/output system*) in computing, the part of the operating system that handles input and output. The term is also used to describe the programs stored in ROM (and called ROM BIOS), which are automatically run when a computer

is switched on allowing it to boot. BIOS is unaffected by upgrades to the operating system stored on disc.

biosensor device based on microelectronic circuits that can directly measure medically significant variables for the purpose of diagnosis or monitoring treatment. One such device measures the blood sugar level of diabetics using a single drop of blood, and shows the result on a liquid crystal display within a few minutes.

biosphere the narrow zone that supports life on our planet. It is limited to the waters of the Earth, a fraction of its crust, and the lower regions of the atmosphere.

BioSphere 2 (BS2) ecological test project, a 'planet in a bottle', in Arizona, USA. Under a sealed glass and metal dome, different habitats are recreated, with representatives of nearly 4,000 species, to test the effects that various environmental factors have on ecosystems. Simulated ecosystems, or 'mesocosms', include savanna, desert, rainforest, marsh and Caribbean reef. The response of such systems to elevated atmospheric concentrations of carbon dioxide gas (CO₂) are among the priorities of Biosphere 2 researchers.

BioSphere 1 Experiments with biospheres that contain relatively simple life forms have been carried out for decades, and a 21-day trial period in 1989 that included humans preceded the construction of BS2. However, BS2 is not in fact the second in a series: the Earth is considered to be Biosphere 1.

human inhabitants Originally, people, called 'Biospherians', were sealed in the dome. The people within were self-sufficient, except for electricity, which was supplied by a 3.7 megawatt power station on the outside (solar panels were considered too expensive). The original team of eight in residence 1991-1993 was replaced March 1994 with a new team of seven people sealed in for six-and-a-half months. In 1995 it was decided that further research would not involve sealing people within the biosphere. Researchers, students, and visitors routinely go in and out of the Biosphere 2 facility.

organization Biosphere 2 was originally run by a private company partly funded by ecology-minded oil millionaire Edward P Bass (1945-) and was called Space Biosphere Ventures. Space Biosphere Ventures investors expected to find commercial applications for the techniques developed in the course of the project. As of 1 January 1996 Columbia University, USA, joined Space Biosphere Ventures to form Biosphere 2 Center, Inc. The purpose of the joint venture is to use the facility for conferences and classes as well as further short-term experiments with the artificial ecosystems that do not involve isolating humans inside.

biosynthesis synthesis of organic chemicals from simple inorganic ones by living cells - for example, the conversion of carbon dioxide and water to glucose by plants during photosynthesis.

Other biosynthetic reactions produce cell constituents including proteins and fats.

biotechnology industrial use of living organisms to manufacture food, drugs, or other products. The brewing and baking industries have long relied on the yeast microorganism for fermentation purposes, while the dairy industry employs a range of bacteria and fungi to convert milk into cheeses and yoghurts. Enzymes, whether extracted from cells or produced artificially, are central to most biotechnological applications.

Recent advances include genetic engineering, in which single-celled organisms with modified cDNA are used to produce insulin and other drugs.

In 1993 two-thirds of biotechnology companies were concentrating on human health developments, whilst only 1 in 10 were concerned with applications for food and agriculture.

biotic factor organic variable affecting an ecosystem - for example, the changing population of elephants and its effect on the African savanna.

biotin or **vitamin H** vitamin of the B complex, found in many different kinds of food; egg yolk, liver, legumes, and yeast contain large amounts. Biotin is essential to the metabolism of fats. Its absence from the diet may lead to dermatitis.

birch any of a group of slender trees with small leaves and fine, peeling bark. About 40 species are found in cool temperate parts of

the northern hemisphere. Birches grow rapidly, and their hard, beautiful wood is used for veneers and cabinet work. (Genus *Betula*, family Betulaceae.)

bird backbone animal of the class Aves, the biggest group of land vertebrates, characterized by warm blood, feathers, wings, breathing through lungs, and egg-laying by the female. Birds are bipedal; feet are usually adapted for perching and never have more than four toes. Hearing and eyesight are well developed, but the sense of smell is usually poor. No existing species of bird possesses teeth.

Most birds fly, but some groups (such as ostriches) are flightless, and others include flightless members. Many communicate by sounds (nearly half of all known species are songbirds) or by visual displays, in connection with which many species are brightly coloured, usually the males. Birds have highly developed patterns of instinctive behaviour. There are nearly 8,500 species of birds.

According to the Red List of endangered species published by the World Conservation Union (IUCN) for 1996, 11% of bird species are threatened with extinction.

wing structure The wing consists of the typical bones of a forelimb, the humerus, radius and ulna, carpus, metacarpus, and digits. The first digit is the pollex, or thumb, to which some feathers, known as alulae, or bastard wing, are attached; the second digit is the index, which bears the large feathers known as the primaries or manuals, usually ten in number. The primary feathers, with the secondaries or cubitals, which are attached to the ulna, form the large wing-quills, called remiges, which are used in flight.

anatomy The sternum, or breastbone, of birds is affected by their powers of flight: those birds which are able to fly have a keel projecting from the sternum and serving as the basis of attachment of the great pectoral muscles which move the wings. In birds that do not fly the keel is absent or greatly reduced. The vertebral column is completed in the tail region by a flat plate known as the pygostyle, which forms a support for the rectrices, or steering tailfeathers.

The legs are composed of the femur, tibia and fibula, and the bones of the foot; the feet usually have four toes, but in many cases there are only three. In swimming birds the legs are placed well back.

BIRD

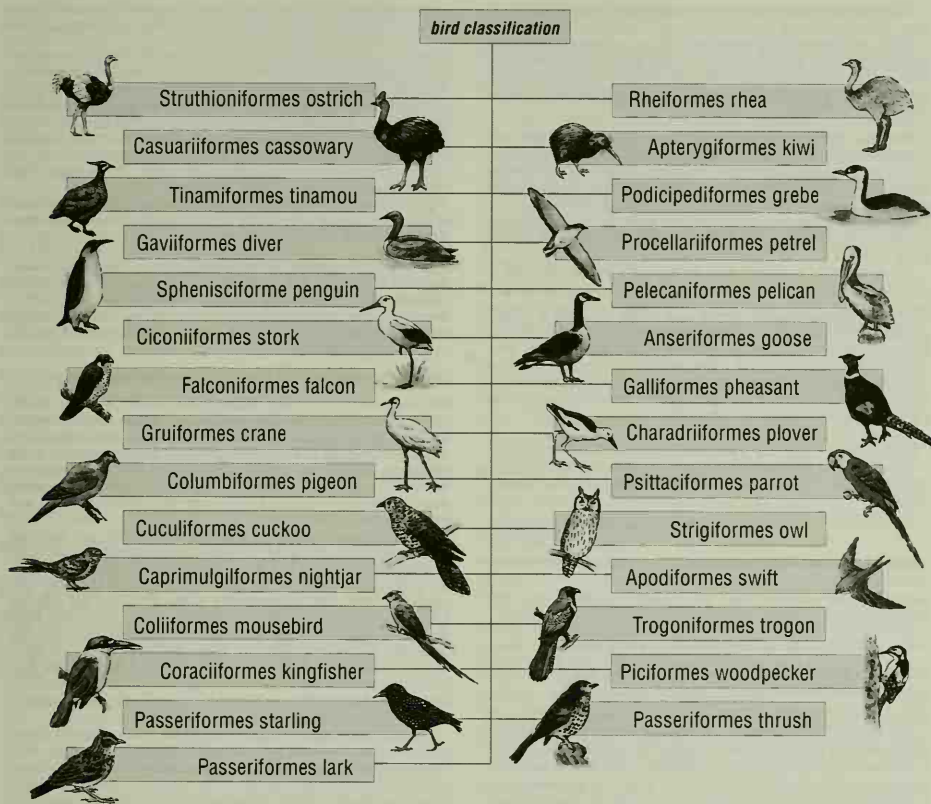

Rifleman, short-tailed pygmy tyrant, frilled coquette, bobwhite, tawny frogmouth, trembler, wattle-eye, fuscous honeyeater, dickcissel, common grackle, and forktailed drongo are all common names for species of bird.

The uropygial gland on the pygostyle (bone in the tail) is an oil gland used by birds in preening their feathers, as their skin contains no sebaceous glands. The eyes have an upper and a lower eyelid and a semi-transparent nictitating membrane with which the bird can cover its eyes at will.

The vascular system contains warm blood, which is kept usually at a higher temperature (about 41°C/106°F) than that of mammals; death from cold is rare unless the bird is starving or ill. The aortic arch (main blood vessel leaving the heart) is on the right side of a bird, whereas it is on the left in a mammal. The heart of a bird consists of a right and a left half with four chambers.

The lungs are small and prolonged into air-sacs connected to a number of air-spaces in the bones. These air-spaces are largest in powerful fliers, but they are not so highly developed in young, small, aquatic, and terrestrial birds. These air-spaces increase the efficiency of the respiratory system and reduce the weight of the bones. The lungs themselves are more efficient than those of mammals; the air is circulated through a system of fine capillary tubes, allowing continuous gas exchange to take place, whereas in mammals the air comes to rest in blind air sacs.

The organ of voice is not the larynx, but usually the syrinx, a peculiarity of this class formed at the bifurcation of the trachea (windpipe) and the modulations are effected by movements of the adjoining muscles.

bird This diagram shows a representative species from each of the 29 orders. There are nearly 8,500 species of birds, of which the largest is the N African ostrich, reaching a height of 2.74 m/9 ft and weighing 156 kg/345 lb. The smallest bird, the bee hummingbird of Cuba and the Isle of Pines, measures 57 mm/2.24 in in length and weighs a mere 1.6 g/0.056 oz.

digestion Digestion takes place in the oesophagus, stomach, and intestines in a manner basically similar to mammals. The tongue aids in feeding, and there is frequently a crop, a dilation of the oesophagus, where food is stored and softened. The stomach is small with little storage capacity and usually consists of the proventriculus, which secretes digestive juices, and the gizzard, which is tough and muscular and grinds the food, sometimes with the aid of grit and stones retained within it. Digestion is completed, and absorption occurs, in the intestine and the digestive caeca. The intestine ends in a cloaca through which both urine and faeces are excreted.

nesting and eggs Typically eggs are brooded in a nest and, on hatching, the young receive a period of parental care. The collection of nest material, nest building, and incubation may be carried out by the male, female, or both. The cuckoo neither builds a nest nor rears its own young, but places the eggs in the nest of another bird and leaves the foster parents to care for them.

The study of birds is called ornithology.

bird louse parasitic biting louse, found mainly on birds, less frequently on mammals. Bird lice are wingless ectoparasites (living on the skin of their hosts), have biting mouthparts (as opposed to true lice which have sucking mouthparts), and reduced eyes.

classification Bird lice are in the order Mallophaga, class Insecta, phylum Arthropoda.

The chicken body louse *Menacanthus stramineus* is small, yellowish, and about 2.8–3.3 mm/0.1–0.13 in long. The parasite feeds on the skin debris and feathers of the chicken. A heavily infested bird can carry over 8,000 lice on its body. The host appears to withstand the usual degree of infestation without apparent ill-effects, but heavy infestation can result in loss of plumage and a decline in the bird's health.

bird of paradise one of 40 species of crowlike birds in the family Paradisidae, native to New Guinea and neighbouring islands. Females are generally drably coloured, but the males have bright and elaborate plumage used in courtship display. Hunted almost

to extinction for their plumage, they are now subject to conservation.

They are smallish birds, extremely active, and have compressed beaks, large toes, and strong feet. Their food consists chiefly of fruits, seeds, and nectar, but it may also include insects and small animals, such as worms. The Australian clobberbirds are closely related.

Birman or 'sacred cat of Burma' breed of domestic cat with medium-length fur, possibly originating in the temples of Burma. Similar to a cColourpoint Longhair or Himalayan cat, the Birman has shorter hair, legs with a longer body. In Britain, the Blue-point variety's fur is beige-gold with blue-grey points (dark face, tail, and legs), with white paws; the US standard calls for bluish-white fur and deep blue points. It has brilliant blue eyes. There are several other varieties.

Birmans were recognized as a breed in France in 1925 and in the USA in 1926.

birth act of producing live young from within the body of female animals. Both viviparous and ovoviviparous animals give birth to young. In viviparous animals, embryos obtain nourishment from the mother via a placenta or other means.

In ovoviviparous animals, fertilized eggs develop and hatch in the oviduct of the mother and gain little or no nourishment from maternal tissues. See also cpregnancy.

There's a time when you have to explain to your children why they're born, and it's a marvelous thing if you know the reason by then.

HAZEL SCOTT US entertainer.
Quoted in Ms. Nov 1974

birth control another name for cfamily planning; see also ccontraceptive.

bisect to divide a line or angle into two equal parts.

bisector a line that bisects an angle or another line (known as a perpendicular bisector when it bisects at right angles).

bismuth hard, brittle, pinkish-white, metallic element, symbol Bi, atomic number 83, relative atomic mass 208.98. It has the highest atomic number of all the stable elements (the elements from atomic number 84 up are radioactive). Bismuth occurs in ores and occasionally as a free metal (cnative metal). It is a poor conductor of heat and electricity, and is used in alloys of low melting point and

in medical compounds to soothe gastric ulcers. The name comes from the Latin *besemutum*, from the earlier German *Wismut*.

bison large, hoofed mammal of the bovine family. There are two species, both brown. The European bison or wisent *Bison bonasus*, of which only a few protected herds survive, is about 2 m/7 ft high and weighs up to 1,100 kg/2,500 lb. The North American bison (often known as 'buffalo') *Bison bison* is slightly smaller, with a heavier mane and more sloping hindquarters. Formerly roaming the prairies in vast numbers, it was almost exterminated in the 19th century, but survives in protected areas. There were about 14,000 bison in North American reserves in 1994.

Crossed with domestic cattle, the latter has produced a hardy hybrid, the 'beefalo', producing a lean carcass on an economical grass diet.

bistable circuit or *flip-flop* simple electronic circuit that remains in one of two stable states until it receives a pulse (logic 1 signal) through one of its inputs, upon which it switches, or 'flips', over to the other state. Because it is a two-state device, it can be used to store binary digits and is widely used in the cintegrated circuits used to build computers.

bisulphate another term for chydrogen sulphate.

bit (contraction of *binary digit*) in computing, a single binary digit, either 0 or 1. A bit is the smallest unit of data stored in a computer; all other data must be coded into a pattern of individual bits. A cbyte represents sufficient computer memory to store a single ccharacter of data, and usually contains eight bits. For example, in the cASCII code system used by most microcomputers the capital letter A would be stored in a single byte of memory as the bit pattern 01000001.

The maximum number of bits that a computer can normally process at once is called a word. Microcomputers are often described according to how many bits of information they can handle at once. For instance, the first microprocessor, the Intel 4004 (launched 1971), was a 4-bit device. In the 1970s several different 8-bit computers, many based on the Zilog Z80 or Rockwell 6502 processors, came into common use. In 1981, the IBM Personal Computer (PC) was introduced, using the Intel 8088 processor, which combined a 16-bit processor with an 8-bit cdata bus. Business micros of the later 1980s began to use 32-bit processors such as the Intel 80386 and Motorola 68030. Machines based on the first 64-bit microprocessor appeared in 1993.

The higher the number of bits a computer can process simultaneously, the more powerful the computer is said to be. However, other factors influence the overall speed of a computer system, such as the cclock rate of the processor and the amount of cRAM available. Tasks that require a high processing speed include sorting a data-

bit map The difference in close-up between a bit-mapped and vector font. As separate sets of bit maps are required for each different type size, scaleable vector graphics (outline) is the preferred medium for fonts.

base or doing long, complex calculations in spreadsheets. A system running slowly with a graphical user interface may benefit more from the addition of extra RAM than from a faster processor.

In the PC industry, new hardware is most readily adopted when it is compatible with old software, which slows the adoption of new software. For example, most people were still using Microsoft's 16-bit Windows 3 program with 16-bit applications in 1995-96, a decade after 32-bit processors like Intel's 80386 became widely available. This was true even though 32-bit operating systems - Unix, IBM's OS/2 and Microsoft's Windows NT - had been available for some years.

bit map in computing, a pattern of bits used to describe the organization of data. Bit maps are used to store typefaces or graphic images (bit-mapped or raster graphics), with 1 representing black (or a colour) and 0 white.

Bit maps may be used to store a typeface or font, but a separate set of bit maps is required for each typeface. A vector font, by contrast, can be held as one set of data and scaled as required. Bit-mapped graphics are not recommended for images that require scaling (compare vector graphics - those stored in the form of geometric formulas).

bit-mapped font font held in computer memory as sets of bit maps.

Bitnet (acronym for *Because It's Time Network*) news network developed in 1983 at the City University of New York, USA. Bitnet operates as a collection of mailing lists using Listserv, which was picked up by the rest of the Internet and is widely used, although Bitnet itself is falling into disuse.

bit pad computer input device; see graphics tablet.

bits per second (bps) commonly used measure of the speed of transmission of a modem. In 1997 the fastest modems readily available were rated at 33,600 bps, with two incompatible 56K systems also competing for sales. Modem speeds should conform to standards, known as V numbers, laid down by the Comité Consultatif International Téléphonique et Télégraphique (CCITT) so that modems from different manufacturers can connect to each other. Many modems transfer data much faster than their nominal speeds via techniques such as data compression.

bitterling freshwater fish *Rhodeus sericeus* of Northern Europe, introduced to North America. It grows to a length of 90 mm/3.5 in. and has an attractive bluish stripe along each side towards the tail. It is found in lakes and slow-moving rivers.

Having selected a mate, the female bitterling deposits her eggs inside a freshwater mussel via a long tube protruding from her body, and the male then deposits his sperm into the mussel. The eggs are nurtured safe from predators (and unharmed by the mussel) within the mussel's gills for two to three weeks before hatching and swimming away.

bittern any of several species of small herons, in particular the common bittern *Botaurus stellaris* of Europe and Asia. It is shy, stoutly built, buff-coloured, speckled with black and tawny brown, with a long bill and a loud, booming call. Its habit of holding its neck and bill in a vertical position conceals it among the reeds, where it rests by day, hunting for frogs, reptiles, and fish towards nightfall. An inhabitant of marshy country, it is now quite rare in Britain.

bittersweet alternative name for the woody nightshade plant.

bitumen impure mixture of hydrocarbons, including such deposits as petroleum, asphalt, and natural gas, although sometimes the term is restricted to a soft kind of pitch resembling asphalt.

Solid bitumen may have arisen as a residue from the evaporation of petroleum. If evaporation took place from a pool or lake of petroleum, the residue might form a pitch or asphalt lake, such as Pitch Lake in Trinidad. Bitumen was used in ancient times as a mortar, and by the Egyptians for embalming.

bivalent in biology, a name given to the pair of homologous chromosomes during reduction division (meiosis). In chemistry, the

term is sometimes used to describe an element or group with a valency of two, although the term 'divalent' is more common.

bivalve marine or freshwater mollusc whose body is enclosed between two shells hinged together by a ligament on the dorsal side of the body.

The shell is closed by strong 'adductor' muscles. Ventrally, a retractile 'foot' can be put out to assist movement in mud or sand. Two large platelike gills are used for breathing and also, with the cilia present on them, make a mechanism for collecting the small particles of food on which bivalves depend. The bivalves form one of the five classes of molluscs, the Lamellibranchiata, otherwise known as Bivalvia or Pelycypoda, containing about 8,000 species.

black beetle another name for cockroach, although cockroaches belong to an entirely different order of insects (Dictyoptera) from the beetles (Coleoptera).

blackberry prickly shrub, closely related to raspberries and dewberries. Native to northern parts of Europe, it produces pink or white blossom and edible black compound fruits. (*Rubus fruticosus*, family Rosaceae.)

blackbird bird *Turdus merula* of the thrush family, Muscicapidae, order Passeriformes, about 25 cm/10 in long. The male is black with a yellow bill and eyelids, the female dark brown with a dark beak. It lays three to five blue-green eggs with brown spots in a nest of grass and moss, plastered with mud, built in thickets or creeper-clad trees. The blackbird feeds on fruit, seeds, worms, grubs, and snails. Its song is rich and flute-like.

Found across Europe, Asia, and North Africa, the blackbird adapts well to human presence and gardens, and is one of the most common British birds. North American 'blackbirds' belong to a different family of birds, the Icteridae.

black body in physics, a hypothetical object that completely absorbs all electromagnetic radiation striking it. It is also a perfect emitter of thermal radiation.

Although a black body is hypothetical, a practical approximation can be made by using a small hole in the wall of a constant-temperature enclosure. The radiation emitted by a black body is of all wavelengths, but with maximum radiation at a particular wavelength that depends on the body's temperature. As the temperature increases, the wavelength of maximum intensity becomes shorter (see Wien's displacement law). The total energy emitted at all wavelengths is proportional to the fourth power of the temperature (see Stefan-Boltzmann law). Attempts to explain these facts failed until the development of quantum theory in 1900.

black box popular name for the unit containing an aeroplane's flight and voice recorders. These monitor the plane's behaviour and the crew's conversation, thus providing valuable clues to the cause of a disaster. The box is nearly indestructible and usually painted orange for easy recovery. The name also refers to any compact electronic device that can be quickly connected or disconnected as a unit.

The maritime equivalent is the voyage recorder, installed in ships from 1989. It has 350 sensors to record the performance of engines, pumps, navigation lights, alarms, radar, and hull stress.

blackbuck antelope *Antelope cervicapra* found in central and NW India. It is related to the gazelle, from which it differs in having spirally-twisted horns. The male is black above and white beneath, whereas the female and young are fawn-coloured above.

It is about 76 cm/2.5 ft in height.

blackcap warbler *Sylvia atricapilla*, family Muscicapidae, order Passeriformes. The male has a black cap, the female a reddish-brown one. The general colour of the bird is an ashen-grey, turning to an olive-brown above and pale or whitish-grey below. About 14 cm/5.5 in long, the blackcap likes wooded areas, and is a summer visitor to N Europe, wintering in Africa.

blackcock or **heathcock** large grouse *Lyrurus tetrix* found on moors and in open woods in N Europe and Asia. The male is mainly black with a lyre-shaped tail, and grows up to 54 cm/1.7 ft in height. The female is speckled brown and only 40 cm/1.3 ft tall.

Their food consists of buds, young shoots, berries, and insects.

Blackcocks are polygamous, and in the spring males attract females by curious crowings. In males a piece of bright red skin above the eyes also becomes more intense during the pairing season.

They are related to the quail, partridge, and capercaillie, in the order Galliformes.

blackcurrant variety of currant.

Black Death great epidemic of bubonic plague that ravaged Europe in the mid-14th century, killing between one-third and half of the population (about 75 million people). The cause of the plague was the bacterium *Yersinia pestis*, transmitted by fleas borne by migrating Asian black rats. The name Black Death was first used in England in the early 19th century.

black earth exceedingly fertile soil that covers a belt of land in NE North America, Europe, and Asia.

In Europe and Asia it extends from Bohemia through Hungary, Romania, S Russia, and Siberia, as far as Manchuria, having been deposited when the great inland ice sheets melted at the close of the last ice age. In North America, it extends from the Great Lakes east through New York State, having been deposited when the last glaciers melted and retreated from the terminal moraine.

blackfly plant-sucking insect, a type of *Chironomus*.

blackfly small but stoutly built blood-sucking flies with short antennae. Blackflies have broad wings with all the obvious veins in the anterior part of the wing. The family is widely distributed, the adults often occurring in such large numbers as to make them a nuisance. They are most abundant in north temperate and subarctic regions.

classification Blackflies are in family Simuliidae, order Diptera, class Insecta, phylum Arthropoda.

There are six larval stages that are found in running water, including cascades and waterfalls; they have a well capsulated head, a solitary thoracic proleg and a posterior sucker composed of small hooks by which they anchor themselves against the current. They are found on stones, reeds, mayfly larvae, and other aquatic forms. The pupae usually rest in a tent of silk in similar situations to the larvae.

Simulium species are the vectors of chonchocerciasis in Central and South America, Africa, and the Yemen. They also transmit other filarial worms to cattle and to ducks. Blackflies are vectors of a large number of avian malaras to many birds including domestic stock, turkeys, ducks, and geese in North America and Canada. In addition, number of blackflies attacking livestock can be so great, and the attacks so fierce, as to kill the livestock, and human deaths have also occurred.

black hole object in space whose gravity is so great that nothing can escape from it, not even light. Thought to form when massive stars shrink at the end of their lives, a black hole sucks in more matter, including other stars, from the space around it. Matter that falls into a black hole is squeezed to infinite density at the centre of the hole. Black holes can be detected because gas falling towards them becomes so hot that it emits X-rays.

Black holes containing the mass of millions of stars are thought to lie at the centres of quasars. Satellites have detected X-rays from a number of objects that may be black holes, but only four likely black holes in our Galaxy had been identified by 1994.

blacksnake any of several species of snake. The blacksnake *Pseustes porphyreus* is a venomous snake of the cobra family found in damp forests and swamps in E Australia. The blacksnake, *Colester constrictor* from the eastern USA, is a relative of the European grass snake, growing up to 1.2 m/4 ft long, and without venom.

blackthorn densely branched spiny European bush. It produces white blossom on bare black branches in early spring. Its sour plumlike blue-black fruit, the sloe, is used to make sloe gin. (*Prunus spinosa*, family Rosaceae.)

Blackwell, Elizabeth (1821-1910) English-born US physician, the first woman to qualify in medicine in the USA in 1849, and the

black widow The term 'black widow' covers a number of different species of *Latrodectus* spiders including *L. mactans*, the southern black widow from the New World. The name derives from the generally held belief that the female spider invariably eats the male after mating. Recent observations indicate that this may be the case in only a few species. Premaphotos Wildlife

first woman to be recognized as a qualified physician in the UK in 1869.

black widow North American spider *Latrodectus mactans*. The male is small and harmless, but the female is 1.3 cm/0.5 in long with a red patch below the abdomen and a powerful venomous bite. The bite causes pain and fever in human victims, but they usually recover.

bladder hollow elastic-walled organ which stores the urine produced in the kidneys. It is present in the urinary systems of some fishes, most amphibians, some reptiles, and all mammals. Urine enters the bladder through two ureters, one leading from each kidney, and leaves it through the urethra.

bladderwort any of a large group of carnivorous aquatic plants. They have leaves with bladders (hollow sacs) that trap small animals living in the water. (Genus *Utricularia*, family Lentibulariaceae.)

blast freezing industrial method of freezing substances such as foods by blowing very cold air over them.

blast furnace smelting furnace used to extract metals from their ores, chiefly pig iron from iron ore. The temperature is raised by the injection of an air blast.

In the extraction of iron the ingredients of the furnace are iron ore, coke (carbon), and limestone. The coke is the fuel and provides the carbon monoxide for the reduction of the iron ore; the limestone acts as a flux, removing impurities.

blastocyst in mammals, the hollow ball of cells which is an early stage in the development of the embryo, roughly equivalent to the blastula of other animal groups.

blastomere in biology, a cell formed in the first stages of embryonic development, after the splitting of the fertilized ovum, but before the formation of the blastula or blastocyst.

blastula early stage in the development of a fertilized egg, when the egg changes from a solid mass of cells (the morula) to a hollow ball of cells (the blastula), containing a fluid-filled cavity (the blastocoel). See also embryology.

bleaching decolorization of coloured materials. The two main types of bleaching agent are the oxidizing bleaches, which bring about the oxidation of pigments and include the ultraviolet rays in sunshine, hydrogen peroxide, and chlorine in household bleaches, and the reducing bleaches, which bring about reduction and include sulphur dioxide.

blast furnace The blast furnace is used to extract iron from a mixture of iron ore, coke, and limestone. The less dense impurities float above the molten iron and are tapped off as slag. The molten iron sinks to the bottom of the furnace and is tapped off into moulds referred to as pigs. The iron extracted this way is also known as pig iron.

blenny Blennies are normally found in coastal rockpools. However, the E African species *Omobranchius striatus*, seen here, spends much of its time out of water, in groups on rocks beside the pool, ready to flip quickly into the water when danger threatens. *Premaphotos Wildlife*

Bleaching processes have been known from antiquity, mainly those acting through sunlight. Both natural and synthetic pigments usually possess highly complex molecules, the colour property often being due only to a part of the molecule. Bleaches usually attack only that small part, yielding another substance similar in chemical structure but colourless.

bleak freshwater fish *Alburnus alburnus* of the carp family. It is up to 20 cm/8 in long, and lives in still or slow-running clear water in Britain and Europe.

In Eastern Europe its scales are used in the preparation of artificial pearls.

bleeding loss of blood from the circulation; see *chaemorrhage*.

blenny any fish of the family Blenniidae, mostly small fish found near rocky shores, with elongated slimy bodies tapering from head to tail, no scales, and long pelvic fins set far forward.

blesbok African antelope *Damaliscus albifrons*, about 1 m/3 ft high, with curved horns, brownish body, and a white blaze on the face. It was seriously depleted in the wild at the end of the 19th century. A few protected herds survive in South Africa. It is farmed for meat.

blesbok Blesbok antelopes, which live on the African savanna, are now scarce. Blesbok males are highly territorial and spend a great deal of time standing near a central dung-heap, attracting females to their harem and driving off rival males. *Premaphotos Wildlife*

blight any of a number of plant diseases caused mainly by parasitic species of fungus, which produce a whitish appearance on leaf and stem surfaces; for example, **potato blight** *Phytophthora infestans*. General damage caused by aphids or pollution is sometimes known as blight.

In 1998 a new virulent strain of *P. infestans*, US-8, was decimating potato and tomato crops throughout the US and eastern Canada, proving to be resistant to previously effective fungicides.

blind carbon copy e-mail message sent to multiple recipients who do not know each other's identities. The facility for blind carbon copies is built into some e-mail software, and is useful in eliminating long lists of recipients which clutter up a mass-distribution message; it also protects the confidentiality of a particular user's contact list.

blindness complete absence or impairment of sight. It may be caused by heredity, accident, disease, or deterioration with age.

Age-related macular degeneration (AMD), the commonest form of blindness, occurs as the retina gradually deteriorates with age. It affects 1% of people over the age of 70, with many more experiencing marked reduction in sight.

Retinitis pigmentosa, a common cause of blindness, is a hereditary disease affecting 1.2 million people worldwide.

Education of the blind was begun by Valentin Haüy, who published a book with raised lettering in 1784, and founded a school. Aids to the blind include the use of the Braille and Moon alphabets in reading and writing. Guide dogs for the blind were first trained in Germany for soldiers blinded in World War I.

Science without religion is lame. Religion without science is blind.

ALBERT EINSTEIN German-born US scientist.

Quoted in A Pais 'Subtle is the Lord...'

The Science and the Life of Albert Einstein 1982

blind signature encryption technique that authenticates a message without revealing any information about the sender. Blind signatures are one element in the attempt to develop technology that protects individual privacy as more and more transactions take place over public networks where users' activities can be tracked.

blind spot area where the optic nerve and blood vessels pass through the retina of the eye. No visual image can be formed as there are no light-sensitive cells in this part of the retina.

Thus the organism is blind to objects that fall in this part of the visual field.

blindworm another name for a cslow-worm.

blink in communications, to log on using an offline reader or other software that uses automated scripts. Blinking saves on communications and telephone charges, but it changes the nature of online interaction because users cannot use chat facilities.

Blinking also encourages repetition, since users replying off-line are unlikely to realize they are echoing each others' comments.

On AmericaOnline, a blink is called a **flashsession**.

blister beetle or **oil beetle** any of a small group of medium sized (3–20 mm/0.1–0.8 in) often brightly coloured beetles. Most give off an evil-smelling liquid, containing the irritant cantharidin, from the joints of their legs as a defence mechanism. When in contact with human skin, the liquid causes inflammation and blisters.

classification Blister beetles are members of the family Meloidae, order Coleoptera, class Insecta, phylum Arthropoda.

The general characteristics of the group include: head strongly bent downwards, narrow neck, and cylindrical and fairly soft body.

The **Spanish fly** *Lytta vesicatoria* was used to produce cantharidin for medicinal purposes, when blistering was a common medical treatment.

BL Lacertae object starlike object that forms the centre of a distant galaxy, with a prodigious energy output. BL Lac objects, as

they are called, seem to be related to quasars and are thought to be the brilliant nuclei of elliptical galaxies. They are so named because the first to be discovered lies in the small constellation Lacerta.

BLOB in computing, contraction of binary large object.

block in computing, a group of records treated as a complete unit for transfer to or from backing storage. For example, many discs drives transfer data in 512-byte blocks.

block and tackle type of pulley.

blocking software any of various software programs that work on the World Wide Web to block access to categories of information considered offensive or dangerous. Typically used by parents or teachers to ensure that children do not see pornographic or other adult material, some blocking products additionally allow the blocking of personal information such as home addresses and telephone numbers; some people regard this as censorship.

Blocking software became even more controversial in mid-1996 when Washington DC-based reporters Brock Meeks and Declan McCullagh revealed that the list of banned sites in some popular products included political material and that some sites were blocked indiscriminately.

Popular blocking software products include Net Nanny, SurfWatch, CyberPatrol, and CyberSitter.

blood fluid circulating in the arteries, veins, and capillaries of vertebrate animals; the term also refers to the corresponding fluid in those invertebrates that possess a closed circulatory system. Blood carries nutrients and oxygen to each body cell and removes waste products, such as carbon dioxide. It is also important in the immune response and, in many animals, in the distribution of heat throughout the body.

In humans blood makes up 5% of the body weight, occupying a volume of 5.5 l/10 pt in the average adult. It is composed of a colourless, transparent liquid called **plasma**, in which are suspended microscopic cells of three main varieties:

Red cells (erythrocytes) form nearly half the volume of the blood, with about 6 million red cells in every millilitre of an adult's blood. Their red colour is caused by haemoglobin.

White cells (leucocytes) are of various kinds. Some (phagocytes) ingest invading bacteria and so protect the body from disease; these also help to repair injured tissues. Others (lymphocytes) produce antibodies, which help provide immunity.

Blood platelets (thrombocytes) assist in the clotting of blood.

Blood cells constantly wear out and die and are replaced from the bone marrow. Red blood cells die at the rate of 200 billion per day but the body produces new cells at an average rate of 9,000 million per hour.

To remember the functions of the blood:

OLD CHARLIE FOSTER HATES WOMEN HAVING DULL CLOTHES.

OXYGEN (TRANSPORT) / CARBON DIOXIDE (TRANSPORT) / FOOD /
HEAT / WASTE / HORMONES / DISEASE / CLOTTING

blood clotting complex series of events (known as the blood clotting cascade) that prevents excessive bleeding after injury. It is triggered by vitamin K. The result is the formation of a meshwork of protein fibres (fibrin) and trapped blood cells over the cut blood vessels.

When platelets (cell fragments) in the bloodstream come into contact with a damaged blood vessel, they and the vessel wall itself release the enzyme **thrombokinase**, which brings about the conversion of the inactive enzyme **prothrombin** into the active **thrombin**. Thrombin in turn catalyses the conversion of the soluble protein **fibrinogen**, present in blood plasma, to the insoluble **fibrin**. This fibrous protein forms a net over the wound that traps red blood cells and seals the wound; the resulting jellylike clot hardens on exposure to air to form a scab. Calcium, vitamin K, and a vari-

ety of enzymes called factors are also necessary for efficient blood clotting. ϕ Haemophilia is one of several diseases in which the clotting mechanism is impaired.

blood group any of the types into which blood is classified according to the presence or otherwise of certain ϕ antigens on the surface of its red cells. Red blood cells of one individual may carry molecules on their surface that act as antigens in another individual whose red blood cells lack these molecules. The two main antigens are designated A and B. These give rise to four blood groups: having A only (A), having B only (B), having both (AB), and having neither (O). Each of these groups may or may not contain the ϕ rhesus factor. Correct typing of blood groups is vital in transfusion, since incompatible types of donor and recipient blood will result in coagulation, with possible death of the recipient.

The ABO system was first described by Austrian scientist Karl Landsteiner in 1902. Subsequent research revealed at least 14 main types of blood group systems, 11 of which are involved with induced ϕ antibody production. Blood typing is also of importance in forensic medicine, cases of disputed paternity, and in anthropological studies.

bloodhound breed of dog that originated as a hunting dog in Belgium in the Middle Ages. Black and tan in colour, it has long, pendulous ears and distinctive wrinkled head and face. It grows to a height of about 65 cm/26 in. Its excellent powers of scent have been employed in tracking and criminal detection from very early times.

blood poisoning presence in the bloodstream of quantities of bacteria or bacterial toxins sufficient to cause serious illness.

blood pressure pressure, or tension, of the blood against the inner walls of blood vessels, especially the arteries, due to the muscular pumping activity of the heart. Abnormally high blood pressure (hypertension) may be associated with various conditions or arise with no obvious cause; abnormally low blood pressure (hypotension) occurs in ϕ shock and after excessive fluid or blood loss from any cause.

In mammals, the left ventricle of the ϕ heart pumps blood into the arterial system. This pumping is assisted by waves of muscular contraction by the arteries themselves, but resisted by the elasticity of the inner and outer walls of the same arteries. Pressure is greatest when the heart ventricle contracts (systole) and lowest when the ventricle relaxes (diastole), and pressure is solely maintained by the elasticity of the arteries. Blood pressure is measured in millimetres of mercury (the height of a column on the measuring instrument, a sphygmomanometer). Normal human blood pressure varies with age, but in a young healthy adult it is around 120/80 mm Hg; the first number represents the systolic pressure and the second the diastolic. Large deviations from this reading usually indicate ill health.

blood test laboratory evaluation of a blood sample. There are numerous blood tests, from simple typing to establish the ϕ blood group to sophisticated biochemical assays of substances, such as hormones, present in the blood only in minute quantities.

The majority of tests fall into one of three categories: haematology (testing the state of the blood itself), microbiology (identifying infection), and blood chemistry (reflecting chemical events elsewhere in the body). Before operations, a common test is haemoglobin estimation to determine how well a patient might tolerate blood loss during surgery.

blood transfusion see ϕ transfusion.

blood vessel tube that conducts blood either away from or towards the heart in multicellular animals. Freshly oxygenated blood is carried in the arteries – major vessels which give way to the arterioles (small arteries) and finally capillaries; deoxygenated blood is returned to the heart by way of capillaries, then venules (small veins) and veins.

bloodworm larvae of the ϕ midge. They are red because their blood plasma contains haemoglobin like human blood, which increases its ability to take up oxygen. This is of value to the larvae, which commonly burrow in the oxygen-poor mud bottom of pools and rivers. They feed on algae and detritus.

Bloodworms are long, with a distinct head, and segmentation of the abdomen. Prolegs (leglike projections) are found on the first thoracic and last abdominal segments. Gills are present on the last abdominal segment, and often on the segment preceding it. On average they measure 6 mm/0.2 in in length.

Bloodworms frequently build tubes of mud around themselves, which may be attached to stones. They constitute a major part of the diet of fish, hence they are often used as bait by anglers.

Not all midge larvae are red. Those that do not live in mud tubes, but frequent the surface waters, are green, and some species have blue bands.

bloom whitish powdery or waxlike coating over the surface of certain fruits that easily rubs off when handled. It often contains ϕ yeasts that live on the sugars in the fruit. The term bloom is also used to describe a rapid increase in number of certain species of algae found in lakes, ponds, and oceans.

Such blooms may be natural but are often the result of nitrate pollution, in which artificial fertilizers, applied to surrounding fields, leach out into the waterways. This type of bloom can lead to the death of almost every other organism in the water; because light cannot penetrate the algal growth, the plants beneath can no longer photosynthesize and therefore do not release oxygen into the water. Only those organisms that are adapted to very low levels of oxygen survive.

BLOWFLY

Blowfly larvae develop in less than two weeks. During this time they can gain 5% of their final larval weight each hour.

blowfly any fly of the genus *Calliphora*, also known as bluebottle, or of the related genus *Lucilia*, when it is greenbottle. It lays its eggs in dead flesh, on which the maggots feed.

blowfly Bluebottles *Calliphora vicina*, commonly known as blowfly, lay eggs on rotting flesh. Premaphotos Wildlife

blubber thick layer of ϕ fat under the skin of marine mammals, which provides an energy store and an effective insulating layer, preventing the loss of body heat to the surrounding water. Blubber has been used (when boiled down) in engineering, food processing, cosmetics, and printing, but all of these products can now be produced synthetically.

bluebell name given in Scotland to the ϕ harebell (*Campanula rotundifolia*), and in England to the wild hyacinth (*Endymion non-scriptus*), belonging to the lily family (Liliaceae).

blueberry any of various North American shrubs belonging to the heath family, growing in acid soil. The genus also includes huckleberries, bilberries, deerberries, and cranberries, many of which resemble each other and are difficult to tell apart from blueberries. All have small oval short-stalked leaves, slender green or reddish twigs, and whitish bell-like blossoms. Only true blueberries, however, have tiny granular speckles on their twigs. Blueberries have black or blue edible fruits, often covered with a white bloom. (Genus *Vaccinium*, family Ericaceae.)

bluebird or **blue robin** or **blue warbler** three species of a North American bird, genus *Sialia*, belonging to the thrush subfamily, Turdinae, order Passeriformes. The eastern bluebird *Sialia sialis* is regarded as the herald of spring as it returns from migration. About 18 cm/7 in long, it has a reddish breast, the upper plumage being sky-blue, and a distinctive song. It lays about six pale-blue eggs.

bluebottle another name for ♀blowfly.

bluebuck any of several species of antelope, including the blue ♂duiker *Cephalophus monticola* of South Africa, about 33 cm/13 in high. The male of the Indian nilgai antelope is also known as the bluebuck.

The bluebuck or blaubok, *Hippotragus leucophaeus*, was a large blue-grey South African antelope. Once abundant, it was hunted to extinction, the last being shot in 1800.

bluegrass dense spreading grass, which is blue-tinted and grows in clumps. Various species are known from the northern hemisphere. Kentucky bluegrass (*Poa pratensis*), introduced to the USA from Europe, provides pasture for horses. (Genus *Poa*, family Gramineae.)

blue-green algae or **cyanobacteria** single-celled, primitive organisms that resemble bacteria in their internal cell organization, sometimes joined together in colonies or filaments. Blue-green algae are among the oldest known living organisms and, with bacteria, belong to the kingdom Monera; remains have been found in rocks up to 3.5 billion years old. They are widely distributed in aquatic habitats, on the damp surfaces of rocks and trees, and in the soil.

Blue-green algae and bacteria are prokaryotic organisms. Some can fix nitrogen and thus are necessary to the nitrogen cycle, while others follow a symbiotic existence – for example, living in association with fungi to form lichens. Fresh water can become polluted by nitrates and phosphates from fertilizers and detergents. This eutrophication, or overenrichment, of the water causes multiplication of the algae in the form of algae blooms. The algae multiply and cover the water's surface, remaining harmless until they give off toxins as they decay. These toxins kill fish and other wildlife and can be harmful to domestic animals, cattle, and people.

blue gum either of two Australian trees: Tasmanian blue gum (*Eucalyptus globulus*) of the myrtle family, with bluish bark, a chief source of eucalyptus oil; or the tall, straight Sydney blue gum (*E. saligna*). The former is widely cultivated in California and has also been planted in South America, India, parts of Africa, and S Europe.

blueprint photographic process used for copying engineering drawings and architectural plans, so called because it produces a white copy of the original against a blue background.

The plan to be copied is made on transparent tracing paper, which is placed in contact with paper sensitized with a mixture of iron ammonium citrate and potassium hexacyanoferrate. The paper is exposed to ultraviolet radiation and then washed in water. Where the light reaches the paper, it turns blue (Prussian blue). The paper underneath the lines of the drawing is unaffected, so remains white.

blue-ribbon campaign campaign for free speech on the Internet. It was launched to protest against various international moves towards censorship on the Internet, especially the Communications Decency Act in 1996. Participation in the campaign is indicated by the small graphic of a looped blue ribbon

displayed on many sites on the World Wide Web and available from the campaign's Web site <http://www.eff.org/blueribbon.html>.

blue shark species of ♀shark with a blue back and white underside. It grows to a length of at least 7 m/23 ft and is found in all oceanic waters except the polar seas.

classification The blue shark *Odontaspis glaucus* belongs in the family Odontaspidae, order Lamniformes (typical sharks), subclass Elasmobranchii, class Chondrichthyes.

blue shift in astronomy, a manifestation of the ♀Doppler effect in which an object appears bluer when it is moving towards the observer or the observer is moving towards it (blue light is of a higher frequency than other colours in the spectrum). The blue shift is the opposite of the ♀red shift.

blue whale the world's largest animal; see ♀whale.

BMP in Windows, a file extension indicating a graphics file in ♀bit-map format. Bit-mapped files are commonly used for icons and wallpaper.

BMR abbreviation for ♀basal metabolic rate.

boa any of various nonvenomous snakes of the family Boidae, found mainly in tropical and subtropical parts of the New World. Boas feed mainly on small mammals and birds. They catch these in their teeth or kill them by constriction (crushing the creature within their coils until it suffocates). The boa constrictor *Constrictor constrictor* can grow up to 5.5 m/18.5 ft long, but rarely reaches more than 4 m/12 ft. Other boas include the anaconda and the emerald tree boa *Boa canina*, about 2 m/6 ft long and bright green.

Some small burrowing boas live in N Africa and W Asia, while other species live on Madagascar and some Pacific islands, but the majority of boas live in South and Central America. The name boa is sometimes used loosely to include the pythons of the Old World, which also belong to the Boidae family, and which share with boas vestiges of hind limbs and constricting habits.

boar wild member of the pig family, such as the Eurasian wild boar *Sus scrofa*, from which domestic pig breeds derive. The wild boar is sturdily built, being 1.5 m/4.5 ft long and 1 m/3 ft high, and possesses formidable tusks. Of gregarious nature and mainly woodland-dwelling, it feeds on roots, nuts, insects, and some carrion.

The dark coat of the adult boar is made up of coarse bristles with varying amounts of underfur, but the young are striped. The male domestic pig is also known as a boar, the female as a sow.

boarfish marine bony fish found chiefly in the Mediterranean and northeast Atlantic. It has a flat oval body that is reddish coloured with seven transverse orange bands on the back. Boarfish are related to the dory.

classification Boarfish *Capros aper* belongs to the order Zeiformes, class Osteichthyes.

The name boarfish is derived from its projecting hoglike snout.

bobcat wild cat *Lynx rufus* living in a variety of habitats from S Canada through to S Mexico. It is similar to the lynx, but only 75 cm/2.5 ft long, with reddish fur and less well-developed ear tufts.

bobolink North American songbird *Dolichonyx oryzivorus*, family Icteridae, order Passeriformes, that takes its common name from the distinctive call of the male. It has a long middle toe and pointed tailfeathers. Breeding males are mostly black, with a white rump; females are buff-coloured with dark streaks. Bobolinks are about 18 cm/7 in long and build their nests on the ground in hayfields and weedy meadows.

Bode's law numerical sequence that gives the approximate distances, in astronomical units (distance between Earth and Sun = one astronomical unit), of the planets from the Sun by adding 4 to each term of the series 0, 3, 6, 12, 24, ... and then dividing by 10. Bode's law predicted the existence of a planet between ♀Mars and ♀Jupiter, which led to the discovery of the asteroids.

The 'law' breaks down for ♀Neptune and ♀Pluto. The relationship was first noted in 1772 by the German mathematician Johann Titius (1729–1796) (it is also known as the Titius–Bode law).

Bohr, Niels Henrik David (1885–1962)

Danish physicist whose theoretical work established the structure of the atom and the validity of quantum theory by showing that the nuclei of atoms are surrounded by shells of electrons, each assigned particular sets of quantum numbers according to their orbits. For this work he was awarded the Nobel Prize for Physics in 1922. He explained the structure and behaviour of the nucleus, as well as the process of nuclear fission. Bohr also proposed the doctrine of complementarity, the theory that a fundamental particle is neither a wave nor a particle, because these are complementary modes of description.

quantum theory and atomic structure Bohr's first model of the atom was developed working in Manchester, UK with Ernest Rutherford, who had proposed a nuclear theory of atomic structure from his work on the scattering of alpha rays in 1911. It was not, however, understood how electrons could continually orbit the nucleus without radiating energy, as classical physics demanded.

Mary Evans Picture Library

In 1913, Bohr developed his theory of atomic structure by applying quantum theory to the observations of radiation emitted by atoms. Ten years earlier, Max Planck had proposed that radiation is emitted or absorbed by atoms in discrete units, or quanta, of energy. Bohr postulated that an atom may exist in only a certain number of stable states, each with a certain amount of energy in which electrons orbit the nucleus without emitting or absorbing energy. He proposed that emission or absorption of energy occurs only with a transition from one stable state to another. When a transition occurs, an electron moving to a higher orbit absorbs energy and an electron moving to a lower orbit emits energy. In so doing, a set number of quanta of energy are emitted or absorbed at a particular frequency. Bohr's atomic theory was validated in 1922 by the discovery of an element he had predicted, hafnium.

the liquid-droplet model In 1939, Bohr proposed his liquid-droplet model for the nucleus, in which nuclear particles are pulled together by short-range forces, similar to the way in which molecules in a drop of liquid are attracted to one another. The extra energy produced by the absorption of a neutron causes the nuclear particles to separate into two groups of approximately the same size, thus breaking the nucleus into two smaller nuclei – as happens in nuclear fission. The model was vindicated when Bohr correctly predicted the differing behaviour of nuclei of uranium-235 and uranium-238 from the fact that the number of neutrons in each nucleus is odd and even respectively.

BODMAS (mnemonic for brackets, of, division, multiplication, addition, subtraction) – the order in which an arithmetical expression should be calculated.

Boeing US military and commercial aircraft manufacturer. Among the models Boeing has produced are the B-17 Flying Fortress, 1935; the B-52 Stratofortress, 1952; the Chinook helicopter, 1961; the first jetliner, the Boeing 707, 1957; the 747 jet or Boeing 747, 1969; the 767, 1975; and the 777-300 jetliner, 1997.

The company was founded in 1916 near Seattle, Washington, by William E Boeing (1881–1956) as the Pacific Aero Products Company. Renamed the following year, the company built its first seaplane and in 1919 set up an airmail service between Seattle and Victoria, British Columbia. The company announced in December 1996 that they would merge with US aircraft manufacturers McDonnell Douglas to create the world's largest aerospace company, with sales of \$48 billion/£29 billion, some 200,000 employees, and an order book of civil and military aircraft worth \$100 billion/£60 billion. The new US group would manufacture about three-quarters of the world's commercial airliners. It would operate under the Boeing name and with its principal headquarters in Seattle, WA. The single aerospace giant would transform the whole industry and threaten all of its rivals, including the European consortium Airbus Industrie, which had a 20% share of the commercial airline market. The merger of Boeing and McDonnell Douglas was approved by the European Union in 1997. Also in 1997 Boeing unveiled its 777-300 jetliner, the world's longest and largest twin-engine aircraft of its kind at the time, which would replace the four-engine Boeing 747.

bog type of wetland where decomposition is slowed down and dead plant matter accumulates as peat. Bogs develop under conditions of low temperature, high acidity, low nutrient supply, stagnant water, and oxygen deficiency. Typical bog plants are sphagnum moss, rushes, and cotton grass; insectivorous plants such as sundews and bladderworts are common in bogs (insect prey make up for the lack of nutrients).

bogbean or **buckbean** aquatic or bog plant belonging to the gentian family, with a creeping rhizome (underground stem) and leaves

and pink flower spikes held above water. It is found over much of the northern hemisphere. (*Menyanthes trifoliata*, family Gentianaceae.)

bohrium synthesized, radioactive element of the δ transactinide series, symbol Bh, atomic number 107, relative atomic mass 262. It was first synthesized by the Joint Institute for Nuclear Research in Dubna, Russia in 1976; in 1981 the Laboratory for Heavy Ion Research in Darmstadt, Germany, confirmed its existence. It was named in 1997 after Danish physicist Niels δ Bohr. Its temporary name was unilseptium.

Bohr model model of the atom conceived by Danish physicist Niels Bohr in 1913. It assumes that the following rules govern the behaviour of electrons: (1) electrons revolve in orbits of specific radius around the nucleus without emitting radiation; (2) within each orbit, each electron has a fixed amount of energy; electrons in orbits farther away from the nucleus have greater energies; (3) an electron may 'jump' from one orbit of high energy to another of lower energy causing the energy difference to be emitted as a photon of electromagnetic radiation such as light. The Bohr model has been superseded by wave mechanics (see δ quantum theory).

boiler any vessel that converts water into steam. Boilers are used in conventional power stations to generate steam to feed steam turbines, which drive the electricity generators. They are also used in steamships, which are propelled by steam turbines, and in steam locomotives. Every boiler has a furnace in which fuel (coal, oil, or gas) is burned to produce hot gases, and a system of tubes in which heat is transferred from the gases to the water.

The common kind of boiler used in ships and power stations is the water-tube type, in which the water circulates in tubes surrounded by the hot furnace gases. The water-tube boilers at power stations produce steam at a pressure of up to 300 atmospheres and at a temperature of up to 600°C/1,100°F to feed to the steam turbines. It is more efficient than the fire-tube type that is used in steam locomotives. In this boiler the hot furnace gases are drawn through tubes surrounded by water.

boiling process of changing a liquid into its vapour, by heating it at the maximum possible temperature for that liquid (see δ boiling point) at atmospheric pressure.

boiling point for any given liquid, the temperature at which the application of heat raises the temperature of the liquid no further, but converts it into vapour.

The boiling point of water under normal pressure is 100°C/212°F. The lower the pressure, the lower the boiling point and vice versa.

boletus any of several fleshy fungi (see *fungus*) with thick stems and caps of various colours. The European *Boletus edulis* is edible, but some species are poisonous. (Genus *Boletus*, class Basidiomycetes.)

boletus The red crack boletus *Boletus chrysenteron*. Like other members of the genus, it releases its spores through a mass of pores beneath the cap, rather than from the more familiar gills seen beneath the cap of an edible mushroom. Premaphotos Wildlife

boll weevil small American beetle *Anthonomus grandis* of the weevil group. The female lays her eggs in the unripe pods or 'bolls' of the cotton plant, and on these the larvae feed, causing great destruction.

bolometer sensitive thermometer that measures the energy of radiation by registering the change in electrical resistance of a fine wire when it is exposed to heat or light.

The US astronomer Samuel Langley devised it in 1880 for measuring radiation from stars.

bolometric magnitude in astronomy, a measure of the brightness of a star over all wavelengths. Bolometric magnitude is related to the total radiation output of the star. See *magnitude*.

Boltzmann, Ludwig Eduard (1844–1906) Austrian physicist who studied the kinetic theory of gases, which explains the properties of gases by reference to the motion of their constituent atoms and molecules. He established the branch of physics now known as statistical mechanics.

He derived a formula, the **Boltzmann distribution**, which gives the number of atoms or molecules with a given energy at a specific temperature. The constant in the formula is called the **Boltzmann constant**.

BOLTZMANN, LUDWIG

<http://www-history.mcs.st-and.ac.uk/~history/Mathematicians/Boltzmann.html>

Biography of the physicist and mathematician. The site contains a description of the work of Boltzmann, and also describes his working relationships with his contemporaries, which due to the radical nature of his work were often strained. Also included are several literature references for further reading, and a photograph of Boltzmann.

Boltzmann constant in physics, the constant (symbol *k*) that relates the kinetic energy (energy of motion) of a gas atom or molecule to temperature. Its value is 1.38066×10^{-23} joules per kelvin. It is equal to the gas constant *R*, divided by *Avogadro's* number.

bolus mouthful of chewed food mixed with saliva, ready for swallowing. Most vertebrates swallow food immediately, but grazing mammals chew their food a great deal, allowing a mechanical and chemical breakdown to begin.

bombardier beetle beetle that emits an evil-smelling fluid from its abdomen, as a defence mechanism. This fluid rapidly evaporates into a gas, which appears like a minute jet of smoke when in contact with air, and blinds the predator about to attack.

classification Bombardier beetles in genus *Brachinus*, family Carabidae, order Coleoptera, class Insecta, phylum Arthropoda.

Bombay duck or *bummalow* small fish *Harpodon nehereus* found in the Indian Ocean. It has a thin body, up to 40 cm/16 in long, and sharp, pointed teeth. It feeds on shellfish and other small fish. It is valuable as a food fish, and is eaten, salted and dried, with dishes such as curry.

bond in chemistry, the result of the forces of attraction that hold together atoms of an element or elements to form a molecule. The principal types of bonding are ionic, covalent, metallic, and intermolecular (such as hydrogen bonding).

bone hard connective tissue comprising the skeleton of most vertebrate animals. Bone is composed of a network of collagen fibres impregnated with mineral salts (largely calcium phosphate and calcium carbonate), a combination that gives it great density and strength, comparable in some cases with that of reinforced concrete. Enclosed within this solid matrix are bone cells, blood vessels, and nerves. The interior of the long bones of the limbs consists of a spongy matrix filled with a soft marrow that produces blood cells.

There are two types of bone: those that develop by replacing cartilage and those that form directly from connective tissue. The latter, which includes the bones of the cranium, are usually plate-like in shape and form in the skin of the developing embryo. Humans have about 206 distinct bones in the skeleton, of which the smallest are the three ossicles in the middle ear.

To remember the bones of the upper limb:

SOME CRIMINALS HAVE UNDERESTIMATED ROYAL CANADIAN MOUNTED POLICE.

SCAPULA / CLAVICLE / HUMERUS / ULNA / RADIUS / CARPALS / METACARPALS / PHALANGES

bone marrow substance found inside the cavity of bones. In early life it produces red blood cells but later on lipids (fat) accumulate and its colour changes from red to yellow.

Bone marrow may be transplanted in the treatment of some diseases, such as leukaemia, using immunosuppressive drugs in the recipient to prevent rejection. Transplants to adult monkeys from early aborted monkey fetuses have successfully bypassed rejection.

section through a long bone (the femur)

bone Bone is a network of fibrous material impregnated with mineral salts and as strong as reinforced concrete. The upper end of the thighbone or femur is made up of spongy bone, which has a fine lacework structure designed to transmit the weight of the body. The shaft of the femur consists of hard compact bone designed to resist bending. Fine channels carrying blood vessels, nerves, and lymphatics interweave even the densest bone.

bongo Central African antelope *Boocercus eurycerus*, living in dense humid forests. Up to 1.4 m/4.5 ft at the shoulder, it has spiral horns which may be 80 cm/2.6 ft or more in length. The body is rich chestnut, with narrow white stripes running vertically down the sides, and a black belly.

bonito any of various species of medium-sized tuna, predatory fish of the genus *Sarda*, in the mackerel family. The ocean bonito *Katsuwonus pelamis* grows to 1 m/3 ft and is common in tropical seas. The Atlantic bonito *Sarda sarda* is found in the Mediterranean and tropical Atlantic and grows to the same length but has a narrower body.

bonobo species of chimpanzee.

boobook owl *Ninox novaeseelandiae* found in Australia, so named because of its call.

booby tropical seabird of the genus *Sula*, in the same family, Sulidae, as the northern gannet, order Pelicaniformes. There are six species, including the circumtropical brown booby *S. leucogaster*. Plumage is white and black or brown, with no feathers on the throat and lower jaw. They inhabit coastal waters, and dive to catch fish. The name was given by sailors who saw the bird's tameness as stupidity.

One species, Abbott's booby, breeds only on Christmas Island, in the western Indian Ocean. Unlike most boobies and gannets, it nests high up in trees. Large parts of its breeding ground have been destroyed by phosphate mining, but conservation measures now protect the site.

booklouse any of numerous species of tiny wingless insects of the order Psocoptera, especially *Atropus pulsatoria*, which lives in books and papers, feeding on starches and moulds.

Most of the other species live in bark, leaves, and lichens. They thrive in dark, damp conditions.

bookmark facility for marking a specific place in electronic documentation to enable easy return to it. It is used in several types of software, including electronic help files and tutorials. Bookmarks are especially important on the World Wide Web, where it can be difficult to remember a uniform resource locator (URL) in order to

Boole, George

(1815–1864)

English mathematician. His work *The Mathematical Analysis of Logic* 1847 established the basis of modern mathematical logic,

and his Boolean algebra can be used in designing computers.

Boole's system is essentially two-valued. By subdividing objects into separate classes, each with a given property, his algebra makes it possible to treat different classes according to the presence or absence of the same property. Hence it involves just two numbers, 0 and 1 – the binary system used in the computer.

Mary Evans Picture Library

BOOLE, GEORGE

<http://www-history.mcs.st-and.ac.uk/~history/Mathematicians/Boole.html>

Extensive biography of the mathematician. The site contains a clear description of his working relationship with his contemporaries, and also includes the title page of his famous book *Investigation of the Laws of Thought*. Several literature references for further reading on the mathematician are also listed, and the Web site also features a portrait of Boole.

return to it. Most Web browsers therefore have built-in bookmark facilities, whereby the browser stores the URL with the page name attached. To return directly to the site, the user picks the page name from the list of saved bookmarks.

Boolean algebra set of algebraic rules, named after mathematician George Boole, in which TRUE and FALSE are equated to 0 and 1. Boolean algebra includes a series of operators (AND, OR, NOT, NAND (NOT AND), NOR, and XOR (exclusive OR)), which can be used to manipulate TRUE and FALSE values (see *truth table*). It is the basis of computer logic because the truth values can be directly associated with *bits*.

These rules are used in searching databases either locally or across the Internet via services like AltaVista to limit the number of hits to those which most closely match a user's requirements. A search instruction such as 'tennis NOT table' would retrieve articles about tennis and reject those about ping-pong.

boomslang rear-fanged venomous African snake *Dispholidus typus*, often green but sometimes brown or blackish, and growing to a length of 2 m/6 ft. It lives in trees, and feeds on tree-dwelling lizards such as chameleons. Its venom can be fatal to humans; however, boomslangs rarely attack people.

boot or **bootstrap** in computing, the process of starting up a computer. Most computers have a small, built-in boot program that starts automatically when the computer is switched on – its only task is to load a slightly larger program, usually from a hard disc, which in turn loads the main operating system.

In microcomputers the operating system is often held in the permanent ROM memory and the boot program simply triggers its operation.

Some boot programs can be customized so that, for example, the computer, when switched on, always loads and runs a program from a particular backing store or always adopts a particular mode of screen display.

boot disc (also known as an *emergency disc*) floppy disc containing the necessary files to boot a computer without needing to access its hard disc. Boot discs are vital in recovering from virus attacks, when it is not known which files on a computer's hard disc may be infected; in recovering from a system crash which has corrupted existing files; or in correcting mistakes introduced into files necessary for starting up the computer by newly installed software programs.

Boötes constellation of the northern hemisphere represented by a herdsman driving a bear (Ursa Major) around the pole. Its brightest star is α Arcturus (or Alpha Boötis), which is about 37 light years from Earth. The herdsman is assisted by the neighbouring γ Canes Venatici, 'the Hunting Dogs'.

borage plant native to S Europe, used in salads and in medicine. It has small blue flowers and hairy leaves. (*Borago officinalis*, family Boraginaceae.)

borax hydrous sodium borate, $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$, found as soft, whitish crystals or encrustations on the shores of hot springs and in the dry beds of salt lakes in arid regions, where it occurs with other borates, halite, and gypsum. It is used in bleaches and washing powders.

A large industrial source is Borax Lake, California. Borax is also used in glazing pottery, in soldering, as a mild antiseptic, and as a metallurgical flux.

Bordeaux mixture a solution made up of equal quantities of copper(II) sulphate and lime in water, used in horticulture and in the wine industry as a fungicide.

border collie breed of *sheepdog* originating in the Borders region of Scotland and still much prized as a versatile working dog with a powerful herding instinct. It has a smooth or fairly long, dense, black and white coat and stands about 53 cm/21 in. tall.

border terrier small, hardy, short-tailed dog with an otterlike head, moderately broad skull and short, strong muzzle. Its small, V-shaped ears drop forward. The coat is hard and dense with a

close undercoat and is red, beige, and tan, or blue and tan. Dogs weigh 6–7 kg/13–15 lb; bitches 5–6.5 kg/ 11–14.5 lb.

bore surge of tidal water up an estuary or a river, caused by the funneling of the rising tide by a narrowing river mouth. A very high tide, possibly fanned by wind, may build up when it is held back by a river current in the river mouth. The result is a broken wave, a metre or a few feet high, that rushes upstream.

Famous bores are found in the rivers Severn (England), Seine (France), Hooghly (India), and Chiang Jiang (China), where bores of over 4 m/13 ft have been reported.

boric acid or **boracic acid** $\text{B}(\text{OH})_3$ acid formed by the combination of hydrogen and oxygen with nonmetallic boron. It is a weak antiseptic and is used in the manufacture of glass and enamels. It is also an efficient insecticide against ants and cockroaches.

boron nonmetallic element, symbol B, atomic number 5, relative atomic mass 10.811. In nature it is found only in compounds, as with sodium and oxygen in borax. It exists in two allotropic forms (see *allotropy*): brown amorphous powder and very hard, brilliant crystals. Its compounds are used in the preparation of boric acid, water softeners, soaps, enamels, glass, and pottery glazes. In alloys it is used to harden steel. Because it absorbs slow neutrons, it is used to make boron carbide control rods for nuclear reactors. It is a necessary trace element in the human diet. The element was named by Humphry Davy, who isolated it in 1808, from borax + -on, as in carbon.

borzoi Russian 'swift' breed of large dog originating in Russia. It is of the greyhound type, white with darker markings, with a thick, silky coat, and stands 75 cm/30 in or more at the shoulder.

The borzoi's original quarry was hares and foxes, but it was selectively bred in the 19th century to produce a larger, stronger dog suitable for hunting wolves.

Bosch, Carl (1874–1940)

German metallurgist and chemist. He developed the Haber process for the production of ammonia into an industrial high-pressure process that made use of water gas as a source of hydrogen. He shared the Nobel Prize for Chemistry in 1931 with Friedrich Bergius.

Mary Evans Picture Library

Bose–Einstein condensate hypothesis put forward 1925 by Albert Einstein and Indian physicist Satyendra Bose, suggesting that when a dense gas is cooled to a little over absolute zero it will condense and its atoms will lose their individuality and act as an organized whole. The first Bose–Einstein condensate was produced in June 1995 by US physicists cooling rubidium atoms to 10 billionths of a degree above zero. The condensate existed for about a minute before becoming rubidium ice.

boson in physics, an elementary particle whose spin can only take values that are whole numbers or zero. Bosons may be classified as *gauge bosons* (carriers of the four fundamental forces) or *mesons*. All elementary particles are either bosons or fermions.

Unlike fermions, more than one boson in a system (such as an atom) can possess the same energy state. When developed mathematically, this statement is known as the Bose–Einstein law, after its discoverers Indian physicist Satyendra Bose and Albert Einstein.

Boston terrier breed of dog developed in the USA for dog fighting during the second half of the 19th century from crosses of English and French bulldogs. It is bred in three sizes, ranging from 7 kg/15 lb to 11 kg/24 lb in weight, has a brindled or black coat with symmetrical white markings on face, chest, and legs, and carries its ears upright.

The name 'Boston terrier' is misleading as it is related to the bulldog breeds rather than terriers.

'bot' (short for **robot**) on the Internet, automated piece of software that performs specific tasks. 'Bots are commonly found on multi-user dungeons (MUDs) and other multi-user role-playing game sites, where they maintain a constant level of activity even when few human users are logged on. On the World Wide Web, 'bots automate maintenance tasks such as indexing Web pages and tracing broken links.

botanical garden place where a wide range of plants is grown, providing the opportunity to see a botanical diversity not likely to be encountered naturally. Among the earliest forms of botanical garden was the physic garden, devoted to the study and growth of medicinal plants; an example is the Chelsea Physic Garden in London, established in 1673 and still in existence. Following increased botanical exploration, botanical gardens were used to test the commercial potential of new plants being sent back from all parts of the world.

Today a botanical garden serves many purposes: education, science, and conservation. Many are associated with universities and also maintain large collections of preserved specimens (see **herbarium**), libraries, research laboratories, and gene banks. There are 1,600 botanical gardens worldwide.

botany Greek *botane* 'herb' the study of living and fossil plants, including form, function, interaction with the environment, and classification.

Botany is subdivided into a number of specialized studies, such as the identification and classification of plants (taxonomy), their external formation (plant morphology), their internal arrangement (plant anatomy), their microscopic examination (plant histology), their functioning and life history (plant physiology), and their distribution over the Earth's surface in relation to their surroundings (plant ecology). Palaeobotany concerns the study of fossil plants, while economic botany deals with the utility of plants. Horticulture, agriculture, and forestry are branches of botany.

botfly any fly of the family Oestridae. The larvae are parasites that feed on the skin (warblefly of cattle) or in the nasal cavity (nos-triffles of sheep and deer). The horse botfly belongs to another family, the Gasterophilidae. It has a parasitic larva that feeds in the horse's stomach.

bo tree or **peepul** Indian fig tree, said to be the tree under which the Buddha became enlightened. (*Ficus religiosa*, family Moraceae.)

bottlebrush any of several trees or shrubs common in Australia, belonging to the myrtle family. They have cylindrical, composite flower heads in green, yellow, white, various shades of red, and violet. (Genus *Callistemon*, family Myrtaceae.)

bottlenose species of dolphin.

botulism rare, often fatal type of food poisoning. Symptoms include vomiting, diarrhoea, muscular paralysis, breathing difficulties and disturbed vision.

It is caused by a toxin produced by the bacterium *Clostridium botulinum*, found in soil and sometimes in improperly canned foods.

Thorough cooking destroys the toxin, which otherwise suppresses the cardiac and respiratory centres of the brain. In neurology, botulinum toxin is sometimes used to treat rare movement disorders.

bougainvillea any plant of a group of South American tropical vines of the four o'clock family, now cultivated in warm countries around the world for the colourful red and purple bracts (leaflike structures) that cover the flowers. They are named after the

French navigator Louis de Bougainville. (Genus *Bougainvillea*, family Nyctaginaceae.)

bounce in computing, system by which an electronic mail message that cannot be delivered to its addressee is returned ('bounced back') to the sender, with a note advising of its failure to reach its destination. Failed delivery is usually due to an incorrect e-mail address or a network problem.

boundary a line around the edge of an area; a perimeter. The boundary of a circle is known as the circumference. The boundary which marks the limit of land may be indicated by a post, ditch, hedge, march of stones, road, or river, or it may be indicated by reference to a plan, or to possession of tenants, or by actual measurement.

Bourbaki, Nicolas pseudonym adopted by a group of mathematicians, most of them French, who, collectively and anonymously, published a definitive survey of mathematics 1939-67. The group, which at any one time contained about 20 members, was centred at the Ecole Normale Supérieure in Paris. The group's founder was André Weil.

Bourdon gauge instrument for measuring pressure, patented by French watchmaker Eugène Bourdon in 1849. The gauge contains a C-shaped tube, closed at one end. When the pressure inside the tube increases, the tube uncurls slightly causing a small movement at its closed end. A system of levers and gears magnifies this movement and turns a pointer, which indicates the pressure on a circular scale. Bourdon gauges are often fitted to cylinders of compressed gas used in industry and hospitals.

Bourdon gauge The most common form of Bourdon gauge is the C-shaped tube. However, in high-pressure gauges spiral tubes are used; the spiral rotates as pressure increases and the tip screws forwards.

Bovidae mammal family that consists of 128 species of antelopes, sheep, goats, and cattle. They are ruminants (chew the cud) and also artiodactylate (even-toed); all the males and some of the females have horns consisting of solid bony extensions of the skull encased in a sheath of true horn.

Bovids occur in all parts of the Old World and in North America, but are not native to Australia and South America.

classification Bovidae is a family in order Artiodactyla.

bovine somatotropin (BST) hormone that increases an injected cow's milk yield by 10-40%. It is a protein naturally occurring in milk and breaks down within the human digestive tract into harmless amino acids. However, doubts have arisen recently as to whether such a degree of protein addition could in the long term be guaranteed harmless either to cattle or to humans.

Although no evidence of adverse side effects to consumers have been found, BST was banned in Europe 1993 until the year 2000. In the USA genetically engineered BST has been in use since February 1994; in Vermont a law requiring milk containing BST to be labelled as such was passed September 1995.

The incidence of mastitis in herds injected with BST is 15-45% higher.

Facts do not cease to exist because they are ignored.

ALDOUS HUXLEY English novelist.
Proper Studies, 'Note on Dogma'

bovine spongiform encephalopathy (BSE) or *mad cow disease* disease of cattle, related to psorale in sheep, which attacks the nervous system, causing aggression, lack of coordination, and collapse. First identified in 1986, it is almost entirely confined to the UK. By 1996 it had claimed 158,000 British cattle.

BSE is one of a group of diseases known as the transmissible spongiform encephalopathies, since they are characterized by the appearance of spongy changes in brain tissue. Some scientists believe that all these conditions, including Creutzfeldt-Jakob disease (CJD) in humans, are in effect the same disease, and in 1996 a link was established between the deaths of 10 young people from CJD and the consumption of beef products.

The cause of these universally fatal diseases is not fully understood, but they may be the result of a rogue protein called a prion. A prion may be inborn or it may be transmitted in contaminated tissue.

According to an official European Commission Report released in Mar 1997, consumers throughout Europe were being exposed to BSE-infected meat. The report also highlighted lax health controls, and supported the view that the extent of BSE throughout the EU was much wider than governments were prepared to admit.

It was also revealed in 1997 that the British government had allowed more than 6,000 carcasses suspected of having BSE to be buried in landfill sites across Britain – in direct contravention of its own regulations. Because of fears that BSE could get into drinking water, or the food chain, both the British government and the EU have insisted the carcasses should be incinerated.

bower bird New Guinean and N Australian bird of the family Ptilonorhynchidae, order Passeriformes, related to the bōbird of paradise. The males are dull-coloured, and build elaborate bowers of sticks and grass, decorated with shells, feathers, or flowers, and even painted with the juice of berries, to attract the females. There are 17 species.

bowfin North American fish *Amia calva* with a swim bladder highly developed as an air sac, enabling it to breathe air. It is the only surviving member of a primitive group of bony fishes.

bowhead Arctic whale *Balaena mysticetus* with strongly curving upper jawbones supporting the plates of baleen with which it sifts planktonic crustaceans from the water. Averaging 15 m/50 ft long and 90 tonnes/100 tons in weight, these slow-moving, placid whales were once extremely common, but by the 17th century were already becoming scarce through hunting. Only an estimated 3,000 remain, and continued hunting by the Inuit may result in extinction.

Bowman's capsule in the vertebrate kidney, a cup-shaped structure enclosing the glomerulus, which is the initial site of filtration of the blood leading to urine formation.

There are approximately a million of these capsules in a human kidney, each containing a tight knot of capillaries and leading into a kidney tubule or nephron where unwanted fluid and waste molecules are filtered from the blood to be excreted in the form of urine.

box any of several small evergreen trees and shrubs, with small, leathery leaves. Some species are used as hedging plants and for shaping into garden ornaments. (Genus *Buxus*, family Buxaceae.)

boxer breed of dog, about 60 cm/24 in tall, with a smooth coat and a set-back nose. The tail is usually docked. A boxer is usually brown, often with white markings, but may be fawn or brindled.

boxfish or *trunkfish*, any fish of the family Ostraciodontidae, with scales that are hexagonal bony plates fused to form a box covering the body, only the mouth and fins being free of the armour. Boxfish swim slowly. The cowfish, genus *Lactophrys*, with two 'horns' above the eyes, is a member of this group.

Boyle, Robert (1627–1691)

Irish chemist and physicist who published the seminal *The Sceptical Chymist* 1661. He formulated Boyle's law in 1662. He was a pioneer in the use of experiment and scientific method.

Boyle questioned the alchemical basis of the chemical theory of his day and taught that the proper object of chemistry was to determine the compositions of substances. The term 'analysis' was coined by Boyle and many of the reactions still used in qualitative work were known to him. He introduced certain plant extracts, notably litmus, for the indication of acids and bases. He was also the first chemist to collect a sample of gas.

Mary Evans Picture Library

Father of Chemistry and Uncle of the Earl of Cork.

ROBERT BOYLE Irish chemist.
On his tombstone in Dublin, quoted in
R.L. Weber *More Random Walks in Science*

Boyle's law law stating that the volume of a given mass of gas at a constant temperature is inversely proportional to its pressure. For example, if the pressure of a gas doubles, its volume will be reduced by a half, and vice versa. The law was discovered in 1662 by Irish physicist and chemist Robert Boyle. See also *gas laws*.

bozo filter facility to eliminate messages from irritating users. It is also known as a *killfile*.

BP abbreviation for *British Pharmacopoeia*; *British Petroleum*.

bps abbreviation for *bits per second*, measure used in specifying data transmission rates.

brachiopod or *lamp shell* any member of the phylum Brachiopoda, marine invertebrates with two shells, resembling but totally unrelated to bivalves.

There are about 300 living species; they were much more numerous in past geological ages. They are suspension feeders, ingesting minute food particles from water. A single internal organ, the lophophore, handles feeding, aspiration, and excretion.

Brachytele primate genus consisting of the single species commonly called the woolly spider monkey.

bracken any of several large ferns (especially *Pteridium aquilinum*) which grow abundantly in the northern hemisphere. The rootstock produces coarse fronds each year, which die down in autumn.

bracket fungus any of a group of fungi (see *fungus*) with fruiting bodies that grow like shelves from the trunks and branches of trees. (Class Basidiomycetes.)

braconid small parasitic wasp closely related to the ichneumon flies, but differing from them mainly by having fewer wing veins. Braconids chiefly parasitize caterpillars, but also some beetle and fly larvae, so they are selectively used in biological control programmes.

bracket fungus This varicoloured *Coriolus versicolor* is one of a large number of often unrelated fungi referred to collectively as bracket fungi because they form bracketlike growths on trees and timber. The fruiting body is the only part that is immediately visible. The mass of hyphae, which form its mycelium, penetrates and feeds upon the dead wood on which the fungus is living. The spore-producing fruiting body is derived from the mycelium. Premaphotos Wildlife

classification Braconids are in the family Braconidae, order Hymenoptera, class Insecta, phylum Arthropoda.

Apanteles glomeratus is a tiny black braconid that parasitizes the cabbage white butterfly. The female lays her eggs in the caterpillar. About autumn, masses of sulphur-yellow cocoons of the parasite can be seen attached to the skin casts of the dead (pupated) caterpillar.

Brahe, Tycho (1546–1601)

Danish astronomer. His accurate observations of the planets enabled German astronomer and mathematician Johannes Kepler to prove that planets orbit the Sun in ellipses. Brahe's discovery and report of the 1572 supernova brought him recognition, and his observations of the comet of 1577 proved that it moved in an orbit among the planets, thus disproving Aristotle's view that comets were in the Earth's atmosphere.

Brahe was a colourful figure who wore a silver nose after his own was cut off in a duel, and who took an interest in alchemy.

In 1576 Frederick II of Denmark gave him the island of Hven, where he set up an observatory. Brahe was the greatest observer in the days before telescopes, making the most accurate measurements of the positions of stars and planets. He moved to Prague as imperial mathematician in 1599, where he was joined by Kepler, who inherited his observations when he died.

Mary Evans Picture Library

BRAHE, TYCHO

Tycho Brahe, the 16th-century Danish astronomer, wore a false nose made of silver. His own had been cut off in a duel while he was a student in Rostock.

bract leaflike structure in whose axil a flower or inflorescence develops. Bracts are generally green and smaller than the true leaves. However, in some plants they may be brightly coloured and conspicuous, taking over the role of attracting pollinating insects to the flowers, whose own petals are small: examples include poinsettia *Euphorbia pulcherrima* and bougainvillea.

A whorl of bracts surrounding an inflorescence is termed an involucre. A bracteole is a leaf-like organ that arises on an individual flower stalk, between the true bract and the calyx.

brain in higher animals, a mass of interconnected nerve cells forming the anterior part of the central nervous system, whose activities it coordinates and controls. In vertebrates, the brain is contained by the skull. At the base of the brainstem, the medulla oblongata contains centres for the control of respiration, heartbeat rate and strength, and blood pressure. Overlying this is the cerebellum, which is concerned with coordinating complex muscular processes such as maintaining posture and moving limbs.

The cerebral hemispheres (cerebrum) are paired outgrowths of the front end of the forebrain, in early vertebrates mainly concerned with the senses, but in higher vertebrates greatly developed and involved in the integration of all sensory input and motor output, and in thought, emotions, memory, and behaviour.

In vertebrates, many of the nerve fibres from the two sides of the body cross over as they enter the brain, so that the left cerebral hemisphere is associated with the right side of the body and vice versa. In humans, a certain asymmetry develops in the two halves of the cerebrum. In right-handed people, the left hemisphere seems to play a greater role in controlling verbal and some mathematical skills, whereas the right hemisphere is more involved in spatial perception. In general, however, skills and abilities are not closely localized. In the brain, nerve impulses are passed across synapses by neurotransmitters, in the same way as in other parts of the nervous system.

In mammals the cerebrum is the largest part of the brain, carrying the cerebral cortex. This consists of a thick surface layer of cell bodies (grey matter), below which fibre tracts (white matter) connect various parts of the cortex to each other and to other points in the central nervous system. As cerebral complexity grows, the surface of the brain becomes convoluted into deep folds. In higher mammals, there are large unassigned areas of the brain that seem to be connected with intelligence, personality, and higher mental faculties. Language is controlled in two special regions usually in the left side of the brain: Broca's area governs the ability to talk, and Wernicke's area is responsible for the comprehension of spoken and written words. In 1990, scientists at Johns Hopkins University, Baltimore, succeeded in culturing human brain cells.

If the cells and fibre of the human brain were stretched out end to end, they would certainly reach to the moon and back. Yet the fact that they are not arranged end to end enabled man to go there himself. The astonishing tangle within our heads makes us what we are.

COLIN BLAKEMORE English physiologist.
BBC Reith Lecture 1976

brain damage impairment which can be caused by trauma (for example, accidents) or disease (such as encephalitis), or which may be present at birth. Depending on the area of the brain that is affected, language, movement, sensation, judgement, or other abilities may be impaired.

brain The structure of the human brain. At the back of the skull lies the cerebellum, which coordinates reflex actions that control muscular activity. The medulla controls respiration, heartbeat, and blood pressure. The hypothalamus is concerned with instinctive drives and emotions. The thalamus relays signals to and from various parts of the brain. The pituitary gland controls the body's hormones. Distinct areas of the large convoluted cerebral hemispheres that fill most of the skull are linked to sensations, such as hearing and sight, and voluntary activities, such as movement.

brainstem region where the top of the spinal cord merges with the undersurface of the brain, consisting largely of the medulla oblongata and midbrain.

The oldest part of the brain in evolutionary terms, the brainstem is the body's life-support centre, containing regulatory mechanisms for vital functions such as breathing, heart rate, and blood pressure. It is also involved in controlling the level of consciousness by acting as a relay station for nerve connections to and from the higher centres of the brain.

In many countries, death of the brainstem is now formally recognized as death of the person as a whole. Such cases are the principal donors of organs for transplantation. So-called 'beating-heart donors' can be maintained for a limited period by life-support equipment.

brake device used to slow down or stop the movement of a moving body or vehicle. The mechanically applied calliper brake used on bicycles uses a scissor action to press hard rubber blocks against the wheel rim. The main braking system of a car works hydraulically: when the driver depresses the brake pedal, liquid pressure forces pistons to apply brakes on each wheel.

Two types of car brakes are used. **Disc brakes** are used on the front wheels of some cars and on all wheels of sports and performance cars, since they are the more efficient and less prone to fading (losing their braking power) when they get hot. Braking pressure forces brake pads against both sides of a steel disc that rotates with the wheel. **Drum brakes** are fitted on the rear wheels of some cars and on all wheels of some passenger cars. Braking pressure

forces brake shoes to expand outwards into contact with a drum rotating with the wheels. The brake pads and shoes have a tough friction lining that grips well and withstands wear.

Many trucks and trains have air brakes, which work by compressed air. On landing, jet planes reverse the thrust of their engines to reduce their speed quickly. Space vehicles use retro-rockets for braking in space and use the air resistance, or drag of the atmosphere, to slow down when they return to Earth.

bramble any of a group of prickly bushes belonging to the rose family. Examples are blackberry, raspberry, and dewberry. (Genus *Rubus*, family Rosaceae.)

brambling or **bramble finch** bird *Fringilla montifringilla* belonging to the finch family Fringillidae, order Passeriformes. It is about 15 cm/6 in long, and breeds in N Europe and Asia.

brass metal alloy of copper and zinc, with not more than 5% or 6% of other metals. The zinc content ranges from 20% to 45%, and the colour of brass varies accordingly from coppery to whitish yellow. Brasses are characterized by the ease with which they may be shaped and machined; they are strong and ductile, resist many forms of corrosion, and are used for electrical fittings, ammunition cases, screws, household fittings, and ornaments.

Brasses are usually classed into those that can be worked cold (up to 25% zinc) and those that are better worked hot (about 40% zinc).

brassica any of a group of plants, many of which are cultivated as vegetables. The most familiar is the common cabbage (*Brassica*

disc brake**drum brake**

brake Two common braking systems: the disc brake (left) and the drum brake (right). In the disc brake, increased hydraulic pressure of the brake fluid in the pistons forces the brake pads against the steel disc attached to the wheel. A self-adjusting mechanism balances the force on each pad. In the drum brake, increased pressure of the brake fluid within the slave cylinder forces the brake pad against the brake drum attached to the wheel.

oleracea), with its varieties broccoli, cauliflower, kale, and Brussels sprouts. (Genus *Brassica*, family Cruciferae.)

In 1990 US experiments in cross-pollinating the wild cabbage (*B. campestris*) with related varieties of cultivated cabbage, turnip, and swede produced a new plant with a life cycle of only five weeks. This is now being used in US schools to enable pupils to carry out plant-breeding experiments that can produce ten generations in one year.

Braun AEG German company, manufacturer of sound equipment and domestic appliances, founded 1921 by Max Braun and based in Frankfurt.

The factory was rebuilt 1945 and in 1951 when Max Braun died his son Artur (1925–) began commissioning a number of young and highly innovative German industrial designers associated with the new design school (Hochschule für Gestaltung) at Ulm – among them Dieter Rams and Hans Gugelot (1920–1965) – to update the company's product range. Their radically new designs quickly became hallmarks of the stark, geometric design style that developed in Germany at that time.

Brazil nut gigantic South American tree; also its seed, which is rich in oil and highly nutritious. The seeds (nuts) are enclosed in a hard outer casing, each fruit containing 10–20 seeds arranged like the segments of an orange. The timber of the tree is also valuable. (*Bertholletia excelsa*, family Lecythidaceae.)

brazing method of joining two metals by melting an alloy or metal into the joint. It is similar to soldering (see *solder*) but takes place at a much higher temperature. Copper and silver alloys are widely used for brazing, at temperatures up to about 900°C/1,650°F.

Where high precision is needed, as in space technology, nickel based filters are used in the temperature range 1,000–1,200°C/1,832–2,192°F.

breadfruit fruit of two tropical trees belonging to the mulberry family. It is highly nutritious and when baked is said to taste like bread. It is native to many South Pacific islands. (*Artocarpus communis* and *A. altiss*, family Moraceae.)

breadfruit Breadfruit trees, native to Polynesia, are now a familiar sight in many tropical countries around the world, where they have been planted for their large nutritious fruits. When cooked, the fruit has a breadlike texture, hence the name. *Premaphotos Wildlife*

breadth thickness, another name for width. The area of a rectangle is given by the formula: area = length times breadth.

bream deep-bodied, flattened fish *Abramis brama* of the carp family, growing to about 50 cm/1.6 ft, typically found in lowland rivers across Europe.

breast one of a pair of organs on the chest of the human female, also known as a mammary gland. Each of the two breasts contains milk-producing cells and a network of tubes or ducts that lead to openings in the nipple.

Milk-producing cells in the breast do not become active until a woman has given birth to a baby. Breast milk is made from sub-

breast The human breast or mammary gland. Milk produced in the tissue of the breast to feed a baby after a woman has given birth passes along ducts which lead to openings in the nipple.

stances extracted from the mother's blood as it passes through the breasts, and contains all the nourishment a baby needs. Breast-fed newborns develop fewer infections than bottle-fed babies because of the antibodies and white blood cells contained in breast milk. These are particularly abundant in the colostrum produced in the first few days of breast-feeding.

breast cancer in medicine, ζ ancer of the ζ breast. It is usually diagnosed following the detection of a painless lump in the breast (either through self-examination or mammography). Other, less common symptoms, include changes in the shape or texture of the breast and discharge from the nipple. It is the commonest cancer amongst women: there are 28,000 new cases of breast cancer in Britain each year and 185,700 in the USA.

treatment If the tumour is caught early, only it and the immediate surrounding tissue needs removing, in a process called lumpectomy, usually accompanied by radiotherapy. In more advanced cases a mastectomy is performed. Chemotherapy or hormone-blocking drugs (such as tamoxifen) may also accompany either procedure. The average survival rate after 5 years was 83.2% in 1996.

risk factors Possible risk factors include a family history of breast cancer (mutations in the genes *BRCA1* and *BRCA2* were found to cause more than 50% of inherited breast cancer cases in the 1990s); childlessness or late childbearing; early onset of menstruation and late menopause.

breast screening in medicine, examination of the breast to detect the presence of breast cancer at an early stage. Screening methods include self-screening by monthly examination of the breasts and formal programmes of screening by palpation (physical examination)

BREAST CANCER AWARENESS

<http://avon.avon.com/showpage.asp?thepage=crusade>

Promotes awareness of this disease through a library of frequently asked questions about breast cancer and mammograms, as well as a glossary of common terms and access to support groups. There is also information here about their fundraising activities and recipients of awards for people and groups seen to be contributing the most to the fight against this disease. It is sponsored by the make-up company Avon.

and mammography in special clinics. Screening may be offered to older women on a routine basis and it is important in women with a family history of breast cancer.

Breathalyzer trademark for an instrument for on-the-spot checking by police of the amount of alcohol consumed by a suspect driver. The driver breathes into a plastic bag connected to a tube containing a chemical (such as a diluted solution of potassium dichromate in 50% sulphuric acid) that changes colour in the presence of alcohol. Another method is to use a gas chromatograph, again from a breath sample.

breathing in terrestrial animals, the muscular movements whereby air is taken into the lungs and then expelled, a form of ζ gas exchange. Breathing is sometimes referred to as external respiration, for true respiration is a cellular (internal) process.

Lungs are specialized for gas exchange but are not themselves muscular, consisting of spongy material. In order for oxygen to be passed to the blood and carbon dioxide removed, air is drawn into the lungs (inhaled) by the contraction of the diaphragm and intercostal muscles; relaxation of these muscles enables air to be breathed out (exhaled). The rate of breathing is controlled by the brain. High levels of activity lead to a greater demand for oxygen and an increased rate of breathing.

breathing rate the number of times a minute the lungs inhale and exhale. The rate increases during exercise because the muscles require an increased supply of oxygen and nutrients. At the same time very active muscles produce a greater volume of carbon dioxide, a waste gas that must be removed by the lungs via the blood.

The regulation of the breathing rate is under both voluntary and involuntary control, although a person can only forcibly stop breathing for a limited time. The regulatory system includes the use of chemoreceptors, which can detect levels of carbon dioxide in the blood. High concentrations of carbon dioxide, occurring for example during exercise, stimulate a fast breathing rate.

breccia coarse-grained clastic ζ sedimentary rock, made up of broken fragments (clasts) of pre-existing rocks held together in a fine-grained matrix. It is similar to ζ conglomerate but the fragments in breccia are jagged in shape.

breed recognizable group of domestic animals, within a species, with distinctive characteristics that have been produced by artificial selection.

breeder reactor or **fast breeder** alternative names for ζ fast reactor, a type of nuclear reactor.

breeding in biology, the crossing and selection of animals and plants to change the characteristics of an existing ζ breed or ζ cultivar (variety), or to produce a new one.

Cattle may be bred for increased meat or milk yield, sheep for thicker or finer wool, and horses for speed or stamina. Plants, such as wheat or maize, may be bred for disease resistance, heavier and more rapid cropping, and hardness to adverse weather.

breeding in nuclear physics, a process in a reactor in which more fissionable material is produced than is consumed in running the reactor.

For example, plutonium-239 can be made from the relatively plentiful (but nonfissile) uranium-238, or uranium-233 can be produced from thorium. The Pu-239 or U-233 can then be used to fuel other reactors.

brewing making of beer, ale, or other alcoholic beverage, from ζ malt and ζ barley by steeping (mashing), boiling, and fermenting.

Mashing the barley releases its sugars. Yeast is then added, which contains the enzymes needed to convert the sugars into ethanol (alcohol) and carbon dioxide. Hops are added to give a bitter taste.

brewster unit (symbol B) for measuring the reaction of optical materials to stress, defined in terms of the slowing down of light passing through the material when it is stretched or compressed.

breathing The two phases of the process of breathing, or respiration. Gas exchange occurs in the alveoli, tiny air tubes in the lungs.

brick common block-shaped building material, with all opposite sides parallel. It is made of clay that has been fired in a kiln. Bricks are made by kneading a mixture of crushed clay and other materials into a stiff mud and extruding it into a ribbon. The ribbon is cut into individual bricks, which are fired at a temperature of up to about 1,000°C/1,800°F. Bricks may alternatively be pressed into shape in moulds.

Refractory bricks used to line furnaces are made from heat-resistant materials such as silica and dolomite. They must withstand operating temperatures of 1,500°C/2,700°F or more.

Facing bricks are designed to be visually more attractive than common bricks, and include specially moulded bricks.

Sun-dried bricks of mud reinforced with straw were first used in Mesopotamia some 8,000 years ago. Similar mud bricks, called adobe, are still used today in Mexico and other areas where the climate is warm and dry.

brickwork method of construction using bricks made of fired clay or sun-dried earth. In wall building, bricks are either laid out as stretchers (long side facing out) or as headers (short side facing out). The two principal patterns of brickwork are **English bond** in which alternate courses, or layers, are made up of stretchers or headers only, and **Flemish bond** in which stretchers and headers alternate within courses.

Some evidence exists of the use of fired bricks in ancient Mesopotamia and Egypt, although the Romans were the first to make extensive use of this technology. Today's mass production of fired bricks tends to be concentrated in temperate regions where there are plentiful supplies of fuel available.

bridge in computing, a device that connects two similar local area networks (LANs). Bridges transfer data in packets between the two

networks, without making any changes or interpreting the data in any way. See also *router* and *brouter*.

bridge structure that provides a continuous path or road over water, valleys, ravines, or above other roads. The basic designs and composites of these are based on the way they bear the weight of the structure and its load. Beam, or girder, bridges are supported at each end by the ground with the weight thrusting downwards. Cantilever bridges are a complex form of girder in which only one end is supported. Arch bridges thrust outwards and downwards at their ends. Suspension bridges use cables under tension to pull inwards against anchorages on either side of the span, so that the roadway hangs from the main cables by the network of vertical cables. The **cable-stayed** bridge relies on diagonal cables connected directly between the bridge deck and supporting towers at each end. Some bridges are too low to allow traffic to pass beneath easily, so they are designed with movable parts, like swing and draw bridges.

history In prehistory, people used logs or wove vines into ropes that were thrown across the obstacle. Clapper bridges, made from flat stones simply laid across or supported by piles of stones, were some of the earliest bridges. By 4000 BC arched structures of stone and/or brick were used in the Middle East, and the Romans built long arched spans, many of which are still standing. Cast iron bridges were introduced in 1779. The *Öttemer* process produced steel that made it possible to build long-lived framed structures that support great weight over long spans.

brill fatfish *Scophthalmus laevis*, living in shallow water over sandy bottoms in the NE Atlantic and Mediterranean. It is a freckled sandy brown, and grows to 60 cm/2 ft.

brine common name for a solution of sodium chloride (NaCl) in water.

Brines are used extensively in the food-manufacturing industry for canning vegetables, pickling vegetables (sauerkraut manufacture), and curing meat. Industrially, brine is the source from which chlorine, caustic soda (sodium hydroxide), and sodium carbonate are made.

Brinell hardness test test of the hardness of a substance according to the area of indentation made by a 10 mm/0.4 in hardened steel or sintered tungsten carbide ball under standard loading conditions in a test machine. The resulting Brinell number is equal to the load (kg) divided by the surface area (mm^2) and is named after its inventor, Swedish metallurgist Johann Brinell.

brisling processed form of sprat *Sprattus sprattus* a small herring, fished in Norwegian fjords, then seasoned and canned.

bristlecone pine the oldest living species of pine tree.

bristletail primitive wingless insect of the order Thysanura. Up to 2 cm/0.8 in long, bristletails have a body tapering from front to back, two long antennae, and three 'tails' at the rear end. They include the silverfish *Lepisma saccharina* and the firebrat *Thermobia domestica*. Two-tailed bristletails constitute another insect order, the Diplura. They live under stones and fallen branches, feeding on decaying material.

bristle-worm or *polychaete* segmented worm of the class Polychaeta, characterized by having a pair of fleshy paddles (parapodia) on each segment, together with prominent bristles (setae), and a well-developed head with a pair each of eyes, antennae, and palps. Most bristle-worms are marine, and live in burrows in sand and mud or in rock crevices and under stones. More than 5,300 species are recognized.

The bristle-worms can be conveniently divided into two loosely defined groups: the Errantia, which are free-living (that is swimming, crawling, or actively burrowing), and the Sedentaria, which live within a tube or a permanent burrow.

British Blue breed of domestic shorthaired cat. It has a fuller face than the Russian Blue, a more compact body, and shorter legs. The coat is a solid blue-grey colour and the eyes should be either orange or copper.

British Standards Institute (BSI) UK national standards body. Although government funded, the institute is independent. The BSI interprets international technical standards for the UK, and also sets its own.

For consumer goods, it sets standards which products should reach (the BS standard), as well as testing products to see that they conform to that standard (as a result of which the product may be given the BSI 'kite' mark).

British Telecom (BT) British telecommunications company. Its principal activity is the supply of local, long-distance, and international telecommunications services and equipment in the UK, serving 27 million exchange lines. BT also offers an international direct-dialled telephone service to more than 200 countries and other overseas territories - covering 99% of the world's 800 million telephones. One of the world's leading providers of telecommunications services and one of the largest private-sector companies in Europe, in 1997 BT had a market capitalization in excess of £28 billion and had established operations in more than 30 countries worldwide, with joint ventures in Spain, Germany, Italy, the Netherlands, Sweden, South Africa, New Zealand, Japan, and India.

BT formed part of the Post Office until 1980, and was privatized in 1984. Previously a monopoly, it now faces commercial competition for some of its services. BT is not allowed to offer other cable services apart from telephones.

British thermal unit imperial unit (symbol Btu) of heat, now replaced in the SI system by the joule (one British thermal unit is approximately 1,055 joules). Burning one cubic foot of natural gas releases about 1,000 Btu of heat.

One British thermal unit is defined as the amount of heat required to raise the temperature of 0.45 kg/1 lb of water by 1°F. The exact value depends on the original temperature of the water.

brittle-star Living mostly on soft seabeds, the brittle-star *Ophiotrix fragilis* feeds on small crustaceans and molluscs. Brittle-stars are distinguished from starfish by the more or less clear demarcation between the five arms and the body. Both starfish and brittle-stars have the ability to regrow their arms if they are broken off. Premaphotos Wildlife

brittle material material that breaks suddenly under stress at a point just beyond its elastic limit (see elasticity). Brittle materials may also break suddenly when given a sharp knock. Pottery, glass, and cast iron are examples of brittle materials. Compare ductile material.

brittle-star any member of the echinoderm class Ophiuroidea. A brittle-star resembles a starfish, and has a small, central, rounded body and long, flexible, spiny arms used for walking. The small brittle-star *Amphipholis squamata* is greyish, about 4.5 cm/2 in across, and found on sea bottoms worldwide. It broods its young, and its arms can be luminous.

About 2,000 species of brittle-stars and basket-stars, whose arms are tangled and rootlike, are included in this group.

broadband in computing, term indicating a high bandwidth.

broadbill primitive perching bird of the family Eurylaimidae, found in Africa and S Asia. Broadbills are forest birds and are often found near water. They are gregarious and noisy, have brilliant coloration and wide bills, and feed largely on insects.

broadcasting the transmission of sound and vision programmes by radio and television. Broadcasting may be organized under private enterprise, as in the USA, or may operate under a compromise system, as in Britain, where a television and radio service controlled by the state-regulated British Broadcasting Corporation (BBC) operates alongside the commercial Independent Television Commission (known as the Independent Broadcasting Authority before 1991).

In the USA, broadcasting is limited only by the issue of licences from the Federal Communications Commission to competing commercial companies; in Britain, the BBC is a centralized body appointed by the state and responsible to Parliament, but with policy and programme content not controlled by the state; in Japan, which ranks next to the USA in the number of television sets owned, there is a semigovernmental radio and television broadcasting corporation (NHK) and numerous private television companies.

Television broadcasting entered a new era with the introduction of high-powered communications satellites in the 1980s. The signals broadcast by these satellites are sufficiently strong to be picked up by a small dish aerial located, for example, on the roof of a house. Direct broadcast by satellite thus became a feasible alternative to land-based television services. See also cable television. A similar revolution will take place when digital television becomes widely available.

broad-leaved tree another name for a tree belonging to the *angiosperms*, such as ash, beech, oak, maple, or birch. The leaves are generally broad and flat, in contrast to the needlelike leaves of most *conifers*. See also *deciduous tree*.

broccoli variety of *cauliflower*. It contains high levels of the glucosinolate compound glucoraphanin. A breakdown product of this was found to neutralize damage to cells and so help to prevent cancer.

brocket name for a male European red deer in its second year, when it has short, straight, pointed antlers. Brocket deer, genus *Mazama*, include a number of species of small, shy, solitary deer found in Central and South America. They are up to 1.3 m/4 ft in body length and 65 cm/2 ft at the shoulder, and have similar small, straight antlers even when adult.

brolga or *native companion*, Australian crane *Grus rubicunda*, about 1.5 m/5 ft tall, mainly grey with a red patch on the head.

brome grass any of several annual grasses found in temperate regions; some are used as food for horses and cattle, but many are weeds. (Genus *Bromus*, family Gramineae.)

bromeliad any tropical or subtropical plant belonging to the pineapple family, usually with stiff leathery leaves, which are often coloured and patterned, and bright, attractive flower spikes. There are about 1,400 species in tropical America; several are cultivated as greenhouse plants. (Family Bromeliaceae.)

Some grow in habitats ranging from scrub desert to tropical forest floor. Many, however, grow on rainforest trees. These are epiphytes: they are supported by the tree but do not take nourishment

bromeliad The large *Bromelia balansae*, shown here, is one of numerous terrestrial bromeliads present on the sand dunes of the Brazilian coast near Rio; it is also widespread in dry areas inland. The flower spikes are regularly visited by hummingbirds, which are the main pollinators of many members of the family. *Premaphotes Wildlife*

from it, using rain and decayed plant and animal remains for independent sustenance.

bromide salt of the halide series containing the Br^- ion, which is formed when a bromine atom gains an electron.

The term 'bromide' is sometimes used to describe an organic compound containing a bromine atom, even though it is not ionic. Modern naming uses the term 'bromo-' in such cases. For example, the compound $\text{C}_2\text{H}_5\text{Br}$ is now called bromoethane; its traditional name, still used sometimes, is ethyl bromide.

bromine Greek *bromos* 'stench' dark, reddish-brown, nonmetallic element, a volatile liquid at room temperature, symbol Br, atomic number 35, relative atomic mass 79.904. It is a member of the halogen group, has an unpleasant odour, and is very irritating to mucous membranes. Its salts are known as bromides.

Bromine was formerly extracted from salt beds but is now mostly obtained from sea water, where it occurs in small quantities. Its compounds are used in photography and in the chemical and pharmaceutical industries.

bronchiole small-bore air tube found in the vertebrate lung responsible for delivering air to the main respiratory surfaces. Bronchioles lead off from the larger bronchus and branch extensively before terminating in the many thousand alveoli that form the bulk of lung tissue.

bronchitis inflammation of the bronchi (air passages) of the lungs, usually caused initially by a viral infection, such as a cold or flu. It is aggravated by environmental pollutants, especially smoking, and results in a persistent cough, irritated mucus-secreting glands, and large amounts of sputum.

bronchodilator drug that relieves obstruction of the airways by causing the bronchi and bronchioles to relax and widen. It is most useful in the treatment of asthma.

bronchus one of a pair of large tubes (bronchi) branching off from the windpipe and passing into the vertebrate lung. Apart from their size, bronchi differ from the bronchioles in possessing cartilaginous rings, which give rigidity and prevent collapse during breathing movements.

Numerous glands in the wall of the bronchus secrete a slimy mucus, which traps dust and other particles; the mucus is constantly being propelled upwards to the mouth by thousands of tiny hairs or cilia. The bronchus is adversely affected by several respiratory diseases and by smoking, which damages the cilia and therefore the lung-cleansing mechanism.

brontosaurus former name of a type of large, plant-eating dinosaur, now better known as *apatosaurus*.

bronze alloy of copper and tin, yellow or brown in colour. It is harder than pure copper, more suitable for casting, and also resists corrosion. Bronze may contain as much as 25% tin, together with small amounts of other metals, mainly lead.

Bronze is one of the first metallic alloys known and used widely by early peoples during the period of history known as the Bronze Age. The first bronze objects date from 3000 BC.

Bell metal, the bronze used for casting bells, contains 15% or more tin. Phosphor bronze is hardened by the addition of a small percentage of phosphorus. Silicon bronze (for telegraph wires) and aluminium bronze are similar alloys of copper with silicon or aluminium and small amounts of iron, nickel, or manganese, but usually no tin.

Bronze Age stage of prehistory and early history when copper and bronze (an alloy of tin and copper) became the first metals worked extensively and used for tools and weapons. One of the classifications of the Danish archaeologist Christian Thomsen's Three Age System, it developed out of the Stone Age and generally preceded the Iron Age. It first began in the Far East and may be dated 5000–1200 BC in the Middle East and about 2000–500 BC in Europe.

Mining and metalworking were the first specialized industries, and the invention of the wheel during this time revolutionized transport.

Agricultural productivity (which began during the New Stone Age, or Neolithic period, about 6000 BC) was transformed by the ox-drawn plough, increasing the size of the population that could be supported by farming.

In some areas, including most of Africa, there was no Bronze Age, and ironworking was introduced directly into the Stone Age economy.

broom any of a group of shrubs (especially species of *Cytisus* and *Spartium*), often cultivated for their bright yellow flowers. (Family Leguminosae.)

router device for connecting computer networks that incorporates the facilities of both a ϕ bridge and a ϕ router. Routers usually offer routing over a limited number of ϕ protocols, operating by routing where possible and bridging the remaining protocols.

Brown, Robert (1773–1858)

Scottish botanist who in 1827 discovered Brownian motion. As a botanist, his more lasting work was in the field of plant morphology. He was the first to establish the real basis for the distinction between gymnosperms (pines) and angiosperms (flowering plants).

On an expedition to Australia in 1801–05 Brown collected 4,000 plant species and later classified them using the 'natural' system of Bernard de Jussieu (1699–1777) rather than relying upon the system of Carolus Linnaeus.

Mary Evans Picture Library

brown bear species of ϕ bear found in N Europe.

brown dwarf in astronomy, an object less massive than a star, but heavier than a planet. Brown dwarfs do not have enough mass to ignite nuclear reactions at their centres, but shine by heat released during their contraction from a gas cloud. Some astronomers believe that vast numbers of brown dwarfs exist throughout the Galaxy. Because of the difficulty of detection, none were spotted until 1995, when US astronomers discovered a brown dwarf, G1229B, in the constellation Lepus. It is about 20–40 times as massive as Jupiter but emits only 1% of the radiation of the smallest known star. In 1996 UK astronomers discovered four possible brown dwarfs within 150 light years of the Sun.

Brownian movement the continuous random motion of particles in a fluid medium (gas or liquid) as they are subjected to impact from the molecules of the medium. The phenomenon was explained by

BROWNIAN MOTION

<http://dbhs.wvusd.k12.ca.us/Chem-History/Brown-1829.html>

Transcript of 'Remarks on Active Molecules' by Robert Brown from *Additional Remarks on Active Molecules* (1829). The text describes Robert Brown's observations of the random motion of particles, which in turn led to the placement of the subject on millions of school exam papers.

German physicist Albert Einstein in 1905 but was probably observed as long ago as 1827 by the Scottish botanist Robert Brown. It provides evidence for the ϕ kinetic theory of matter.

brown ring test in analytical chemistry, a test for the presence of ϕ nitrate.

To an aqueous solution containing the test substance is added iron(II) sulphate. Concentrated sulphuric acid is then carefully poured down the inside wall of the test tube so that it forms a distinct layer at the bottom. The formation of a brown colour at the boundary between the two layers indicates the presence of nitrate.

browse to explore a computer system or network for particular files or information. To browse in Windows is to search for a particular file to open or run. On the World Wide Web, browsing is the activity of moving from site to site to view information. This is sometimes also called 'surfing'.

browser in computing, any program that allows the user to search for and view data. Browsers are usually limited to a particular type of data, so, for example, a graphics browser will display graphics files stored in many different file formats. Browsers usually do not permit the user to edit data, but are sometimes able to convert data from one file format to another.

Web browsers allow access to the ϕ World Wide Web. Netscape Navigator and Microsoft's Internet Explorer were the leading Web browsers in 1996–97. They act as a graphical interface to information available on the Internet – they read ϕ HTML (hypertext markup language) documents and display them as graphical documents which may include images, video, sound, and ϕ hypertext links to other documents.

The first widespread browser for personal computers (PCs) was the text-based program Lynx, which is still used via ϕ gateways from text-based online systems such as Delphi and CIX. Browsers using ϕ graphical user interfaces became widely available from 1993 with the release of ϕ Mosaic, written by Marc Andreessen and Eric Bina. For some specialist applications such as viewing the virtual reality sites beginning to appear on the Web, a special virtual reality modelling language (ϕ VRL) browser is needed.

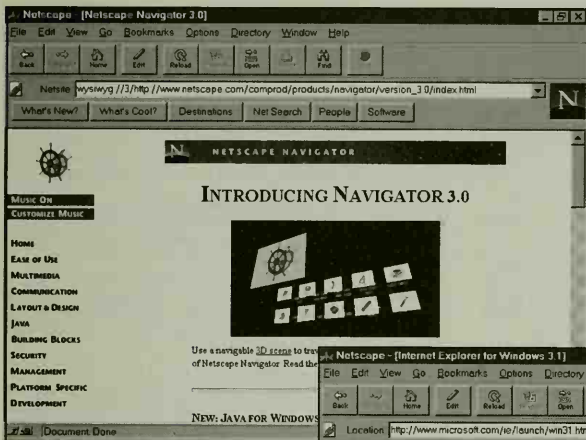

brucellosis disease of cattle, goats, and pigs, also known when transmitted to humans as undulant fever since it remains in the body and recurs. It was named after Australian doctor David Bruce (1855–1931), and is caused by bacteria (genus *Brucella*). It is transmitted by contact with an infected animal or by drinking contaminated milk.

Brunel, Isambard Kingdom (1806–1859)

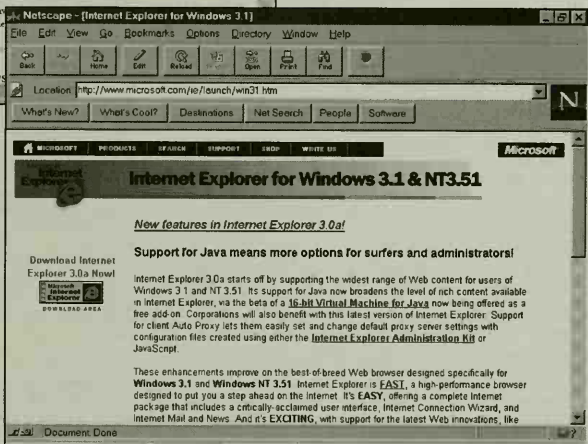

British engineer and inventor. In 1833 he became engineer to the Great Western Railway, which adopted the 2.1-m/7-ft gauge on his advice. He built the Clifton Suspension Bridge over the river Avon at Bristol and the Saltash Bridge over the river Tamar near Plymouth. His shipbuilding designs include the Great Western 1837, the first steamship to cross the Atlantic regularly; the Great Britain 1843, the first large iron ship to have a screw propeller; and the Great Eastern 1858, which laid the first transatlantic telegraph cable.

Mary Evans Picture Library

Netscape Navigator

Microsoft Internet Explorer

browser Two popular World Wide Web browsers, Netscape Navigator and Microsoft Internet Explorer, which provide the user with a straightforward method of accessing information available online.

It has largely been eradicated in the West through vaccination of livestock and pasteurization of milk. Brucellosis is especially prevalent in the Mediterranean and in Central and South America. It can be treated with antibacterial drugs.

brush in certain electric motors, one of a pair of contacts that pass electric current into and out of the rotating coils by means of a device known as a commutator. The brushes, which are often replaceable, are usually made of a soft, carbon material to reduce wear of the copper contacts on the rotating commutator.

Brussels sprout one of the small edible buds along the stem of a variety of cabbage. (*Brassica oleracea* var. *gemmifera*.) They are high in the glucosinolate compound sinigrin. Sinigrin was found to destroy precancerous cells in laboratory rats in 1996.

briony either of two climbing hedgerow plants found in Britain: white briony (*Bryonia dioica*) belonging to the gourd family (Cucurbitaceae), and black briony (*Tamus communis*) of the yam family (Dioscoreaceae).

bryophyte member of the Bryophyta, a division of the plant kingdom containing three classes: the Hepaticae (liverwort), Musci (moss), and Anthocerotae (hornwort). Bryophytes are generally small, low-growing, terrestrial plants with no vascular (water-conducting) system as in higher plants. Their life cycle shows a marked alternation of generations. Bryophytes chiefly occur in damp habitats and require water for the dispersal of the male gametes (antherozoids).

In bryophytes, the (sporophyte), consisting only of a spore-bearing capsule on a slender stalk, is wholly or partially dependent on the (gametophyte) for water and nutrients. In some liverworts the plant body is a simple (thallus), but in the majority of bryophytes it is differentiated into stem, leaves, and (rhizoids).

BSI abbreviation for (British Standards Institute).

BST abbreviation for (British Summer Time) and (bovine somatotropin).

To remember when we lose an hour, and when we gain an hour:

SPRING FORWARD, FALL BACK

OR

**REMEMBER THAT CLOCKS GO FORWARD AN HOUR IN SPRING,
SINCE THEY ARE EAGER FOR THE SUMMER; CLOCKS GO BACK
AN HOUR IN AUTUMN, SINCE THEY ARE WINTER AWAY FROM
THE BITTER CHILL OF WINTER**

BT abbreviation for British Telecom.

Btu symbol for British thermal unit.

bubble chamber in physics, a device for observing the nature and movement of atomic particles, and their interaction with radiation. It is a vessel filled with a superheated liquid through which ionizing particles move and collide. The paths of these particles are shown by strings of bubbles, which can be photographed and studied. By using a pressurized liquid medium instead of a gas, it overcomes drawbacks inherent in the earlier cloud chamber. It was invented by US physicist Donald Glaser in 1952. See *particle detector*.

bubble-jet printer in computing, an ink-jet printer in which the ink is heated to boiling point so that it forms a bubble at the end of a nozzle. When the bubble bursts, the ink is transferred to the paper.

bubble memory in computing, a memory device based on the creation of small 'bubbles' on a magnetic surface. Bubble memories typically store up to 4 megabits (4 million bits) of information. They are not sensitive to shock and vibration, unlike other memory devices such as disc drives, yet, like magnetic discs, they are nonvolatile and do not lose their information when the computer is switched off.

bubbleshell marine mollusc with a tiny shell. It burrows in the sand and feeds on animal matter.

bubble sort in computing, a technique for sorting data. Adjacent items are continually exchanged until the data are in sequence.

bubonic plague epidemic disease of the Middle Ages; see *plague* and *Black Death*.

buckminsterfullerene form of carbon, made up of molecules (buckyballs) consisting of 60 carbon atoms arranged in 12 pentagons and 20 hexagons to form a perfect sphere. It was named after the US architect and engineer Richard Buckminster Fuller because of its structural similarity to the geodesic dome that he designed. See *fullerene*.

buckthorn any of several thorny shrubs. The buckthorn (*Rhamnus cathartica*) is native to Britain, but is also found throughout Europe, W Asia, and N Africa. Its berries were formerly used in medicine as a purgative, to clean out the bowels. (Genus *Rhamnus*, family Rhamnaceae.)

buckwheat any of a group of cereal plants. The name usually refers to *Fagopyrum esculentum*, which reaches about 1 m/3 ft in height and can grow on poor soil in a short summer. The highly nutritious black triangular seeds (groats) are eaten by both animals and humans. They can be cooked and eaten whole or as a cracked meal (kasha), or ground into flour, often made into pancakes. (Genus *Fagopyrum*, family Polygonaceae.)

buckyballs popular name for molecules of *buckminsterfullerene*.

bud undeveloped shoot usually enclosed by protective scales; inside is a very short stem and numerous undeveloped leaves, or flower parts, or both. Terminal buds are found at the tips of shoots, while axillary buds develop in the axils of the leaves, often remaining dormant unless the terminal bud is removed or damaged. Adventitious buds may be produced anywhere on the plant, their formation sometimes stimulated by an injury, such as that caused by pruning.

budding type of asexual reproduction in which an outgrowth develops from a cell to form a new individual. Most yeasts reproduce in this way.

In a suitable environment, yeasts grow rapidly, forming long chains of cells as the buds themselves produce further buds before being separated from the parent. Simple invertebrates, such as *hydras*, can also reproduce by budding.

In horticulture, the term is used for a technique of plant propagation whereby a bud (or scion) and a sliver of bark from one plant are transferred to an incision made in the bark of another plant (the stock). This method of grafting is often used for roses.

buddleia any of a group of ornamental shrubs or trees with spikes of fragrant flowers. The purple or white flower heads of the butterfly bush (*Buddleia davidii*) attract large numbers of butterflies. (Genus *Buddleia*, family Buddleiaceae.)

budgerigar small Australian parakeet *Melopsittacus undulatus* of the parrot family, Psittacidae, order Psittaciformes, that feeds mainly on grass seeds. Normally it is bright green, but yellow, white, blue, and mauve varieties have been bred for the pet market. It breeds freely in captivity.

buffalo either of two species of wild cattle. The Asiatic water buffalo *Bubalis bubalis* is found domesticated throughout S Asia and wild in parts of India and Nepal. It likes moist conditions. Usually grey or black, up to 1.8 m/6 ft high, both sexes carry large horns. The African buffalo *Synceus caffer* is found in Africa, south of the Sahara, where there is grass, water, and cover in which to retreat. There are a number of subspecies, the biggest up to 1.6 m/5 ft high, and black, with massive horns set close together over the head. The name is also commonly applied to the American bison.

buffer in chemistry, mixture of compounds chosen to maintain a steady pH. The commonest buffers consist of a mixture of a weak organic acid and one of its salts or a mixture of acid salts of phosphoric acid. The addition of either an acid or a base causes a shift in the chemical equilibrium, thus keeping the pH constant.

buffer in computing, a part of the memory used to store data temporarily while it is waiting to be used. For example, a program might store data in a printer buffer until the printer is ready to print it.

bug in computing, an error in a program. It can be an error in the logical structure of a program or a syntax error, such as a spelling mistake. Some bugs cause a program to fail immediately; others remain dormant, causing problems only when a particular combination of events occurs. The process of finding and removing errors from a program is called *debugging*.

bug in entomology, an insect belonging to the order Hemiptera. All these have two pairs of wings with forewings partly thickened.

They also have piercing mouthparts adapted for sucking the juices of plants or animals, the 'beak' being tucked under the body when not in use.

They include: the bedbug, which sucks human blood; the shieldbug, or stinkbug, which has a strong odour and feeds on plants; and the water boatman and other water bugs.

bugle any of a group of low-growing plants belonging to the mint family, with spikes of white, pink, or blue flowers. The leaves may be smooth-edged or slightly toothed, the lower ones with a long stalk. They are often grown as ground cover. (Genus *Ajuga*, family Labiateae.)

bugloss any of several plants native to Europe and Asia, distinguished by their rough, bristly leaves and small blue flowers. (Genera *Anchusa*, *Lycopsis*, and *Echium*, family Boraginaceae.)

bulb underground bud with fleshy leaves containing a reserve food supply and with roots growing from its base. Bulbs function in vegetative reproduction and are characteristic of many monocotyledonous plants such as the daffodil, snowdrop, and onion. Bulbs are grown on a commercial scale in temperate countries, such as England and the Netherlands.

Millennium Bug: Preparing Computers for the Year 2000

BY SCOTT KIRSNER

Digital Disarray

It sounds like a bad riddle: how will two missing digits create a \$600 billion industry when the calendar flips from 1999 to 2000?

Unfortunately, it's not a riddle; it's reality. As the 20th century draws to a close, an expensive computer problem dubbed 'the millennium bug' has emerged. In brief, most computers handle dates using a two-digit shorthand: 98 instead of the four-digit 1998. When presented with a date like 00, they become hopelessly confused. Since they're missing the two digits that indicate what millennium and century the date is in (19 or 20), computers tend to assume that 00 is actually 1900. So they'll either begin making errors of calculation or they'll stop working altogether. Reprogramming them to be capable of comprehending dates in the new millennium is expected to cost as much as \$600 billion worldwide.

The origins of the problem are simple. First, the programmers who wrote software in the 1960s for the first generation of commercial mainframe computers were shortsighted. They didn't imagine that the programs they were creating – or the machines they were creating them for – would still be in service in the far-off year of 2000. So they conserved the computers' memory by using a two-digit shorthand for the year. Every byte of memory was precious in those days, and lopping off 19 from dates was an obvious way to save a few bytes here and there.

Banks were among the first institutions to notice the downside to that approach. When they began writing long-term mortgages and approving loans that lasted past 1999, they were forced to confront the millennium bug. But the problem received little widespread attention until the mid-1990s. Technology consultants began writing articles and giving speeches about 'the year 2000 problem'. Business executives began to take notice, and even consumers couldn't ignore the problem when credit card issuers and driver's licence organizations began to renew cards and licences for shorter periods of time, because their systems couldn't handle an expiration date past 1999.

How might businesses and consumers be affected by the millennium bug? Computers, both new and old, in every industry are vulnerable. They might shut down as a result of being asked to process the date 00. Some say that is the best-case scenario, because at least businesses will know something is wrong. Worse would be if computers continued to operate, making numerous date-related errors that would be difficult to identify and fix.

The areas of greatest concern are defence, health care, transportation, telecommunications, financial services, and national and local governments. Technology experts warn of the hazards of air travel if the Federal Aviation Administration's computers can't manage data properly, the danger of hospital stays if the computers that monitor patients go awry, and the possibility of social unrest if the federal government can't provide services in 2000.

Date Expansion or Windowing?

Fixing the millennium bug is a labour-intensive endeavour. An organization can opt to replace its systems entirely with new ones that can function in the 21st century, or it may pursue one of two basic repair strategies – 'date expansion' or 'windowing'.

Date expansion involves changing the two-digit dates to four. That entails converting all of the data an organization has stored from one format to the other, and reprogramming systems to handle four-digit dates like 2001.

Windowing is considered a simpler, less expensive solution, but it's only a temporary patch. Rather than converting all of a

company's data, the windowing approach merely adds logic to a program to help it determine whether a two-digit date belongs in the 20th century or the 21st. Programmers might create a 'window' of time – from 00 to 30, for example – and then instruct the computer to assume that those dates should all be preceded by 19. But when 2031 rolls around, that hypothetical company would have a new problem on its hands. Windowing assumes that an organization will either replace its older systems before the window of time closes, or reprogram them yet again.

Eradicating the millennium bug is a multi-stage process. An organization must first assess which of its systems will be unable to handle dates in the 21st century. Then, it must convert those systems, either through expansion or windowing. Finally, it has to test the systems to ensure that they will work after the clock ticks past midnight on 31 December, 1999.

Ripple Effects

But even if companies successfully repair their own systems, they're still vulnerable to what has been dubbed 'the ripple effect'. One of their suppliers or customers, or a government regulator, could send them unconverted data and contaminate their systems. Or even worse, a key supplier might be unable to provide services or raw materials as a result of the bug, hamstringing its customers. For those reasons, organizations must make sure that everyone else with whom they do business is solving their own year 2000 problems. Certain sectors of the economy, like the financial services arena, are even coordinating massive, interorganizational tests to make sure that stock exchanges, banks, regulators, and clearing houses will be able to work together in the new millennium.

And waiting in the wings are the lawyers. If software or hardware fails, they'll be scrutinizing contracts to see who is liable. If a conversion project turns out to have been defective, they may bring litigation against the service provider that was contracted to perform the fix. And if a company's stock takes a dive as a result of year 2000-related failures, lawyers may file negligence lawsuits against the Board of Directors. Once litigation and damages are figured into the cost of the millennium bug, some analysts believe the total worldwide cost could skyrocket to as much as \$3.6 trillion.

The sudden emergence of the year 2000 problem has created an entire mini-economy. Programmers and technology managers are finding that they can demand and receive higher salaries, computer consultants have more work than they can handle, and software companies have begun to market tools aimed at making assessment, conversion, and testing more efficient. There are dozens of Web sites and books devoted to the problem. The American Stock Exchange has even created an options index that enables investors to speculate on the fortunes of 18 companies selling software or services intended to solve the year 2000 problem.

Few participants in this mini-economy are willing to speculate about the extent to which the world will be affected by the millennium bug. Will 1 January, 2000, arrive without a hitch, or will, as some technology experts predict, the front pages of every major newspaper be filled with stories about date-related computer crises? All that's certain is that programmers and their technology managers won't be among the celebrants on New Year's Eve, 1999; they'll be huddled over their mainframes, fingers crossed.

bulbil small bulb that develops above ground from a bud. Bulbils may be formed on the stem from axillary buds, as in members of the saxifrage family, or in the place of flowers, as seen in many species of onion *Allium*. They drop off the parent plant and develop into new individuals, providing a means of vegetative reproduction and dispersal.

bulbul fruit-eating bird of the family Pycnonotidae, order Passeriformes, that ranges in size from that of a sparrow to a blackbird. They are mostly rather dull coloured and very secretive, living in dense forests. They are widely distributed throughout Africa and Asia; there are about 120 species.

bulimia Greek 'or hunger' eating disorder in which large amounts of food are consumed in a short time ('binge'), usually followed by depression and self-criticism. The term is often used for *bulimia nervosa*, an emotional disorder in which eating is followed by deliberate vomiting and purging. This may be a chronic stage in *anorexia nervosa*.

Bulinus large genus of tiny freshwater and land snails, comprising over 1,000 species. They have external shells, and are related to the hedge- and grass-snails.

Certain species of this snail act as the intermediate host for the microscopic worm that causes *bilharzia*, one of the most common parasitic diseases.

classification *Bulinus* is in class Gastropoda of phylum Mollusca.

bulldog British breed of dog of ancient but uncertain origin, formerly bred for bull-baiting. The head is broad and square, with deeply wrinkled cheeks, small folded ears, very short muzzle, and massive jaws, the peculiar set of the lower jaw making it difficult for the dog to release its grip. Thickest in build, the bulldog grows to about 45 cm/18 in and has a smooth beige, tawny, or brindle coat. The French bulldog is much lighter in build and has large upright ears.

bulldozer earth-moving machine widely used in construction work for clearing rocks and tree stumps and levelling a site. The bulldozer is a kind of tractor with a powerful engine and a curved, shovel-like blade at the front, which can be lifted and forced down by hydraulic rams. It usually has caterpillar tracks so that it can move easily over rough ground.

bulletin board in computing, a centre for the electronic storage of messages, usually accessed over the telephone network via a *modem* but also sometimes accessed via *Telnet* across the Internet. Bulletin board systems (often abbreviated to BBSs) are usually dedicated to specific interest groups, and may carry public and private messages, notices, and programs.

bullfinch Eurasian finch with a thick head and neck, and short heavy bill, genus *Pyrrhula pyrrhula*, family Fringillidae, order Passeriformes. It is small and blue-grey or black in colour, the males being reddish and the females brown on the breast. Bullfinches are 15 cm/6 in long, and usually seen in pairs. They feed on tree buds as well as seeds and berries, and are usually seen in woodland. They also live in the Aleutians and on the Alaska mainland.

bullfrog North American species of *Rana*.

bullhead or *miller's thumb* small fish *Cottus gobio* found in fresh water in the northern hemisphere, often under stones. It has a large head, a spine on the gill cover, and grows to 10 cm/4 in.

Related bullheads, such as the *father lasher* *Myxoxcephalus scorpius*, live in coastal waters. They are up to 30 cm/1 ft long. The male guards the eggs and fans them with his tail.

bul terrier breed of dog, originating as a cross between a terrier and a bulldog. Very powerfully built, it grows to about 40 cm/16 in tall, and has a short, usually white, coat, narrow eyes, and distinctive egg-shaped head. It was formerly used in bull-baiting. Pit bull terriers are used in illegal dog fights. The *Staffordshire bull terrier* is a distinct breed.

bulrush either of two plants: the great reed mace or cat's tail (*Typha latifolia*) with velvety chocolate-brown spikes of tightly

packed flowers reaching up to 15 cm/6 in long; and a type of sedge (*Scirpus lacustris*) with tufts of reddish-brown flowers at the top of a rounded, rushlike stem.

bumblebee any large *bombus*, 2–5 cm/1–2 in, usually dark-coloured but banded with yellow, orange, or white, belonging to the genus *Bombus*.

Most species live in small colonies, usually underground, often in an old mousehole. The queen lays her eggs in a hollow nest of moss or grass at the beginning of the season. The larvae are fed on pollen and honey, and develop into workers. All the bees die at the end of the season except fertilized females, which hibernate and produce fresh colonies in the spring. Bumblebees are found naturally all over the world, with the exception of Australia, where they have been introduced to facilitate the pollination of some cultivated varieties of clover.

bundling computer industry practice of selling different, often unrelated, products in a single package. Bundles may consist of hardware or software or both; for example, a *modem* or a selection of software may be bundled with a personal computer to make the purchase of the computer seem more attractive.

Bunsen burner gas burner used in laboratories, consisting of a vertical metal tube through which a fine jet of fuel gas is directed. Air is drawn in through airholes near the base of the tube and the mixture is ignited and burns at the tube's upper opening.

The invention of the burner is attributed to German chemist Robert von Bunsen in 1855 but English chemist and physicist Michael Faraday is known to have produced a similar device at an earlier date. A later refinement was the metal collar that can be turned to close or partially close the airholes, thereby regulating the amount of air sucked in and hence the heat of the burner's flame.

bunting any of a number of sturdy, finchlike birds with short, thick bills, of the family Emberizidae, order Passeriformes, especially the genera *Passerim* and *Emberiza*. Most of these brightly coloured birds are native to the New World.

Bunsen burner The Bunsen burner, used for heating laboratory equipment and chemicals. The flame can reach temperatures of 1,500°C/2,732°F and is at its hottest when the collar is open.

Bunsen, Robert Wilhelm (1811–1899)

German chemist credited with the invention of the Bunsen burner. His name is also given to the carbon-zinc electric cell, which he invented in 1841 for use in arc lamps. In 1860 he discovered two new elements, caesium and rubidium.

Mary Evans Picture Library

buoy floating object used to mark channels for shipping or warn of hazards to navigation. Buoys come in different shapes, such as a pole (spar buoy), cylinder (car buoy), and cone (nun buoy). Light buoys carry a small tower surmounted by a flashing lantern, and bell buoys house a bell, which rings as the buoy moves up and down with the waves. Mooring buoys are heavy and have a ring on top to which a ship can be tied.

buoyancy lifting effect of a fluid on a body wholly or partly immersed in it. This was studied by Archimedes in the 3rd century BC.

bur or **burr** in botany, a type of 'false fruit' or pseudocarp, surrounded by numerous hooks; for instance, that of burdock *Arctium*, where the hooks are formed from bracts surrounding the flower-head. Burs catch in the feathers or fur of passing animals, and thus may be dispersed over considerable distances.

burbot or **eelpout** long, rounded fish *Lota lota* of the cod family, the only one living entirely in fresh water. Up to 1 m/3 ft long, it lives on the bottom of clear lakes and rivers, often in holes or under rocks, throughout Europe, Asia, and North America.

burdock any of several bushy herbs characterized by hairy leaves and ripe fruit enclosed in burs with strong hooks. (Genus *Arctium*, family Compositae.)

burette in chemistry, a piece of apparatus, used in titration, for the controlled delivery of measured variable quantities of a liquid.

It consists of a long, narrow, calibrated glass tube, with a tap at the bottom, leading to a narrow-bore exit.

Burmese cat breed of domestic short-haired cat of ancient origin. The modern breed is descended from a cat introduced into the USA in 1930 from Burma and crossed with a Siamese. The original Burmese has a sable brown coat with lighter shading on the underside; the medium-length body is muscular and more rounded than a Siamese.

It was first recognized as a true breed in the USA in 1936 and in the UK in 1952. The standards vary for the Burmese in the USA and Britain; for instance, the British eye shape is specified as oval, while the American standard demands a rounder look. There are many varieties.

burn in medicine, destruction of body tissue by extremes of temperature, corrosive chemicals, electricity, or radiation. First-degree burns may cause reddening; second-degree burns cause blistering and irritation but usually heal spontaneously; third-degree burns are disfiguring and may be life-threatening.

Burns cause plasma, the fluid component of the blood, to leak from the blood vessels, and it is this loss of circulating fluid that engenders shock. Emergency treatment is needed for third-degree burns in order to replace the fluid volume, prevent infection (a serious threat to the severely burned), and reduce the pain. Plastic, or reconstructive, surgery, including skin grafting, may be

required to compensate for damaged tissue and minimize disfigurement. If a skin graft is necessary, dead tissue must be removed from a burn (a process known as debridement) so that the patient's blood supply can nourish the graft.

burnet herb belonging to the rose family, also known as **salad burnet**. It smells of cucumber and can be used in salads. The name is also used for other members of the genus. (*Sanguisorba minor*, family Rosaceae.)

burning common name for combustion.

burying beetle another name for the sexton beetle.

bus in computing, the electrical pathway through which a computer processor communicates with some of its parts and/or peripherals. Physically, a bus is a set of parallel tracks that can carry digital signals; it may take the form of copper tracks laid down on the computer's printed circuit boards (PCBs), or of an external cable or connection.

A computer typically has three internal buses laid down on its main circuit board: a **data bus**, which carries data between the components of the computer; an **address bus**, which selects the route to be followed by any particular data item travelling along the data bus; and a **control bus**, which is used to decide whether data is written to or read from the data bus. An external expansion bus is used for linking the computer processor to peripheral devices, such as modems and printers.

bus The communication path used between the component parts of a computer.

Bush, Vannevar (1890–1974)

US electrical engineer and scientist. During the 1920s and 1930s he developed several mechanical and mechanical-electrical analogue computers which were highly effective in the solution of differential equations. The standard electricity meter is based on one of his designs.

bushbaby small nocturnal African prosimian with long feet, long, bushy tail, and large ears. Bushbabies are active tree dwellers and feed on fruit, insects, eggs, and small birds.

classification Bushbabies are members of the loris family Lorisidae, order Primates.

bushbuck antelope *Tragelaphus scriptus* found over most of Africa south of the Sahara. Up to 1 m/3 ft high, the males have keeled horns twisted into spirals, and are brown to blackish. The females are generally hornless, lighter, and redder. All have white markings, including stripes or vertical rows of dots down the sides. Rarely far from water, bushbuck live in woods and thick brush.

bushel dry or liquid measure equal to eight gallons or four pecks (2,219.36 cu in/36.37 litres) in the UK; some US states have different standards according to the goods measured.

bushman's rabbit or **riverine rabbit** a wild rodent *Bunolagus montianus* found in dense riverine bush in South Africa. It lives in small populations, and individuals are only seen very occasionally; it is now at extreme risk of extinction owing to loss of habitat to agriculture. Very little is known about its life or habits.

bushmaster large snake *Lachesis muta*. It is a type of pit viper, and is related to the rattlesnakes. Up to 4 m/12 ft long, it is found in wooded areas of South and Central America, and is the largest venomous snake in the New World. When alarmed, it produces a noise by vibrating its tail among dry leaves.

bush pig wild pig found in forested regions of Africa. Typically it is dark brown in colour, about 60 cm/24 in high and has short tusks no more than 15 cm/6 in long.

The red river hog is a West African variety of the same species but is rusty red in colour with prominent black and white markings on the face.

classification The bush pig *Potamochoerus porcus* is in family Suidae, order Artiodactyla.

bustard bird of the family Otididae, order Gruiformes, related to cranes but with a rounder body, thicker neck, and a relatively short beak. Bustards are found on the ground on open plains and fields.

The great bustard *Otis tarda* is one of the heaviest flying birds at 18 kg/40 lb, and the larger males may have a length of 1 m/3 ft and wingspan of 2.3 m/7.5 ft. It is found in N Asia and Europe, although there are fewer than 30,000 great bustards left in Europe; two-thirds of these live on the Spanish steppes.

butadiene or **buta-1,3-diene** $\text{CH}_2\text{=CHCH=CH}_2$ inflammable gas derived from petroleum, used in making synthetic rubber and resins.

butane C_4H_{10} one of two gaseous alkanes (paraffin hydrocarbons) having the same formula but differing in structure. Normal butane is derived from natural gas; isobutane is a by-product of petroleum manufacture. Liquefied under pressure, it is used as a fuel for industrial and domestic purposes (for example, in portable cookers).

butcherbird another name for a shrike.

butene C_4H_8 fourth member of the alkene series of hydrocarbons. It is an unsaturated compound, containing one double bond.

buttercup any plant of the buttercup family with divided leaves and yellow flowers. (Genus *Ranunculus*, family Ranunculaceae.)

butterfly insect belonging, like moths, to the order Lepidoptera, in which the wings are covered with tiny scales, often brightly coloured. There are some 15,000 species of butterfly, many of which are under threat throughout the world because of the destruction of habitat.

Butterflies have a tubular proboscis through which they suck up nectar, or, in some species, carrion, dung, or urine.

BUTTERFLY

The sensors on the feet of a red admiral butterfly are 200 times more sensitive to sugar than the human tongue.

Metamorphosis is complete; the pupa, or chrysalis, is usually without the protection of a cocoon. Adult lifespan may be only a few weeks, but some species hibernate and lay eggs in the spring.

The largest family, Nymphalidae, has some 6,000 species; it includes the peacock, tortoiseshells, and fritillaries. The family Pieridae includes the cabbage white, one of the few butterflies injurious to crops. The Lycaenidae are chiefly small, often with metallic coloration, for example the blues, coppers, and hairstreaks. The large blue *Lycaena arion* has a complex life history: it lays its eggs on wild thyme, and the caterpillars are then taken by Myrmica ants to their nests. The ants milk their honey glands, while the caterpillars feed on the ant larvae. In the spring, the caterpillars finally pupate and emerge as butterflies. The mainly tropical Papilionidae, or swallowtails, are large and very beautiful, especially the South American species. The world's largest butterfly is Queen Alexandra's birdwing *Ornithoptera alexandrae* of Papua New Guinea, with a body 7.5 cm/3 in long and a wingspan of 25 cm/10 in. The most spectacular migrant is the orange and black monarch butterfly *Danaus plexippus*, which may fly from N Canada to Mexico in the autumn.

Butterflies usually differ from moths in having the antennae club-shaped rather than plumed or feathery, no 'lock' between the fore- and hindwing, and resting with the wings in the vertical position rather than flat or sloping.

butterfly fish any of several fishes, not all related. They include the freshwater butterfly fish *Pantodon buchholzi* of western Africa and the tropical marine butterfly fishes in family Chaetodontidae.

P. buchholzi can leap from the water and glide for a short distance on its large winglike pectoral fins. Up to 10 cm/4 in long, it lives in stagnant water, at the water surface during the day, lying beneath floating leaves. At night it hunts for insects, jumping out of the water to catch them.

The members of Chaetodontidae are brightly coloured with laterally flattened bodies, often with long snouts which they poke into crevices in rocks and coral when feeding. They have a flattened narrow body with one dorsal fin and a fairly long snout. Their bristlelike teeth are closely set in rows for feeding on small animals and green algae. The commonest colours are black, yellow, and brilliant metallic blues and greens.

classification Chaetodontidae is in order Perciformes; *Pantodon buchholzi* is in order Osteoglossiformes; both are in class Osteichthyes.

butterwort insectivorous plant belonging to the bladderwort family, with purplish flowers and a rosette of flat leaves covered with a sticky substance that traps insects. (Genus *Pinguicula*, family Lentibulariaceae.)

buzzard species of medium-sized hawk with broad wings, often seen soaring. Buzzards are in the falcon family, Falconidae, order Falconiformes. The common buzzard *Buteo buteo* of Europe and Asia is about 55 cm/1.8 ft long with a wingspan of over 1.2 m/4 ft. It preys on a variety of small animals up to the size of a rabbit.

The rough-legged buzzard *B. lagopus* lives in the northern tundra and eats lemmings. The honey buzzard *Pernis ptilorhynchus* feeds largely, as its name suggests, on honey and insect larvae. It spends the summer in Europe and W Asia and winters in Africa. The red-shouldered hawk *B. lineatus* and red-tailed hawk *B. jamaicensis* occur in North America.

by-product substance formed incidentally during the manufacture of some other substance; for example, slag is a by-product of the production of iron in a blast furnace. For industrial processes to be economical, by-products must be recycled or used in other ways as far as possible; in this example, slag is used for making roads.

Often, a poisonous by-product is removed by transforming it into another substance, which although less harmful is often still inconvenient. For example, the sulphur dioxide produced as a by-product of electricity generation can be removed from the smoke stack using blue-gas desulphurization. This process produces large amounts of gypsum, some of which can be used in the building industry.

bysuss tough protein fibres secreted by the foot of sessile (fixed) bivalves, such as mussels, as a means of attachment to rocks.

The byssus of some rock creatures can be woven into fabrics. A delicate silk called byssus is made from the byssus of mussels found in the Mediterranean.

byte sufficient computer memory to store a single character of data. The character is stored in the byte of memory as a pattern of 8 bits (binary digits), using a code such as ASCII. A byte usually

contains eight bits – for example, the capital letter F can be stored as the bit pattern 01000110.

A single byte can specify 256 values, such as the decimal numbers from 0 to 255; in the case of a single-byte *opixel* (picture element), it can specify 256 different colours. Three bytes (24 bits) can specify 16,777,216 values. Computer memory size is measured in kilobytes (1,024 bytes) or megabytes (1,024 kilobytes).

°C symbol for degrees Celsius, sometimes called centigrade.

C++ in computing, a high-level programming language used in object-oriented applications. It is derived from the language C.

C in computing, a high-level, general-purpose programming language popular on minicomputers and microcomputers. Developed in the early 1970s from an earlier language called BCPL, C was first used as the language of the operating system UNIX, though it has since become widespread beyond UNIX. It is useful for writing fast and efficient systems programs, such as operating systems (which control the operations of the computer).

cabbage vegetable plant related to the turnip and wild mustard, or charlock. It was cultivated as early as 2000 BC, and the many commercial varieties include kale, Brussels sprouts, common cabbage, savoy, cauliflower, sprouting broccoli, and kohlrabi. (*Brassica oleracea*, family Cruciferae.)

cabbage butterfly one of several butterfly species, the caterpillars of which feed on the leaves of members of the cabbage family, particularly as pests on cabbages. Chalcid wasps parasitize the caterpillars, thereby controlling their numbers.

classification Cabbage butterflies are in genus *Pieris* in order Lepidoptera, class Insecta, phylum Arthropoda.

species The large white *Pieris brassicae* is found in Europe and North Africa. The expanded wings measure 7.5 cm/3 in across, and are white with black edgings. The female, which has black spots on the upper surfaces of the wings, lays her yellow eggs in clusters on cabbage leaves. The fully grown caterpillar sometimes measures 4 cm/1.5 in, and will eat twice its own weight of leaf in 24 hours. After it has hung for some time by its tail from a ledge, it changes into a shining pale green chrysalis. The butterfly, which in the case of the autumn brood waits till winter is past before emerging, lives on nectar.

The small white butterfly *Pieris rapae*, has a wing expansion of about 5 cm/2 in, lays its eggs singly on the underside of vegetable leaves, and produces a velvety caterpillar which devours the hearts, instead of merely the leaves, of cabbages. The chrysalis is brownish-yellow with black spots.

A third species, the green-veined white butterfly *Pieris napi*, which is similar to the small white, cannot multiply so fast, because both the butterfly and its caterpillar are a favourite food of small birds.

cabbage-tree palm tall, fan-leaf palm *Livistona australis* of the coastal areas of E Australia. Aborigines eat the cabbagelike hearts of the young leaves.

cable unit of length, used on ships, originally the length of a ship's anchor cable or 120 fathoms (219 m/720 ft), but now taken as one-tenth of a nautical mile (185.3 m/608 ft).

cable car method of transporting passengers up steep slopes by cable. In the cable railway, passenger cars are hauled along rails by a cable wound by a powerful winch. A pair of cars usually operates together on the funicular principle, one going up as the other goes down. The other main type is the aerial cable car, where the passenger car is suspended from a trolley that runs along an aerial cableway.

A cable-car system has operated in San Francisco since 1873. The streetcars travel along rails and are hauled by moving cables under the ground.

cable modem box supplied by cable companies to provide television and telephone services, including Internet. The advantages of cable modems over traditional modems, which operate over standard telephone lines, are greatly increased speed of communications as well as the ability to transmit video and two-way audio, and lower costs.

cable television distribution of broadcast signals through cable relay systems.

Narrow-band systems were originally used to deliver services to areas with poor regular reception; systems with wider bands, using coaxial and fibreoptic cable, are increasingly used for distribution and development of home-based interactive services, typically telephones.

In 1997, the USA had 65 million cable television subscribers using more than 11,000 cable systems. The systems were to spend more than \$3.5 billion on basic programming in 1997, up 14% from 1996. In 1998, the 65 million US subscribers paid an average of more than \$31 a month. The cost for 1998 represented the third straight year the price has increased by 8%, four times the inflation rate.

cacao tropical American evergreen tree, now also cultivated in W Africa and Sri Lanka. Its seeds are cocoa beans, from which cocoa and chocolate are prepared. (*Theobroma cacao*, family Sterculiaceae.)

The trees mature at five to eight years and produce two crops a year. The fruit is 17–25 cm/6.5–9.5 in long, hard, and ridged, with the beans inside. The seeds are called cocoa nibs; when left to ferment, then roasted and separated from the husks, they contain about 50% fat, part of which is removed to make chocolate and cocoa.

The Aztecs revered cacao and made a drink exclusively for the nobility from cocoa beans and chillies, which they called chocolatl. In the 16th century Spanish traders brought cacao to Europe. It was used to make a drink, which came to rival coffee and tea in popularity.

cachalot alternative name for the sperm whale; see *whale*.

cache memory in computing, a reserved area of the immediate access memory used to increase the running speed of a computer program.

The cache memory may be constructed from ψ SRAM, which is faster but more expensive than the normal ψ DRAM. Most programs access the same instructions or data repeatedly. If these frequently used instructions and data are stored in a fast-access SRAM memory cache, the program will run more quickly. In other cases, the memory cache is normal DRAM, but is used to store frequently used instructions and data that would normally be accessed from ψ backing storage. Access to DRAM is faster than access to backing storage so, again, the program runs more quickly. This type of cache memory is often called a disc cache.

cactus (plural *cacti*) strictly, any plant of the family Cactaceae, although the word is commonly used to describe many different succulent and prickly plants. True cacti have a woody axis (central core) surrounded by a large fleshy stem, which takes various forms and is usually covered with spines (actually reduced leaves). They are all specially adapted to growing in dry areas.

Cactus flowers are often large and brightly coloured; the fruit is fleshy and often edible, as in the case of the prickly pear. The Cactaceae are a New World family and include the tree-like saguaro and the night-blooming cereus with blossoms 30 cm/12 in across.

CACTUS AND SUCCULENT PLANT MALL

<http://www.cactus-mall.com/index.html>

Huge source of information on cacti and how to grow them. There are also reports on conservation of cacti and succulents. There are links to a large number of international cacti associations.

CAD (acronym for *computer-aided design*) the use of computers in creating and editing design drawings. CAD also allows such things as automatic testing of designs and multiple or animated three-dimensional views of designs. CAD systems are widely used in architecture, electronics, and engineering, for example in the motor-vehicle industry, where cars designed with the assistance of computers are now commonplace.

A related development is ϕ CAM (computer-assisted manufacturing).

Cadarache French nuclear research site, NE of Aix-en-Provence.

caddis fly insect of the order Trichoptera. Adults are generally dull brown, mothlike, with wings covered in tiny hairs. Mouthparts are poorly developed, and many caddis flies do not feed as adults. They are usually found near water.

The larvae are aquatic, and many live in cases, open at both ends, which they make out of sand or plant remains. Some species make silk nets among aquatic vegetation to help trap food.

caddis fly Caddis fly adults are generally rather drab insects most likely to be seen by ponds, lakes, and rivers where they may form dense mating swarms. The larvae fashion intricate cases from materials such as sand grains, twigs, empty snail shells, or other debris. Premaphotos Wildlife

cadmium soft, silver-white, ductile, and malleable metallic element, symbol Cd, atomic number 48, relative atomic mass 112.40. Cadmium occurs in nature as a sulphide or carbonate in zinc ores. It is a toxic metal that, because of industrial dumping, has become an environmental pollutant. It is used in batteries, electroplating, and as a constituent of alloys used for bearings with low coefficients of friction; it is also a constituent of an alloy with a very low melting point.

Cadmium is also used in the control rods of nuclear reactors, because of its high absorption of neutrons. It was named in 1817 by the German chemist Friedrich Strohmeyer (1776-1835) after the Greek mythological character Cadmus.

caecilian tropical amphibian of wormlike appearance. There are about 170 species known in the family Caeciliidae, forming the amphibian order Apoda (also known as Caecilia or Gymnophiona). Caecilians have a grooved skin that gives a 'segmented' appearance; they have no trace of limbs or pelvis. The body is 20-130 cm/8-50 in long, beige to black in colour. The eyes are very small and weak or blind. They eat insects and small worms. Some species bear live young, others lay eggs.

Caecilians live in burrows in damp ground in the tropical Americas, Africa, Asia, and the Seychelles Islands.

caecum in the ϕ digestive system of animals, a blind-ending tube branching off from the first part of the large intestine, terminating

CAECILIANS WEB SITE

<http://www.sfo.com/~morriss/eels.html>

Many facts about these legless amphibians, especially *Typhlonectes natans*, an aquatic caecilian often found in aquariums in the USA. Tips on care, health, and breeding can also be found at this site.

in the appendix. It has no function in humans but is used for the digestion of cellulose by some grass-eating mammals.

The rabbit caecum and appendix contains millions of bacteria that produce cellulase, the enzyme necessary for the breakdown of cellulose to glucose. In order to be able to absorb nutrients released by the breakdown of cellulose, rabbits pass food twice down the intestine. They ingest soft pellets which are then re-eaten. This is known as coprophagy.

Caesarean section surgical operation to deliver a baby by way of an incision in the mother's abdominal and uterine walls. It may be recommended for almost any obstetric complication implying a threat to mother or baby.

Caesarean section was named after the Roman emperor Julius Caesar, who was born this way. In medieval Europe, it was performed mostly in attempts to save the life of a child whose mother had died in labour. The Christian Church forbade cutting open the mother before she was dead.

caesium Latin *caesius* 'bluish-grey' soft, silvery-white, ductile metallic element, symbol Cs, atomic number 55, relative atomic mass 132.905. It is one of the alkali metals, and is the most electropositive of all the elements. In air it ignites spontaneously, and it reacts vigorously with water. It is used in the manufacture of photocells. The name comes from the blueness of its spectral line.

The rate of vibration of caesium atoms is used as the standard of measuring time. Its radioactive isotope Cs-137 (half-life 30.17 years) is a product of fission in nuclear explosions and in nuclear reactors; it is one of the most dangerous waste products of the nuclear industry, being a highly radioactive biological analogue for potassium.

caffeine ϕ alkaloid organic substance found in tea, coffee, and kola nuts; it stimulates the heart and central nervous system. When isolated, it is a bitter crystalline compound, $C_8H_{10}N_4O_2$. Too much caffeine (more than six average cups of tea or coffee a day) can be detrimental to health.

caiman or **caymán** large reptile, related to the ϕ alligator.

All caimans are found only in Central and South America. **types of caiman** The black caiman *Melanosuchus niger* is the largest South American predator, reaching 6 m in length. Cuvier's dwarf caiman *Paleosuchus palpebrosus* may be as little as 1.2 m in length when fully grown (females). Schneider's dwarf caiman *Paleosuchus trigonatus* reaches 1.7 m and is reasonably common in the Amazonian rainforests. Broad-snouted caiman *Caiman latirostris* is found in freshwater swamps and grows up to 3.5 m. Common caiman *Caiman crocodilus* is found from southern Mexico to northern Argentina and can grow up to 3 m.

cairn Scottish breed of terrier. Shaggy, short-legged, and compact, it can be sandy, greyish brindle, or red. It was formerly used for flushing out foxes and badgers.

caisson hollow cylindrical or boxlike structure, usually of reinforced ϕ concrete, sunk into a riverbed to form the foundations of a bridge.

An open caisson is open at the top and at the bottom, where there is a wedge-shaped cutting edge. Material is excavated from inside, allowing the caisson to sink. A pneumatic caisson has a pressurized chamber at the bottom, in which workers carry out the excavation. The air pressure prevents the surrounding water entering; the workers enter and leave the chamber through an airlock, allowing for a suitable decompression period to prevent ϕ decompression sickness (the so-called bends).

cal symbol for calorie.

CAL (acronym for **computer-assisted learning**) the use of computers in education and training: the computer displays instructional material to a student and asks questions about the information given; the student's answers determine the sequence of the lessons.

calabash tropical South American evergreen tree with gourds (fruits) 50 cm/20 in across, whose dried skins are used as water containers. The Old World tropical-vine bottle gourd (*Lagenaria siceraria*, of the gourd family Cucurbitaceae) is sometimes also called a calabash, and it produces equally large gourds. (*Crescentia cujete*, family Bignoniaceae.)

calamine ZnCO_3 zinc carbonate, an ore of zinc. The term also refers to a pink powder made of a mixture of zinc oxide and iron(II) oxide used in lotions and ointments as an astringent for treating, for example, sunburn, eczema, measles rash, and insect bites and stings.

In the USA the term refers to zinc silicate $\text{Zn}_2\text{Si}_2\text{O}_7(\text{OH})_2 \cdot \text{H}_2\text{O}$.

calceolaria plant with brilliantly coloured slipper-shaped flowers. Native to South America, calceolarias were introduced to Europe and the USA in the 1830s. (Genus *Calceolaria*, family Scrophulariaceae.)

calcination oxidation of metals by burning in air.

calcite colourless, white, or light-coloured common rock-forming mineral, calcium carbonate, CaCO_3 . It is the main constituent of limestone and marble and forms many types of invertebrate shell.

Calcite often forms stalactites and stalagmites in caves and is also found deposited in veins through many rocks because of the ease with which it is dissolved and transported by groundwater; oolite is a rock consisting of spheroidal calcite grains. It rates 3 on the Mohs' scale of hardness. Large crystals up to 1 m/3 ft have been found in Oklahoma and Missouri, USA. Iceland spar is a transparent form of calcite used in the optical industry; as limestone it is used in the building industry.

calcium *Latin calx* 'lime' soft, silvery-white metallic element, symbol Ca, atomic number 20, relative atomic mass 40.08. It is one of the alkaline-earth metals. It is the fifth most abundant element (the third most abundant metal) in the Earth's crust. It is found mainly as its carbonate CaCO_3 , which occurs in a fairly pure condition as chalk and limestone (see calcite). Calcium is an essential component of bones, teeth, shells, milk, and leaves, and it forms 1.5% of the human body by mass.

Calcium ions in animal cells are involved in regulating muscle contraction, blood clotting, hormone secretion, digestion, and glycogen metabolism in the liver. It is acquired mainly from milk and cheese, and its uptake is facilitated by vitamin D. Calcium deficiency leads to chronic muscle spasms (tetany); an excess of calcium may lead to the formation of stones in the kidney or gall bladder.

The element was discovered and named by the English chemist Humphry Davy in 1808. Its compounds include slaked lime (calcium hydroxide, $\text{Ca}(\text{OH})_2$), plaster of Paris (calcium sulphate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$), calcium phosphate ($\text{Ca}_3(\text{PO}_4)_2$), the main constituent of animal bones; calcium hypochlorite (CaOCl_2), a bleaching agent; calcium nitrate ($\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$), a nitrogenous fertilizer; calcium carbide (CaC_2), which reacts with water to give ethyne (acetylene); calcium cyanamide (CaCN_2), the basis of many pharmaceuticals, fertilizers, and plastics, including melamine; calcium cyanide (CaCN_2), used in the extraction of gold and silver and in electroplating; and others used in baking powders and fillers for paints.

calcium carbonate CaCO_3 white solid, found in nature as limestone, marble, and chalk. It is a valuable resource, used in the making of iron, steel, cement, glass, slaked lime, bleaching powder, sodium carbonate and bicarbonate, and many other industrially useful substances.

calcium hydrogencarbonate $\text{Ca}(\text{HCO}_3)_2$ substance found in hard water, formed when rainwater passes over limestone rock.

calabash Like many tropical trees, the flowers of the calabash tree grow directly from the wood of the trunk and branches. At night the flowers give off an unpleasant odour, attracting numerous pollinating bats. Premaphotos Wildlife

When this water is boiled it reforms calcium carbonate, removing the hardness; this type of hardness is therefore known as temporary hardness.

calcium hydrogenphosphate $\text{Ca}(\text{H}_2\text{PO}_4)_2$ substance made by heating calcium phosphate with 70% sulphuric acid. It is more soluble in water than calcium phosphate, and is used as a fertilizer.

calcium hydroxide $\text{Ca}(\text{OH})_2$ or *slaked lime* white solid, slightly soluble in water. A solution of calcium hydroxide is called limewater and is used in the laboratory to test for the presence of carbon dioxide. It is manufactured industrially by adding water to calcium oxide (quicklime) in a strongly exothermic reaction.

It is used to reduce soil acidity and as a cheap alkali in many industrial processes.

calcium nitrate $\text{Ca}(\text{NO}_3)_2$ white, crystalline compound that is very soluble in water. The solid decomposes on heating to form oxygen, brown nitrogen(IV) oxide gas, and the white solid calcium oxide.

calcium oxide or *quicklime* CaO white solid compound, formed by heating calcium carbonate.

When water is added it forms calcium hydroxide (slaked lime) in an exothermic reaction.

It is a typical basic oxide, turning litmus blue.

calcium phosphate $\text{Ca}_3(\text{PO}_4)_2$ or *calcium orthophosphate* white solid, the main constituent of animal bones. It occurs naturally as the mineral apatite and in rock phosphate, and is used in the preparation of phosphate fertilizers.

calcium sulphate CaSO_4 , white, solid compound, found in nature as gypsum and anhydrite. It dissolves slightly in water to form hard water; this hardness is not removed by boiling, and hence is sometimes called permanent hardness.

calcium superphosphate common name for ϕ calcium hydrogen-phosphate.

calculator pocket-sized electronic computing device for performing numerical calculations. It can add, subtract, multiply, and divide; many calculators also compute squares and roots and have advanced trigonometric and statistical functions. Input is by a small keyboard and results are shown on a one-line computer screen, typically a liquid-crystal display (LCD) or a light-emitting diode (LED). The first electronic calculator was manufactured by the Bell Punch Company in the USA in 1963.

calculus *Latin* 'pebble' branch of mathematics which uses the concept of a derivative (see differentiation) to analyse the way in which the values of a function vary. Calculus is probably the most widely used part of mathematics. Many real-life problems are analysed by expressing one quantity as a function of another – position of a moving object as a function of time, temperature of an object as a function of distance from a heat source, force on an object as a function of distance from the source of the force, and so on – and calculus is concerned with such functions.

There are several branches of calculus. Differential and integral calculus, both dealing with small quantities which during manipulation are made smaller and smaller, compose the infinitesimal calculus. Differential equations relate to the derivatives of a set of variables and may include the variables. Many give the mathematical models for physical phenomena such as simple harmonic motion. Differential equations are solved generally by integration, depending on their degree. If no analytical processes are available, integration can be performed numerically. Other branches of calculus include calculus of variations and calculus of errors.

caldera in geology, a very large basin-shaped crater. Calderas are found at the tops of volcanoes, where the original peak has collapsed into an empty chamber beneath. The basin, many times larger than the original volcanic vent, may be flooded, producing a crater lake, or the flat floor may contain a number of small volcanic cones, produced by volcanic activity after the collapse.

Typical calderas are Kilauea, Hawaii; Crater Lake, Oregon, USA; and the summit of Olympus Mons, on Mars. Some calderas are wrongly referred to as craters, such as Ngorongoro, Tanzania.

calendar division of the year into months, weeks, and days and the method of ordering the years. From year one, an assumed date of the birth of Jesus, dates are calculated backwards (BC 'before Christ' or BCE 'before common era') and forwards (AD, *Latin anno Domini* 'in the year of the Lord', or CE 'common era'). The lunar month (period between one new moon and the next) naturally averages 29.5 days, but the Western calendar uses for convenience a calendar month with a complete number of days, 30 or 31 (February has 28). For adjustments, since there are slightly fewer than six extra hours a year left over, they are added to Feb as a 29th day every fourth year (leap year), century years being excepted unless they are divisible by 400. For example, 1896 was a leap year; 1900 was not.

The month names in most European languages were probably derived as follows: January from Janus, Roman god; February from *Februus*, Roman festival of purification; March from Mars, Roman god; April from *Latin aperire*, 'to open'; May from Maia, Roman goddess; June from Juno, Roman goddess; July from Julius Caesar, Roman general; August from Augustus, Roman emperor; September, October, November, December (originally the seventh to tenth months) from the Latin words meaning seventh, eighth, ninth, and tenth, respectively.

The days of the week are Monday named after the Moon; Tuesday from Tiu or Tyr, Anglo-Saxon and Norse god; Wednesday from Woden or Odin, Norse god; Thursday from Thor, Norse god; Friday from Freya, Norse goddess; Saturday from Saturn, Roman god; and Sunday named after the Sun.

All early calendars except the ancient Egyptian were lunar. The word calendar comes from the Latin *Calendar* or *calendae*, the first day of each month on which, in ancient Rome, solemn proclamation was made of the appearance of the new moon.

The Western or Gregorian calendar derives from the Julian calendar instituted by Julius Caesar 46 BC. It was adjusted by Pope Gregory XIII 1582, who eliminated the accumulated error caused by a faulty calculation of the length of a year and avoided its recurrence by restricting century leap years to those divisible by 400. Other states only gradually changed from Old Style to New Style; Britain and its colonies adopted the Gregorian calendar 1752, when the error amounted to 11 days, and 3 September 1752 became 14 September (at the same time the beginning of the year was put back from 25 March to 1 January). Russia did not adopt it until the October Revolution of 1917, so that the event (then 25 October) is currently celebrated 7 November.

The Jewish calendar is a complex combination of lunar and solar cycles, varied by considerations of religious observance. A year may have 12 or 13 months, each of which normally alternates between 29 and 30 days; the New Year (Rosh Hashanah) falls between 5 September and 5 October. The calendar dates from the hypothetical creation of the world (taken as 7 October 3761 BC).

The Chinese calendar is lunar, with a cycle of 60 years. Both the traditional and, from 1911, the Western calendar are in use in China.

The Muslim calendar, also lunar, has 12 months of alternately 30 and 29 days, and a year of 354 days. This results in the calendar rotating around the seasons in a 30-year cycle. The era is counted as beginning on the day Muhammad fled from Mecca AD 622.

calibration the preparation of a usable scale on a measuring instrument. A mercury thermometer, for example, can be calibrated with a Celsius scale by noting the heights of the mercury column at two standard temperatures – the freezing point (0°C) and boiling point (100°C) of water – and dividing the distance between them into 100 equal parts and continuing these divisions above and below.

Science is all those things which are confirmed to such a degree that it would be unreasonable to withhold one's provisional consent.

STEPHEN JAY GOULD US palaeontologist and writer.
Lecture on Evolution

California current cold ocean current in the E Pacific Ocean flowing southwards down the West coast of North America. It is part of the North Pacific gyre (a vast, circular movement of ocean water).

californium synthesized, radioactive, metallic element of the actinide series, symbol Cf, atomic number 98, relative atomic mass 251. It is produced in very small quantities and used in nuclear reactors as a neutron source. The longest-lived isotope, Cf-251, has a half-life of 800 years.

It is named after the state of California, where it was first synthesized 1950 by US nuclear chemist Glenn Seaborg and his team at the University of California at Berkeley.

calla alternative name for ϕ arum lily.

call for votes in computing, on CUSENET, process by which the nature and scope of a new newsgroup is determined. Calls for votes are posted to news.announce.newgroups. In the case of the ϕ Big Seven hierarchies, the call for votes is a requirement; it is recommended but not compulsory for ϕ alt hierarchy groups. The point is to ensure that newsgroup names follow a consistent pattern and that new newsgroups are formed in response to genuine interest.

Callichthys genus of South American ϕ catfish. Its body is protected by large, hard, scaly plates.

classification *Callichthys* belongs to the family Callichthyidae (armoured catfish), order Siluriformes, class Osteichthyes.

callipers measuring instrument used, for example, to measure the internal and external diameters of pipes. Some callipers are made like a pair of compasses, having two legs, often curved, pivoting about a screw at one end. The ends of the legs are placed in contact with the object to be measured, and the gap between the ends is then measured against a rule. The slide calliper looks like an adjustable spanner, and carries a scale for direct measuring, usually with a vernier scale for accuracy.

callistemon the genus of the Australian bottlebrush.

Callisto second-largest moon of Jupiter, 4,800 km/3,000 mi in diameter, orbiting every 16.7 days at a distance of 1.9 million km/1.2 million mi from the planet. Its surface is covered with large craters.

The space probe *Galileo* detected molecules containing both carbon and nitrogen atoms on the surface of Callisto. US astronomers announced in March 1997. Their presence may indicate that Callisto harboured life at some time.

callus in botany, a tissue that forms at a damaged plant surface. Composed of large, thin-walled parenchyma cells, it grows over and around the wound, eventually covering the exposed area.

In animals, a callus is a thickened pad of skin, formed where there is repeated rubbing against a hard surface. In humans, calluses often develop on the hands and feet of those involved in heavy manual work.

calomel Hg_2Cl_2 (technical name *mercury(I) chloride*) white, heavy powder formerly used as a laxative, now used as a pesticide and fungicide.

calorie c.g.s. unit of heat, now replaced by the joule (one calorie is approximately 4.2 joules). It is the heat required to raise the temperature of one gram of water by 1°C. In dietetics, the Calorie or kilocalorie is equal to 1,000 calories.

The kilocalorie measures the energy value of food in terms of its heat output: 28 g/1 oz of protein yields 120 kilocalories, of carbohydrate 110, of fat 270, and of alcohol 200.

calorific value the amount of heat generated by a given mass of fuel when it is completely burned. It is measured in joules per kilogram. Calorific values are measured experimentally with a bomb calorimeter.

calorimeter instrument used in physics to measure various thermal properties, such as heat capacity or the heat produced by fuel. A simple calorimeter consists of a heavy copper vessel that is polished (to reduce heat losses by radiation) and covered with insulating material (to reduce losses by convection and conduction).

In a typical experiment, such as to measure the heat capacity of a piece of metal, the calorimeter is filled with water, whose temperature rise is measured using a thermometer when a known mass of the heated metal is immersed in it. Chemists use a bomb calorimeter to measure the heat produced by burning a fuel completely in oxygen.

calotype paper-based photograph using a wax paper negative, the first example of the negative/positive process invented by the English photographer Fox Talbot around 1834.

calyptra in mosses and liverworts, a layer of cells that encloses and protects the young sporophyte (spore capsule), forming a sheathlike hood around the capsule. The term is also used to describe the root cap, a layer of parenchyma cells covering the end of a root that gives protection to the root tip as it grows through the soil. This is constantly being worn away and replaced by new cells from a special meristem, the calyptragen.

calyx collective term for the sepals of a flower, forming the outermost whorl of the perianth. It surrounds the other flower parts and protects them while in bud. In some flowers, for example, the champions *Silene*, the sepals are fused along their sides, forming a tubular calyx.

CAM (acronym for *computer-aided manufacturing*) the use of computers to control production processes; in particular, the

Calvin, Melvin (1911–1997)

US chemist who, using radioactive carbon-14 as a tracer, determined the biochemical processes of photosynthesis, in which green plants use chlorophyll to convert carbon dioxide and water into sugar and oxygen. Nobel prize 1961.

Mary Evans Picture Library

control of machine tools and robots in factories. In some factories, the whole design and production system has been automated by linking CAD (computer-aided design) to CAM.

Linking flexible CAD/CAM manufacturing to computer-based sales and distribution methods makes it possible to produce semi-customized goods cheaply and in large numbers.

cam part of a machine that converts circular motion to linear motion or vice versa. The edge cam in a car engine is in the form of a rounded projection on a shaft, the camshaft. When the camshaft turns, the cams press against linkages (plungers or followers) that open the valves in the cylinders.

A face cam is a disc with a groove in its face, in which the follower travels. A cylindrical cam carries angled parallel grooves, which impart a to-and-fro motion to the follower when it rotates.

Camberwell beauty species of butterfly.

cambium in botany, a layer of actively dividing cells (lateral meristem), found within stems and roots, that gives rise to secondary growth in perennial plants, causing an increase in girth. There are two main types of cambium: **vascular cambium**, which gives rise to secondary xylem and phloem tissues, and **cork cambium** (or phellogen), which gives rise to secondary cortex and cork tissues (see bark).

Cambrian period of geological time 570–510 million years ago; the first period of the Palaeozoic era. All invertebrate animal life appeared, and marine algae were widespread. The **Cambrian Explosion** 530–520 million years ago saw the first appearance in the fossil record of all modern animal phyla; the earliest fossils with hard shells, such as trilobites, date from this period.

The name comes from Cambria, the medieval Latin name for Wales, where Cambrian rocks are typically exposed and were first described.

camcorder another name for a video camera.

camel large cud-chewing mammal of the even-toed hoofed order Artiodactyla. Unlike typical ruminants, it has a three-chambered stomach. It has two toes which have broad soft soles for walking on sand, and hooves resembling nails. There are two species, the single-humped **Arabian camel** *Camelus dromedarius* and the twin-humped **Bactrian camel** *C. bactrianus* from Asia. They carry a food reserve of fatty tissue in the hump, can go without drinking for long periods, can feed on salty vegetation, and withstand extremes of heat and cold, thus being well adapted to desert conditions.

The Arabian camel has long been domesticated, so that its original range is not known. It is used throughout Arabia and N Africa, and has been taken to other places such as North America and Australia, in the latter country playing a crucial part in the development of the interior. The **dromedary** is, strictly speaking, a lightly built, fast, riding variety of the Arabian camel, but often the name is applied to all one-humped camels. Arabian camels can be

used as pack animals, for riding, racing, milk production, and for meat. The Bactrian camel is native to the central Asian deserts, where a small number still live wild, but most are domestic animals. With a head and body length of 3 m/10 ft and shoulder height of about 2 m/6 ft, the Bactrian camel is a large animal, but not so long in the leg as the Arabian. It has a shaggy winter coat. In 1995 there were only about 730–880 Bactrian camels remaining in the wild. Smaller, flat-backed members of the camel family include the alpaca, the guanaco, the llama, and the vicuña.

camellia any oriental evergreen shrub with roselike flowers belonging to the tea family. Many species, including *Camellia japonica* and *C. reticulata*, have been introduced into Europe, the USA, and Australia; they are widely cultivated as ornamental shrubs. (Genus *Camellia*, family Theaceae.)

CAMERAS: THE TECHNOLOGY OF PHOTOGRAPHIC IMAGING

<http://www.mhs.ox.ac.uk/cameras/index.htm>

General presentation of the camera collection at the Museum of the History of Science, Oxford, UK. Of the many highlights perhaps the most distinguished are some very early photographs, the photographic works of Sarah A Acland, and the cameras of T E Lawrence.

camera apparatus used in photography, consisting of a lens system set in a light-proof box inside of which a sensitized film or plate can be placed. The lens collects rays of light reflected from the subject and brings them together as a sharp image on the film. The opening or hole at the front of the camera, through which light enters, is called an aperture. The aperture size controls the amount of light that can enter. A shutter controls the amount of

time light has to affect the film. There are small-, medium-, and large-format cameras; the format refers to the size of recorded image and the dimensions of the image obtained.

A simple camera has a fixed shutter speed and aperture, chosen so that on a sunny day the correct amount of light is admitted. More complex cameras allow the shutter speed and aperture to be adjusted; most have a built-in exposure meter to help choose the correct combination of shutter speed and aperture for the ambient conditions and subject matter. The most versatile camera is the single lens reflex (SLR) which allows the lens to be removed and special lenses attached. A pin-hole camera has a small (pin-sized) hole instead of a lens. It must be left on a firm support during exposures, which are up to ten seconds with slow film, two seconds with fast film and five minutes for paper negatives in daylight. The pin-hole camera gives sharp images from close-up to infinity.

camera obscura darkened box with a tiny hole for projecting the inverted image of the scene outside on to a screen inside. For its development as a device for producing photographs, see photography.

camouflage colours or structures that allow an animal to blend with its surroundings to avoid detection by other animals. Camouflage can take the form of matching the background colour; of countershading (darker on top, lighter below, to counteract natural shadows); or of irregular patterns that break up the outline of the animal's body. More elaborate camouflage involves closely resembling a feature of the natural environment, as with the stick insect; this is closely akin to mimicry. Camouflage is also important as a military technique, disguising either equipment, troops, or a position in order to conceal them from an enemy.

camphor $C_{10}H_{16}O$ volatile, aromatic ketone substance obtained from the camphor tree *Cinnamomum camphora*. It is distilled from chips of the wood, and is used in insect repellents and medicinal inhalants and liniments, and in the manufacture of celluloid.

The camphor tree, a member of the family Lauraceae, is native to China, Taiwan, and Japan.

camera The single-lens reflex (SLR) camera in which an image can be seen through the lens before a picture is taken. The reflex mirror directs light entering the lens to the viewfinder. The SLR allows different lenses, such as close-up or zoom, to be used because the photographer can see exactly what is being focused on.

campion any of several plants belonging to the pink family. They include the garden campion (*Lychnis coronaria*), the wild white and red campions (*Silene alba* and *S. dioica*), and the bladder campion (*S. vulgaris*). (Genera *Lychnis* and *Silene*, family Caryophyllaceae.)

campus-wide information system (CWIS) computerized information service used on US university campuses, often hooked to the Internet. These systems typically include local events listings, general campus information, access to the library catalogue, weather reports, directories, and even a bulletin-board and messaging services.

One of the first such systems was Cornell University's CUINFO, developed by a team led by technical administrator Steve Worona 1982. The development of Gopher servers 1991 made these systems much easier to navigate, and many systems were redesigned to take advantage of the new technology. In the mid-1990s these systems began moving to the World Wide Web.

Campylobacter genus of bacteria that cause serious outbreaks of gastroenteritis. They grow best at 43°C, and so are well suited to the digestive tract of birds. Poultry is therefore the most likely source of a *Campylobacter* outbreak, although the bacteria can also be transmitted via beef or milk. *Campylobacter* can survive in water for up to 15 days, so may be present in drinking water if supplies are contaminated by sewage or reservoirs are polluted by seagulls.

canal artificial waterway constructed for drainage, irrigation, or navigation. **Irrigation canals** carry water for irrigation from rivers, reservoirs, or wells, and are designed to maintain an even flow of water over the whole length. **Navigation and ship canals** are constructed at one level between locks, and frequently link with rivers or sea inlets to form a waterway system. The Suez Canal in 1869 and the Panama Canal in 1914 eliminated long trips around continents and dramatically shortened shipping routes.

Irrigation canals The river Nile has fed canals to maintain life in Egypt since the earliest times. The division of the waters of the Upper Indus and its tributaries, which form an extensive system in Pakistan and Punjab, India, was, for more than ten years, a major cause of dispute between India and Pakistan, settled by a treaty 1960. The Murray basin, Victoria, Australia, and the Imperial and Central Valley projects in California, USA, are examples of 19th- and 20th-century irrigation-canal development. Excessive extraction of water for irrigation from rivers and lakes can cause environmental damage.

ship canals Probably the oldest ship canal to be still in use, as well as the longest, is the Grand Canal in China, which links Tianjin and Hangzhou and connects the Huang He (Yellow River) and Chang Jiang. It was originally built in three stages 485 BC-AD 283, reaching a total length of 1,780 km/1,110 mi. Large sections silted up in later years, but the entire system was dredged, widened, and rebuilt between 1958 and 1972 in conjunction with work on flood protection, irrigation, and hydroelectric schemes. It carries millions of tonnes of freight every year.

Where speed is not a prime factor, the cost-effectiveness of transporting goods by canal has encouraged a revival; Belgium, France, Germany, and the states of the former USSR are among countries that have extended and streamlined their canals. The Baltic-Volga waterway links the Lithuanian port of Klaipėda with Kalvica, at the mouth of the Dnieper on the Black Sea, a distance of 2,430 km/1,510 mi. A further canal cuts across the north Crimea, thus shortening the voyage of ships from the Dnieper through the Black Sea to the Sea of Azov. In Central America, the Panama Canal 1904-14 links the Atlantic and Pacific oceans (64 km/40 mi). In North America, the Erie Canal 1825 links the Great Lakes with the Hudson River and opened up the northeast and Midwest to commerce; the St Lawrence Seaway 1954-59 extends from Montréal to Lake Ontario (290 km/180 mi) and, with the deepening of the Welland Ship Canal and some of the river channels, provides a waterway that enables ocean going vessels to travel (during the ice-free months) between the Atlantic and Duluth, Minnesota, USA, at the western end of Lake Superior, some 3,770 km/2,342 mi.

Canaries current cold ocean current in the North Atlantic Ocean flowing SW from Spain along the NW coast of Africa. It meets the northern equatorial current at a latitude of 20° N.

canary bird *Serinus canaria* of the finch family Fringillidae, found wild in the Canary Islands and Madeira. In its wild state the plumage is green, sometimes streaked with brown. The wild canary builds its nest of moss, feathers, and hair in thick high shrubs or trees, and produces two to four broods in a season.

Canaries have been bred as cage birds in Europe since the 15th century, and many domestic varieties are yellow or orange as a result of artificial selection.

Some canaries were used in mines as detectors of traces of poisonous gas in the air.

CANARY FAQ

<http://www2.upatsix.com/faq/canary.htm>

Answers to frequently asked questions about canaries provide a wealth of information on all breeds of these cage birds. Every conceivable aspect of caring for canaries is covered and there are useful links to other canary sites.

cancel in mathematics, to simplify a fraction or ratio by dividing both numerator and denominator by the same number (which must be a common factor of both of them). For example, $\frac{52}{25}$ cancels to $\frac{5}{2}$ when divided top and bottom by 5.

cancelbot automated software program (see bot) that cancels messages on Usenet. The arrival of spamming (advertising) on the Net prompted the development of technology to use features built into Usenet to cancel messages. While single messages are easily cancelled manually, an automated routine is needed to handle mass postings, which may go out to more than 14,000 newsgroups. Cancelbot is activated by the CCancelMoose.

CancelMoose anonymous individual who fires off the Ccancelbot. The CancelMoose (usually written as 'CancelMoose™' on the Net) monitors newsgroups such as alt.current-events.net-abuse and news.admin.net-abuse for complaints about spamming (advertising), usually defined as messages posted to more than 25 newsgroups of widely varying content. The CancelMoose's identity is kept secret for reasons of personal safety.

cancer group of diseases characterized by abnormal proliferation of cells. Cancer (malignant) cells are usually degenerate, capable only of reproducing themselves (tumour formation). Malignant cells tend to spread from their site of origin by travelling through the bloodstream or lymphatic system. Cancer kills about 6 million people a year worldwide.

causes There are more than 100 types of cancer. Some, like lung or bowel cancer, are common; others are rare. The likely causes remain unexplained. Triggering agents (carcinogens) include chemicals such as those found in cigarette smoke, other forms of smoke, asbestos dust, exhaust fumes, and many industrial chemicals. Some viruses can also trigger the cancerous growth of cells (see oncogenes), as can X-rays and radioactivity. Dietary factors are important in some cancers; for example, lack of fibre in the diet may predispose people to bowel cancer and a diet high in animal fats and low in fresh vegetables and fruit increases the risk of breast cancer. Psychological stress may increase the risk of cancer, more so if the person concerned is not able to control the source of the stress.

cancer genes In some families there is a genetic tendency towards a particular type of cancer. In 1993 researchers isolated the first gene that predisposes individuals to cancer. About 1 in 200 people in the West carry the gene. If the gene mutates, those with the altered gene have a 70% chance of developing colon cancer, and female carriers have a 50% chance of developing cancer of the

uterus. This accounts for an estimated 10% of all colon cancer.

In 1994 a gene that triggers breast cancer was identified. BRCA1 was found to be responsible for almost half the cases of inherited breast cancer, and most cases of ovarian cancer. In 1995 a link between BRCA1 and non-inherited breast cancer was discovered. Women with the gene have an 85% chance of developing breast or ovarian cancer during their lifetime. A second breast cancer gene BRCA2 was identified later in 1995.

The commonest cancer in young men is testicular cancer, the incidence of which has been rising by 3% a year since 1974 (1998).

Cancer faintest of the zodiacal constellations (its brightest stars are fourth magnitude). It lies in the northern hemisphere between ζ Leo and ζ Gemini, and is represented as a crab. The Sun passes through the constellation during late July and early August. In astrology, the dates for Cancer are between about 22 June and 22 July (see ζ precession).

Cancer's most distinctive feature is the open star cluster Praesepe, popularly known as the Beehive, visible to the naked eye as a nebulous patch.

candela SI unit (symbol cd) of luminous intensity, which replaced the old units of candle and standard candle. It measures the brightness of a light itself rather than the amount of light falling on an object, which is called illuminance and measured in lux.

One candela is defined as the luminous intensity in a given direction of a source that emits monochromatic radiation of frequency 540×10^{12} Hz and whose radiant energy in that direction is 1/683 watt per steradian.

Candida albicans yeastlike fungus present in the human digestive tract and in the vagina, which causes no harm in most healthy people. However, it can cause problems if it multiplies excessively, as in vaginal candidiasis or ζ thrush, the main symptom of which is intense itching.

The most common form of thrush is oral, which often occurs in those taking steroids or prolonged courses of antibiotics.

Newborn babies may pick up the yeast during birth and suffer an infection of the mouth and throat. There is also some evidence that overgrowth of *Candida* may occur in the intestines, causing diarrhoea, bloating, and other symptoms such as headache and fatigue, but this is not yet proven. Occasionally, *Candida* can infect immunocompromised patients, such as those with AIDS. Treatment for candidiasis is based on antifungal drugs.

candle cylinder of wax (such as tallow or paraffin wax) with a central wick of string. A flame applied to the end of the wick melts the wax, thereby producing a luminous flame. The wick is treated with a substance such as alum so that it carbonizes but does not rapidly burn out.

Candles and oil lamps were an early form of artificial lighting. Accurately made candles – which burned at a steady rate – were calibrated against their lengths and used as a type of clock. The candle was also the name of a unit of luminous intensity, replaced in 1940 by the *candela* (cd), equal to $\frac{1}{683}$ of the luminance of 1 sq cm of a black body radiator at a temperature of 2,042K (the temperature of solidification of platinum).

CANDLE MAKING

<http://www.southwest.com.au/~snorth/crafts.htm#contents>

Mainly text guide to making and designing your own candles. There are a few general pictures of the finished product, but the text is very instructive.

cane reedlike stem of various plants such as the sugar cane, bamboo, and, in particular, the group of palms called rattans, consisting of the genus *Calamus* and its allies. Their slender stems are dried and used for making walking sticks, baskets, and furniture.

Canes Venatici constellation of the northern hemisphere near ζ Ursa Major, identified with the hunting dogs of ζ Boötes, the herder. Its stars are faint, and it contains the Whirlpool galaxy (M51), the first spiral galaxy to be recognized.

It contains many objects of telescopic interest, including the relatively bright globular cluster M3. The brightest star, a third magnitude double, is called ζ Caroli or Alpha Canum Venaticorum.

cane toad toad of the genus *Bufo marinus*, family Bufonidae. Also known as the giant or marine toad, the cane toad is the largest in the world. It acquired its name after being introduced to Australia during the 1930s to eradicate the cane beetle, which had become a serious pest there. However, having few natural enemies, the cane toad itself has now become a pest in Australia.

The cane toad's defence system consists of highly developed glands on each side of its neck which can squirt a poisonous fluid to a distance of around 1 m/3.3 ft.

CANE TOAD

<http://share.jcu.edu.au/dept/PHTM/staff/rsbufo.htm>

Profile of the world's largest toad, its unwise introduction to Australia, and the damage it has wrought. There's a photo of a cane toad, another of the massive number of eggs it can produce, and a complete bibliography of books and articles written about *Bufo marinus*.

canine in mammalian carnivores, any of the long, often pointed teeth found at the front of the mouth between the incisors and premolars. Canine teeth are used for catching prey, for killing, and for tearing flesh. They are absent in herbivores such as rabbits and sheep, and are much reduced in humans.

Canis Major brilliant constellation of the southern hemisphere, represented (with Canis Minor) as one of the two dogs following at the heel of ζ Orion. Its main star, ζ Sirius, is the brightest star in the night sky.

Epsilon Canis Majoris is also of the first magnitude, and there are three second magnitude stars.

Canis Minor small constellation along the celestial equator (see ζ celestial sphere), represented as the smaller of the two dogs of ζ Orion (the other dog being ζ Canis Major). Its brightest star is the first magnitude ζ Procyon.

Procyon and Beta Canis Minoris form what the Arabs called 'the Short Cubit', in contrast to 'the Long Cubit' formed by ζ Castor and ζ Pollux (Alpha and Beta Geminorum).

cannabis dried leaves and female flowers (marijuana) and ζ resin (hashish) of certain varieties of ζ hemp, which are smoked or swallowed to produce a range of effects, including feelings of great happiness and altered perception. (*Cannabis sativa*, family Cannabaceae.)

Cannabis is a soft drug in that any dependence is psychological rather than physical. It is illegal in many countries and has not been much used in medicine since the 1930s. However, recent research has led to the discovery of cannabis receptors (sensory nerve endings) in the brain, and the discovery of a naturally occurring brain chemical which produces the same effects as smoking cannabis. Researchers believe this work could lead to the use of cannabislike compounds to treat physical illness without affecting the mind. Cannabis is claimed to have beneficial effects in treating chronic diseases such as AIDS and ζ multiple sclerosis. The main psychoactive ingredient in cannabis is delta-9-tetrahydrocannabinol (THC) which is available legally as a prescribed drug in capsule form.

canning food preservation in hermetically sealed containers by the application of heat. Originated by Nicolas Appert in France 1809 with glass containers, it was developed by Peter Durand in

England in 1810 with cans made of sheet steel thinly coated with tin to delay corrosion. Cans for beer and soft drinks are now generally made of aluminium.

Canneries were established in the USA before 1820, but the US canning industry expanded considerably in the 1870s when the manufacture of cans was mechanized and factory methods of processing were used. The quality and taste of early canned food was frequently inferior but by the end of the 19th century, scientific research made greater understanding possible of the food-preserving process, and standards improved. More than half the aluminium cans used in the USA are now recycled.

Canopus or *Alpha Carinae* second brightest star in the night sky (after Sirius), lying in the southern constellation Carina. It is a first-magnitude yellow-white supergiant about 120 light years from Earth, and thousands of times more luminous than the Sun.

cantaloupe any of several small varieties of muskmelon *Cucumis melo*, distinguished by their round, ribbed fruits with orange-coloured flesh.

cantilever beam or structure that is fixed at one end only, though it may be supported at some point along its length; for example, a diving board. The cantilever principle, widely used in construction engineering, eliminates the need for a second main support at the free end of the beam, allowing for more elegant structures and reducing the amount of materials required. Many large-span bridges have been built on the cantilever principle.

A typical cantilever bridge consists of two beams cantilevered out from either bank, each supported part way along, with their free ends meeting in the middle. The multiple-cantilever Forth Rail Bridge (completed 1890) across the Firth of Forth in Scotland has twin main spans of 521 m/1,710 ft.

canyon *Spanish cañon* 'tube' deep, narrow valley or gorge running through mountains. Canyons are formed by stream down-cutting, usually in arid areas, where the rate of down-cutting is greater than the rate of weathering, and where the stream or river receives water from outside the area.

There are many canyons in the western USA and in Mexico, for example the Grand Canyon of the Colorado River in Arizona, the canyon in Yellowstone National Park, and the Black Canyon in Colorado.

cap another name for a diaphragm contraceptive.

capacitance, electrical property of a capacitor that determines how much charge can be stored in it for a given potential difference between its terminals. It is equal to the ratio of the electrical charge stored to the potential difference. It is measured in μfarads .

capacitor or **condenser** device for storing electric charge, used in electronic circuits; it consists of two or more metal plates separated by an insulating layer called a dielectric.

Its **capacitance** is the ratio of the charge stored on either plate to the potential difference between the plates. The SI unit of capacitance is the farad, but most capacitors have much smaller capacitances, and the microfarad (a millionth of a farad) is the commonly used practical unit.

capacity alternative term for ϕ volume, generally used to refer to the amount of liquid or gas that may be held in a container. Units of capacity include litre and millilitre (metric); pint and gallon (imperial).

Cape Canaveral promontory on the Atlantic coast of Florida, USA, 367 km/228 mi N of Miami, used as a rocket launch site by NASA.

Cape gooseberry plant *Physalis peruviana* of the potato family. Originating in South America, it is grown in South Africa, from where it takes its name. It is cultivated for its fruit, a yellow berry surrounded by a papery calyx.

Capella or *Alpha Aurigae* brightest star in the constellation Auriga and the sixth brightest star in the night sky. It is a visual and spectroscopic binary that consists of a pair of yellow-giant stars 45 light years from Earth, orbiting each other every 104 days.

It is a first-magnitude star, whose Latin name means the 'little Nanny Goat': its kids are the three adjacent stars Epsilon, Eta, and Zeta Aurigae.

Cape mountain zebra *zebra* subspecies *Equus zebra zebra*, confined to South Africa. It almost became extinct in the 1940s, and in 1993 had a population of only 450, despite attempts at conservation. The main population is in Mountain Zebra Park in the east of the country, although some zebras have been moved to other parks in an attempt to build up other viable breeding herds.

caper trailing shrub native to the Mediterranean. Its flower buds are preserved in vinegar as a condiment. (*Capparis spinosa*, family Capparidaceae.)

capercaillie or **wood-grouse** or **cock of the wood** (*Gaelic capall coile*, 'cock of the wood') large bird *Tetrao urogallus* of the ϕ grouse family, Tetraonidae, order Galliformes. Found in coniferous woodland in Europe and N Asia, it is about the size of the turkey and resembles the blackcock in appearance and polygamous habit. The general colour of the male is blackish-grey above, black below, with a dark green chest, and rounded tail which is fanned out in courtship. The female is smaller, mottled, and has a reddish breast barred with black. The feathers on the legs and feet are longest in winter time, and the toes are naked. The capercaillie feeds on insects, worms, berries, and young pine-shoots. At nearly 1 m/3 ft long, the male is the biggest gamebird in Europe. The female is about 60 cm/2 ft long.

Hunted to extinction in Britain in the 18th century, the capercaillie was reintroduced from Sweden in the 1830s and has re-established itself in Scotland.

capillarity spontaneous movement of liquids up or down narrow tubes, or capillaries. The movement is due to unbalanced molecular attraction at the boundary between the liquid and the tube. If liquid molecules near the boundary are more strongly attracted to molecules in the material of the tube than to other nearby liquid molecules, the liquid will rise in the tube. If liquid molecules are less attracted to the material of the tube than to other liquid molecules, the liquid will fall.

capillary in biology, narrowest blood vessel in vertebrates, 0.008–0.02 mm in diameter, barely wider than a red blood cell. Capillaries are distributed as **beds**, complex networks connecting arteries and veins. Capillary walls are extremely thin, consisting of a single layer of cells, and so nutrients, dissolved gases, and waste products can easily pass through them. This makes the capillaries the main area of exchange between the fluid (ϕ lymph) bathing body tissues and the blood.

To remember the principles of capillary action:

WATER RISES TO THE TOPS OF PLANTS BY CAPILLARY ACTION (CA), WHICH DEPENDS UPON COHESIVE AND ADHESIVE (C+A) PROPERTIES OF WATER

capillary in physics, a very narrow, thick-walled tube, usually made of glass, such as in a thermometer. Properties of fluids, such as surface tension and viscosity, can be studied using capillary tubes.

capitulum in botany, a flattened or rounded head (inflorescence) of numerous, small, stalkless flowers. The capitulum is surrounded by a corolla of petal-like bracts and has the appearance of a large, single flower.

Capricorn alternative term for Capricornus.

Capricornus zodiacal constellation in the southern hemisphere next to Sagittarius. It is represented as a fish-tailed goat, and its brightest stars are third magnitude. The Sun passes through it late January to mid-February. In astrology, the dates for Capricornus (popularly known as Capricorn) are between about 22 December and 19 January (see ϕ precession).

capsicum any of a group of pepper plants belonging to the nightshade family, native to Central and South America. The different species produce green to red fruits that vary in size. The small ones are used whole to give the hot flavour of chilli, or ground to produce cayenne or red pepper; the large pointed or squarish pods, known as sweet peppers or pimientos (green, red, or yellow peppers), are mild-flavoured and used as a vegetable. (Genus *Capsicum*, family Solanaceae.)

Capstone long-term US government project to develop a set of standards for publicly available cryptography as authorized by the Computer Security Act 1987. The initiative has four elements: a data encryption algorithm (skipjack), a hash function, a key exchange protocol, and a digital signature algorithm.

The project is managed primarily by the National Security Agency (NSA) and the National Institute of Standards and Technology (NIST).

capsule in botany, a dry, usually many-seeded fruit formed from an ovary composed of two or more fused carpels, which splits open to release the seeds. The same term is used for the spore-containing structure of mosses and liverworts; this is borne at the top of a long stalk or seta.

Capsules burst open (dehiscence) in various ways, including lengthwise, by a transverse lid – for example, scarlet pimpernel *Anagallis arvensis* – or by a number of pores, either towards the top of the capsule, as in the poppy *Papaver*, or near the base, as in certain species of bellflower *Campanula*.

capture saving of user actions as digital data that can be read by a computer. In real-time data communications, it refers to using software to log a session so that the session can be saved to a file. The term is also used with reference to screens, where the graphical material displayed on a computer screen may be saved as a picture file. In the study of human-computer interaction, the data captured are user keystrokes, mouse movements, and even facial expressions and muttered complaints so that developers can replay the session to help them design better user interfaces.

captured rotation or **synchronous rotation** in astronomy, the circumstance in which one body in orbit around another, such as the moon of a planet, rotates on its axis in the same time as it takes to complete one orbit. As a result, the orbiting body keeps one face permanently turned towards the body about which it is orbiting. An example is the rotation of our own Moon, which arises because of the tidal effects of the Earth over a long period of time.

capuchin monkey of the genus *Cebus* found in Central and South America, so called because the hairs on the head resemble the cowl of a Capuchin monk. Capuchins live in small groups, feed on fruit and insects, and have a long tail that is semiprehensile and can give support when climbing through the trees.

There are now thought to be only 800 yellow-breasted capuchins left in the wild, found only in the Atlantic forest in Bahia state, Brazil.

capybara world's largest rodent *Hydrochoerus hydrochaeris*, up to 1.3 m/4 ft long and 50 kg/110 lb in weight. It is found in South America, and belongs to the guinea-pig family. The capybara inhabits marshes and dense vegetation around water. It has thin, yellowish hair, swims well, and can rest underwater with just eyes, ears, and nose above the surface.

car small, driver-guided, passenger-carrying motor vehicle; originally the automated version of the horse-drawn carriage, meant to convey people and their goods over streets and roads.

Over 50 million motor cars are produced each year worldwide. The number of cars in the world in 1997 exceeded 500 million. Most are four-wheeled and have water-cooled, piston-type internal-combustion engines fuelled by petrol or diesel. Variations have existed for decades that use ingenious and often nonpolluting power plants, but the motor industry long ago settled on this general formula for the consumer market. Experimental and sports models are streamlined, energy-efficient, and hand-built.

origins Although it is recorded that in 1479 Gilles de Dom was paid 25 livres (the equivalent of 25 pounds of silver) by the trea-

surer of Antwerp in the Low Countries for supplying a self-propelled vehicle, the ancestor of the automobile is generally agreed to be the cumbersome steam carriage made by Nicolas-Joseph Cugnot in 1769, still preserved in Paris. Steam was an attractive form of power to the English pioneers, and in 1803 Richard Trevithick built a working steam carriage. Later in the 19th century, practical steam coaches were used for public transport until stifled out of existence by punitive road tolls and legislation.

the first motorcars Although a Frenchman, Jean Etienne Lenoir, patented the first internal-combustion engine (gas-driven but immobile) in 1860, and an Austrian, Siegfried Marcus, built a vehicle which was shown at the Vienna Exhibition (1873), two Germans, Gottlieb Daimler and Karl Benz are generally regarded as the creators of the motorcar. In 1885 Daimler and Benz built and ran the first petrol-driven motorcar (they worked independently with Daimler building a very efficient engine and Benz designing a car but with a poor engine). The pattern for the modern motorcar was set by Panhard in 1891 (front radiator, Daimler engine under bonnet, sliding-pinion gearbox, wooden ladder-chassis) and Mercedes in 1901 (honeycomb radiator, in-line four-cylinder engine, gate-change gearbox, pressed-steel chassis) set the pattern for the modern car. Emerging with Haynes and Duryea in the early 1890s, US demand was so fervent that 300 makers existed by 1895; only 109 were left by 1900.

In Britain, cars were still considered to be light locomotives in the eyes of the law and, since the Red Flag Act 1865, had theoretically required someone to walk in front with a red flag (by night, a lantern). Despite these obstacles, which put UK development another ten years behind all others, in 1896 (after the Red Flag Act had been repealed) Frederick Lanchester produced an advanced and reliable vehicle, later much copied.

motorcars as an industry The period 1905–06 inaugurated a world motorcar boom continuing to the present day. Among the legendary cars of the early 20th century are: De Dion Bouton, with the first practical high-speed engines; Mors, notable first for racing and later as a silent tourer; Napier, the 24-hour record-holder at Brooklands 1907, unbeaten for 17 years; the incomparable Rolls-Royce Silver Ghost; the enduring Model T Ford; and the many types of Bugatti and Delage, from record-breakers to luxury tourers. After World War I popular motoring began with the era of cheap, light (baby) cars made by Citroën, Peugeot, and Renault (France); Austin, Morris, Clyno, and Swift (England); Fiat (Italy); Volkswagen (Germany); and the cheap though bigger Ford, Chevrolet, and Dodge in the USA. During the interwar years a great deal of racing took place, and the experience gained benefited the everyday motorist in improved efficiency, reliability, and safety. There was a divergence between the lighter, economical European car, with its good handling, and the heavier US car, cheap, rugged, and well adapted to long distances on straight roads at speed. By this time motoring had become a universal pursuit.

After World War II small European cars tended to fall into three categories, in about equal numbers: front engine and rear drive, the classic arrangement; front engine and front-wheel drive; rear engine and rear-wheel drive. Racing cars have the engine situated in the middle for balance. From the 1950s a creative resurgence produced in practical form automatic transmission for small cars, rubber suspension, transverse engine mounting, self-leveling ride, disc brakes, and safer wet-weather tyres.

By the mid-1980s, Japan was building 8 million cars a year, on par with the US. The largest Japanese manufacturer, Toyota, was producing 2.5 million cars per year.

The car has become the carapace, the protective and aggressive shell, of urban and suburban man.

MARSHALL McLuhan Canadian communications theorist.
Understanding Media ch 22

caracal cat *Felis caracal* related to the lynx. It has long black ear tufts, a short tail, and short reddish-fawn fur. It lives in bush and desert country in Africa, Arabia, and India, hunting birds and small mammals at night. Head and body length is about 75 cm/2.5 ft.

carambola small evergreen tree of SE Asia. The fruits, called **star fruit**, are yellowish, about 12 cm/4 in long, with a five-pointed star-shaped cross-section. They can be eaten raw, cooked, or pickled, and are juicy acid. The juice is also used to remove stains from hands and clothes. (*Averrhoa carambola*, family *Averrhoaceae*.)

caramel complex mixture of substances produced by heating sugars, without charring, until they turn brown. Caramel is used as colouring and flavouring in foods. Its production in the manufacture of sugar confection gives rise to a toffee-like sweet of the same name.

The intricate chemical reactions involved in the production of caramel (caramelization) are not fully understood, but are known to result in the formation of a number of compounds. Two compounds in particular (acetylformoin and 4-hydroxy-2,5-dimethyl-3-furanone) are thought to contribute to caramel's characteristic flavour.

Commercially, the caramelization process is speeded up by the addition of selected amino acids.

carapace protective covering of many animals, particularly the arched bony plate characteristic of the order Chelonia (tortoises, terrapins, and turtles), and the shield that protects the fore parts of crustaceans, such as crabs.

carat *Arabic qirrat 'seed'* unit for measuring the mass of precious stones; it is equal to 0.2 g/0.00705 oz, and is part of the troy system of weights. It is also the unit of purity in gold (US karat). Pure gold is 24-carat; 22-carat (the purest used in jewellery) is 22 parts gold and two parts alloy (to give greater strength).

Originally, one carat was the weight of a carob seed.

caraway herb belonging to the carrot family. Native to northern temperate regions of Europe and Asia, it is grown for its spicy, aromatic seeds, which are used in cookery, medicine, and perfumery. (*Carum carvi*, family *Umbelliferae*.)

carbide compound of carbon and one other chemical element, usually a metal, silicon, or boron.

Calcium carbide (CaC_2) can be used as the starting material for many basic organic chemical syntheses, by the addition of water and generation of ethyne (acetylene). Some metallic carbides are used in engineering because of their extreme hardness and strength. Tungsten carbide is an essential ingredient of carbide tools and high-speed tools. The 'carbide process' was used during World War II to make organic chemicals from coal rather than from oil.

carbohydrate chemical compound composed of carbon, hydrogen, and oxygen, with the basic formula $\text{C}_m(\text{H}_2\text{O})_n$, and related compounds with the same basic structure but modified functional groups. As sugar and starch, carbohydrates form a major energy-providing part of the human diet.

The simplest carbohydrates are sugars (monosaccharides, such as glucose and fructose, and disaccharides, such as sucrose), which are soluble compounds, some with a sweet taste. When these basic sugar units are joined together in long chains or branching structures they form polysaccharides, such as starch and glycogen, which often serve as food stores in living organisms. Even

more complex carbohydrates are known, including chitin, which is found in the cell walls of fungi and the hard outer skeletons of insects, and cellulose, which makes up the cell walls of plants. Carbohydrates form the chief foodstuffs of herbivorous animals.

carbolic acid common name for the aromatic compound phenol.

CHEMISTRY OF CARBON

<http://cwis.nyu.edu/pages/mathmol/modules/carbon/carbon1.html>

Excellent introduction to carbon, the element at the heart of life as we know it. This site is illustrated throughout and explains the main basic forms of carbon and the importance of the way scientists choose to represent these various structures.

carbon *Latin carbo, carbonaris 'coal'* nonmetallic element, symbol C, atomic number 6, relative atomic mass 12.011. It occurs on its own as diamond, graphite, and as fullerenes (the allotropes), as compounds in carbonate rocks such as chalk and limestone, as carbon dioxide in the atmosphere, as hydrocarbons in petroleum, coal, and natural gas, and as a constituent of all organic substances.

In its amorphous form, it is familiar as coal, charcoal, and soot. The atoms of carbon can link with one another in rings or chains, giving rise to innumerable complex compounds. Of the inorganic carbon compounds, the chief ones are carbon dioxide, a colourless gas formed when carbon is burned in an adequate supply of air; and carbon monoxide (CO), formed when carbon is oxidized in a limited supply of air. Carbon disulphide (CS_2) is a dense liquid with a sweetish odour. Another group of compounds is the carbon halides, including carbon tetrachloride (tetrachloromethane, CCl_4).

When added to steel, carbon forms a wide range of alloys with useful properties. In pure form, it is used as a moderator in nuclear reactors; as colloidal graphite it is a good lubricant and, when deposited on a surface in a vacuum, reduces photoelectric and secondary emission of electrons. Carbon is used as a fuel in the form of coal or coke. The radioactive isotope carbon-14 (half-life 5,730 years) is used as a tracer in biological research and in radiocarbon dating. Analysis of interstellar dust has led to the discovery of discrete carbon molecules, each containing 60 carbon atoms. The C_{60} molecules have been named buckminsterfullerenes because of their structural similarity to the geodesic domes designed by US architect and engineer Buckminster Fuller.

Life exists in the universe only because the carbon atom possesses certain exceptional properties.

JAMES HOPWOOD JEANS English mathematician and scientist.
Mysterious Universe

carbohydrate A molecule of the polysaccharide glycogen (animal starch) is formed from linked glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) molecules. A typical glycogen molecule has 100–1,000 glucose units.

carbonate CO_3^{2-} ion formed when carbon dioxide dissolves in water; any salt formed by this ion and another chemical element, usually a metal.

Carbon dioxide (CO_2) dissolves sparingly in water (for example, when rain falls through the air) to form carbonic acid (H_2CO_3), which unites with various basic substances to form carbonates. Calcium carbonate (CaCO_3) (chalk, limestone, and marble) is one of the most abundant carbonates known, being a constituent of mollusc shells and the hard outer skeletons of crustaceans.

carbonated water water in which carbon dioxide is dissolved under pressure. It forms the basis of many fizzy soft drinks such as soda water and lemonade.

carbon copy in e-mail, a duplicate copy of a message sent to multiple recipients; a nod to traditional office systems. It is often abbreviated in software and on line to 'cc'.

carbon cycle sequence by which carbon circulates and is recycled through the natural world. The carbon element from carbon dioxide, released into the atmosphere by living things as a result of respiration, is taken up by plants during photosynthesis and converted into carbohydrates; the oxygen component is released back into the atmosphere. Some of this carbon becomes locked up in coal and petroleum and other sediments. The simplest link in the carbon cycle occurs when an animal eats a plant and carbon is transferred from, say, a leaf cell to the animal body. The oceans absorb 25–40% of all carbon dioxide released into the atmosphere.

Today, the carbon cycle is in danger of being disrupted by the

increased consumption and burning of fossil fuels, and the burning of large tracts of tropical forests, as a result of which levels of carbon dioxide are building up in the atmosphere and probably contributing to the greenhouse effect.

carbon cycle in astrophysics, a sequence of nuclear fusion reactions in which carbon atoms act as a catalyst to convert four hydrogen atoms into one helium atom with the release of energy. The carbon cycle is the dominant energy source for ordinary stars of mass greater than about 1.5 times the mass of the Sun.

Nitrogen and oxygen are also involved in the sequence so it is sometimes known as the carbon-nitrogen-oxygen cycle or CNO cycle.

carbon dating alternative name for radiocarbon dating.

carbon dioxide CO_2 colourless, odourless gas, slightly soluble in water and denser than air. It is formed by the complete oxidation of carbon.

It is produced by living things during the processes of respiration and the decay of organic matter, and plays a vital role in the carbon cycle. It is used as a coolant in its solid form (known as 'dry ice'), and in the chemical industry. Its increasing density contributes to the greenhouse effect and global warming. Britain has 1% of the world's population, yet it produces 3% of CO_2 emissions; the USA has 5% of the world's population and produces 25% of CO_2 emissions. Annual releases of carbon dioxide reached 23 billion tonnes in 1997. According to a 1997 estimate by the World Energy council, carbon dioxide emissions rose by 7.8% between 1986 and 1996.

carbon cycle The carbon cycle is necessary for the continuation of life. Since there is only a limited amount of carbon in the Earth and its atmosphere, carbon must be continuously recycled if life is to continue. Other chemicals necessary for life – nitrogen, sulphur, and phosphorus, for example – also circulate in natural cycles.

carbon fibre fine, black, silky filament of pure carbon produced by heat treatment from a special grade of Courteille acrylic fibre and, used for reinforcing plastics. The resulting composite is very stiff and, weight for weight, has four times the strength of high-tensile steel. It is used in the aerospace industry, cars, and electrical and sports equipment.

carbonic acid H_2CO_3 weak, dibasic acid formed by dissolving carbon dioxide in water.

It forms two series of salts: carbonates and hydrogencarbonates. Fizzy drinks are made by dissolving carbon dioxide in water under pressure; soda water is a solution of carbonic acid.

Carboniferous period of geological time 362.5–290 million years ago, the fifth period of the Palaeozoic era. In the USA it is divided into two periods: the Mississippian (lower) and the Pennsylvanian (upper).

Typical of the lower-Carboniferous rocks are shallow-water limestones, while upper-Carboniferous rocks have delta deposits with coal (hence the name). Amphibians were abundant, and reptiles evolved during this period.

carbon monoxide CO colourless, odourless gas formed when carbon is oxidized in a limited supply of air. It is a poisonous constituent of car exhaust fumes, forming a stable compound with haemoglobin in the blood, thus preventing the haemoglobin from transporting oxygen to the body tissues.

In industry, carbon monoxide is used as a reducing agent in metallurgical processes – for example, in the extraction of iron in blast furnaces – and is a constituent of cheap fuels such as water gas. It burns in air with a luminous blue flame to form carbon dioxide.

carbon sequestration disposal of carbon dioxide waste in solid or liquid form. From 1993 energy conglomerates such as Shell, Exxon, and British coal have been researching ways to reduce their carbon dioxide emissions by developing efficient technologies to trap the gas and store it securely – for example, by burying it or dumping it in the oceans. See also greenhouse effect.

carbon tetrachloride former name for the chlorinated organic compound tetrachloromethane.

Carborundum trademark for a very hard, black abrasive, consisting of silicon carbide (SiC), an artificial compound of carbon and silicon. It is harder than corundum but not as hard as diamond.

It was first produced 1891 by US chemist Edward Acheson (1856–1931).

carboxyl group $-\text{COOH}$ in organic chemistry, the acidic functional group that determines the properties of fatty acids (carboxylic acids) and amino acids.

carboxylic acid organic acid containing the carboxyl group ($-\text{COOH}$) attached to another group (R), which can be hydrogen (giving methanoic acid, HCOOH) or a larger molecule (up to 24 carbon atoms). When R is a straight-chain alkyl group (such as CH_3 or CH_2CH_2), the acid is known as a fatty acid.

Examples of carboxylic acids include acetic acid, found in vinegar, malic acid, found in rhubarb, and citric acid, contained in oranges and lemons.

To remember the (alpha, omega) dicarboxylic acids from C_2 – C_{10} :

OH MY, SUCH GOOD APPLE PIE, SWEET AS SUGAR

OXALIC, MALONIC, SUCCINIC, GLUTARIC, ADIPIC, PIMELIC, SUBERIC, AZELAIC, SEBACIC

carburation mixing of a gas, such as air, with a volatile hydrocarbon fuel, such as petrol, kerosene, or fuel oil, in order to form an explosive mixture. The process, which ensures that the maxi-

mum amount of heat energy is released during combustion, is used in internal-combustion engines. In most petrol engines the liquid fuel is atomized and mixed with air by means of a device called a carburettor.

carcinogen any agent that increases the chance of a cell becoming cancerous (see cancer), including various chemical compounds, some viruses, X-rays, and other forms of ionizing radiation. The term is often used more narrowly to mean chemical carcinogens only.

carcinoma malignant tumour arising from the skin, the glandular tissues, or the mucous membranes that line the gut and lungs.

cardinal number in mathematics, one of the series of numbers 0, 1, 2, 3, 4, ... Cardinal numbers relate to quantity, whereas ordinal numbers (first, second, third, fourth, ...) relate to order.

cardioid heart-shaped curve traced out by a point on the circumference of a circle, resulting from the circle rolling around the edge of another circle of the same diameter.

The polar equation of the cardioid is of the form:

$$r = a(1 + \cos \theta)$$

cardioid The cardioid is the curve formed when one circle rolls around the edge of another circle of the same size. It is named after its heart shape.

caribou the reindeer of North America.

caries decay and disintegration, usually of the substance of teeth (cavity) or bone, caused by acids produced when the bacteria that live in the mouth break down sugars in the food. Fluoride, a low sugar intake, and regular brushing are all protective. Caries form mainly in the 45 minutes following consumption of sugary food.

Carina constellation of the southern hemisphere, represented as a ship's keel. Its brightest star is α Canopus, the second brightest in the night sky; it also contains Eta Carinae, a massive and highly luminous star embedded in a gas cloud, perhaps 8,000 light years away.

Carina was formerly regarded as part of Argo, and is situated in one of the brightest parts of the Milky Way.

Carnac site of prehistoric megaliths in Brittany, France, where remains of tombs and stone alignments of the period 2000–1500 BC (Neolithic and early Bronze Age) are found. Stones removed for local building have left some gaps in the alignments.

There are various groups of menhirs round the village of Carnac in the département of Morbihan, situated at Kermario (place of the dead), Kerlescan (place of burning), Erdevén, and St-Barbe. The largest of the stone alignments has 1,000 blocks of grey granite up to 4 m/13 ft high, extending over 2 km/1.2 mi. These menhirs

(standing stones) are arranged in 11 parallel rows, with a circle at the western end.

Stone circles and alignments are thought to be associated with astronomical and religious ritual, and those at Carnac may possibly have been used for calculating the phases of the moon.

carnassial tooth one of a powerful scissorlike pair of molars, found in all mammalian carnivores except seals. Carnassials are formed from an upper premolar and lower molar, and are shaped to produce a sharp cutting surface. Carnivores such as dogs transfer meat to the back of the mouth, where the carnassials slice up the food ready for swallowing.

carnation any of a large number of double-flowered cultivated varieties of a plant belonging to the *pink* family. The flowers smell like cloves; they are divided into flake, bizarre, and picotee, according to whether the petals have one or more colours on their white base, have the colour appearing in strips, or have a coloured border to the petals. (*Dianthus caryophyllus*, family Carophyllaceae.)

carnauba palm tree native to South America, especially Brazil. It produces fine timber and a hard wax, used for polishes and lipsticks. (*Copernicia cerifera*.)

carnivore in zoology, mammal of the order Carnivora. Although its name describes the flesh-eating ancestry of the order, it includes pandas, which are herbivorous, and civet cats, which eat fruit.

Carnivores have the greatest range of body size of any mammalian order, from the 100 g/3.5 oz weasel to the 800 kg/1,764 lb polar bear.

The characteristics of the Carnivora are sharp teeth, small incisors, a well-developed brain, a simple stomach, a reduced or absent caecum, and incomplete or absent clavicles (collarbones); there are never less than four toes on each foot; the scaphoid and lunar bones are fused in the hand; and the claws are generally sharp and powerful.

Carnot, (Nicolas Leonard) Sadi (1796-1832) French scientist and military engineer who founded the science of thermodynamics. His pioneering work was *Reflexions sur la puissance motrice du feu* (*On the Motive Power of Fire*, which considered the changes that would take place in an idealized, frictionless steam engine).

Carnot's theorem showed that the amount of work that an engine can produce depends only on the temperature difference that occurs in the engine. He described the maximum amount of heat convertible into work by the formula $(T_1 - T_2)/T_2$, where T_1 is the temperature of the hottest part of the machine and T_2 is the coldest part.

Carnot cycle series of changes in the physical condition of a gas in a reversible heat engine, necessarily in the following order: (1) isothermal expansion (without change of temperature), (2) adiabatic expansion (without change of heat content), (3) isothermal compression, and (4) adiabatic compression.

The principles derived from a study of this cycle are important in the fundamentals of heat and thermodynamics.

carob small Mediterranean tree belonging to the legume family. Its pods, 20 cm/8 in. long, are used as an animal feed; they are also the source of a chocolate substitute. (*Ceratonia siliqua*, family Leguminosae.)

carotene naturally occurring pigment of the carotenoid group. Carotenes produce the orange, yellow, and red colours of carrots, tomatoes, oranges, and crustaceans.

carotenoid any of a group of yellow, orange, red, or brown pigments found in many living organisms, particularly in the chloroplasts of plants. There are two main types, the carotenes and the xanthophylls. Both types are long-chain lipids (fats).

Some carotenoids act as accessory pigments in photosynthesis, and in certain algae they are the principal light-absorbing pigments functioning more efficiently than chlorophyll in low-intensity light. Carotenoids can also occur in organs such as petals, roots, and fruits, giving them their characteristic colour, as in the yellow and orange petals of wallflowers *Cheiranthus*. They are also

responsible for the autumn colours of leaves, persisting longer than the green chlorophyll, which masks them during the summer.

carotid artery one of a pair of major blood vessels, one on each side of the neck, supplying blood to the head.

carp fish *Cyprinus carpio* found all over the world. It commonly grows to 50 cm/1.8 ft and 3 kg/7 lb, but may be even larger. It lives in lakes, ponds, and slow rivers. The wild form is drab, but cultivated forms may be golden, or may have few large scales (mirror carp) or be scaleless (leather carp). Koi carp are highly prized and can grow up to 1 m/3 ft long with a distinctive pink, red, white, or black colouring.

A large proportion of European freshwater fish belong to the carp family, Cyprinidae, and related fishes are found in Asia, Africa, and North America. The carp's fast growth, large size, and ability to live in still water with little oxygen have made it a good fish to farm, and it has been cultivated for hundreds of years and spread by human agency. Members of this family have a single non-spiral dorsal fin, pelvic fins well back on the body, and toothless jaws, although teeth in the throat form an efficient grinding apparatus. Minnows, roach, rudd, and many others, including goldfish, belong to this family. Chinese grass carp *Ctenopharyngodon idella* have been introduced (one sex only) to European rivers for weed control.

carpel female reproductive unit in flowering plants (angiosperms). It usually comprises an ovary containing one or more ovules, the stalk or style, and a stigma at its top which receives the pollen. A flower may have one or more carpels, and they may be separate or fused together. Collectively the carpels of a flower are known as the gynoecium.

carpet beetle small black or brown beetle. The larvae are covered with hairs and often known as woolly bears; they feed on carpets, fabrics, and hides causing damage.

The common carpet beetle *Anthrenus scrophularia* measures 3-4 mm/0.1-0.2 in. It is oval, black, and has yellow scales on the shield (pronotum) and ginger red on the wing cases (elytra). This species prefers fabrics to carpets, and the larvae, which are brownish, hairy grubs, eat holes into fabrics or make slits in the carpet.

Larvae of *Anthrenus muscorum* can do extensive damage to museum collections. Specimens of stuffed animals or entire insect collections, which have been inadequately treated prior to storage, can be destroyed.

classification Carpet beetles are in the genus *Anthrenus* and *Attagenus* in the family Dermestidae of order Coleoptera, class Insecta, phylum Arthropoda.

carrageen species of deep-reddish branched seaweed. Named after Carrageen, near Waterford, in the Republic of Ireland, it is found on rocky shores on both sides of the Atlantic. It is exploited commercially in food and medicines and as cattle feed. (*Chondrus crispus*.)

carriage return (CR) in computing, a special code (ASCII value 13) that moves the screen cursor or a print head to the beginning of the current line. Most word processors and the CMS-DOS operating system use a combination of CR and line feed (LF - ASCII value 10) to represent a hard return. The UNIX system, however, uses only LF and therefore files transferred between MS-DOS and UNIX require a conversion program.

carrier in medicine, anyone who harbours an infectious organism without ill effects but can pass the infection to others. The term is also applied to those who carry a recessive gene for a disease or defect without manifesting the condition.

carriion crow British bird *Corvus corone* of family Corvidae, order Passeriformes, closely related to *C. cornix*, the hooded crow. In the USA the name refers to the black vulture.

carrot hardy European biennial plant with feathery leaves and an orange tapering root that is eaten as a vegetable. It has been cultivated since the 16th century. The root has a high sugar content and also contains carotene, which is converted into vitamin A by the human liver. (*Daucus carota*, family Umbelliferae.)

carrying capacity in ecology, the maximum number of animals of a given species that a particular area can support. When the carrying capacity is exceeded, there is insufficient food (or other resources) for the members of the population. The population may then be reduced by emigration, reproductive failure, or death through starvation.

Cartesian coordinates in coordinate geometry, components used to define the position of a point by its perpendicular distance from a set of two or more axes, or reference lines. For a two-dimensional area defined by two axes at right angles (a horizontal x -axis and a vertical y -axis), the coordinates of a point are given by its perpendicular distances from the y -axis and x -axis, written in the form (x, y) . For example, a point P that lies three units from the y -axis and four units from the x -axis has Cartesian coordinates $(3, 4)$ (see *abscissa* and *ordinate*). In three-dimensional coordinate geometry, points are located with reference to a third, z -axis, mutually at right angles to the x and y axes.

The Cartesian coordinate system can be extended to any finite number of dimensions (axes), and is used thus in theoretical mathematics. It is named after the French mathematician, René Descartes. The system is useful in creating technical drawings of machines or buildings, and in computer-aided design (CAD).

cartilage flexible bluish-white connective tissue made up of the protein collagen. In cartilaginous fish it forms the skeleton; in other vertebrates it forms the greater part of the embryonic skeleton, and is replaced by bone in the course of development, except in areas of wear such as bone endings, and the discs between the backbones. It also forms structural tissue in the larynx, nose, and external ear of mammals.

Cartilage does not heal itself, so where injury is severe the joint may need to be replaced surgically. In a 1994 trial, Swedish doctors repaired damaged knee joints by implanting cells cultured from the patient's own cartilage.

cartography art and practice of drawing maps.

caryopsis dry, one-seeded fruit in which the wall of the seed becomes fused to the carpel wall during its development. It is a type of achene, and therefore develops from one ovary and does not split open to release the seed. Caryopses are typical of members of the grass family (Gramineae), including the cereals.

casein main protein of milk, from which it can be separated by the action of acid, the enzyme rennin, or bacteria (souring); it is also the main protein in cheese. Casein is used as a protein supplement in the treatment of malnutrition. It is used commercially in cosmetics, glues, and as a sizing for coating paper.

case-sensitive term describing a system that distinguishes between capitals and lower-case letters. Domain names and Internet addresses are typically not case-sensitive; however, a particular system may be case-sensitive for user IDs. On most systems, the software controlling passwords is case-sensitive, making it harder for an unauthorized user to guess a password.

cash crop crop grown solely for sale rather than for the farmer's own use, for example, coffee, cotton, or sugar beet. Many Third World countries grow cash crops to meet their debt repayments rather than grow food for their own people. The price for these crops depends on financial interests, such as those of the multinational companies and the International Monetary Fund.

In 1990 Uganda, Rwanda, Nicaragua, and Somalia were the countries most dependent on cash crops for income.

cashew tropical American tree. Widely cultivated in India and Africa, it produces poisonous kidney-shaped nuts that become edible after being roasted. (*Anacardium occidentale*, family Anacardiaceae.)

cassava or **manioc** plant belonging to the spurge family. Native to South America, it is now widely grown throughout the tropics for its starch-containing roots, from which tapioca and bread are made. (*Manihot utilissima*, family Euphorbiaceae.)

Cassava is grown as a staple crop in rural Africa, Asia, and South America. Altogether, it provides a staple crop for approxi-

mately 200 million people. The root cells contain the poison cyanoglucoside (converted to hydrogen cyanide in the body) but the plant's latex (milky fluid) contains enzymes that break down the poison. During the processing of cassava the two must mix; the commonest method is by fermentation, although some poison may remain. In Congo (formerly Zaïre) and Mozambique at least 10,000 women and children suffered from chronic poisoning between 1985 and 1995.

Cassegrain telescope or **Cassegrain reflector** type of reflecting telescope in which light collected by a concave primary mirror is reflected on to a convex secondary mirror, which in turn directs it back through a hole in the primary mirror to a focus behind it. As a result, the telescope tube can be kept short, allowing equipment for analyzing and recording starlight to be mounted behind the main mirror. All modern large astronomical telescopes are of the Cassegrain type.

It is named after the 17th century French astronomer, Cassegrain who first devised it as an improvement to the simpler Newtonian telescope.

cassia bark of an aromatic SE Asian plant (*Cinnamomum cassia*) belonging to the laurel family (Lauraceae). It is very similar to cinnamon, and is often used as a substitute for it. *Cassia* is also a genus of pod-bearing tropical plants of the family Caesalpiniaceae, many of which have strong purgative (cleansing) properties; *C. senna* is the source of the laxative drug senna (which causes the bowels to empty).

Cassini joint space probe of the US agency NASA and the European Space Agency to the planet Saturn. *Cassini* was launched in October 1997, to go into orbit around Saturn 2004, dropping off a sub-probe, *Huygens*, to land on Saturn's largest moon, Titan.

It was launched on a Titan 4 rocket, with its electricity supplied by 32 kg/70 lb of plutonium. This is the largest amount of plutonium ever to be sent into space, and provoked fears of contamination should Cassini, or its rocket, malfunction. A Titan 4 exploded in flight 1993.

CASSINI MISSION TO SATURN

<http://miranda.colorado.edu/cassini/>

Well-presented information on the purposes of the Cassini space probe. The complexities of designing the probe and its instruments and navigating it to the distant planet are explained in easy to understand language with the aid of good graphics. There are also interesting details of what is already known about Saturn's moons.

Cassiopeia prominent constellation of the northern hemisphere, named after the mother of Andromeda. It has a distinctive W-shape, and contains one of the most powerful radio sources in the sky, Cassiopeia A. This is the remains of a (supernova (star explosion) that occurred c. AD 1702, too far away to be seen from Earth.

It was in Cassiopeia that Tycho Brahe observed a new star 1572, probably a supernova, since it was visible in daylight and outshone Venus for ten days.

cassiterite or **tinestone** mineral consisting of reddish-brown to black stannic oxide (SnO₂), usually found in granite rocks. It is the chief ore of tin. When fresh it has a bright ('adamantine') lustre. It was formerly extensively mined in Cornwall, England; today Malaysia is the world's main supplier. Other sources of cassiterite are Africa, Indonesia, and South America.

cassowary large flightless bird, genus *Casuarus*, of the family Casuariidae, order Casuariiformes, found in New Guinea and N Australia, usually in forests. Related to the emu, the cassowary has a bare head with a horny casque, or helmet, on top, and brightly-coloured skin on the neck. Its loose plumage is black and its wings tiny, but it can run and leap well and defends itself by kicking.

Cassowaries stand up to 1.5 m/5 ft tall. They live in pairs and the male usually incubates the eggs, about six in number, which the female lays in a nest of leaves and grass.

casting process of producing solid objects by pouring molten material into a shaped mould and allowing it to cool. Casting is used to shape such materials as glass and plastics, as well as metals and alloys.

The casting of metals has been practised for more than 6,000 years, using first copper and bronze, then iron, and now alloys of zinc and other metals. The traditional method of casting metal is sand casting. Using a model of the object to be produced, a hollow mould is made in a damp sand and clay mix. Molten metal is then poured into the mould, taking its shape when it cools and solidifies. The sand mould is broken to release the casting. Permanent metal moulds called dies are also used for casting, in particular, small items in mass-production processes where molten metal is injected under pressure into cooled dies. **Continuous casting** is a method of shaping bars and slabs that involves pouring molten metal into a hollow, water-cooled mould of the desired cross section.

cast iron cheap but invaluable constructional material, most commonly used for car engine blocks. Cast iron is partly refined pig (crude) iron, which is very fluid when molten and highly suitable for shaping by casting; it contains too many impurities (for example, carbon) to be readily shaped in any other way. Solid cast iron is heavy and can absorb great shock but is very brittle.

Castor or *Alpha Geminorum* second brightest star in the constellation Gemini and the 23rd brightest star in the night sky. Along with the brighter Pollux, it forms a prominent pair at the eastern end of Gemini, representing the head of the twins.

Second-magnitude Castor is 45 light years from Earth, and is one of the finest binary stars in the sky for small telescopes. The two main components orbit each other over a period of 467 years. A third, much fainter, star orbits the main pair over a period probably exceeding 10,000 years. Each of the three visible components is a spectroscopic binary, making Castor a sextuple star system.

castoreum preputial follicles of the beaver, abbreviated as 'castor', and used in perfumery.

castor-oil plant tall tropical and subtropical shrub belonging to the spurge family. The seeds, called 'castor beans' in North America, yield the purgative castor oil (which cleans out the bowels) and also ricin, one of the most powerful poisons known. Ricin can be used to destroy cancer cells, leaving normal cells untouched. (*Ricinus communis*, family Euphorbiaceae.)

castration removal of the sex glands (either ovaries or testes). Male domestic animals may be castrated to prevent reproduction, to make them larger or more docile, or to eradicate disease.

Castration of humans was used in ancient and medieval times and occasionally later to preserve the treble voice of boy singers or, by Muslims, to provide eunuchs, trustworthy harem guards. If done in childhood, it inhibits sexual development; for instance, the voice remains high, and growth of hair on the face and body is reduced, owing to the absence of the hormones normally secreted by the testes.

CASTRATION

Exceptional boy singers used to be castrated to preserve their very high voices. Many of these castrati earned very high fees as opera singers.

casuarina any of a group of trees or shrubs with many species in Australia and New Guinea, also found in Africa and Asia. Commonly known as she-oaks, casuarinas have taken their Latin name from the similarity of their long, drooping branchlets to the feathers of the cassowary bird (whose genus is *Casuarus*). (Genus *Casuarina*, family Casuarinaceae.)

cat small, domesticated, carnivorous mammal *Felis catus*, often kept as a pet or for catching small pests such as rodents. Found in many colour variants, it may have short, long, or no hair, but the general shape and size is constant. Cats have short muzzles, strong limbs, and flexible spines which enable them to jump and climb. All walk on the pads of their toes (digitigrade) and have retractile claws, so are able to stalk their prey silently. They have large eyes and an acute sense of hearing. The canine teeth are long and well-developed, as are the shearing teeth in the side of the mouth.

origins Domestic cats have a common ancestor, the African wild cat *Felis libyca*, found across Africa and Arabia. This is similar to the European wild cat *F. silvestris*. Domestic cats can interbreed with either of these wild relatives. Various other species of small wild cat live in all continents except Antarctica and Australia. Large cats such as the lion, tiger, leopard, puma, and jaguar also belong to the cat family Felidae.

CAT

A tenth of the diet of feral cats is made up of vegetable material.

catabolism in biology, the destructive part of metabolism where living tissue is changed into energy and waste products.

It is the opposite of anabolism. It occurs continuously in the body, but is accelerated during many disease processes, such as fever, and in starvation.

catalpa any of a group of trees belonging to the trumpet creeper family, found in North America, China, and the West Indies. The northern catalpa (*Catalpa speciosa*) of North America grows to 30 m/100 ft and has heart-shaped deciduous leaves and tubular white flowers with purple borders. (Genus *Catalpa*, family Bignoniaceae.)

catalytic substance that alters the speed of, or makes possible, a chemical or biochemical reaction but remains unchanged at the end of the reaction. Enzymes are natural biochemical catalysts. In practice most catalysts are used to speed up reactions.

catalytic converter device fitted to the exhaust system of a motor vehicle in order to reduce toxic emissions from the engine. It converts harmful exhaust products to relatively harmless ones by passing the exhaust gases over a mixture of catalysts coated on a metal or ceramic honeycomb (a structure that increases the surface area and therefore the amount of active catalyst with which the exhaust gases will come into contact). Oxidation catalysts (small amounts of precious palladium and platinum metals) convert hydrocarbons (unburnt fuel) and carbon monoxide into carbon dioxide and water, but do not affect nitrogen oxide emissions. Three-way catalysts (platinum and rhodium metals) convert nitrogen oxide gases into nitrogen and oxygen.

Over the lifetime of a vehicle, a catalytic converter can reduce hydrocarbon emissions by 87%, carbon monoxide emissions by 85%, and nitrogen oxide emissions by 62%, but will cause a slight increase in the amount of carbon dioxide emitted. Catalytic converters are standard in the USA, where a 90% reduction in pollution from cars was achieved without loss of engine performance or fuel economy. Only 10% of cars in Britain had catalytic converters in 1993.

Catalytic converters are destroyed by emissions from leaded petrol and work best at a temperature of 300°C. The benefits of catalytic converters are offset by any increase in the number of cars in use.

catamaran Tamil 'tied log' twin-hulled sailing vessel, based on the native craft of South America and the Indies, made of logs lashed together, with an outrigger. A similar vessel with three hulls is known as a trimaran. Car ferries with a wave-piercing catamaran design are also in use in parts of Europe and North America. They have a pointed main hull and two outriggers and travel at a speed of 35 knots (84.5 kph/52.5 mph).

cataract eye disease in which the crystalline lens or its capsule becomes cloudy, causing blindness. Fluid accumulates between the fibres of the lens and gives place to deposits of γ albumin. These coalesce into rounded bodies, the lens fibres break down, and areas of the lens or the lens capsule become filled with opaque products of degeneration. The condition is estimated to have blinded more than 25 million people worldwide, and 150,000 in the UK.

The condition nearly always affects both eyes, usually one more than the other. In most cases, the treatment is replacement of the opaque lens with an artificial implant.

catarrh inflammation of any mucous membrane, especially of the nose and throat, with increased production of mucus.

Catarrhini Old World monkeys and apes, including macaques and baboons (Cercopithecidae) and chimpanzees and orang-utans (Pongidae). The term is now rarely used.

Catarrhines are characterized by having their nostrils close to each other and facing downwards. Many species have cheek pouches and brightly coloured buttocks. They have 32 teeth and do not have prehensile tails. Compare with the New World ϕ Platyrrhini.

catastrophe theory mathematical theory developed by René Thom 1972, in which he showed that the growth of an organism proceeds by a series of gradual changes that are triggered by, and in turn trigger, large-scale changes or 'catastrophic' jumps. It also has applications in engineering – for example, the gradual strain on the structure of a bridge that can eventually result in a sudden collapse – and has been extended to economic and psychological events.

It is characteristic of science that the full explanations are often seized in their essence by the perceptive scientist long in advance of any possible proof.

JOHN DESMOND BERNAL
The Origin of Life 1967

catecholamine chemical that functions as a ϕ neurotransmitter or a ϕ hormone. Dopamine, adrenaline (epinephrine), and noradrenaline (norepinephrine) are catecholamines.

catenary curve taken up by a flexible cable suspended between two points, under gravity; for example, the curve of overhead suspension cables that hold the conductor wire of an electric railway or tramway.

catenary Construction utilizing the form of a catenary can be seen in this suspension bridge.

caterpillar larval stage of a ϕ butterfly or ϕ moth. Wormlike in form, the body is segmented, may be hairy, and often has scent

caterpillar A caterpillar of a notodontid moth from the rainforest of New Guinea. Its aposematic (warning) coloration is a signal to potential predators that it has an unpleasant taste. Premaphotos Wildlife

glands. The head has strong biting mandibles, silk glands, and a spinneret.

Many caterpillars resemble the plant on which they feed, dry twigs, or rolled leaves. Others are highly coloured and rely for their protection on their irritant hairs, disagreeable smell, or on their power to eject a corrosive fluid. Yet others take up a 'threat attitude' when attacked. Caterpillars emerge from eggs that have been laid by the female insect on the food plant and feed greedily, increasing greatly in size and casting their skins several times, until the pupal stage is reached. The abdominal segments bear a varying number of 'prolegs' as well as the six true legs on the thoracic segments.

CATERPILLAR

The caterpillars of some swallowtail butterflies deter predators by their uncanny resemblance to fresh bird droppings.

caterpillar track trade name for an endless flexible belt of metal plates on which certain vehicles such as tanks and bulldozers run, which takes the place of ordinary tyre wheels and improves performance on wet or uneven surfaces.

A track-laying vehicle has a track on each side, and its engine drives small cogwheels that run along the top of the track in contact with the ground. The advantage of such tracks over wheels is that they distribute the vehicle's weight over a wider area and are thus ideal for use on soft and waterlogged as well as rough and rocky ground.

catfish fish belonging to the order Siluriformes, in which barbels (feelers) on the head are well-developed, so giving a resemblance to the whiskers of a cat. Catfishes are found worldwide, mainly but not exclusively in fresh water, and are plentiful in South America.

The E European giant catfish or wels *Silurus glanis* grows to 1.5 m/5 ft long or more. It has been introduced to several places in Britain. The unrelated marine wolfish *Anarhichas lupus*, a deep-sea relative of the blenny, growing 1.2 m/4 ft long, is sometimes called a catfish.

catheter fine tube inserted into the body to introduce or remove fluids. The urinary catheter, passed by way of the urethra (the duct that leads urine away from the bladder) was the first to be used. In today's practice, catheters can be inserted into blood vessels, either in the limbs or trunk, to provide blood samples and local pressure measurements, and to deliver drugs and/or nutrients directly into the bloodstream.

cathode in chemistry, the negative electrode of an electrolytic cell, towards which positive particles (cations), usually in solution, are attracted. See *electrolysis*.

A cathode is given its negative charge by connecting it to the negative side of an external electrical supply. This is in contrast to the negative electrode of an electrical (battery) cell, which acquires its charge in the course of a spontaneous chemical reaction taking place within the cell.

cathode in electronics, the part of an electronic device in which electrons are generated. In a thermionic valve, electrons are produced by the heating effect of an applied current; in a photocell, they are produced by the interaction of light and a semiconducting material. The cathode is kept at a negative potential relative to the device's other electrodes (anodes) in order to ensure that the liberated electrons stream away from the cathode and towards the anodes.

cathode-ray oscilloscope (CRO) instrument used to measure electrical potentials or voltages that vary over time and to display the waveforms of electrical oscillations or signals. Readings are displayed graphically on the screen of a cathode-ray tube.

cathode-ray tube vacuum tube in which a beam of electrons is produced and focused onto a fluorescent screen. It is an essential component of television receivers, computer visual display units, and oscilloscopes.

The electrons' kinetic energy is converted into light energy as they collide with the screen.

cation ion carrying a positive charge. During electrolysis, cations in the electrolyte move to the cathode (negative electrode).

To remember that cations are atoms that have lost an electron:

CAT LOST AN EYE

catkin in flowering plants (angiosperms), a pendulous inflorescence, bearing numerous small, usually unisexual flowers. The tiny flowers are stalkless and the petals and sepals are usually absent or much reduced in size. Many types of trees bear catkins, including willows, poplars, and birches. Most plants with catkins are wind-pollinated, so the male catkins produce large quantities of pollen. Some gymnosperms also have catkin-like structures that produce pollen, for example, the swamp cypress *Taxodium*.

CAT scan or **CT scan** (acronym for *computerized axial tomography scan*) sophisticated method of X-ray imaging. Quick and non-invasive, CAT scanning is used in medicine as an aid to diagnosis, helping to pinpoint problem areas without the need for exploratory surgery. It is also used in archaeology to investigate mummies.

The CAT scanner passes a narrow fan of X-rays through successive slices of the suspect body part. These slices are picked up by crystal detectors in a scintillator and converted electronically into cross-sectional images displayed on a viewing screen. Gradually, using views taken from various angles, a three-dimensional picture of the organ or tissue can be built up and irregularities analysed.

cattle any large, ruminant, even-toed, hoofed mammal of the genus *Bos*, family Bovidae, including wild species such as the yak, gaur, gaval, banteng, and kouprey, as well as domestic breeds. Asiatic water buffaloes *Bubalus*, African buffaloes *Syncaerus*, and American bison *Bison* are not considered true cattle. Cattle are bred for meat (beef cattle) or milk (dairy cattle).

Cattle were first domesticated in the Middle East during the Neolithic period, about 8000 BC. They were brought north into Europe by migrating Neolithic farmers. Fermentation in the four-chambered stomach allows cattle to make good use of the grass that is normally the main part of the diet. There are two main types of domesticated cattle: the European breeds, variants of *Bos taurus* descended from the aurochs, and the various breeds of zebu *Bos indicus*, the humped cattle of India, which are useful in the tropics for their ability to withstand the heat and diseases to which

European breeds succumb. The old-established beef breeds are mostly British in origin. The Hereford, for example, is the premier English breed, ideally suited to rich lowland pastures but it will also thrive on poorer land such as that found in the US Midwest and the Argentine pampas.

Of the Scottish beef breeds, the Aberdeen Angus, a black and hornless variety, produces high-quality meat through intensive feeding methods. Other breeds include the Devon, a hardy early-maturing type, and the Beef Shorthorn, now less important than formerly, but still valued for an ability to produce good calves when crossed with less promising cattle. In recent years, more interest has been shown in other European breeds, their tendency to have less fat being more suited to modern tastes. Examples include the Charolais and the Limousin from central France, and the Simmental, originally from Switzerland. In the USA, four varieties of zebu, called Brahman, have been introduced. They interbreed with *B. taurus* varieties and produce valuable hybrids that resist heat, ticks, and insects. For dairying purposes, a breed raised in many countries is variously known as the Friesian, Holstein, or Black and White. It can give enormous milk yields, up to 13,000/3,450 gal in a single lactation, and will produce calves ideally suited for intensive beef production. Other dairying types include the Jersey and Guernsey, whose milk has a high butterfat content, and the Ayrshire, a smaller breed capable of staying outside all year.

cauda tail, or taillike appendage; part of the *cauda equina*, a bundle of nerves at the bottom of the spinal cord in vertebrates.

cauliflower variety of cabbage, with a large edible head of fleshy, cream-coloured flowers which do not fully mature. It is similar to broccoli but less hardy. (*Brassica oleracea botrytis*, family Cruciferae.)

caustic soda former name for sodium hydroxide (NaOH).

cauterization in medicine, the use of special instruments to burn or fuse small areas of body tissue to destroy dead cells, prevent the spread of infection, or seal tiny blood vessels to minimize blood loss during surgery.

Cavalier King Charles spaniel breed of toy dog very similar to the related King Charles spaniel. It is slightly larger (up to 8 kg/18 lb) and with a longer muzzle, and may be black and tan, tricoloured, ruby (a rich red) or Blenheim (chestnut and white).

cave roofed-over cavity in the Earth's crust usually produced by the action of underground water or by waves on a seacoast. Caves of the former type commonly occur in areas underlain by limestone, such as Kentucky and many Balkan regions, where the rocks are soluble in water. A pothole is a vertical hole in rock caused by water descending a crack; it is thus open to the sky.

Cave animals often show loss of pigmentation or sight, and under isolation, specialized species may develop. The scientific study of caves is called speleology. During the Ice age, humans began living in caves leaving many layers of debris that archaeologists have unearthed and dated in the Old World and the New. They also left cave art, paintings of extinct animals often with hunters on their trail. Celebrated caves include the Mammoth Cave in Kentucky, USA, 6.4 km/4 mi long and 38 m/125 ft high; the Caverns of Adelsberg (Postumia) near Trieste, Italy, which extend for many miles; Carlsbad Cave, New Mexico, the largest in the USA; the Cheddar Caves, England; Fingal's Cave, Scotland, which has a range of basalt columns; and Peak Cavern, England.

VIRTUAL CAVE

<http://www.vol.it/MIRROR2/EN/CAVE/virtcave.html>

Browse the mineral wonders unique to the cave environment – from bell canopies and bottlebrushes to splattermites and stalactites.

cave animal animal that has adapted to life within caves. The chief characteristics of cave animals are reduced or absent eyes and consequently other well-developed sense organs, such as antennae and feelers, and their lack of colour. Most are predators, owing to the lack of vegetable matter in this dark habitat.

Cave-dwellers include several species of snails found in Austrian caves that have developed blindness as a result of their mode of life and a genus of small cockroaches in caves of the Philippine Islands where the females are blind and flightless. There are numerous species of cavefish including *Amblyopsis*, which occurs in the Mammoth Cave of Kentucky, USA. Cave-dwelling amphibians include several blind salamanders, such as the olm.

cavefish cave-dwelling fish, which may belong to one of several quite unrelated groups, independently adapted to life in underground waters. Cavefish have in common a tendency to blindness and atrophy of the eye, enhanced touch-sensitive organs in the skin, and loss of pigment.

The **Kentucky blindfish** *Amblyopsis spelaea*, which lives underground in limestone caves, has eyes that are vestigial and beneath the skin, and a colourless body. The Mexican cave **characin** is a blind, colourless form of *Astyanax fasciatus* found in surface rivers of Mexico.

Cavendish experiment measurement of the gravitational attraction between lead spheres, which enabled English physicist and chemist Henry Cavendish to calculate 1798 a mean value for the mass and density of Earth, using Isaac Newton's law of universal gravitation.

cave spider small spider *Meta menardi* found in caves, cellars, and other dark places. It spins a small open web to catch insects. Its presence can be detected by its spherical egg sacs suspended by thick silk.

cavitation formation of partial vacuums (or cavities) in fluids at high velocities, produced by propellers or other machine parts in hydraulic engines, in accordance with Bernoulli's principle. When

these vacuums collapse, pitting, vibration, and noise can occur in the metal parts in contact with the fluids.

cavy short-tailed South American rodent, family Caviidae, of which the guinea-pig *Cavia porcellus* is an example. Wild caviaries are greyish or brownish with rather coarse hair. They live in small groups in burrows, and have been kept for food since ancient times.

cayenne pepper or **red pepper** spice produced from the dried fruits of several species of capsicum (especially *Capsicum frutescens*), a tropical American group of plants. Its origins are completely different from black or white pepper, which comes from an East Indian plant (*Piper nigrum*).

cc symbol for **cubic centimetre**; abbreviation for **carbon copy/copies**.

CCITT abbreviation for **Comité Consultatif International Téléphonique et Télégraphique**, an organization that sets international communications standards.

CD abbreviation for **compact disc**; **Corps Diplomatique** (French 'Diplomatic Corps'); **certificate of deposit**.

CD-I or **CD-i** (abbreviation for **compact disc-interactive**) compact disc developed by Philips for storing a combination of video, audio, text, and pictures. It was intended principally for the consumer market to be used in systems using a combination of computer and television. It flopped as a consumer system but is still used in education and training.

CD-quality sound digitized sound at 44.1 KHz and 16 bits, the standard defined in ISO 10149, known as the Red Book. CD-quality sound was designed to be the minimum standard required to reproduce every sound the human ear can hear. Most audio CDs are recorded to this level.

CD-R (abbreviation for **compact disc-recordable**) compact disc on which data can be overwritten (compare **CD-ROM**, compact disc

CD-ROM drive Data is obtained by the CD-ROM drive by converting the reflections from a disc's surface into digital form.

read-only memory). The disc combines magnetic and optical technology: during the writing process, a laser melts the surface of the disc, thereby allowing the magnetic elements of the surface layer to be realigned.

CD-ROM (abbreviation for *compact-disc read-only memory*) computer storage device developed from the technology of the audio compact disc. It consists of a plastic-coated metal disc, on which binary digital information is etched in the form of microscopic pits. This can then be read optically by passing a laser beam over the disc. CD-ROMs typically hold about 650 megabytes of data, and are used in distributing large amounts of text, graphics, audio, and video, such as encyclopedias, catalogues, technical manuals, and games.

Standard CD-ROMs cannot have information written onto them by computer, but must be manufactured from a master, although recordable CDs, called CD-R discs, have been developed for use as computer discs. A compact disc, CD-RW, that can be overwritten repeatedly by a computer has also been developed. The compact disc, with its enormous storage capability, may eventually replace the magnetic disc as the most common form of backing store for computers.

The technology is being developed rapidly: a standard CD-ROM disc spins at between 240–1170 rpm, but faster discs have been introduced which speed up data retrieval to many times the standard speed. Research is being conducted into high-density CDs capable of storing many gigabytes of data, made possible by using multiple layers on the surface of the disc, and by using double-sided discs. The first commercial examples of this research include DVD players and DVD-ROM computer discs launched in 1997.

PhotoCD, developed by Kodak and released in 1992, transfers ordinary still photographs onto CD-ROM discs.

CD-ROM drive in computing, a disc drive for reading CD-ROM discs. The vast majority of CD-ROM drives conform to the Yellow Book standard, defined by Philips and Sony. Because of this, all drives are essentially interchangeable. CD-ROM drives are available either as stand-alone or built-in units with a variety of interfaces (connections) and access times. (See illustration on page 140.)

CD-ROM XA (CD-ROM extended architecture) in computing, a set of standards for storing multimedia information on CD-ROM. Developed by Philips, Sony, and Microsoft, it is a partial development of the ϕ CD-I standard. It interleaves data (as in CD-I) so that blocks of audio data are sandwiched between blocks of text, graphics, or video. This allows parallel streams of data to be handled, so that information can be seen and heard simultaneously.

Cebidae largest family of South American monkeys. The Cebidae is divided into five subfamilies represented by titis, squirrel monkeys, sakis, howlers, capuchins, and spider monkeys. They are all tree-living and are found in the rainforest where they feed on vegetable matter and small animals.

Cebus genus of South American monkey. The species have a well-developed big toe, a hairy prehensile tail, and 36 teeth. They include the capuchin monkeys.

classification *Cebus* monkeys are typical of the family Cebidae in the order Primates.

cedar any of an Old World group of coniferous trees belonging to the pine family. The cedar of Lebanon (*Cedrus libani*) grows to great height and age in the mountains of Syria and Asia Minor. Of the historic forests on Mount Lebanon itself, only a few groups of trees remain. (Genus *Cedrus*, family Pinaceae.)

Ceefax 'see facts' one of Britain's two teletext systems (the other is Teletext), or 'magazines of the air', developed by the BBC and first broadcast in 1973.

In 1995 the BBC began testing a scheme to allow Ceefax (repackaged in HTML, hypertext markup language, to enable it to behave like Web pages) to be viewed on a PC by connecting a DAB (digital audio broadcasting) radio to the PC like a modem.

CEGB abbreviation for the former (until 1990) UK *Central Electricity Generating Board*. For current industry structure see *electricity*.

celandine either of two plants belonging to different families, the only similarity being their bright yellow flowers. The greater celandine (*Chelidonium majus*) belongs to the poppy family and is common in hedgerows. The lesser celandine (*Ranunculus ficaria*) is a member of the buttercup family and is a common wayside and meadow plant in Europe.

celeriac variety of garden celery belonging to the carrot family, with an edible turniplike root and small bitter stems. (*Apium graveolens* var. *rapaceum*, family Umbelliferae.)

celery Old World plant belonging to the carrot family. It grows wild in ditches and salt marshes and has a coarse texture and sharp taste. Cultivated varieties of celery are grown under cover to make the edible stalks less bitter. (*Apium graveolens*, family Umbelliferae.)

celestial mechanics the branch of astronomy that deals with the calculation of the orbits of celestial bodies, their gravitational attractions (such as those that produce the Earth's tides), and also the orbits of artificial satellites and space probes. It is based on the laws of motion and gravity laid down by Isaac Newton.

celestial sphere imaginary sphere surrounding the Earth, on which the celestial bodies seem to lie. The positions of bodies such as stars, planets, and galaxies are specified by their coordinates on the celestial sphere. The equivalents of latitude and longitude on the celestial sphere are called declination and right ascension (which is measured in hours from 0 to 24). The celestial poles lie directly above the Earth's poles, and the celestial equator lies over the Earth's Equator. The celestial sphere appears to rotate once around the Earth each day, actually a result of the rotation of the Earth on its axis.

celestial sphere The main features of the celestial sphere. The equivalents of latitude and longitude on the celestial sphere are declination and right ascension. Declination runs from 0° at the celestial equator to 90° at the celestial poles. Right ascension is measured in hours eastwards from the vernal equinox, one hour corresponding to 15° of longitude.

cell in biology, a discrete, membrane-bound portion of living matter, the smallest unit capable of an independent existence. All living organisms consist of one or more cells, with the exception of

cell Typical plant and animal cell. Plant and animal cells share many structures, such as ribosomes, mitochondria, and chromosomes, but they also have notable differences: plant cells have chloroplasts, a large vacuole, and a cellulose cell wall. Animal cells do not have a rigid cell wall but have an outside cell membrane only.

viruses. Bacteria, protozoa, and many other microorganisms consist of single cells, whereas a human is made up of billions of cells. Essential features of a cell are the membrane, which encloses it and restricts the flow of substances in and out; the jellylike material within, the cytoplasm; the ribosomes, which carry out protein synthesis; and the DNA, which forms the hereditary material.

To remember the phases of cell division:

PRIME MINISTER – A TOAD!

PROPHASE, METAPHASE, ANAPHASE, TELOPHASE

Truth is ever to be found in simplicity, and not in the multiplicity and confusion of things ... He is the God of order and not of confusion.

ISAAC NEWTON English physicist and mathematician.
Quoted in R L Weber, *More Random Walks in Science*

cell differentiation in developing embryos, the process by which cells acquire their specialization, such as heart cells, muscle cells, skin cells, and brain cells. The seven-day-old human pre-embryo consists of thousands of individual cells, each of which is destined to assist in the formation of individual organs in the body.

Research has shown that the eventual function of a cell, in for example, a chicken embryo, is determined by the cell's position. The embryo can be mapped into areas corresponding with the spinal cord, the wings, the legs, and many other tissues. If the embryo is relatively young, a cell transplanted from one area to another will develop according to its new position. As the embryo develops the cells lose their flexibility and become unable to change their destiny.

cell division the process by which a cell divides, either meiosis, associated with sexual reproduction, or mitosis, associated with growth, cell replacement, or repair. Both forms involve the duplication of DNA and the splitting of the nucleus.

cell, electrical or voltaic cell or galvanic cell device in which chemical energy is converted into electrical energy; the popular name is 'battery', but this actually refers to a collection of cells in one unit. The reactive chemicals of a **primary cell** cannot be replenished, whereas **secondary cells** – such as storage batteries – are rechargeable: their chemical reactions can be reversed and the original condition restored by applying an electrical current. It is dangerous to attempt to recharge a primary cell.

cell, electrolytic device to which electrical energy is applied in order to bring about a chemical reaction; see electrolysis.

cell membrane or plasma membrane thin layer of protein and fat surrounding cells that controls substances passing between the cytoplasm and the intercellular space. The cell membrane is semipermeable, allowing some substances to pass through and some not.

Generally, small molecules such as water, glucose, and amino acids can penetrate the membrane, while large molecules, such as starch, cannot. Membranes also play a part in active transport, hormonal response, and cell metabolism.

cellophane transparent wrapping film made from wood cellulose, widely used for packaging, first produced by Swiss chemist Jacques Edwin Brandenberger in 1908.

Cellophane is made from wood pulp, in much the same way that the artificial fibre rayon is made: the pulp is dissolved in chemicals to form a viscose solution, which is then pumped through a long narrow slit into an acid bath where the emergent viscose stream turns into a film of pure cellulose.

CELLS ALIVE

<http://www.cellsalive.com/>

Lively and attractive collection of microscopic and computer-generated images of living cells and microorganisms. It includes sections on HIV infection, penicillin, and how antibodies are made.

basic principles

a simple cell

cell, electrical When electrical energy is produced from chemical energy using two metals acting as electrodes in an aqueous solution, it is sometimes known as a galvanic cell or voltaic cell. Here the two metals copper (+) and zinc (–) are immersed in dilute sulphuric acid, which acts as an electrolyte. If a light bulb is connected between the two, an electric current will flow with bubbles of gas being deposited on the electrodes in a process known as polarization.

cellphone short for ϕ cellular phone.

cell sap dilute fluid found in the large central vacuole of many plant cells. It is made up of water, amino acids, glucose, and salts. The sap has many functions, including storage of useful materials, and provides mechanical support for non-woody plants.

cellular modem type of ϕ modem that connects to a ϕ cellular phone for the wireless transmission of data.

cellular phone or **cellphone** mobile radio telephone, one of a network connected to the telephone system by a computer-controlled communication system. Service areas are divided into small 'cells', about 5 km/3 mi across, each with a separate low-power transmitter.

The cellular system allows the use of the same set of frequencies with the minimum risk of interference. Nevertheless, in crowded city areas, cells can become overloaded. This has led to a move away from analogue transmissions to digital methods that allow more calls to be made within a limited frequency range.

cellular phone wireless phone that operates over radio frequencies and links calls to the public telephone system via a base sta-

tion; the area covered by each base station is called a cell. Unlike phones connected up by telephone lines, cellular phones allow mobility, as calls can be made while moving from one radio cell to another. A network of connected base stations and exchanges connects the cellular calls to the public telephone system.

cellulite fatty compound alleged by some dietitians to be produced in the body by liver disorder and to cause lumpy deposits on the hips and thighs. Medical opinion generally denies its existence, attributing the lumpy appearance to a type of subcutaneous fat deposit.

celluloid transparent or translucent, highly flammable, plastic material (a ϕ thermoplastic) made from cellulose nitrate and camphor. It was once used for toilet articles, novelties, and photographic film, but has now been replaced by the nonflammable substance ϕ cellulose acetate.

cellulose complex ϕ carbohydrate composed of long chains of glucose units, joined by chemical bonds called glycosidic links. It is the principal constituent of the cell wall of higher plants, and a vital ingredient in the diet of many ϕ herbivores. Molecules of cellulose are organized into long, unbranched microfibrils that give support to the cell wall. No mammal produces the enzyme cellulase, necessary for digesting cellulose; mammals such as rabbits and cows are only able to digest grass because the bacteria present in their gut can manufacture it.

Cellulose is the most abundant substance found in the plant kingdom. It has numerous uses in industry: in rope-making; as a source of textiles (linen, cotton, viscose, and acetate) and plastics (cellophane and celluloid); in the manufacture of nondrip paint; and in such foods as whipped dessert toppings.

Japanese chemists produced the first synthetic cellulose in 1996 and the gene for the plant enzyme that makes cellulose was identified by Australian biologists in 1998.

cellulose acetate or **cellulose ethanoate** chemical (an ϕ ester) made by the action of acetic acid (ethanoic acid) on cellulose. It is used in making transparent film, especially photographic film; unlike its predecessor, celluloid, it is not flammable.

cellulose nitrate or **nitrocellulose** series of esters of cellulose with up to three nitrate (NO_3) groups per monosaccharide unit. It is made by the action of concentrated nitric acid on cellulose (for example, cotton waste) in the presence of concentrated sulphuric acid. Fully nitrated cellulose (gun cotton) is explosive, but esters with fewer nitrate groups were once used in making lacquers, rayon, and plastics, such as coloured and photographic film, until replaced by the nonflammable cellulose acetate. ϕ Celluloid is a form of cellulose nitrate.

cell wall in plants, the tough outer surface of the cell. It is constructed from a mesh of ϕ cellulose and is very strong and relatively inelastic. Most living cells are turgid (swollen with water; see ϕ turgor) and develop an internal hydrostatic pressure (wall pressure) that acts against the cellulose wall. The result of this turgor pressure is to give the cell, and therefore the plant, rigidity. Plants that are not woody are particularly reliant on this form of support.

The cellulose in cell walls plays a vital role in global nutrition. No vertebrate is able to produce cellulase, the enzyme necessary for the breakdown of cellulose into sugar. Yet most mammalian herbivores rely on cellulose, using secretions from microorganisms living in the gut to break it down. Humans cannot digest the cellulose of the cell walls; they possess neither the correct gut microorganisms nor the necessary grinding teeth. However, cellulose still forms a necessary part of the human diet as ϕ fibre (roughage).

Celsius scale of temperature, previously called centigrade, in which the range from freezing to boiling of water is divided into 100 degrees, freezing point being 0 degrees and boiling point 100 degrees.

The degree centigrade ($^{\circ}\text{C}$) was officially renamed Celsius in 1948 to avoid confusion with the angular measure known as the centigrade (one hundredth of a grade). The Celsius scale is named after the Swedish astronomer Anders Celsius (1701–1744), who devised it in 1742 but in reverse (freezing point was 100° ; boiling point 0°).

Celsius, Anders (1701–1744)

Swedish astronomer, physicist, and mathematician who introduced the Celsius scale of temperature. His other scientific works include a paper on accurately determining the shape and size of the Earth, some of the first attempts to gauge the magnitude of the stars in the constellation Aries, and a study of the falling water level of the Baltic Sea.

Mary Evans Picture Library

CELSIUS, ANDERS (1701–1744)

http://www.astro.uu.se/history/Celsius_eng.html

Biography of Swedish astronomer Anders Celsius. Famous for his creation of the Celsius temperature scale, the astronomer was also the first to realise that the aurora phenomenon was magnetic in nature. A portrait of Celsius is also available from this page.

cement any bonding agent used to unite particles in a single mass or to cause one surface to adhere to another. Portland cement is a powder obtained from burning together a mixture of lime (or chalk) and clay, which when mixed with water and sand or gravel turns into mortar or concrete.

In geology, cement refers to a chemically precipitated material such as carbonate that occupies the interstices of clastic rocks.

The term 'cement' covers a variety of materials, such as fluxes and pastes, and also bituminous products obtained from tar. In 1824 English bricklayer Joseph Aspdin (1779–1855) created and patented the first Portland cement, so named because its colour in the hardened state resembled that of Portland stone, a limestone used in building.

Cenozoic or *Caenozoic* era of geological time that began 65 million years ago and continues to the present day. It is divided into the Tertiary and Quaternary periods. The Cenozoic marks the emergence of mammals as a dominant group, including humans, and the formation of the mountain chains of the Himalayas and the Alps.

ensorship banning of certain types of information from public access. Concerns over the ready availability of material such as bomb recipes and pornography have led a number of countries to pass laws attempting to censor the Internet. The best known of these is the US Communications Decency Act 1996, but initiatives have been taken in other countries, for example Singapore, which announced 1996 new regulations bringing the Internet under the Singapore Broadcasting Authority and requiring all access providers and users to be registered and licensed. Loss formal pressures have been applied against Internet Service Providers in Germany and the UK to block specific types of material.

centaur in astronomy, cometlike object with an unstable orbit of less than 200 years. They are 100–400 km in diameter and are redder than other asteroids. The six known centaurs originated in the Oort Kuiper belt. Chiron and Pholus are centaurs.

Centaurus large, bright constellation of the southern hemisphere, represented as a centaur. Its brightest star, Alpha Centauri, is a

triple star, and contains the closest star to the Sun, Proxima Centauri, which is only 4.3 light years away. Omega Centauri, which is just visible to the naked eye as a hazy patch, is the largest and brightest globular cluster of stars in the sky. 16,000 light years away.

Alpha and Beta Centauri are both of the first magnitude and, like Alpha and Beta Ursae Majoris, are known as 'the Pointers', as a line joining them leads to Crux. Centaurus A, a galaxy 15 million light years away, is a strong source of radio waves and X-rays.

centigrade former name for the Celsius temperature scale.

centipede jointed-legged animal of the group Chilopoda, members of which have a distinct head and a single pair of long antennae. Their bodies are composed of segments (which may number nearly 200), each of similar form and bearing a single pair of legs. Most are small, but the tropical *Scolopendra gigantea* may reach 30 cm/1 ft in length. Millipedes, class Diplopoda, have fewer segments (up to 100), but have two pairs of legs on each.

Nocturnal, frequently blind, and all carnivorous, centipedes live in moist, dark places, and protect themselves by a poisonous secretion. They have a pair of poison claws, and strong jaws with poison fangs. The bite of some tropical species is dangerous to humans. Several species live in Britain, *Lithobius forficatus* being the most common.

centipede A giant centipede of the species *Scolopendra*, active at night in the forests of Madagascar. Unlike millipedes, which have two pairs of legs to each body segment, centipedes have one pair of legs to a segment. They also have venomous fangs with which to immobilize their prey, mostly worms and insects but occasionally small vertebrates. Premphotos Wildlife

central dogma in genetics and evolution, the fundamental belief that genes can affect the nature of the physical body, but that changes in the body (acquired character, for example, through use or accident) cannot be translated into changes in the genes.

central heating system of heating from a central source, typically of a house, larger building, or group of buildings, as opposed to heating each room individually. Steam heat and hot-water heat are the most common systems in use. Water is heated in a furnace burning oil, gas, or solid fuel, and, as steam or hot water, is then pumped through radiators in each room. The level of temperature can be selected by adjusting a thermostat on the burner or in a room.

Central heating has its origins in the hypocaust heating system introduced by the Romans nearly 2,000 years ago. From the 18th century, steam central heating, usually by pipe, was available in the West and installed in individual houses on an ad hoc basis. The Scottish engineer James Watt heated his study with a steam pipe connected to a boiler, and Matthew Boulton installed steam heating in a friend's Birmingham house. Not until the latter half of the

20th century was central heating in general use. Central heating systems are usually switched on and off by a time switch. Another kind of central heating system uses hot air, which is pumped through ducts (called risers) to grills in the rooms. Underfloor heating (called radiant heat) is used in some houses, the heat coming from electric elements buried in the floor. New energy-efficient houses use heat from the Sun and good insulation to replace some central heating.

central nervous system (CNS) the brain and spinal cord, as distinct from other components of the nervous system. The CNS integrates all nervous function.

In invertebrates it consists of a paired ventral nerve cord with concentrations of nerve-cell bodies, known as ganglia in each segment, and a small brain in the head. Some simple invertebrates, such as sponges and jellyfishes, have no CNS but a simple network of nerve cells called a nerve net.

central processing unit (CPU) main component of a computer, the part that executes individual program instructions and controls the operation of other parts. It is sometimes called the central processor or, when contained on a single integrated circuit, a microprocessor.

The CPU has three main components: the **arithmetic and logic unit (ALU)**, where all calculations and logical operations are carried out; a **control unit**, which decodes, synchronizes, and executes program instructions; and the **immediate access memory**, which stores the data and programs on which the computer is currently working. All these components contain registers, which are memory locations reserved for specific purposes.

central processing unit The relationship between the three main areas of a computer's central processing unit. The arithmetic and logic unit (ALU) does the arithmetic, using the registers to store intermediate results, supervised by the control unit. Input and output circuits connect the ALU to external memory, input, and output devices.

centre of gravity the point in an object about which its weight is evenly balanced. In a uniform gravitational field, this is the same as the centre of mass.

central nervous system The central nervous system (CNS) with its associated nerves. The CNS controls and integrates body functions. In humans and other vertebrates it consists of a brain and a spinal cord, which are linked to the body's muscles and organs by means of the peripheral nervous system.

Were it not for gravity one man might hurl another by a puff of his breath into the depths of space, beyond recall for all eternity.

ROGGERIO GIUSEPPE BOSCOVICH Croatian-born Italian scientist.
Theoria

centre of mass point in or near an object at which the whole mass of the object may be considered to be concentrated. A symmetrical homogeneous object such as a sphere or cube has its centre of mass at its geometrical centre; a hollow object (such as a cup) may have its centre of mass in space inside the hollow.

For an object to be in stable equilibrium, a vertical line down through its centre of mass must run within the boundaries of its base; if tilted until this line falls outside the base, the object becomes unstable and topples over.

centrifugal force useful concept in physics, based on an apparent (but not real) force. It may be regarded as a force that acts radially outward from a spinning or orbiting object, thus balancing the centripetal force (which is real). For an object of mass m moving with a velocity v in a circle of radius r , the centrifugal force F equals mv^2/r (outward).

centrifuge apparatus that rotates containers at high speeds, creating centrifugal forces. One use is for separating mixtures of substances of different densities.

The mixtures are usually spun horizontally in balanced containers ('buckets'), and the rotation sets up centrifugal forces, causing their components to separate according to their densities. A common example is the separation of the lighter plasma from the heavier blood corpuscles in certain blood tests. The **ultracentrifuge** is a very high-speed centrifuge, used in biochemistry for separating colloids and organic substances; it may operate at several million revolutions per minute. The centrifuges used in the industrial separation of cream from milk, and yeast from fermented wort (infused malt), operate by having mixtures pumped through a continually rotating chamber, the components being tapped off at different points. Large centrifuges are used for physiological research – for example, in astronaut training where bodily responses to gravitational forces many times the normal level are tested.

centriole structure found in the cells of animals that plays a role in the processes of cytokinesis and mitosis (cell division).

centripetal force force that acts radially inward on an object moving in a curved path. For example, with a weight whirled in a circle at the end of a length of string, the centripetal force is the tension in the string. For an object of mass m moving with a velocity v in a circle of radius r , the centripetal force F equals mv^2/r (inward). The reaction to this force is the centrifugal force.

centromere part of the chromosome where there are no genes. Under the microscope, it usually appears as a constriction in the strand of the chromosome, and is the point at which the spindle fibres are attached during cytokinesis and mitosis (cell division).

Centronics interface standard type of computer interface, used to connect computers to parallel devices, usually printers. (Centronics was an important printer manufacturer in the early days of microcomputing.)

centrosome cell body that contains the centrioles. During cell division the centrosomes organize the microtubules to form the spindle that divides the chromosomes into daughter cells. Centrosomes were first described in 1887, independently by German biologist Theodor Boveri (1862–1915) and Edouard van Beneden.

cephalopod any predatory marine mollusc of the class Cephalopoda, with the mouth and head surrounded by tentacles. Cephalopods are the most intelligent, the fastest-moving, and the largest of all animals without backbones, and there are remarkable luminescent forms which swim or drift at great depths. They have

the most highly developed nervous and sensory systems of all invertebrates, the eye in some closely paralleling that found in vertebrates. Examples include squid, octopus, and cuttlefish. Shells are rudimentary or absent in most cephalopods.

Typically, they move by swimming with the mantle (fold of outer skin) aided by the arms, but can squirt water out of the siphon (funnel) to propel themselves backwards by jet propulsion. Squid, for example, can escape predators at speeds of 11 kph/7mph. Cephalopods grow very rapidly and may be mature in a year. The female common octopus lays 150,000 eggs after copulation, and stays to brood them for as long as six weeks. After they hatch the female dies, and, although reproductive habits of many cephalopods are not known, it is thought that dying after spawning may be typical.

CEPHALOPOD PAGE

<http://is.dal.ca/~ceph/wood.html>

Introduction to the world of cephalopods, the class which includes the squids, cuttlefish, and octopuses, maintained by a graduate student at Dalhousie University, Canada. As well as some excellent images of marine life, this site also contains biological information about each subgroup.

cephalosporin any of a class of broad-spectrum antibiotics derived from a fungus (genus *Cephalosporium*). They are similar to penicillins and are used on penicillin-resistant infections.

The first cephalosporin was extracted from sewage-contaminated water, and other naturally occurring ones have been isolated from moulds taken from soil samples. Side effects include allergic reactions and digestive upsets. Synthetic cephalosporins can be designed to be effective against a particular pathogen.

Cepheid variable yellow supergiant star that varies regularly in brightness every few days or weeks as a result of pulsations. The time that a Cepheid variable takes to pulsate is directly related to its average brightness; the longer the pulsation period, the brighter the star.

This relationship, the **period luminosity law** (discovered by US astronomer Henrietta Leavitt), allows astronomers to use Cepheid variables as 'standard candles' to measure distances in our Galaxy and to nearby galaxies. They are named after their prototype, Delta Cephei, whose light variations were observed 1784 by English astronomer John Goodricke (1764–1786).

Cepheus constellation of the north polar region, named after King Cepheus of Greek mythology, husband of Cassiopeia and father of Andromeda. It contains the Garnet Star (Mu Cephei), a red supergiant of variable brightness that is one of the reddest-coloured stars known, and Delta Cephei, prototype of the Cepheid variables, which are important both as distance indicators and for the information they give about stellar evolution.

Cerberus genus of viviparous (bearing their young live) and aquatic snakes. They are common to the rivers and estuaries of the East Indies from Bengal to Australia.

C. rhynchops has large ventral scales. None of the species is fatally poisonous to humans.

classification *Cerberus* is in family Colubridae, suborder Serpentes, order Squamata, class Reptilia.

Cercopithecus genus of monkeys consisting of the guenons.

cereal grass grown for its edible, nutrient-rich, starchy seeds. The term refers primarily to wheat, oats, rye, and barley, but may also refer to maize (corn), millet, and rice. Cereals contain about 75% complex carbohydrates and 10% protein, plus fats and fibre (roughage). They store well. If all of the world's cereal crop were consumed as whole-grain products directly by humans, everyone could obtain adequate protein and carbohydrate; however, a large proportion of cereal production in affluent nations is used as animal feed to boost the production of meat, dairy products, and eggs.

The term also refers to breakfast foods prepared from the seeds of cereal crops. Some cereals require cooking (porridge oats), but most are ready to eat. Mass-marketed cereals include refined and sweetened varieties as well as whole cereals such as muesli. Whole cereals are more nutritious and provide more fibre than the refined cereals, which often have vitamins and flavourings added to replace those lost in the refining process.

cerebellum part of the brain of vertebrate animals which controls muscle tone, movement, balance, and coordination. It is relatively small in lower animals such as newts and lizards, but large in birds since flight demands precise coordination. The human cerebellum is also well developed, because of the need for balance when walking or running, and for finely coordinated hand movements.

cerebral haemorrhage or *apopleptic fit* in medicine, a form of stroke in which there is bleeding from a cerebral blood vessel into the surrounding brain tissue. It is generally caused by degenerative disease of the arteries and high blood pressure. Depending on the site and extent of bleeding, the symptoms vary from transient weakness and numbness to deep coma and death. Damage to the brain is permanent, though some recovery can be made. Strokes are likely to recur.

cerebral hemisphere one of the two halves of the cerebrum.

cerebral palsy any nonprogressive abnormality of the brain occurring during or shortly after birth. It is caused by oxygen deprivation, injury during birth, haemorrhage, meningitis, viral infection, or faulty development. Premature babies are at greater risk of being born with cerebral palsy, and in 1996 US researchers linked this to low levels of the thyroid hormone thyroxine. The condition is characterized by muscle spasm, weakness, lack of coordination, and impaired movement; or there may be spastic paralysis, with fixed deformities of the limbs. Intelligence is not always affected.

CEREBRAL PALSY TUTORIAL

<http://galen.med.virginia.edu/~smb4v/tutorials/cp/cp.htm>

Multimedia tutorial on cerebral palsy for children and parents. It discusses the causes and different kinds of the disorder, describes a series of therapeutic interventions, and presents equipment of different kinds that can prove useful for children with this debilitating disease.

cerebrum part of the vertebrate brain, formed from the two paired cerebral hemispheres, separated by a central fissure. In birds and mammals it is the largest and most developed part of the brain. It is covered with an infolded layer of grey matter, the cerebral cortex, which integrates brain functions. The cerebrum coordinates all voluntary activity.

Ceres the largest asteroid, 940 km/584 mi in diameter, and the first to be discovered (by Italian astronomer Giuseppe Piazzi 1801). Ceres orbits the Sun every 4.6 years at an average distance of 414 million km/257 million mi. Its mass is about one-seventieth of that of the Moon.

cerium malleable and ductile, grey, metallic element, symbol Ce, atomic number 58, relative atomic mass 140.12. It is the most abundant member of the lanthanide series, and is used in alloys, electronic components, nuclear fuels, and lighter flints. It was discovered 1804 by the Swedish chemists Jöns Berzelius and Wilhelm Hisinger (1766–1852), and, independently, by Martin Klaproth. The element was named after the then recently discovered asteroid Ceres.

cermet (contraction of *ceramics* and *metal*) bonded material containing ceramics and metal, widely used in jet engines and nuclear reactors. Cermet behaves much like metals but have the

great heat resistance of ceramics. Tungsten carbide, molybdenum boride, and aluminium oxide are among the ceramics used; iron, cobalt, nickel, and chromium are among the metals.

CERN particle physics research organization founded 1954 as a cooperative enterprise among European governments. It has laboratories at Meyrin, near Geneva, Switzerland. It was originally known as the Conseil Européen pour la Recherche Nucléaire but subsequently renamed Organisation Européenne pour la Recherche Nucléaire, although still familiarly known as CERN. It houses the world's largest particle accelerator, the Large Electron Positron Collider (LEP), with which notable advances have been made in particle physics.

In 1965 the original laboratory was doubled in size by extension across the border from Switzerland into France. In 1994 the 19 member nations of CERN approved the construction of the Large Hadron Collider. It is expected to cost £1.25 million and to be fully functional in 2005.

Cerro Tololo Inter-American Observatory observatory on Cerro Tololo mountain in the Chilean Andes operated by AURA (the Association of Universities for Research in Astronomy). Its main instrument is a 4-m/15-ft reflector, opened in 1974, a twin of that at Kitt Peak, Arizona, USA.

CERT abbreviation for Computer Emergency Response Team.

cervical cancer in medicine, cancer of the cervix (neck of the womb).

cervical smear in medicine, removal of a small sample of tissue from the cervix (neck of the womb) to screen for changes implying a likelihood of cancer. The procedure is also known as the Pap test after its originator, George Papanicolaou.

CET abbreviation for Central European Time.

Cetus Latin 'whale' large constellation on the celestial equator (see celestial sphere), represented as a sea monster or a whale. Cetus contains the long-period variable star Mira, and Tau Ceti, one of the nearest stars, which is visible with the naked eye.

It is named after the sea monster sent to devour Andromeda. Mira is sometimes the most conspicuous object in the constellation, but it is more usually invisible to the naked eye.

CFC abbreviation for chlorofluorocarbon.

CGA (abbreviation for *colour graphics adapter*) in computing, first colour display system for IBM PCs and compatible machines. It has been superseded by VGA, SVGA, and XGA.

CGI abbreviation for common gateway interface.

c.g.s. system system of units based on the centimetre, gram, and second, as units of length, mass, and time, respectively. It has been replaced for scientific work by the SI units to avoid inconsistencies in definition of the thermal calorie and electrical quantities.

chama species of baboon.

Chaetodon genus of spiny-rayed fishes known as butterfly fishes.

Chaetopterus large sedentary bristle-worm (polychaete) that inhabits U-shaped tubes in sand or mud. The tube can be 23 cm/9 in long and the two ends protrude from the surface and can be seen at a very low spring tide.

The worm's body, which is phosphorescent, is divided into three regions with various sizes of fans and bristles. These aid in spinning a mucous net, which filters out particles suspended in the sea water and is then eaten by the worm, another being spun in its place about once an hour.

classification *Chaetopterus* is a member of class Polychaeta in phylum Annelida.

chafer beetle of the family Scarabaeidae. The adults eat foliage or flowers, and the underground larvae feed on roots, chiefly those of grasses and cereals, and can be very destructive. Examples are the cockchafer and the rose chafer *Cetonia aurata*, about 2 cm/0.8 in long and bright green.

chaffinch bird *Fringilla coelebs* of the finch family, common throughout much of Europe and W Asia. About 15 cm/6 in long, the male is olive-brown above, with a bright chestnut breast, a bluish-grey cap, and two white bands on the upper part of the wing; the female is duller. During winter they form single-sex flocks.

Chagas's disease disease common in Central and South America, infecting approximately 18 million people worldwide. It is caused by a trypanosome parasite, *Trypanosoma cruzi*, transmitted by several species of blood-sucking insect; it results in incurable damage to the heart, intestines, and brain. It is named after Brazilian doctor Carlos Chagas (1879–1934).

It is the world's third most prevalent parasitic disease, after malaria and schistosomiasis. In its first stage symptoms resemble flu but 20–30% of sufferers develop inflammation of the heart muscles up to 20 years later.

chain reaction in chemistry, a succession of reactions, usually involving free radicals, where the products of one stage are the reactants of the next. A chain reaction is characterized by the continual generation of reactive substances.

A chain reaction comprises three separate stages: **initiation** – the initial generation of reactive species; **propagation** – reactions that involve reactive species and generate similar or different reactive species; and **termination** – reactions that involve the reactive species but produce only stable, nonreactive substances. Chain reactions may occur slowly (for example, the oxidation of edible oils) or accelerate as the number of reactive species increases, ultimately resulting in explosion.

chain reaction in nuclear physics, a fission reaction that is maintained because neutrons released by the splitting of some atomic nuclei themselves go on to split others, releasing even more neutrons. Such a reaction can be controlled (as in a nuclear reactor) by using moderators to absorb excess neutrons. Uncontrolled, a chain reaction produces a nuclear explosion (as in an atom bomb).

chalaza glutinous mass of transparent albumen supporting the yolk inside birds' eggs. The chalaza is formed as the egg slowly passes down the oviduct, when it also acquires its coiled structure.

chalcid form of the mineral quartz, SiO_2 , in which the crystals are so fine-grained that they are impossible to distinguish with a microscope (cryptocrystalline). Agate, onyx, and carnelian are gem varieties of chalcid.

chalcopryite copper iron sulphide mineral, CuFeS_2 , the most common ore of copper. It is brassy yellow in colour and may have an iridescent surface tarnish. It occurs in many different types of mineral vein, in rocks ranging from basalt to limestone.

chalk soft, fine-grained, whitish sedimentary rock composed of calcium carbonate, CaCO_3 , extensively quarried for use in cement, lime, and mortar, and in the manufacture of cosmetics and toothpaste. Blackboard chalk in fact consists of gypsum (calcium sulphate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$).

Chalk was once thought to derive from the remains of microscopic animals or foraminifera. In 1953, however, it was seen under the electron microscope to be composed chiefly of *Foraminifera*, unicellular lime-secreting algae, and hence primarily of plant origin. It is formed from deposits of deep-sea sediments called ooze.

Challenger orbiter used in the US *space shuttle* programme which on 28 January 1986 exploded on takeoff, killing all seven crew members.

chameleon any of 80 or so species of lizard of the family Chamaeleonidae. Some species have highly developed colour-changing abilities, caused by stress and changes in the intensity of light and temperature, which alter the dispersal of pigment granules in the layers of cells beneath the outer skin.

The tail is long and highly prehensile, assisting the animal when climbing. Most chameleons live in trees and move very slowly.

The tongue is very long, protrusile, and covered with a viscous secretion; it can be shot out with great rapidity to 20 cm/8 in for the capture of insects. The eyes are on 'turrets', move independently,

and can swivel forward to give stereoscopic vision for 'shooting'. Most live in Africa and Madagascar, but the common chameleon *Chamaeleo chamaeleon* is found in Mediterranean countries; two species live in SW Arabia, and one species in India and Sri Lanka.

Some species of chameleon, such as the African species *C. bitaeniatus* give birth to live young; the female 'gives birth' to a fully-formed young enclosed in a membrane, which is immediately shed.

chamois goatlike mammal *Rupicapra rupicapra* found in mountain ranges of SW Europe and Asia Minor. It is brown, with dark patches running through the eyes, and can be up to 80 cm/2.6 ft high. Chamois are very sure-footed, and live in herds of up to 30 members.

Both sexes have horns which may be 20 cm/8 in long. These are set close together and go up vertically, forming a hook at the top. Chamois skin is very soft, and excellent for cleaning glass, but the chamois is now comparatively rare and 'chamois leather' is often made from the skin of sheep and goats.

champion any of a number of edible fungi (see *fungus*). The fairy ring champion (*Marasmius oreades*) has this name because its fruiting bodies (mushrooms) grow in rings around the outer edge of the underground mycelium (threadlike body) of the fungus. (Family Agaricaceae.)

chance likelihood, or probability, of an event taking place, expressed as a fraction or percentage. For example, the chance that a tossed coin will land heads up is 50%.

As a science, it originated when the Chevalier de Méré consulted Blaise Pascal about how to reduce his gambling losses. In 1664, in correspondence with another mathematician, Pierre de Fermat, Pascal worked out the foundations of the theory of chance. This underlies the science of statistics.

I have been trying to point out that in our lives chance may have an astonishing influence and, if I may offer advice to the young laboratory worker, it would be this – never to neglect an extraordinary appearance or happening. It may be – usually is, in fact – a false alarm that leads to nothing, but it may on the other hand be the clue provided by fate to lead you to some important advance.

ALEXANDER FLEMING Scottish bacteriologist.

Lecture at Harvard

chancroid or **soft sore** acute localized, sexually transmitted ulcer on or about the genitals caused by the bacterium *Haemophilus ducreyi*.

It causes painful enlargement and suppuration of lymph nodes in the groin area.

Chandrasekhar limit or **Chandrasekhar mass** in astrophysics, the maximum possible mass of a white dwarf star. The limit depends slightly on the composition of the star but is equivalent to 1.4 times the mass of the Sun. A white dwarf heavier than the Chandrasekhar limit would collapse under its own weight to form a neutron star or a black hole. The limit is named after the

CHAMELEONS

<http://www.skypoint.com/members/mikefry/chams.html>

Excellent guide to the expensive and time-consuming business of looking after a pet chameleon. Would-be owners are warned not to support the trade in endangered species. Dietary and housing requirements are well-explained, together with advice on what to do if your lizard is stressed, goes on hunger strike, has parasites, or does not get enough unfiltered sunlight. There are links to a number of specialist sites related to chameleons in the wild or in captivity.

Indian-US astrophysicist Subrahmanyan Chandrasekhar who developed the theory of white dwarfs in the 1930s.

change of state in science, a change in the physical state (solid, liquid, or gas) of a material. For instance, melting, boiling, evaporation, and their opposites, solidification and condensation, are changes of state. The former set of changes are brought about by heating or decreased pressure; the latter by cooling or increased pressure.

These changes involve the absorption or release of heat energy, called latent heat, even though the temperature of the material does not change during the transition between states.

See also **states of matter**. In the unusual change of state called **sublimation**, a solid changes directly to a gas without passing through the liquid state. For example, solid carbon dioxide (dry ice) sublimates to carbon dioxide gas.

channel in computing, path connecting a computer to peripheral devices along which data can be transferred.

channel efficiency measure of the ability of a river channel to discharge water. Channel efficiency can be assessed by calculating the channel's hydraulic radius. The most efficient channels are generally semicircular in cross-section, and it is this shape that water engineers try to create when altering a river channel to reduce the risk of flooding.

Surely John Bull will not endanger his birthright, his liberty, his property, simply in order that men and women may cross between England and France without running the risk of sea-sickness.

GARNET WOLSELEY English soldier.

On the Channel Tunnel proposals of 1882

Channel Tunnel tunnel built beneath the English Channel, linking Britain with mainland Europe. It comprises twin rail tunnels, 50 km/31 mi long and 7.3 m/24 ft in diameter, located 40 m/130 ft beneath the seabed. Construction began in 1987, and the French and English sections were linked in December 1990. It was officially opened on 6 May 1994. The shuttle train service, Le Shuttle, opened to lorries in May 1994 and to cars in December 1994. The tunnel's high-speed train service, Eurostar, linking London to Paris and Brussels, opened in November 1994.

The estimated cost of the tunnel has continually been revised upwards to a figure of £8 billion (1995). In 1995 Eurotunnel plc, the Anglo-French company that built the tunnel, made a loss of £925 million.

chanterelle edible fungus that is bright yellow and funnel-shaped. It grows in deciduous woodland. (*Cantharellus cibarius*, family Cantharellaceae.)

Chaos Theory: The Mathematics of Chaos

BY IAN STEWART

The mathematics of chaos

Why are tides predictable years ahead, whereas weather forecasts often go wrong within a few days?

Both tides and weather are governed by natural laws. Tides are caused by the gravitational attraction of the Sun and Moon; the weather by the motion of the atmosphere under the influence of heat from the Sun. The law of gravitation is not noticeably simpler than the laws of fluid dynamics; yet for weather the resulting behaviour seems to be far more complicated.

The reason for this is 'chaos', which lies at the heart of one of the most exciting and most rapidly expanding areas of mathematical research, the theory of nonlinear dynamic systems.

Random behaviour in dynamic systems

It has been known for a long time that dynamic systems – systems that change with time according to fixed laws – can exhibit regular patterns, such as repetitive cycles. Thanks to new mathematical techniques, emphasizing shape rather than number, and to fast and sophisticated computer graphics, we now know that dynamic systems can also behave randomly. The difference lies not in the complexity of the formulae that define their mathematics, but in the geometrical features of the dynamics. This is a remarkable discovery: random behaviour in a system whose mathematical description contains no hint whatsoever of randomness.

Simple geometric structure produces simple dynamics. For example, if the geometry shrinks everything towards a fixed point, then the motion tends towards a steady state. But if the dynamics keep stretching things apart and then folding them together again, the motion tends to be chaotic – like food being mixed in a bowl. The motion of the Sun and Moon, on the kind of timescale that matters when we want to predict the tides, is a series of regular cycles, so prediction is easy. The changing patterns of the weather involve a great deal of stretching and folding, so here chaos reigns.

Fractals

The geometry of chaos can be explored using theoretical mathematical techniques such as topology – 'rubber-sheet geometry' – but the most vivid pictures are obtained using computer graphics. The geometric structures of chaos are 'fractals': they have detailed form on all scales of magnification.

Order and chaos, traditionally seen as opposites, are now viewed as two aspects of the same basic process, the evolution of a system in time. Indeed, there are now examples where both order and chaos occur naturally within a single geometrical form.

Predicting the unpredictable

Does chaos make randomness predictable? Sometimes. If what looks like random behaviour is actually governed by a dynamic system, then short-term prediction becomes possible. Long-term prediction is not as easy, however. In chaotic systems any initial error of measurement, however small, will grow rapidly and eventually ruin the prediction. This is known as the butterfly effect: if a butterfly flaps its wings, a month later the air disturbance created may cause a hurricane.

Chaos can be applied to many areas of science, such as chemistry, engineering, computer science, biology, electronics, and astronomy. For example, although the short-term motions of the Sun and Moon are not chaotic, the long-term motion of the Solar System is chaotic. It is impossible to predict on which side of the Sun Pluto will lie in 200 million years' time. Saturn's satellite Hyperion tumbles chaotically. Chaos caused by Jupiter's gravitational field can fling asteroids out of orbit, towards the Earth. Disease epidemics, locust plagues, and irregular heartbeats are more down-to-earth examples of chaos, on a more human timescale.

Making sense of chaos

Chaos places limits on science: it implies that even when we know the equations that govern a system's behaviour, we may not in practice be able to make effective predictions. On the other hand, it opens up new avenues for discovery, because it implies that apparently random phenomena may have simple, nonrandom explanations. So chaos is changing the way scientists think about what they do: the relation between determinism and chance, the role of experiment, the computability of the world, the prospects for prediction, and the interaction between mathematics, science, and nature. Chaos cuts right across traditional subject boundaries, and distinctions between pure and applied mathematicians, between mathematicians and physicists, between physicists and biologists, become meaningless when compared to the unity revealed by their joint efforts.

chaos theory or *chaology* or *complexity theory* branch of mathematics that attempts to describe irregular, unpredictable systems – that is, systems whose behaviour is difficult to predict because there are so many variable or unknown factors. Weather is an example of a chaotic system.

Chaos theory, which attempts to predict the *probable* behaviour of such systems, based on a rapid calculation of the impact of as wide a range of elements as possible, emerged in the 1970s with the development of sophisticated computers. First developed for use in meteorology, it has also been used in such fields as economics.

char or **charr** fish *Salvelinus alpinus* related to the trout, living in the Arctic coastal waters, and also in Europe and North America in some upland lakes. It is one of Britain's rarest fish, and is at risk from growing acidification.

Numerous variants have been described, but they probably all belong to the same species.

characin freshwater fish belonging to the family Characidae. There are over 1,300 species, mostly in South and Central America, but also in Africa. Most are carnivores. In typical characins, unlike the somewhat similar carp family, the mouth is toothed, and there is a small dorsal adipose fin just in front of the tail.

Characins are small fishes, often colourful, and they include tetras and piranhas.

character one of the symbols that can be represented in a computer. Characters include letters, numbers, spaces, punctuation marks, and special symbols.

characteristic in mathematics, the integral (whole-number) part of a logarithm. The fractional part is the mantissa.

For example, in base ten, $10^0 = 1$, $10^1 = 10$, $10^2 = 100$, and so on; the powers to which 10 is raised are the characteristics. To determine the power to which 10 must be raised to obtain a number between 10 and 100, say 20 (2×10 , or $\log 2 + \log 10$), the logarithm for 2 is found (0.3010), and the characteristic 1 added to make 1.3010.

character printer computer printer that prints one character at a time.

character set in computing, the complete set of symbols that can be used in a program or recognized by a computer. It may include letters, digits, spaces, punctuation marks, and special symbols.

extended character set in PC-based computing, the set of 254 characters stored in ROM. Besides the 128 ASCII characters, the set includes block graphics and foreign language characters.

character type check in computing, a validation check to ensure that an input data item does not contain invalid characters. For example, an input name may be checked to ensure that it contains only letters of the alphabet or an input six-figure date may be checked to ensure it contains only numbers.

charcoal black, porous form of carbon, produced by heating wood or other organic materials in the absence of air. It is used as a fuel in the smelting of metals such as copper and zinc, and by artists for making black line drawings. Activated charcoal has been powdered and dried so that it presents a much increased surface area for adsorption; it is used for filtering and purifying liquids and gases – for example, in drinking-water filters and gas masks.

Charcoal was traditionally produced by burning dried wood in a kiln, a process lasting several days. The kiln was either a simple hole in the ground, or an earth-covered mound. Today kilns are of brick or iron, both of which allow the waste gases to be collected and used. Charcoal had many uses in earlier centuries. Because of the high temperature at which it burns ($2,012^\circ\text{F}/1,100^\circ\text{C}$), it was used in furnaces and blast furnaces before the development of coke. It was also used in an industrial process for obtaining ethanoic acid (acetic acid), in producing wood tar and wood pitch, and (when produced from alder or willow trees) as a component of gunpowder.

charge see electric charge.

charge-coupled device (CCD) device for forming images electronically, using a layer of silicon that releases electrons when

struck by incoming light. The electrons are stored in pixels and read off into a computer at the end of the exposure. CCDs have now almost entirely replaced photographic film for applications such as astrophotography where extreme sensitivity to light is paramount.

charged particle beam high-energy beam of electrons or protons. Such beams are being developed as weapons.

Charles, Jacques Alexandre César

(1746–1823)

French physicist who studied gases and made the first ascent in a hydrogen-filled balloon in 1783. His work on the expansion of gases led to the formulation of Charles's law.

Hearing of the hot-air balloons of the Montgolfier brothers, Charles and his brothers began experimenting with hydrogen balloons and made their ascent only ten days after the Montgolfiers' first flight. In later flights Charles ascended to an altitude of 3,000 m/10,000 ft.

Mary Evans Picture Library

Charles's law law stating that the volume of a given mass of gas at constant pressure is directly proportional to its absolute temperature (temperature in kelvin). It was discovered by French physicist Jacques Charles 1787, and independently by French chemist Joseph Gay-Lussac in 1802.

The gas increases by 1/273 of its volume at 0°C for each $^\circ\text{C}$ rise of temperature. This means that the coefficient of expansion of all gases is the same. The law is only approximately true and the coefficient of expansion is generally taken as 0.003663 per $^\circ\text{C}$.

charlock or **wild mustard** annual plant belonging to the cress family, found in Europe and Asia. It has hairy stems and leaves and yellow flowers. (*Sinapis arvensis*, family Cruciferae.)

charm in physics, a property possessed by one type of quark (very small particles found inside protons and neutrons), called the charm quark. The effects of charm are only seen in experiments with particle accelerators. See elementary particles.

chat real-time exchange of messages between users of a particular system. Chat allows people who are geographically far apart to type messages to each other which are sent and received instantly. On a system like America Online, users may chat while playing competitive games or while reading messages, as well as joining public or private 'rooms' to talk with a variety of other users. The biggest chat system is Internet Relay Chat (IRC), which is used for the exchange of information and software as well as for social interaction.

check box small, square box used as a control in dialog boxes. Check boxes toggle functions and are operated by moving the cursor over the box and clicking the mouse button to check or clear the box.

check digit in computing, a digit attached to an important code number as a validation check.

checksum in computing, a control total of specific items of data. A checksum is used as a check that data have been input or transmitted correctly. It is used in communications and in, for example, accounts programs. See also validation.

cheetah large wild cat *Acinonyx jubatus* native to Africa, Arabia, and SW Asia, but now rare in some areas. Yellowish with black spots, it has a slim lithe build. It is up to 1 m/3 ft tall at the shoulder, and up to 1.5 m/5 ft long. It can reach 103 kph/64 mph, but tires after about 400 yards. Cheetahs live in open country where they hunt small antelopes, hares, and birds.

A cheetah's claws do not retract as fully as in most cats. It is the world's fastest mammal. Cheetahs face threats both from ranchers who shoot them as vermin and from general habitat destruction that is reducing the prey on which they feed, especially gazelles. As a result the wild population is thought to have fallen by over half since the 1970s; there are now thought to be no more than 5,000–12,000 left.

CHEETAH

The cheetah can accelerate from zero to 72 kmph/45 mph in two seconds.

chelate chemical compound whose molecules consist of one or more metal atoms or charged ions joined to chains of organic residues by coordinate (or dative covalent) chemical bonds.

The parent organic compound is known as a **chelating agent** – for example, EDTA (ethylene-diaminetetraacetic acid), used in chemical analysis. Chelates are used in analytical chemistry, in agriculture and horticulture as carriers of essential trace metals, in water softening, and in the treatment of thalassaemia by removing excess iron, which may build up to toxic levels in the body. Metalloproteins (natural chelates) may influence the performance of enzymes or provide a mechanism for the storage of iron in the spleen and plasma of the human body.

Chelonian order of reptiles containing some 250 species of tortoises, terrapins, and turtles. Members possess a shell made up of bony plates. The upper part of the shell, the carapace, may be fused to the vertebrae and ribs. Chelonians are toothless, with a hardened horny beak.

chemical change change that occurs when two or more substances (reactants) interact with each other, resulting in the production of different substances (products) with different chemical compositions. A simple example of chemical change is the burning of carbon in oxygen to produce carbon dioxide.

chemical element alternative name for **element**.

chemical equation method of indicating the reactants and products of a chemical reaction by using chemical symbols and formulae. A chemical equation gives two basic pieces of information: (1) the reactants (on the left-hand side) and products (right-hand side); and (2) the reacting proportions (stoichiometry) – that is, how many units of each reactant and product are involved. The equation must balance; that is, the total number of atoms of a particular element on the left-hand side must be the same as the number of atoms of that element on the right-hand side.

reactants \rightarrow products

This equation states that one molecule of sodium carbonate combines with two molecules of hydrochloric acid to form two molecules of sodium chloride, one of carbon dioxide, and one of water. Double arrows indicate that the reaction is reversible – in the formation of ammonia from hydrogen and nitrogen, the direction depends on the temperature and pressure of the reactants.

chemical equilibrium condition in which the products of a reversible chemical reaction are formed at the same rate at which they decompose back into the reactants, so that the concentration of each reactant and product remains constant.

The amounts of reactant and product present at equilibrium are defined by the **equilibrium constant** for that reaction and specific temperature.

chemical family collection of elements that have very similar chemical and physical properties. In the periodic table of the elements such collections are to be found in the vertical columns (groups). The groups that contain the most markedly similar elements are group I, the alkali metals; group II, the alkaline-earth metals; group VII, the halogens; and group 0, the noble or inert gases.

chemical oxygen demand (COD) measure of water and effluent quality, expressed as the amount of oxygen (in parts per million) required to oxidize the reducing substances present.

Under controlled conditions of time and temperature, a chemical oxidizing agent (potassium permanganate or dichromate) is added to the sample of water or effluent under consideration, and the amount needed to oxidize the reducing materials present is measured. From this the chemically equivalent amount of oxygen can be calculated. Since the reducing substances typically include remains of living organisms, COD may be regarded as reflecting the extent to which the sample is polluted. Compare **biological oxygen demand**.

chemical weathering form of weathering brought about by chemical attack of rocks, usually in the presence of water. Chemical weathering involves the 'rotting', or breakdown, of the original minerals within a rock to produce new minerals (such as clay minerals, bauxite, and calcite). Some chemicals are dissolved and carried away from the weathering source.

A number of processes bring about chemical weathering, such as carbonation (breakdown by weakly acidic rainwater), hydrolysis (breakdown by water), hydration (breakdown by the absorption of water), and oxidation (breakdown by the oxygen in water). The reaction of carbon dioxide gas in the atmosphere with silicate minerals in rocks to produce carbonate minerals (see calcite) is called the 'Urey reaction' after the chemist who proposed it, Harold Urey. The Urey reaction is an important link between Earth's climate and the geology of the planet. It has been proposed that chemical weathering of large mountain ranges like the Himalayas of Nepal can remove carbon dioxide from the atmosphere by the Urey reaction (or other more complicated reactions like it), leading to a cooler climate as the greenhouse effects of the lost carbon dioxide are diminished.

chemiluminescence the emission of light from a substance as a result of a chemical reaction (rather than raising its temperature). See **luminescence**.

chemisorption the attachment, by chemical means, of a single layer of molecules, atoms, or ions of gas to the surface of a solid or, less frequently, a liquid. It is the basis of catalysis (see **catalyst**) and is of great industrial importance.

chemistry branch of science concerned with the study of the structure and composition of the different kinds of matter, the changes which matter may undergo and the phenomena which occur in the course of these changes.

Organic chemistry is the branch of chemistry that deals with carbon compounds. **Inorganic chemistry** deals with the description, properties, reactions, and preparation of all the elements and their compounds, with the exception of carbon compounds. **Physical chemistry** is concerned with the quantitative explanation of chemical phenomena and reactions, and the measurement of data required for such explanations. This branch studies in particular the movement of molecules and the effects of temperature and pressure, often with regard to gases and liquids.

molecules, atoms, and elements All matter can exist in three states: gas, liquid, or solid. It is composed of minute particles termed **molecules**, which are constantly moving, and may be further divided into **atoms**.

Molecules that contain atoms of one kind only are known as **elements**; those that contain atoms of different kinds are called **compounds**.

compounds and mixtures Chemical compounds are produced by a chemical action that alters the arrangement of the atoms in the

Chemistry: chronology

- c. 3000 BC** Egyptians were producing bronze – an alloy of copper and tin.
- c. 450 BC** Greek philosopher Empedocles proposed that all substances are made up of a combination of four elements – Earth, air, fire, and water – an idea that was developed by Plato and Aristotle and persisted for over 2,000 years.
- c. 400 BC** Greek philosopher Democritus theorized that matter consists ultimately of tiny, indivisible particles, atoms.
- AD 1** Gold, silver, copper, lead, iron, tin, and mercury were known.
- 900** The techniques of solution, filtration, and distillation were known.
- 7th–17th centuries** Chemistry was dominated by alchemy, the attempt to transform nonprecious metals such as lead and copper into gold. Though misguided, it led to the discovery of many new chemicals and techniques, such as sublimation and distillation. Alcohol was first distilled in Europe.
- 12th century**
- 1242** Gunpowder introduced to Europe from the Far East.
- 1620** Scientific method of reasoning expounded by Francis Bacon in his *Novum Organum*.
- 1650** Leyden University in the Netherlands set up the first chemistry laboratory.
- 1661** Robert Boyle defined an element as any substance that cannot be broken down into still simpler substances and asserted that matter is composed of 'corpuscles' (atoms) of various sorts and sizes, capable of arranging themselves into groups, each of which constitutes a chemical substance.
- 1662** Boyle described the inverse relationship between the volume and pressure of a fixed mass of gas (Boyle's law).
- 1697** Georg Stahl proposed the erroneous theory that substances burn because they are rich in a certain substance, called phlogiston.
- 1755** Joseph Black discovered carbon dioxide.
- 1774** Joseph Priestley discovered oxygen, which he called 'dephlogisticated air'. Antoine Lavoisier demonstrated his law of conservation of mass.
- 1777** Lavoisier showed air to be made up of a mixture of gases, and showed that one of these – oxygen – is the substance necessary for combustion (burning) and rusting to take place.
- 1781** Henry Cavendish showed water to be a compound.
- 1792** Alessandro Volta demonstrated the electrochemical series.
- 1807** Humphry Davy passed electric current through molten compounds (the process of electrolysis) in order to isolate elements, such as potassium, that had never been separated by chemical means. Jöns Berzelius proposed that chemicals produced by living creatures should be termed 'organic'.
- 1808** John Dalton published his atomic theory, which states that every element consists of similar indivisible particles – called atoms – which differ from the atoms of other elements in their mass; he also drew up a list of relative atomic masses. Joseph Gay-Lussac announced that the volumes of gases that combine chemically with one another are in simple ratios.
- 1811** Publication of Amedeo Avogadro's hypothesis on the relation between the volume and number of molecules of a gas, and its temperature and pressure.
- 1813–14** Berzelius devised the chemical symbols and formulae still used to represent elements and compounds.
- 1828** Franz Wohler converted ammonium cyanate into urea – the first synthesis of an organic compound from an inorganic substance.
- 1832–33** Michael Faraday expounded the laws of electrolysis, and adopted the term 'ion' for the particles believed to be responsible for carrying current.
- 1846** Thomas Graham expounded his law of diffusion.
- 1853** Robert Bunsen invented the Bunsen burner.
- 1858** Stanislao Cannizzaro differentiated between atomic and molecular weights (masses).
- 1861** Organic chemistry was defined by German chemist Friedrich Kekulé as the chemistry of carbon compounds.
- 1864** John Newlands devised the first periodic table of the elements.
- 1869** Dmitri Mendeleev expounded his periodic table of the elements (based on atomic mass), leaving gaps for elements that had not yet been discovered.
- 1874** Jacobus van't Hoff suggested that the four bonds of carbon are arranged tetrahedrally, and that carbon compounds can therefore be three-dimensional and asymmetric.
- 1884** Swedish chemist Svante Arrhenius suggested that electrolytes (solutions or molten compounds that conduct electricity) dissociate into ions, atoms or groups of atoms that carry a positive or negative charge.
- 1894** William Ramsay and Lord Rayleigh discovered the first inert gases, argon.
- 1897** The electron was discovered by J.J. Thomson.
- 1901** Mikhail Tsvet invented paper chromatography as a means of separating pigments.
- 1909** Søren Sørensen devised the pH scale of acidity.
- 1912** Max von Laue showed crystals to be composed of regular, repeating arrays of atoms by studying the patterns in which they diffract X-rays.
- 1913–14** Henry Moseley equated the atomic number of an element with the positive charge on its nuclei, and drew up the periodic table, based on atomic number, that is used today.
- 1916** Gilbert Newton Lewis explained covalent bonding between atoms as a sharing of electrons.
- 1927** Nevil Sidgwick published his theory of valency, based on the numbers of electrons in the outer shells of the reacting atoms.
- 1930** Electrophoresis, which separates particles in suspension in an electric field, was invented by Arne Tiselius.
- 1932** Deuterium (heavy hydrogen), an isotope of hydrogen, was discovered by Harold Urey.
- 1940** Edwin McMillan and Philip Abelson showed that new elements with a higher atomic number than uranium can be formed by bombarding uranium with neutrons, and synthesized the first transuranic element, neptunium.
- 1942** Plutonium was first synthesized by Glenn T. Seaborg and Edwin McMillan.
- 1950** Derek Barton deduced that some properties of organic compounds are affected by the orientation of their functional groups (the study of which became known as conformational analysis).
- 1954** Einsteinium and fermium were synthesized.
- 1955** Ilya Prigogine described the thermodynamics of irreversible processes (the transformations of energy that take place in, for example, many reactions within living cells).
- 1962** Neil Bartlett prepared the first compound of an inert gas, xenon hexafluoroplatinate; it was previously believed that inert gases could not take part in a chemical reaction.
- 1965** Robert B Woodward synthesized complex organic compounds.
- 1981** Quantum mechanics applied to predict course of chemical reactions by US chemist Roald Hoffmann and Kenichi Fukui of Japan.
- 1982** Element 109, unnilennium, synthesized.
- 1985** Fullerenes, a new class of carbon solids made up of closed cages of carbon atoms, were discovered by Harold Kroto and David Walton at the University of Sussex, England.
- 1987** US chemists Donald Cram and Charles Pedersen, and Jean-Marie Lehn of France created artificial molecules that mimic the vital chemical reactions of life processes.
- 1990** Jean-Marie Lehn, Ulrich Koert, and Margaret Harding reported the synthesis of a new class of compounds, called nuchelicates, that mimic the double helical structure of DNA, turned inside out.
- 1993** US chemists at the University of California and the Scripps Institute synthesized rapamycin, one of a group of complex, naturally occurring antibiotics and immunosuppressants that are being tested as anticancer agents.
- 1994** Elements 110 (ununilium) and 111 (unununium) discovered at the GSI heavy-ion cyclotron, Darmstadt, Germany.
- 1995** German chemists built the largest ever wheel molecule made up of 154 molybdenum atoms surrounded by oxygen atoms. It has a relative molecular mass of 24,000 and is soluble in water.
- 1996** Element 112 discovered at the GSI heavy-ion cyclotron, Darmstadt, Germany.
- 1997** The International Union of Pure and Applied Chemistry (IUPAC) stated that elements 104–109 should be named rutherfordium (104), dubnium (105), seaborgium (106), bohrium (107), hassium (108), and meitnerium (109).

reacting molecules. Heat, light, vibration, catalytic action, radiation, or pressure, as well as moisture (for ionization), may be necessary to produce a chemical change. Examination and possible breakdown of compounds to determine their components is analysis, and the building up of compounds from their components is synthesis. When substances are brought together without changing their molecular structures they are said to be mixtures.

formulas and equations Symbols are used to denote the elements. The symbol is usually the first letter or letters of the English or Latin name of the element – for example, C for carbon; Ca for calcium; Fe for iron (*ferrum*). These symbols represent one atom of the element; molecules containing more than one atom of an element are denoted by a subscript figure – for example, water is H_2O . In some substances a group of atoms acts as a single entity, and these are enclosed in parentheses in the symbol – for example $(NH_4)_2SO_4$ denotes ammonium sulphate. The symbolic representation of a molecule is known as a formula. A figure placed before a formula represents the number of molecules of a substance taking part in, or being produced by, a chemical reaction – for example, $2H_2O$ indicates two molecules of water. Chemical reactions are expressed by means of equations as in:

This equation states the fact that sodium chloride (NaCl) on being treated with sulphuric acid (H_2SO_4) is converted into sodium bisulphate (sodium hydrogensulphate, $NaHSO_4$) and hydrogen chloride (HCl). See also chemical equation.

metals, nonmetals, and the periodic system Elements are divided into metals, which have lustre and conduct heat and electricity, and nonmetals, which usually lack these properties. The periodic system, developed by John Newlands in 1863 and established by Dmitri Mendeleev in 1869, classified elements according to their relative atomic masses. Those elements that resemble each other in general properties were found to bear a relation to one another by weight, and these were placed in groups or families. Certain anomalies in this system were later removed by classifying the elements according to their atomic numbers. The latter is equivalent to the positive charge on the nucleus of the atom.

The true use of chemistry is not to make gold but to prepare medicines.

PARACELUS Swiss physician, alchemist, and scientist.
Attributed remark

chemosynthesis method of making protoplasm (contents of a cell) using the energy from chemical reactions, in contrast to the use of light energy employed for the same purpose in photosynthesis. The process is used by certain bacteria, which can synthesize organic compounds from carbon dioxide and water using the energy from special methods of respiration.

Nitrifying bacteria are a group of chemosynthetic organisms which change free nitrogen into a form that can be taken up by plants; nitrobacteria, for example, oxidize nitrites to nitrates. This is a vital part of the nitrogen cycle. As chemosynthetic bacteria can survive without light energy, they can live in dark and inhospitable regions, including the hydrothermal vents of the Pacific ocean. Around these vents, where temperatures reach up to $350^\circ C/662^\circ F$, the chemosynthetic bacteria are the basis of a food web supporting fishes and other marine life.

chemotaxis in biology, the property that certain cells have of attracting or repelling other cells. For example, white blood cells are attracted to the site of infection by the release of substances during certain types of immune response.

chemotherapy any medical treatment with chemicals. It usually refers to treatment of cancer with cytotoxic and other drugs. The term was coined by the German bacteriologist Paul Ehrlich for the use of synthetic chemicals against infectious diseases.

chemotropism movement by part of a plant in response to a chemical stimulus. The response by the plant is termed 'positive' if

the growth is towards the stimulus or 'negative' if the growth is away from the stimulus.

Fertilization of flowers by pollen is achieved because the ovary releases chemicals that produce a positive chemotropic response from the developing pollen tube.

Cherenkov radiation a type of electromagnetic radiation emitted by charged particles entering a transparent medium at a speed greater than the speed of light in the medium. It appears as a bluish light. Cherenkov radiation can be detected from high-energy cosmic rays entering the Earth's atmosphere. It is named after Pavel Alexseevich Cherenkov, the Russian physicist who first observed it.

Chernobyl town in northern Ukraine, 100 km/62 mi north of Kiev; site of a nuclear power station. On 26 April 1986, two huge explosions occurred at the plant, destroying a central reactor and breaching its 1,000-tonne roof. In the immediate vicinity of Chernobyl, 31 people died (all firemen or workers at the plant) and 135,000 were permanently evacuated. It has been estimated that there will be an additional 20–40,000 deaths from cancer in the following 60 years; 600,000 are officially classified as at risk. According to WHO figures of 1995, the incidence of thyroid cancer in children has increased 200-fold in Belarus as a result of fallout from the disaster.

The Chernobyl disaster occurred as the result of an unauthorized test being conducted, in which the reactor was run while its cooling system was inoperative. The resulting clouds of radioactive isotopes spread all over Europe, from Ireland to Greece. A total of 9 tonnes of radioactive material were released into the atmosphere, 90 times the amount produced by the Hiroshima A-bomb. In all, 5 million people are thought to have been exposed to radioactivity following the blast. In Ukraine, Belarus, and Russia more than 500,000 people were displaced from affected towns and villages and thousands of square miles of land were contaminated.

cherry any of a group of fruit-bearing trees distinguished from plums and apricots by their fruits, which are round and smooth and not covered with a bloom. They are cultivated in temperate regions with warm summers and grow best in deep fertile soil. (Genus *Prunus*, family Rosaceae.)

chervil any of several plants belonging to the carrot family. The garden chervil (*Anthriscus cerefolium*) has leaves with a sweetish smell, similar to parsley. It is used as a garnish and in soups. Chervil originated on the borders of Europe and Asia and was introduced to W Europe by the Romans. (Genus *Anthriscus*, family Umbelliferae.)

chestnut any of a group of trees belonging to the beech family. The Spanish or sweet chestnut (*Castanea sativa*) produces edible nuts inside husks; its timber is also valuable. Horse chestnuts are quite distinct, belonging to the genus *Aesculus*, family Hippocastanaceae. (True chestnut genus *Castanea*, family Fagaceae.)

chevrotain or **mouse deer** small forest-dwelling mammals resembling deer. Horns are absent and they reach a maximum height at the shoulder of about 35 cm/14 in. They are active at night and feed mainly on plants and fruit.

There are four species in two genera, *Tragulus* and *Hyemoschus*. *Tragulus* contains three species of small animals, which have more or less the characteristics and habits of some rodents. They inhabit Asia, Malaysia, Sri Lanka, and India. *Hyemoschus* contains only one species, the African water chevrotain.

classification Chevrotains are members of the family Tragulidae in the mammalian order Artiodactyla.

chicken domestic fowl; see under *oultry*.

chickenpox or **varicella** common, usually mild disease, caused by a virus of the herpes group and transmitted by airborne droplets. Chickenpox chiefly attacks children under the age of ten. The incubation period is two to three weeks. One attack normally gives immunity for life.

The temperature rises and spots (later inflamed blisters) develop on the torso, then on the face and limbs. The sufferer recovers

within a week, but remains infectious until the last scab disappears.

The US Food and Drug Administration approved a chickenpox vaccine in March 1995. Based on a weakened form of the live virus, the vaccine is expected to be 70–90% effective. A vaccine is available in Europe, but is only used in children with an impaired immune system.

chickpea annual leguminous plant (see *legume*), grown for food in India and the Middle East. Its short hairy pods contain edible seeds similar to peas. (*Cicer arietinum*, family Leguminosae.)

chickweed any of several low-growing plants belonging to the pink family, with small white starlike flowers. (Genera *Stellaria* and *Cerastium*, family Caryophyllaceae.)

chicle milky juice from the sapodilla tree *Achras zapota* of Central America; it forms the basis of chewing gum.

chicory plant native to Europe and W Asia, with large, usually blue, flowers. Its long taproot is used dried and roasted as a coffee substitute. As a garden vegetable, grown under cover, its blanched leaves are used in salads. It is related to *chendive*. (*Cichorium intybus*, family Compositae.)

chiffchaff small songbird *Phylloscopus collybita* of the warbler family, Muscicapidae, order Passeriformes. It is found in woodlands and thickets in Europe and N Asia during the summer, migrating south for winter. About 11 cm/4.3 in long, olive above, greyish below, with yellow-white nether parts, an eyestripe, and usually dark legs, it looks similar to a willow warbler but has a distinctive song.

chigger or **harvest mite** scarlet or rusty brown *mite* genus *Trombicula*, family Trombiculidae, in the order Acarina, common in summer and autumn. Chiggers are parasitic, and their tiny red larvae cause intensely irritating bites in places where the skin is thin, such as behind the knees or between the toes. After a time they leave their host and drop to the ground where they feed upon minute insects.

Chiggers are medically important and can be harmful to humans in two ways: either by the feeding activities of the larval mite, on folds of skin or the edges of hair follicles resulting in painful lesions 0.4–2 cm/0.16–0.8 in long, or by acting as carriers of disease, for example scrub typhus or haemorrhagic fever.

chihuahua smallest breed of dog, 15 cm/10 in high, developed in the USA from Mexican origins. It may weigh only 1 kg/2.2 lb. The domed head and wide-set ears are characteristic, and the skull is large compared to the body. It can be almost any colour, and occurs in both smooth (or even hairless) and long-coated varieties.

chilblain painful inflammation of the skin of the feet, hands, or ears, due to cold. The parts turn red, swell, itch violently, and are very tender. In bad cases, the skin cracks, blisters, or ulcerates.

childbirth the expulsion of a baby from its mother's body following pregnancy. In a broader sense, it is the period of time involving labour and delivery of the baby.

chilli (*North American chilli*) pod, or powder made from the pod, of a variety of *capsicum* (*Capsicum frutescens*), a small, hot, red pepper. It is widely used in cooking. The hot ingredient of chilli is capsaicin. It causes a burning sensation in the mouth by triggering nerve branches in the eyes, nose, tongue, and mouth.

Capsaicin does not activate the taste buds and therefore has no flavour. It is claimed that people can become physically addicted to it.

CHILLI

<http://www.tpoint.net/~wallen/chili.html>

Online adulation of the hottest food in the world with personal recommendations on the many varieties and recipes, as well as how to prepare the chillies themselves.

chimaera fish of the group Holocephali. Chimaeras have thick bodies that taper to a long thin tail, large fins, smooth skin, and a cartilaginous skeleton. They can grow to 1.5 m/4.5 ft. Most chimaeras are deep-water fish, and even *Chimaera monstrosa*, a relatively shallow-living form caught around European coasts, lives at a depth of 300–500 m/1,000–1,600 ft.

chimera or **chimaera** in biology, an organism composed of tissues that are genetically different. Chimeras can develop naturally if a mutation occurs in a cell of a developing embryo, but are more commonly produced artificially by implanting cells from one organism into the embryo of another.

CHIMPANZEE

http://www.seaworld.org/animal_bytes/chimpanzeeab.html

Illustrated guide to the chimpanzee including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

chimpanzee highly intelligent African ape *Pan troglodytes* that lives mainly in rain forests but sometimes in wooded savanna. Chimpanzees are covered in thin but long black body hair, except for the face, hands, and feet, which may have pink or black skin. They normally walk on all fours, supporting the front of the body on the knuckles of the fingers, but can stand or walk upright for a short distance. They can grow to 1.4 m/4.5 ft tall, and weigh up to 50 kg/110 lb. They are strong and climb well, but spend time on the ground, living in loose social groups. The bulk of the diet is fruit, with some leaves, insects, and occasional meat. Chimpanzees can use 'tools', fashioning twigs to extract termites from their nests.

The bonobo or pygmy chimpanzee, *Pan paniscus* is found only in a small area of rainforest in Congo (formerly Zaire). Bonobos are about the same height as 'common' chimpanzees, but they are of a slighter build, with less hair, and stand upright more frequently. They are a distinct species, numbering approximately 10,000.

Chimpanzees are found in an area from W Africa to W Uganda and Tanzania in the east. Studies of chromosomes suggest that chimpanzees are the closest apes to humans, perhaps sharing 99% of the same genes. Trained chimpanzees can learn to communicate with humans with the aid of machines or sign language, but are probably precluded from human speech by the position of the voicebox.

CHIMPANZEE

Sick chimpanzees use natural remedies to heal themselves. Internal parasites are purged by eating certain leaves, and stomach upsets are treated with mouthfuls of earth rich in clay minerals, sodium, iron, and aluminium.

china clay commercial name for *kaolin*.

chinchinchee poisonous plant *Ornithogalum thyrsoides* of the lily family Liliaceae. It is native to South Africa, and has spikes of long-lasting, white or yellow, waxlike flowers.

chinchilla South American rodent *Chinchilla laniger* found in high, rather barren areas of the Andes in Bolivia and Chile. About the size of a small rabbit, it has long ears and a long bushy tail, and shelters in rock crevices. These gregarious animals have thick, soft, silver-grey fur, and were hunted almost to extinction for it. They are now farmed and protected in the wild.

Chinese crested dog breed of toy dog developed in China, notable for being hairless except for large plumes on its head, feet and tail. Its skin has a blue or pink tinge, sometimes with black spots. Lightly built, it weighs up to 5.5 kg/12 lb.

The 'Powder Puff' variety has long, plume-like, very fine hair all over its body.

chip or **silicon chip** another name for a \int integrated circuit, a complete electronic circuit on a slice of silicon (or other semiconductor) crystal only a few millimetres square.

chipmunk any of several species of small ground squirrel with characteristic stripes along its side. Chipmunks live in North America and E Asia, in a variety of habitats, usually wooded, and take shelter in burrows. They have pouches in their cheeks for carrying food. They climb well but spend most of their time on or near the ground.

The Siberian chipmunk *Eutamias sibiricus*, about 13 cm/5 in long, is found in N Russia, N China, and Japan.

chip-set in computing, group of chips that work together to perform a particular set of functions. Standard chip-sets, for example, manage graphics or form the working parts of a modem.

Chiron unusual Solar-System object orbiting between Saturn and Uranus, discovered 1977 by US astronomer Charles T Kowal (1940–).

Initially classified as an asteroid, it is now believed to be a giant cometary nucleus about 200 km/120 mi across, composed of ice with a dark crust of carbon dust. It has a 51-year orbit and a coma (cloud of gas and dust) caused by evaporation from its surface, resembling that of a comet. It is classified as a ζ centaur.

chiropractic in alternative medicine, technique of manipulation of the spine and other parts of the body, based on the principle that physical disorders are attributable to aberrations in the functioning of the nervous system, which manipulation can correct.

Developed in the 1890s by US practitioner Daniel David Palmer, chiropractic is widely practised today by accredited therapists, although orthodox medicine remains sceptical of its efficacy except for the treatment of back problems.

chiru Tibetan species of antelope. It is pale fawn in colour with coarse hair; the male alone has horns, and these are long, straight, ringed and gazelle-like. It is nearly 1 m/3.3 ft in height.

classification The chiru *Pantholops hodgsoni* is in the family Bovidae (cattle and antelopes) of order Artiodactyla.

chital another name for the ϕ axis deer.

chitin complex long-chain compound, or ϕ polymer; a nitrogenous derivative of glucose. Chitin is widely found in invertebrates. It forms the ϕ exoskeleton of insects and other arthropods. It combines with protein to form a covering that can be hard and tough, as in beetles, or soft and flexible, as in caterpillars and other insect larvae. It is insoluble in water and resistant to acids, alkalis, and many organic solvents. In crustaceans such as crabs, it is impregnated with calcium carbonate for extra strength.

Chitin also occurs in some ϕ protozoans and coelenterates (such as certain jellyfishes), in the jaws of annelid worms, and as the cell-wall polymer of fungi. Its uses include coating apples (still fresh after six months), coating seeds, and dressing wounds. In 1993 chemists at North Carolina State University found that it can be used to filter pollutants from industrial waste water.

chiton group of marine molluscs, ranging in size from 1 cm/0.4 in to 15 cm/6 in; some are littoral (intertidal) whilst others live at greater depths. They live on vegetable matter and are like limpets in habit; they usually attach themselves to rocks, but can crawl by means of their long foot, and are capable of rolling themselves up.

All the species are bilaterally symmetrical, have eight shell-plates embedded partially or entirely in the mantle, and are covered with spicules.

classification Chitons are in class Polyplacophora, phylum Mollusca.

chive or *chives* perennial European plant belonging to the lily family, related to onions and leeks. It has an underground bulb,

long hollow tubular leaves, and globe-shaped purple flower heads. The leaves are used as a garnish for salads. (*Allium schoenoprasum*, family Liliaceae.)

chlamydia viruslike bacteria which live parasitically in animal cells, and cause disease in humans and birds. Chlamydiae are thought to be descendants of bacteria that have lost certain metabolic processes. In humans, a strain of chlamydia causes (trachoma, a disease found mainly in the tropics (a leading cause of blindness); venereally transmitted chlamydiae cause genital and urinary infections.

Protein from *C. Pneumoniae* (which accounts for 10% of pneumonia cases) has been found in 79% of cases of atheroma (furring up of the arteries) in a US study, and it has also been cultured from a diseased coronary artery, providing a possible link between chlamydia infection and heart disease. A link has also been established between *C. Pneumoniae* infection and chronic high blood pressure.

chloral or **trichloroethanal** CCl_3CHO oily, colourless liquid with a characteristic pungent smell, produced by the action of chlorine on ethanol. It is soluble in water and its compound chloral hydrate is a powerful sleep-inducing agent.

chlorate any salt derived from an acid containing both chlorine and oxygen and possessing the negative ion ClO_2^- , ClO_3^- , or ClO_4^- . Common chlorates are those of sodium, potassium, and barium. Certain chlorates are used in weedkillers.

chlorella any single-celled, green, freshwater alga of the genus *Chlorella*, 3–10 micrometres in diameter, which can increase its weight by four times in 12 hours. Nutritive content: 50% protein, 20% fat, 20% carbohydrate, 10% phosphate, calcium, and ϕ trace elements.

chloride Cl^- negative ion formed when hydrogen chloride dissolves in water, and any salt containing this ion, commonly formed by the action of hydrochloric acid (HCl) on various metals or by direct combination of a metal and chlorine. Sodium chloride (NaCl) is common table salt.

chlorinated solvent any liquid organic compound that contains chlorine atoms, often two or more. These compounds are very effective solvents for fats and greases, but many have toxic properties.

They include trichloromethane (chloroform, CHCl_3), tetrachloromethane (carbon tetrachloride, CCl_4), and trichloroethene ($\text{CH}_2\text{ClCHCl}_2$).

chlorination the treatment of water with chlorine in order to disinfect it; also, any chemical reaction in which a chlorine atom is introduced into a chemical compound.

chlorine Greek *chloros* 'green' greenish-yellow, gaseous, non-metallic element with a pungent odour, symbol Cl, atomic number 17, relative atomic mass 35.453. It is a member of the ϕ halogen group and is widely distributed, in combination with the ϕ alkali metals, as chlorates or chlorides.

Chlorine was discovered in 1774 by the German chemist Karl Scheele, but English chemist Humphry Davy first proved it to be an element in 1810 and named it after its colour. In nature it is always found in the combined form, as in hydrochloric acid, produced in the mammalian stomach for digestion. Chlorine is obtained commercially by the electrolysis of concentrated brine and is an important bleaching agent and ermicide, used for sterilizing both drinking water and swimming-pools. As an oxidizing agent it finds many

CHLORINE

<http://c3.org/>

Designed to promote better understanding of the science of chlorine chemistry, examining how it contributes to an enhancement of our standard of living and quality of life.

applications in organic chemistry. The pure gas (Cl_2) is a poison and was used in gas warfare in World War I, where its release seared the membranes of the nose, throat, and lungs, producing pneumonia. Chlorine is a component of chlorofluorocarbons (CFCs) and is partially responsible for the depletion of the ozone layer; it is released from the CFC molecule by the action of ultraviolet radiation in the upper atmosphere, making it available to react with and destroy the ozone. The concentration of chlorine in the atmosphere in 1997 reached just over 3 parts per billion. It is expected to reach its peak in 1999 and then start falling rapidly due to international action to curb ozone-destroying chemicals.

PROBLEM OF CHLOROFLUOROCARBONS

<http://pooh.chem.wm.edu/chemWWW/courses/chem105/projects/group2/page5.html>

Excellent graphical presentation of the effect of CFCs on the ozone layer. The information can be readily understood by a general reader wishing to learn more about the chemistry of ozone depletion and why more ultraviolet radiation is reaching the surface of the earth.

chlorofluorocarbon (CFC) a class of synthetic chemicals that are odourless, nontoxic, nonflammable, and chemically inert. The first CFC was synthesized in 1892, but no use was found for it until the 1920s. Since then their stability and apparently harmless properties have made CFCs popular as propellants in aerosol cans, as refrigerants in refrigerators and air conditioners, as degreasing agents, and in the manufacture of foam packaging. They are partly responsible for the destruction of the ozone layer. In June 1990 representatives of 93 nations, including the UK and the USA, agreed to phase out production of CFCs and various other ozone-depleting chemicals by the end of the 20th century.

When CFCs are released into the atmosphere, they drift up slowly into the stratosphere, where, under the influence of ultraviolet radiation from the Sun, they react with ozone (O_3) to form free chlorine (Cl) atoms and molecular oxygen (O_2), thereby destroying the ozone layer that protects Earth's surface from the Sun's harmful ultraviolet rays. The chlorine liberated during ozone breakdown can react with still more ozone, making the CFCs particularly dangerous to the environment. CFCs can remain in the atmosphere for more than 100 years. Replacements for CFCs are being developed, and research into safe methods for destroying existing CFCs is being carried out. In 1996 it was reported that US chemists at Yale University had developed a process for breaking down freons and other gases containing CFCs into nonhazardous compounds.

Since their initial introduction, different CFC compounds have been introduced into the environment as new applications have evolved. Comparisons of the concentrations of different CFC compounds can therefore be used to date ground water flows and even ocean circulation patterns. Ironically, CFC dating provides the environmental industry and research scientists with a powerful new tool for understanding the factors that affect Earth's environment.

The European Union agreed to ban by the end of 1995 the five 'full hydrogenated' CFCs that are restricted under the Montreal Protocol and a range of CFCs used as industrial solvents, refrigerants, and in fire extinguishers.

The tragedy of a scientific man is that he has found no way to guide his own discoveries to a constructive end.

CHARLES A LINDBERGH US aviator.
Attributed remark

sickly sweet smell and taste, formerly used as an anaesthetic (now superseded by less harmful substances).

It is used as a solvent and in the synthesis of organic chemical compounds.

chlorophyll green pigment present in most plants; it is responsible for the absorption of light energy during photosynthesis.

The pigment absorbs the red and blue-violet parts of sunlight but reflects the green, thus giving plants their characteristic colour.

Chlorophyll is found within chloroplasts, present in large numbers in leaves. Cyanobacteria (blue-green algae) and other photosynthetic bacteria also have chlorophyll, though of a slightly different type. Chlorophyll is similar in structure to haemoglobin, but with magnesium instead of iron as the reactive part of the molecule.

chloroplast structure (organelle) within a plant cell containing the green pigment chlorophyll. Chloroplasts occur in most cells of the green plant that are exposed to light, often in large numbers. Typically, they are flattened and disclike, with a double membrane enclosing the stroma, a gel-like matrix. Within the stroma are stacks of fluid-containing cavities, or vesicles, where photosynthesis occurs.

It is thought that the chloroplasts were originally free-living cyanobacteria (blue-green algae) which invaded larger, non-photosynthetic cells and developed a symbiotic relationship with them. Like mitochondria, they contain a small amount of DNA and divide by fission. Chloroplasts are a type of plastid.

chloroplast Green chlorophyll molecules on the membranes of the vesicle stacks capture light energy to produce food by photosynthesis.

chlorosis abnormal condition of green plants in which the stems and leaves turn pale green or yellow. The yellowing is due to a reduction in the levels of the green chlorophyll pigments. It may be caused by a deficiency in essential elements (such as magnesium, iron, or manganese), a lack of light, genetic factors, or viral infection.

choke coil in physics, a coil employed to limit or suppress alternating current without stopping direct current, particularly the type used as a 'starter' in the circuit of fluorescent lighting.

cholecalciferol or **vitamin D** fat-soluble chemical important in the uptake of calcium and phosphorus for bones. It is found in liver, fish oils and margarine. It can be produced in the skin, provided that the skin is adequately exposed to sunlight. Lack of vitamin D leads to rickets and other bone diseases.

cholecystectomy surgical removal of the gall bladder. It is carried out when gallstones or infection lead to inflammation of the gall bladder, which may then be removed either by conventional surgery or by a 'keyhole' procedure (see endoscopy).

chloroform (technical name *trichloromethane*) CHCl_3 clear, colourless, toxic, carcinogenic liquid with a characteristic pungent,

cholera disease caused by infection with various strains of the bacillus *Vibrio cholerae*, transmitted in contaminated water and characterized by violent diarrhoea and vomiting. It is prevalent in many tropical areas.

The formerly high death rate during epidemics has been much reduced by treatments to prevent dehydration and loss of body salts, together with the use of antibiotics. There is an effective vaccine that must be repeated at frequent intervals for people exposed to continuous risk of infection. The worst epidemic in the Western hemisphere for 70 years occurred in Peru in 1991, with 55,000 confirmed cases and 258 deaths. It was believed to have been spread by the consumption of seafood contaminated by untreated sewage. 1991 was also the worst year on record for cholera in Africa with 13,000 deaths.

cholesterol white, crystalline ester found throughout the body, especially in fats, blood, nerve tissue, and bile; it is also provided in the diet by foods such as eggs, meat, and butter. A high level of cholesterol in the blood is thought to contribute to atherosclerosis (hardening of the arteries).

Cholesterol is an integral part of all cell membranes and the starting point for steroid hormones, including the sex hormones. It is broken down by the liver into bile salts, which are involved in fat absorption in the digestive system, and it is an essential component of lipoproteins, which transport fats and fatty acids in the blood. Low-density lipoprotein cholesterol (LDL-cholesterol), when present in excess, can enter the tissues and become deposited on the surface of the arteries, causing atherosclerosis. High-density lipoprotein cholesterol (HDL-cholesterol) acts as a scavenger, transporting fat and cholesterol from the tissues to the liver to be broken down. The composition of HDL-cholesterol can vary and some forms may not be as effective as others. Blood cholesterol levels can be altered by reducing the amount of alcohol and fat in the diet and by substituting some of the saturated fat for polyunsaturated fat, which gives a reduction in LDL-cholesterol. HDL-cholesterol can be increased by exercise.

CHOLESTEROL

The Inuit people rarely suffer from heart disease. One explanation for this may be the high amount of fish, notably salmon, in their diet, which reduces the level of blood cholesterol.

chondrite type of meteorite characterized by chondrules, small spheres, about 1 mm in diameter, made up of the silicate minerals olivine and orthopyroxene.

chondrule in astronomy a small, round mass of silicate material found. Chondrites (stony meteorites) are characterized by the presence of chondrules.

Chondrules are thought to be mineral grains that condensed from hot gas in the early Solar System, most of which were later incorporated into larger bodies from which the planets formed.

chord in geometry, a straight line joining any two points on a curve. The chord that passes through the centre of a circle (its longest chord) is the diameter. The longest and shortest chords of an ellipse (a regular oval) are called the major and minor axes, respectively.

Chordata phylum of animals, members of which are called chordates.

chordate animal belonging to the phylum Chordata, which includes vertebrates, sea squirts, amphioxys, and others. All these animals, at some stage of their lives, have a supporting rod of tissue (notochord or backbone) running down their bodies.

Chordates are divided into three major groups: tunicates, cephalochordates (see lancelet), and craniates (including all vertebrates).

chorea condition featuring involuntary movements of the face muscles and limbs. It is seen in a number of neurological diseases, including Huntington's chorea.

chorion outermost of the three membranes enclosing the embryo of reptiles, birds, and mammals; the amnion is the innermost membrane.

chorionic villus sampling (CVS) biopsy of a small sample of placental tissue, carried out in early pregnancy at 10–12 weeks' gestation. Since the placenta forms from embryonic cells, the tissue obtained can be tested to reveal genetic abnormality in the fetus. The advantage of CVS over amniocentesis is that it provides an earlier diagnosis, so that if any abnormality is discovered, and the parents opt for an abortion, it can be carried out more safely.

choroid layer found at the rear of the eye beyond the retina. By absorbing light that has already passed through the retina, it stops back-reflection and so prevents blurred vision.

chough bird *Pyrrhocorax pyrrhocorax* of the crow family, Corvidae, order Passeriformes, about 38 cm/15 in long, black-feathered, with red bill and legs, and long hooked claws. Choughs are frugivorous and insectivorous. They make mud-walled nests and live on sea cliffs and mountains from Europe to E Asia, but are now rare.

The alpine chough *Pyrrhocorax graculus* is similar, but has a shorter yellow bill and is found up to the snowline in mountains from the Pyrenees to Central Asia.

chow chow breed of dog originating in China in ancient times. About 45 cm/1.5 ft tall, it has a broad neck and head, round catlike feet, a soft woolly undercoat with a coarse outer coat, and a mane. Its coat should be of one colour, and it has an unusual blue-black tongue.

Christmas rose decorative species of hellebore.

Christmas tree any evergreen tree brought indoors and decorated for Christmas. The custom was a medieval German tradition and is now practised in many Western countries.

chroma key in television, technique for substituting backgrounds. For example, the empty studio behind a newscaster may be replaced with an outdoor scene or a frame of video footage. This technique is commonly used on news programmes and other shows that feature 'talking heads'.

A computer analyses the image of the newscaster, who is placed in front of a plain background, usually blue, to identify the exact pixels where the talking figure begins and ends. It can then substitute a new image for just the area specified. The technique allows broadcasters to add visual interest while keeping costs down.

chromatography Greek *chromas* 'colour' technique for separating or analysing a mixture of gases, liquids, or dissolved substances. This is brought about by means of two immiscible substances, one of which (the mobile phase) transports the sample mixture through the other (the stationary phase). The mobile phase may be a gas or a liquid; the stationary phase may be a liquid or a solid, and may be in a column, on paper, or in a thin layer on a glass or plastic support. The components of the mixture are absorbed or impeded by the stationary phase to different extents

CHROMATOGRAPHY

<http://www.eng.rpi.edu/dept/chem-eng/Biotech-Environ/CHROMO/chromintro.html>

Explanation of the theory and practice of chromatography. Designed for school students (and introduced by a Biotech Bunny), the contents include equipment, analysing a chromatogram, and details of the various kinds of chromatography.

and therefore become separated. The technique is used for both qualitative and quantitative analyses in biology and chemistry.

In **paper chromatography**, the mixture separates because the components have differing solubilities in the solvent flowing through the paper and in the chemically bound water of the paper.

In **thin-layer chromatography**, a wafer-thin layer of adsorbent medium on a glass plate replaces the filter paper. The mixture separates because of the differing solubilities of the components in the solvent flowing up the solid layer, and their differing tendencies to stick to the solid (adsorption). The same principles apply in column chromatography.

In **gas-liquid chromatography**, a gaseous mixture is passed into a long, coiled tube (enclosed in an oven) filled with an inert powder coated in a liquid. A carrier gas flows through the tube. As the mixture proceeds along the tube it separates as the components dissolve in the liquid to differing extents or stay as a gas. A detector locates the different components as they emerge from the tube. The technique is very powerful, allowing tiny quantities of substances (fractions of parts per million) to be separated and analysed.

Preparative chromatography is carried out on a large scale for the purification and collection of one or more of a mixture's constituents; for example, in the recovery of protein from abattoir wastes.

Analytical chromatography is carried out on far smaller quantities, often as little as one microgram (one-millionth of a gram), in order to identify and quantify the component parts of a mixture. It is used to determine the identities and amounts of amino acids in a protein, and the alcohol content of blood and urine samples. The technique was first used in the separation of coloured mixtures into their component pigments.

chromite FeCr_2O_4 , iron chromium oxide, the main chromium ore. It is one of the Ospinel group of minerals, and crystallizes in dark-coloured octahedra of the cubic system. Chromite is usually found in association with ultrabasic and basic rocks; in Cyprus, for example, it occurs with serpentine , and in South Africa it forms continuous layers in a layered intrusion.

chromium Greek *chromos* 'colour' hard, brittle, grey-white, metallic element, symbol Cr, atomic number 24, relative atomic mass 51.996. It takes a high polish, has a high melting point, and is very resistant to corrosion. It is used in chromium electroplating, in the manufacture of stainless steel and other alloys, and as a catalyst. Its compounds are used for tanning leather and for dye s. In human nutrition it is a vital trace element. In nature, it occurs chiefly as chrome iron ore or chromite (FeCr_2O_4). Kazakhstan, Zimbabwe, and Brazil are sources.

The element was named 1797 by the French chemist Louis Vauquelin (1763-1829) after its brightly coloured compounds.

chromium ore essentially the mineral chromite, FeCr_2O_4 , from which chromium is extracted. South Africa and Zimbabwe are major producers.

chromogranin protein released by the adrenal gland, along with the hormone *adrenaline*, during times of stress. There are three types, chromogranin A, B, and C. The function of chromogranins is poorly understood, but they do have an antibacterial effect that could boost the immune system when it is suppressed during times of stress. Chromogranin A also stimulates insulin release and relaxes blood vessels - functions similarly reduced by *adrenaline* during stress.

chromosome structure in a cell nucleus that carries the genes . Each chromosome consists of one very long strand of DNA, coiled and folded to produce a compact body. The point on a chromosome where a particular gene occurs is known as its locus. Most higher organisms have two copies of each chromosome (they are *diploid*) but some have only one (they are *haploid*). There are 46 chromosomes in a normal human cell. See also *mitosis* and *meiosis*.

Chromosomes are only visible during cell division; at other times they exist in a less dense form called *chromatin*.

The first artificial human chromosome was built by US geneticists in 1997. They constructed telomeres, centromeres, and DNA containing genetic information, which they removed from white blood cells, and inserted them into human cancer cells. The cells

chromosome The 23 pairs of chromosomes of a normal human male.

assembled the material into chromosomes. The artificial chromosome was successfully passed onto all daughter cells.

chromosphere Greek 'colour' and 'sphere' layer of mostly hydrogen gas about 10,000 km/6,000 mi deep above the visible surface of the Sun (the photosphere). It appears pinkish red during eclipses of the Sun.

chronic in medicine, term used to describe a condition that is of slow onset and then runs a prolonged course, such as *rheumatoid arthritis* or *chronic bronchitis*. In contrast, an acute condition develops quickly and may be of relatively short duration.

chronic fatigue syndrome a common debilitating condition also known as *myalgic encephalomyelitis* (ME), *postviral fatigue syndrome*, or 'yuppie flu'. It is characterized by a diffuse range of symptoms present for at least six months including extreme fatigue, muscular pain, weakness, depression, poor balance and coordination, joint pains, and gastric upset. It is usually diagnosed after exclusion of other diseases and frequently follows a flu-like illness.

CHRONIC FATIGUE SYNDROME FAQ

<http://www.cais.com/cfs-news/faq.htm>

Extensive answer sheet shedding light on the hottest questions regarding chronic fatigue syndrome. The site deals with issues such as the relation to stress and depression, the possible causes and duration of the illness, and the onset and clinical symptoms of the disease. It also discusses a series of common misunderstandings related to the syndrome.

The cause of CFS remains unknown, but it is believed to have its origin in a combination of viral, social, and psychological factors. Theories based on one specific cause (such as Epstein-Barr virus) have been largely discredited. There is no definitive treatment, but with time the symptoms become less severe. Depression is treated if present, and recent research has demonstrated the effectiveness of cognitive therapy.

chronometer instrument for measuring time precisely, originally used at sea. It is designed to remain accurate through all conditions of temperature and pressure. The first accurate marine chronometer, capable of an accuracy of half a minute a year, was made in 1761 by John Harrison in England.

chrysalis pupa of an insect, but especially that of a butterfly or moth. It is essentially a static stage of the creature's life, when the adult insect, benefiting from the large amounts of food laid down by the actively feeding larva, is built up from the disintegrating larval tissues. The chrysalis may be exposed or within a cocoon.

chrysanthemum any of a large group of plants with colourful, showy flowers, containing about 200 species. There are hundreds of cultivated varieties, whose exact wild ancestry is uncertain. In the Far East the common chrysanthemum has been cultivated for more than 2,000 years and is the imperial emblem of Japan. Chrysanthemums can be grown from seed, but new plants are more commonly produced from cuttings or by dividing up established plants. (Genus *Chrysanthemum*, family Compositae.)

chrysotile mineral in the serpentine group, $Mg_3Si_2O_5(OH)_4$. A soft, fibrous, silky mineral, the primary source of asbestos.

chub freshwater fish *Leuciscus cephalus* of the carp family. Thickset and cylindrical, it grows up to 60 cm/2 ft, is dark greenish or grey on the back, silvery yellow below, with metallic flashes on the flanks. It lives generally in clean rivers throughout Europe.

chyme general term for the stomach contents. Chyme resembles a thick creamy fluid and is made up of partly digested food, hydrochloric acid, and a range of enzymes.

The muscular activity of the stomach churns this fluid constantly, continuing the mechanical processes initiated by the mouth. By the time the chyme leaves the stomach for the duodenum, it is a smooth liquid ready for further digestion and absorption by the small intestine.

Cibachrome in photography, a process of printing directly from transparencies. It can be home-processed and the rich, saturated colours are highly resistant to fading. It was introduced 1963.

cidada any of several insects of the family Cicadidae. Most species are tropical, but a few occur in Europe and North America. Young cicadas live underground, for up to 17 years in some species. The adults live on trees, whose juices they suck. The males produce a loud, almost continuous, chirping by vibrating membranes in resonating cavities in the abdomen.

CICHLID HOME PAGE

<http://trans4.neep.wisc.edu/~gracy/fish/opener.html>

Comprehensive source of information on cichlidae, their habitats, and how to keep them in an aquarium. There are a large number of photographs. Fish can be searched for by scientific or common names.

cichlid any freshwater fish of the family Cichlidae. Cichlids are somewhat perchlike, but have a single nostril on each side instead of two. They are mostly predatory, and have deep, colourful bodies, flattened from side to side so that some are almost disc-shaped. Many are territorial in the breeding season and may show care of the young. There are more than 1,000 species found in South and

Central America, Africa, and India.

The discus fish *Symphysodon* produces a skin secretion on which the young feed. Other cichlids, such as those of the genus *Tilapia*, brood their young in the mouth.

cigarette beetle small beetle that feeds preferentially on tobacco products, such as cigarettes and cigars. It may, however, feed on a wide range of other products for example, raisins, ginger, cocoa, drugs, and even straw.

classification The cigarette beetle *Lasioderma serricorne* is a member of the family Anobiidae (furniture beetles) in order Coleoptera, class Insecta, phylum Arthropoda.

cilia (singular *cilium*) small hairlike organs on the surface of some cells, particularly the cells lining the upper respiratory tract. Their wavelike movements waft particles of dust and debris towards the exterior. Some single-celled organisms move by means of cilia. In multicellular animals, they keep lubricated surfaces clear of debris. They also move food in the digestive tracts of some invertebrates.

ciliary muscle ring of muscle surrounding and controlling the lens inside the vertebrate eye, used in accommodation (focusing). Suspensory ligaments, resembling spokes of a wheel, connect the lens to the ciliary muscle and pull the lens into a flatter shape when the muscle relaxes. When the muscle is relaxed the lens has its longest (focal length) and focuses rays from distant objects. On contraction, the lens returns to its normal spherical state and therefore has a shorter focal length and focuses images of near objects.

cinchona any of a group of tropical American shrubs or trees belonging to the madder family. The drug quinine is produced from the bark of some species, and these are now cultivated in India, Sri Lanka, the Philippines, and Indonesia. (Genus *Chinchona*, family Rubiaceae.)

cine camera camera that takes a rapid sequence of still photographs called frames. When the frames are projected one after the other on to a screen, they appear to show movement, because our eyes hold on to the image of one picture until the next one appears.

The cine camera differs from an ordinary still camera in having a motor that winds the film on. The film is held still by a claw mechanism while each frame is exposed. When the film is moved between frames, a semicircular disc slides between the lens and the film and prevents exposure.

CinePak in computing, software method of compressing and decompressing QuickTime 'movies', also called a software codec. CinePak takes a recorded QuickTime file and reduces it in size, frame by frame. This is a slow process, but the result is a file that can be played back efficiently by computers with QuickTime installed.

cinnabar mercuric sulphide mineral, HgS, the only commercially useful ore of mercury. It is deposited in veins and impregnations near recent volcanic rocks and hot springs. The mineral itself is used as a red pigment, commonly known as vermilion. Cinnabar is found in the USA (California), Spain (Almadén), Peru, Italy, and Slovenia.

cinnamon dried inner bark of a tree belonging to the laurel family, grown in India and Sri Lanka. The bark is ground to make the spice used in curries and confectionery. Oil of cinnamon is obtained from waste bark and is used as flavouring in food and medicine. (*Cinnamomum zeylanicum*, family Lauraceae.)

cinquefoil any of a group of plants that usually have five-lobed leaves and brightly coloured flowers. They are widespread in northern temperate regions. (Genus *Potentilla*, family Rosaceae.)

circadian rhythm metabolic rhythm found in most organisms, which generally coincides with the 24-hour day. Its most obvious manifestation is the regular cycle of sleeping and waking, but body temperature and the concentration of hormones that influence mood and behaviour also vary over the day. In humans, alteration of habits (such as rapid air travel round the world) may result in

the circadian rhythm being out of phase with actual activity patterns, causing malaise until it has had time to adjust.

In mammals the circadian rhythm is controlled by the suprachiasmatic nucleus in the hypothalamus. US researchers discovered a second circadian control mechanism in 1996; they found that cells within the retina also produced the hormone melatonin. In 1997, US geneticists identified a gene, *clock*, in chromosome 5 in mice, that regulated the circadian rhythm.

circle perfectly round shape, the path of a point that moves so as to keep a constant distance from a fixed point (the centre). Each circle has a **radius** (the distance from any point on the circle to the centre), a **circumference** (the boundary of the circle), **diameters** (straight lines crossing the circle through the centre), **chords** (lines joining two points on the circumference), **tangents** (lines that touch the circumference at one point only), **sectors** (regions inside the circle between two radii), and **segments** (regions between a chord and the circumference).

The ratio of the distance all around the circle (the circumference) to the diameter is an irrational number called π (pi), roughly equal to 3.1416. A circle of radius r and diameter d has a circumference $C = \pi d$, or $C = 2\pi r$, and an area $A = \pi r^2$. The area of a circle can be shown by dividing it into very thin sectors and reassembling them to make an approximate rectangle. The proof of $A = \pi r^2$ can be done only by using integral calculus.

To remember the circumference and area of a circle:

FIDDLEDEEM, FIDDLEDEEE, A RING ROUND THE MOON IS
 π TIMES D. IF A HOLE IN YOUR SOCK YOU WANT REPAIRED, YOU
USE THE FORMULA πR SQUARED.

circuit in physics or electrical engineering, an arrangement of electrical components through which a current can flow. There are two basic circuits, series and parallel. In a series circuit, the components are connected end to end so that the current flows through all components one after the other. In a parallel circuit, components are connected side by side so that part of the current passes through each component. A circuit diagram shows in graphical form how components are connected together, using standard symbols for the components.

circuit breaker switching device designed to protect an electric circuit by breaking the circuit if excessive current flows. It has the same action as a fuse, and many houses now have a circuit breaker between the incoming mains supply and the domestic circuits. Circuit breakers usually work by means of solenoids. Those at electricity-generating stations have to be specially designed to prevent dangerous arcing (the release of luminous discharge) when

the high-voltage supply is switched off. They may use an air blast or oil immersion to quench the arc.

circuit diagram simplified drawing of an electric circuit. The circuit's components are represented by internationally recognized symbols, and the connecting wires by straight lines. A dot indicates where wires join.

circulatory system system of vessels in an animal's body that transports essential substances (blood or other circulatory fluid) to and from the different parts of the body. Except for simple animals such as sponges and coelenterates (jellyfishes, sea anemones, corals), all animals have a circulatory system.

In fishes, blood passes once around the body before returning to a two-chambered heart (single circulation). In birds and mammals, blood passes to the lungs and back to the heart before circulating around the remainder of the body (double circulation). In all vertebrates, blood flows in one direction. Valves in the heart, large arteries, and veins prevent backflow, and the muscular walls of the arteries assist in pushing the blood around the body.

Although most animals have a heart or hearts to pump the blood, normal body movements circulate the fluid in some small invertebrates. In the open system, found in snails and other mol-

circuit diagram A circuit diagram shows in graphical form how the components of an electric circuit are connected together. Each component is represented by an internationally recognized symbol, and the connecting wires are shown by straight lines. A dot indicates where wires join.

circulatory system Blood flows through 96,500 km/60,000 mi of arteries and veins, supplying oxygen and nutrients to organs and limbs. Oxygen-poor blood (blue) circulates from the heart to the lungs where oxygen is absorbed. Oxygen-rich blood (red) flows back to the heart and is then pumped round the body through the aorta, the largest artery, to smaller arteries and capillaries. Here oxygen and nutrients are exchanged with carbon dioxide and waste products and the blood returns to the heart via the veins. Waste products are filtered by the liver, spleen, and kidneys, and nutrients are absorbed from the stomach and small intestine.

Blood: the Discovery of Circulation

by JULIAN ROWE

Background

After completing a preliminary medical course at the University of Cambridge, where would an ambitious young man in the 17th century go to get a really good medical training? To the University of Padua in Italy, where the great Italian anatomist Hieronymus Fabricius (1537–1619) taught. So this is where English physician William Harvey (1578–1657) naturally went.

William Harvey had a consuming interest in the movement of the blood in the body. In 1579, Fabricius had publicly demonstrated the valves, which he termed 'sluice gates', in the veins: his principal anatomical work was an accurate and detailed description of them.

Galen's theory

Galen, a Greek physician (c. 130–c. 200), had 1,500 years previously written a monumental treatise covering every aspect of medicine. In this work, he asserted that food turned to blood in the liver, ebbed and flowed in vessels and, on reaching the heart, flowed through pores in the septum (the dividing wall) from the right to left side, and was sent on its way by heart spasms. The blood did not circulate. This doctrine was still accepted and taught well into the 16th century.

One-way flow

Harvey was unconvinced. He had done a simple calculation. He worked out that for each human heart beat, about 60 cm³ of blood left the heart, which meant that the heart pumped out 259 litres every hour. This is more than three times the weight of the average man.

Harvey examined the heart and blood vessels of 128 mammals and found that the valve which separated the left side of the heart from the right ventricle is a one-way structure, as were the valves in the veins discovered by his tutor Fabricius. For this reason he

decided that the blood in the veins must flow only towards the heart.

Harvey's experiment

Harvey was now in a position to do his famous experiment. He tied a tourniquet round the upper part of his arm. It was just tight enough to prevent the blood from flowing through the veins back into his heart – but not so tight that arterial blood could not enter the arms. Below the tourniquet, the veins swelled up; above it, they remained empty. This showed that the blood could be entering the arm only through the arteries. Further, by carefully stroking the blood out of a short length of vein, Harvey showed that it could fill up only when blood was allowed to enter it from the end that was furthest away from the heart. He had proved that blood in the veins must flow only towards the heart.

A new theory of circulation

Galen's pores in the septum of the heart had never been found. Belgian physician Andreas Versalius (1514–1564) was another alumnus of Padua University. Although brought up in the Galen tradition, he had carried out secret dissections to discover the pores, and had failed. He did, however, show that men and women had the same number of ribs!

Harvey clinched his researches into the movement of the blood when he demonstrated that no blood seeps through the septum of the heart. He reasoned that blood must pass from the right side of the heart to the left through the lungs. He had discovered the circulation of the blood, and thus, some 20 years after he left Padua, became the father of modern physiology. In 1628 Harvey published his proof of the circulation of the blood in his classic book

On the Motion of the Heart and Blood in Animals. A new age in medicine and biology had begun.

luses, the blood (more correctly called haemolymph) passes from the arteries into a body cavity (haemocoel), and from here is gradually returned to the heart, via the gills, by other blood vessels. Insects and other arthropods have an open system with a heart. In the closed system of earthworms, blood flows directly from the main artery to the main vein, via smaller lateral vessels in each body segment. Vertebrates, too, have a closed system with a network of tiny capillaries carrying the blood from arteries to veins.

circumcision surgical removal of all or part of the foreskin (prepuce) of the penis, usually performed on the newborn; it is practised among Jews and Muslims. In some societies in Africa and the Middle East, female circumcision or clitoridectomy (removal of the labia minora and/or clitoris) is practised on adolescents as well as babies; it is illegal in the West.

Female circumcision has no medical benefit and often causes disease and complications in childbirth; in 1994 there were at least 90 million women and girls worldwide who had undergone circumcision. Male circumcision too is usually carried out for cultural reasons and not as a medical necessity, apart from cases where the opening of the prepuce is so small as to obstruct the flow of urine. Some evidence indicates that it protects against the development of cancer of the penis later in life and that women with circumcised partners are at less risk from cancer of the cervix.

circumference in geometry, the curved line that encloses a curved plane figure, for example a circle or an ellipse. Its length varies according to the nature of the curve, and may be ascertained by the appropriate formula. The circumference of a circle is πd or $2\pi r$, where d is the diameter of the circle, r is its radius, and π is the constant pi, approximately equal to 3.1416.

circumpolar in astronomy, a description applied to celestial objects that remain above the horizon at all times and do not set as seen from a given location. The amount of sky that is circumpolar depends on the observer's latitude on Earth. At the Earth's poles, all the visible sky is circumpolar, but at the Earth's equator none of it is circumpolar.

circumscribe in geometry, to surround a figure with a circle which passes through all the vertices of the figure. Any triangle may be circumscribed and so may any regular polygon. Only certain quadrilaterals may be circumscribed (their opposite angles must add up to 180°).

cirque French name for a corrie, a steep-sided hollow in a mountain-side.

cirrhosis any degenerative disease in an organ of the body, especially the liver, characterized by excessive development of connective tissue, causing scarring and painful swelling. Cirrhosis of the liver may be caused by an infection such as viral hepatitis, chronic obstruction of the common bile duct, chronic alcoholism or drug use, blood disorder, heart failure, or malnutrition. However, often no cause is apparent. If cirrhosis is diagnosed early, it can be arrested by treating the cause; otherwise it will progress to coma and death.

CIS, CIs abbreviations for *CompuServe Information Service*; see CompuServe.

CISC (acronym for *complex instruction-set computer*) in computing, a microprocessor (processor on a single chip) that can carry out a large number of machine code instructions – for example,

the Intel 80386. The term was introduced to distinguish them from the more rapid δ RISC (reduced instruction-set computer) processors, which handle only a smaller set of instructions.

cistron in genetics, the segment of δ DNA that is required to synthesize a complete polypeptide chain. It is the molecular equivalent of a δ gene.

CITES (abbreviation for *Convention on International Trade in Endangered Species*) international agreement under the auspices of the IUCN with the aim of regulating trade in δ endangered species of animals and plants. The agreement came into force 1975 and by 1997 had been signed by 138 states. It prohibits any trade in a category of 8,000 highly endangered species and controls trade in a further 30,000 species.

Animals and plants listed in Appendix 1 of CITES are classified endangered; those listed in Appendix 2 are classified vulnerable.

citizens' band (CB) short-range radio communication facility (around 27 MHz) used by members of the public in the USA and many European countries to talk to one another or call for emergency assistance.

citric acid $\text{HOOCCH}_2\text{C}(\text{OH})(\text{COOH})\text{CH}_2\text{COOH}$ organic acid widely distributed in the plant kingdom; it is found in high concentrations in citrus fruits and has a sharp, sour taste. At one time it was commercially prepared from concentrated lemon juice, but now the main source is the fermentation of sugar with certain moulds.

citronella lemon-scented oil used in cosmetics and insect repellents, obtained from a S Asian grass (*Cymbopogon nardus*).

citrus any of a group of evergreen and aromatic trees or shrubs, found in warm parts of the world. Several species – the orange, lemon, lime, citron, and grapefruit – are cultivated for their fruit. (Genus *Citrus*, family Rutaceae.)

civet small to medium-sized carnivorous mammal found in Africa and Asia, belonging to the family Viverridae, which also includes δ mongoose and δ genets. Distant relatives of cats, they generally have longer jaws and more teeth. All have a scent gland in the inguinal (groin) region. Extracts from this gland are taken from the δ African civet *Civetictis civetta* and used in perfumery.

As well as eating animal matter, many species, for example, the SE Asian palm civet *Arctogalidia trivirgata*, are fond of fruit.

civil aviation operation of passenger and freight transport by air. With increasing traffic, control of air space is a major problem, and in 1963 Eurocontrol was established by Belgium, France, West Germany, Luxembourg, the Netherlands, and the UK to supervise both military and civil movement in the air space over member countries. There is also a tendency to coordinate services and other facilities between national airlines; for example, the establishment of Air Union in 1963 by France (Air France), West Germany (Lufthansa), Italy (Alitalia), and Belgium (Sabena).

In the UK there are about 170 airports. Heathrow, City, Gatwick, and Stansted (all serving London), Prestwick, and Edinburgh are managed by the British Airports Authority (founded 1965). Close cooperation is maintained with authorities in other countries, including the Federal Aviation Agency, which is responsible for regulating development of aircraft, air navigation, traffic control, and communications in the USA. The Civil Aeronautics Board is the US authority prescribing safety regulations and investigating accidents. There are no state airlines in the USA, although many of the private airlines are large. The world's largest airline was the USSR's government-owned Aeroflot (split among republics in 1992), which operated 1,300 aircraft over 1 million km/620,000 mi of routes. It once carried over 110 million passengers a year, falling to 62 million by 1992.

civil engineering branch of engineering that is concerned with the construction of roads, bridges, airports, aqueducts, waterworks, tunnels, canals, irrigation works, and harbours.

The term is thought to have been used for the first time by British engineer John Smeaton in about 1750 to distinguish civil from military engineering projects.

Civil Engineers, Institution of the first national body concerned with the engineering profession in England, founded in 1818. The celebrated builder of roads, bridges and canals, Thomas Telford, became its first president.

CIX abbreviation for δ Compulink Information eXchange.

cladistics method of biological δ classification (taxonomy) that uses a formal step-by-step procedure for objectively assessing the extent to which organisms share particular characters, and for assigning them to taxonomic groups. Taxonomic groups (for example, δ species, δ genus, family) are termed clades.

cladode in botany, a flattened stem that is leaflike in appearance and function. It is an adaptation to dry conditions because a stem contains fewer δ stomata than a leaf, and water loss is thus minimized. The true leaves in such plants are usually reduced to spines or small scales. Examples of plants with cladodes are butcher's-broom *Ruscus aculeatus*, asparagus, and certain cacti. Cladodes may bear flowers or fruit on their surface, and this distinguishes them from leaves.

clam common name for a δ bivalve mollusc. The giant clam *Tridacna gigas* of the Indopacific can grow to 1 m/3 ft across in 50 years and weigh, with the shell, 500 kg/1,000 lb.

A giant clam produces a billion eggs in a single spawning. The term is usually applied to edible species, such as the North American hard clam *Unio mercenaria*, used in clam chowder, and whose shells were formerly used as money by North American Indians. A giant clam may produce a billion eggs in a single spawning.

ClariNet commercial news service distributed via USENET. It is not available on all sites since companies must pay to receive ClariNet, which is owned by ClariNet Communications Corp. Under the service's terms and conditions, professional media personnel are banned from using ClariNet news as a source in their work.

Clarke orbit alternative name for δ geostationary orbit, an orbit 35,900 km/22,300 mi high, in which satellites circle at the same speed as the Earth turns. This orbit was first suggested by space writer Arthur C Clarke in 1945.

class in biological classification, a group of related δ orders. For example, all mammals belong to the class Mammalia and all birds to the class Aves. Among plants, all class names end in 'idae' (such as Asteridae) and among fungi in 'mycetes'; there are no equivalent conventions among animals. Related classes are grouped together in a δ phylum.

class in mathematics another name for a δ set.

classification in biology, the arrangement of organisms into a hierarchy of groups on the basis of their similarities in biochemical, anatomical, or physiological characters. The basic grouping is a δ species, several of which may constitute a δ genus, which in turn are grouped into families, and so on up through orders, classes, phyla (in plants, sometimes called divisions), to kingdoms.

To remember the order of taxonomic classification:

KRAKATOA POSITIVELY CASTS OFF FUMES GENERATING SULPHUROUS VAPOURS.

OR

KINDLY PLACE COVER ON FRESH GREEN SPRING VEGETABLES.

KINGDOM / PHYLUM / CLASS / ORDER / FAMILY / GENUS / SPECIES / VARIETY

Classification of Living Things

Classification is the grouping of organisms based on similar traits and evolutionary histories. Taxonomy and systematics are the two sciences that attempt to classify living things. In taxonomy, organisms are generally assigned to groups based on their characteristics. In modern systematics, the placement of organisms into groups is based on evolutionary relationships among organisms. Thus, the groupings are based on evolutionary relatedness or family histories called phylogenies.

The groups into which organisms are classified are called taxa (singular, taxon). The taxon that includes the fewest members is the species, which consists of a single organism. Closely related species are placed into a genus (plural, genera). Related genera are placed into families, families into orders, orders into classes, classes into phyla (singular, phylum) or, in the case of plants and fungi, into divisions, and phyla into divisions or kingdoms. The kingdom level, of which five are generally recognized, is the broadest taxonomic group and includes the greatest number of species. The table below provides an example of the classification of an organism representative of the animal kingdom and the plant kingdom.

| Taxonomic Groups ¹ | Common name Genus ³ | Kingdom | Phylum/division ² | Class | Order | Family Species ³ |
|-------------------------------|-----------------------------------|--------------|------------------------------|-------------|-------------|--------------------------------|
| human | Animalia | Chordata | Mammalia | Primates | Hominioidea | <i>Homo sapiens</i> |
| Douglas fir | Plantae | Tracheophyta | Gymnospermae | Coniferales | Pinaceae | <i>Pseudotsuga douglasii</i> |

¹ Intermediate taxonomic levels can be created by adding the prefixes "super-" or "sub-" to the name of any taxonomic level.

² The term division is generally used in place of phylum/phyla for the classification of plants and fungi.

³ An individual organism is given a two-part name made up of its genus and species names. For example, Douglas fir is correctly known as *Pseudotsuga douglasii*.

It takes a very unusual mind to undertake the analysis of the obvious.

ALFRED NORTH WHITEHEAD English philosopher and mathematician.
Science and the Modern World

classify in mathematics, to put into separate classes, or ζ sets, which may be uniquely defined.

class interval in statistics, the range of each class of data, used when dealing with large amounts of data. To obtain an idea of the distribution, the data are broken down into convenient classes, which must be mutually exclusive and are usually equal. The class interval defines the range of each class; for example, if the class interval is five and the data begin at zero, the classes are 0-4, 5-9, 10-14, and so on.

clathrate compound formed when the small molecules of one substance fill in the holes in the structural lattice of another, solid, substance - for example, sulphur dioxide molecules in ice crystals. Clathrates are therefore intermediate between mixtures and true compounds (which are held together by ζ ionic or covalent chemical bonds).

clathration in chemistry, a method of removing water from an aqueous solution, and therefore increasing the solution's concentration, by trapping it in a matrix with inert gases such as freons.

clausius in engineering, a unit of ζ entropy (the loss of energy as heat in any physical process). It is defined as the ratio of energy to temperature above absolute zero.

claustrophobia ϕ phobia involving fear of enclosed spaces.

clavicle *Latin clavis 'key'* the collar bone of many vertebrates. In humans it is vulnerable to fracture, since falls involving a sudden force on the arm may result in very high stresses passing into the chest region by way of the clavicle and other bones. It is connected at one end with the sternum (breastbone), and at the other end with the shoulder-blade, together with which it forms the arm socket. The wishbone of a chicken is composed of its two fused clavicles.

claw hard, hooked, pointed outgrowth of the digits of mammals, birds, and most reptiles. Claws are composed of the protein keratin, and grow continuously from a bundle of cells in the lower skin layer. Hooves and nails are modified structures with the same origin as claws.

clay very fine-grained ζ sedimentary deposit that has undergone a greater or lesser degree of consolidation. When moistened it is

plastic, and it hardens on heating, which renders it impermeable. It may be white, grey, red, yellow, blue, or black, depending on its composition. Clay minerals consist largely of hydrous silicates of aluminium and magnesium together with iron, potassium, sodium, and organic substances. The crystals of clay minerals have a layered structure, capable of holding water, and are responsible for its plastic properties. According to international classification, in mechanical analysis of soil, clay has a grain size of less than 0.002 mm/0.00008 in.

clay mineral one of a group of hydrous silicate minerals that form most of the fine-grained particles in clays. Clay minerals are normally formed by weathering or alteration of other silicate minerals. Virtually all have sheet silicate structures similar to the micas. They exhibit the following useful properties: loss of water on heating; swelling and shrinking in different conditions; cation exchange with other media; and plasticity when wet. Examples are kaolinite, illite, and montmorillonite.

Kaolinite $Al_2Si_2O_5(OH)_4$ is a common white clay mineral derived from alteration of aluminium silicates, especially feldspars. Illite contains the same constituents as kaolinite, plus potassium, and is the main mineral of clay sediments, mudstones, and shales; it is a weathering product of feldspars and other silicates. Montmorillonite contains the constituents of kaolinite plus sodium and magnesium; along with related magnesium- and iron-bearing clay minerals, it is derived from alteration and weathering of mafic igneous rocks. Kaolinite (the mineral name for kaolin or china clay) is economically important in the ceramic and paper industries. Illite, along with other clay minerals, may also be used in ceramics. Montmorillonite is the chief constituent of fuller's earth, and is also used in drilling muds (muds used to cool and lubricate drilling equipment). Vermiculite (similar to montmorillonite) will expand on heating to produce a material used in insulation.

cleanliness unit unit for measuring air pollution: the number of particles greater than 0.5 micrometres in diameter per cubic foot of air. A more usual measure is the weight of contaminants per cubic metre of air.

cleartext or *plaintext* in encryption, the original, unencrypted message.

cleavage in mineralogy, the tendency of a mineral to split along defined, parallel planes related to its internal structure. It is a useful distinguishing feature in mineral identification. Cleavage occurs where bonding between atoms is weakest, and cleavages may be perfect, good, or poor, depending on the bond strengths; a given mineral may possess one, two, three, or more orientations along which it will cleave.

Some minerals have no cleavage, for example, quartz will fracture to give curved surfaces similar to those of broken glass. Some other minerals, such as apatite, have very poor cleavage that is

sometimes known as a parting. Micas have one perfect cleavage and therefore split easily into very thin flakes. Pyroxenes have two good cleavages and break (less perfectly) into long prisms. Galena has three perfect cleavages parallel to the cube edges, and readily breaks into smaller and smaller cubes. Baryte has one perfect cleavage plus good cleavages in other orientations.

cleg another name for ϕ horselly.

cleistogamy production of flowers that never fully open and that are automatically self-fertilized. Cleistogamous flowers are often formed late in the year, after the production of normal flowers, or during a period of cold weather, as seen in several species of violet *Viola*.

It frequently happens that in the ordinary affairs ... of life opportunities present themselves of contemplating the most curious operations of nature.

BENJAMIN THOMPSON, COUNT RUMFORD RUMFORD US-born British physicist.
Addressing the Royal Society 1798

clematis any of a group of temperate woody climbing plants with colourful showy flowers. They belong to the buttercup family. (Genus *Clematis*, family Ranunculaceae.)

click in computing, to press down and then immediately release a button on a mouse. The phrase 'to click on' means to select an icon on a computer screen by moving the mouse cursor to the icon's position and clicking a mouse button. See also ϕ double click.

click beetle ϕ beetle that can regain its feet from lying on its back by jumping into the air and turning over, clicking as it does so.

clickstream unedited log of mouse-clicks that records visitor actions on a site on the World Wide Web. This data is analysed to create feedback for advertisers, enabling them to check whether their strategies are successful in attracting user attention.

client in ϕ client-server architecture, software that enables a user to access a store of data or programs on a ϕ server. On the Internet, client software is the software that users need to run on home com-

puters in order to be able to use services such as the World Wide Web.

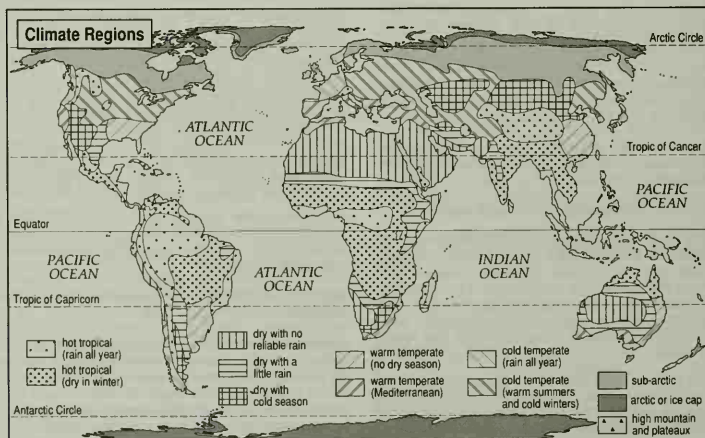

client-server architecture in computing, a system in which the mechanics of looking after data are separated from the programs that use the data. For example, the 'server' might be a central database, typically located on a large computer that is reserved for this purpose. The 'client' would be an ordinary program that requests data from the server as needed.

Most Internet services are examples of client-server applications, including the World Wide Web, FTP, Telnet, and Gopher.

climactichnite flat, soft-bodied animal of the Cambrian period, about 25 cm/10 in in length. Climactichnites pulled themselves along the sand, possibly using flaps on either side of the body, feeding on microorganisms. Although an evolutionary dead end, they may have been some of the first animals to move on land.

climate combination of weather conditions at a particular place over a period of time – usually a minimum of 30 years. A classification of climate encompasses the averages, extremes, and frequencies of all meteorological elements such as temperature, atmospheric pressure, precipitation, wind, humidity, and sunshine, together with the factors that influence them. The primary factors involved are: the Earth's rotation and latitudinal effects; ocean currents; large-scale movements of wind belts and air masses over the Earth's surface; temperature differences between land and sea surfaces; and topography. Climatology, the scientific study of climate, includes the construction of computer-generated models, and considers not only present-day climates, their effects and their classification, but also long-term climate changes, covering both past climates (paleoclimates) and future predictions. Climatologists are especially concerned with the influence of human activity on climate change, among the most important of which, at both a local and global level, are those currently linked with ϕ ozone depleters and the ϕ greenhouse effect.

climate classification The word climate comes from the Greek *klima*, meaning an inclination or slope (referring to the angle of the Sun's rays, and thus latitude) and the earliest known classification of climate was that of the ancient Greeks, who based their system on latitudes. In recent times, many different systems of classifying climate have been devised, most of which follow that formulated by the German climatologist Wladimir Köppen (1846–1940) in 1900.

climate The world's climatic zones. There are many systems of classifying climate. One system, that of Wladimir Köppen, was based on temperature and plant type. Other systems take into account the distribution of global winds.

These systems use vegetation-based classifications such as desert, tundra, and rainforest. Classification by air mass is used in conjunction with this method. This idea was first introduced in 1928 by the Norwegian meteorologist Tor Bergeron, and links the climate of an area with the movement of the air masses it experiences.

In the 18th century, the British scientist George Hadley developed a model of the general circulation of atmosphere based on convection. He proposed a simple pattern of cells of warm air rising at the Equator and descending at the poles. In fact, due to the rotation of the Earth, there are three such cells in each hemisphere. The first two of these consist of air that rises at the Equator and sinks at latitudes north and south of the tropics; the second two exist at the mid-latitudes where the rising air from the sub-tropics flows towards the cold air masses of the third pair of cells circulating from the two polar regions. Thus, in this model, there are six main circulating cells of air above ground producing seven terrestrial zones – three rainy regions (at the Equator and the temperate latitudes) resulting from the moisture-laden rising air, interspersed and bounded by four dry or desert regions (at the poles and sub-tropics) resulting from the dry descending air.

climax community assemblage of plants and animals that is relatively stable in its environment. It is brought about by ecological succession, and represents the point at which succession ceases to occur.

In temperate or tropical conditions, a typical climax community comprises woodland or forest and its associated fauna (for example, an oak wood in the UK). In essence, most land management is a series of interferences with the process of succession.

The theory, created by Frederic Clement in 1916, has been criticized for not explaining 'retrogressive' succession, when some areas revert naturally to pre-climax vegetation.

climax vegetation the plants in a climax community.

clinical psychology branch of psychology dealing with the understanding and treatment of health problems, particularly mental disorders. The main problems dealt with include anxiety, phobias, depression, obsessions, sexual and marital problems, drug and alcohol dependence, childhood behavioural problems, psychoses (such as schizophrenia), mental disability, and brain disease (such as dementia) and damage. Other areas of work include forensic psychology (concerned with criminal behaviour) and health psychology.

Assessment procedures assess intelligence and cognition (for example, in detecting the effects of brain damage) by using psychometric tests. **Behavioural approaches** are methods of treatment that apply learning theories to clinical problems. **Behaviour therapy** helps clients change unwanted behaviours (such as phobias, obsessions, sexual problems) and to develop new skills (such as improving social interactions). **Behaviour modification** relies on operant conditioning, making selective use of rewards (such as praise) to change behaviour. This is helpful for children, the mentally disabled, and for patients in institutions, such as mental hospitals. **Cognitive therapy** is a new approach to treating emotional problems, such as anxiety and depression, by teaching clients how to deal with negative thoughts and attitudes. **Counselling**, developed by Carl Rogers, is widely used to help clients solve their own problems. **Psychoanalysis**, as developed by Sigmund Freud and Carl Jung, is little used by clinical psychologists today. It emphasizes childhood conflicts as a source of adult problems.

clinometer hand-held surveying instrument for measuring angles of slope.

clip art small graphics used to liven up documents and presentations. Many software packages such as word processors and presentation graphics packages come with a selection of clip art.

clipboard in computing, a temporary file or memory area where data can be stored before being copied into an application file. It is used, for example, in cut-and-paste operations.

Clipper chip controversial encryption hardware system that contains built-in facilities to allow authorized third parties access to the encrypted data. Adopted as a US government standard in 1994,

the Clipper chip was a chip that used public-key cryptography and a proprietary algorithm called Skipjack, and could be built into any communications device, such as a telephone or modem. It was developed by the US National Security Agency as part of its Capstone project.

Clipper was instantly unpopular on the Net because of privacy concerns: it contained a system for depositing a copy of the user's private key in escrow (see key escrow), from where it could be obtained by law enforcement officials equipped with an appropriate court order.

Clipper suffered further defeat when Matt Blaze, a researcher at AT&T Bell Labs cracked the technology in 1995. In 1996, the US government proposed the development of a network of trusted third parties to hold keys in escrow; the initiative was dubbed 'Clipper III'.

clo unit of thermal insulation of clothing. Standard clothes have an insulation of about 1 clo; the warmest clothing is about 4 clo per 2.5 cm² in of thickness. See also \dot{c} log.

cloaca the common posterior chamber of most vertebrates into which the digestive, urinary, and reproductive tracts all enter; a cloaca is found in most reptiles, birds, and amphibians; many fish; and, to a reduced degree, marsupial mammals. Placental mammals, however, have a separate digestive opening (the anus) and urogenital opening. The cloaca forms a chamber in which products can be stored before being voided from the body via a muscular opening, the cloacal aperture.

clock any device that measures the passage of time, usually shown by means of pointers moving over a dial or by a digital display. Traditionally a timepiece consists of a train of wheels driven by a spring or weight controlled by a balance wheel or pendulum. Many clocks now run by batteries rather than clockwork. The watch is a portable clock.

history In ancient Egypt the time during the day was measured by a shadow clock, a primitive form of sundial, and at night the water clock was used. Up to the late 16th century the only clock available for use at sea was the sand clock, of which the most familiar form is the hourglass. During the Middle Ages various types of sundial were widely used, and portable sundials were in use from the 16th to the 18th century. Watches were invented in the 16th century – the first were made in Nürnberg, Germany, shortly after 1500 – but it was not until the 19th century that they became cheap enough to be widely available. The first known public clock was set up in Milan, Italy, in 1353. The timekeeping of both clocks and watches was revolutionized in the 17th century by the application of pendulums to clocks and of balance springs to watches.

types of clock The marine chronometer is a precision timepiece of special design, used at sea for giving Greenwich mean time (GMT). Electric timepieces were made possible by the discovery early in the 19th century of the magnetic effects of electric currents. One of the earliest and most satisfactory methods of electrical control of a clock was invented by Matthaeus Hipp in 1842. In one kind of electric clock, the place of the pendulum or spring-controlled balance wheel is taken by a small synchronous electric motor, which counts up the alternations (frequency) of the incoming electric supply and, by a suitable train of wheels, records the time by means of hands on a dial. The quartz crystal clock (made possible by the piezoelectric effect of certain crystals) has great precision, with a short-term variation in accuracy of about one-thousandth of a second per day. More accurate still is the atomic clock. This utilizes the natural resonance of certain atoms (for example, caesium) as a regulator controlling the frequency of a quartz crystal oscillator. Atomic clocks can be accurate to within one second in 300 million years.

clock interrupt in computing, an interrupt signal generated by the computer's internal electronic clock.

clock rate the frequency of a computer's internal electronic clock. Every computer contains an electronic clock, which produces a sequence of regular electrical pulses used by the control unit to synchronize the components of the computer and regulate the fetch-execute cycle by which program instructions are processed.

A fixed number of time pulses is required in order to execute each particular instruction. The speed at which a computer can process instructions therefore depends on the clock rate: increasing the clock rate will decrease the time required to complete each particular instruction.

Clock rates are measured in megahertz (MHz), or millions of pulses a second. Microcomputers commonly have a clock rate of 5–50 MHz.

clockwise the direction in which the hands of a traditional clock turn.

clone in genetics, any one of a group of genetically identical cells or organisms. An identical (twin) is a clone; so, too, are bacteria living in the same colony. The term 'clone' has also been adopted by computer technology to describe a (nonexistent) device that mimics an actual one to enable certain software programs to run correctly.

In August 1996, scientists in Oregon, USA, cloned two rhesus monkeys from embryo cells. President Clinton announced in March 1997 a ban on using federal funds to support human cloning research, and called for a moratorium on this type of scientific research. He also asked the National Bioethics Advisory Commission to review and issue a report on the ramifications that cloning would have on humans.

British scientists confirmed in February 1997 that they had cloned an adult sheep from a single cell to produce a lamb with the same genes as its mother. A cell was taken from the udder of the mother sheep, and its DNA combined with an unfertilized egg that had had its DNA removed. The fused cells were grown in the laboratory and then implanted into the uterus of a surrogate mother sheep. The resulting lamb, Dolly, came from an animal that was six years old, whose genes have already been damaged by environmental toxins and cosmic rays; the sheep could therefore develop cancers abnormally early.

It was the first time cloning had been achieved using cells other than reproductive cells. The cloning breakthrough has ethical implications, as the same principle could be used with human cells and eggs. The news was met with international calls to prevent the cloning of humans. The UK, Spain, Germany, Canada, and Denmark already have laws against cloning humans, as do some individual states in the USA (legislators introduced bills to ban human cloning and associated research nationally March 1997). France and Portugal also have very restrictive laws on cloning.

In June 1997, in response to the recommendations of the National Bioethics Advisory Commission, President Clinton proposed a five-year ban on cloning a human being. He said this would not stop the cloning of animals or of human DNA. The first binding international ban on human cloning was signed in January 1998 by 19 European countries. The text, which was an addition to the

European Convention on Human Rights and Biomedicine, placed a total ban on human cloning although it allowed the cloning of cells for research purposes. The 40-member Council of Europe called the protocol 'Europe's response to the threat' of human cloning.

Britain did not sign the protocol because it was not yet a signatory to the convention of which it was a part. The cloning protocol, agreed to by European leaders at a summit October 1997, would also not include Germany, which claimed the measure was weaker than the current German law that forbids all research on human embryos.

A calf cloned from fetal muscle cells by French geneticists was born near Paris in 1998. She only survived for about a month.

People must understand that science is inherently neither a potential for good nor for evil. It is a potential to be harnessed by man to do his bidding.

GLENN T SEABORG US physicist.

Associated Press interview with Alton Blakeslee, 29 Sept 1964

clone in computing, copy of hardware or software that may not be identical to the original design but provides the same functions. All personal computers (PCs) are to some extent clones of the original IBM PC and PC AT launched by IBM in 1981 and 1984, respectively – including IBM's current machines. Clones typically compete by being cheaper and are sometimes less well made than the branded product but this is not always the case. Compaq, for example, competed with IBM by producing the first portable PC and by building better desktop machines, while Dell competed by building PCs to individual orders and supplying customers direct.

Cloning a disc drive or workstation, however, means making an exact copy of all the files or software so that the new drive or machine functions identically to the original one.

closed in mathematics, descriptive of a set of data for which an operation (such as addition or multiplication) done on any members of the set gives a result that is also a member of the set.

For example, the set of even numbers is closed with respect to addition, because two even numbers added to each other always give another even number.

closed-circuit television (CCTV) localized television system in which programmes are sent over relatively short distances, the camera, receiver, and controls being linked by cable. Closed-circuit TV systems are used in department stores and large offices as a means of internal security, monitoring people's movements.

clothes moth moth whose larvae feed on clothes, upholstery, and carpets. The adults are small golden or silvery moths. The natural

Dolly – the Cloning Debate

BY STEPHEN WEBSTER

On Sunday, 23 February 1997, the *New York Times* announced the existence of a new kind of animal. Dolly, a 7-month-old Finn Dorset sheep, was alive and well and living in a guarded pen in the Roslin Institute, a research station just outside Edinburgh, Scotland. What made Dolly uniquely interesting to the newspapers, and soon after to almost everyone, was that she arose not by the union of egg and sperm but by cloning. For the first time a mammal had been cloned from an adult cell: a tiny fleck of skin, scraped from the udder of another sheep and stored for months in a refrigerator, had been treated in such a way that it started to grow. As reported in the newspapers, the embryo, implanted in a surrogate mother, became a fetus and was born in the ordinary way. These were the facts of Dolly's life; yet why Dolly had come and whether any good could come from her were issues largely ignored in the ensuing media frenzy. Along with many others,

President Clinton was quick to see the popular significance: if Dolly proves that clones can be made from the cells of adult mammals, then presumably the technique can be used on that other well-known mammal, *Homo sapiens*. On the day following the announcement, Clinton declared that Dolly 'raises serious ethical questions, particularly with respect to the possible use of this technology to clone human embryos'. Meanwhile, across the Atlantic in the UK, a House of Commons committee summoned Ian Wilmut, the team leader of Roslin's Dolly project, to explain the meaning of his work. Wilmut confirmed that his technology could be applied to humans and that, given the resources, it might lead to cloned humans 'within a couple of years'. He said, however, that such a use of the technique would be 'pointless', and declared himself glad that there were laws in the UK banning the cloning of humans.

Advantages of cloning

It is important, therefore, in assessing the significance of Dolly, to understand the background to cloning, and to appreciate why Wilmut's small agricultural research institute persisted for so long in its attempts to clone an adult mammal. The motive is simple, and relates to the commercial breeding of animals. If a farmer has a successful animal, for example a cow that produces a great quantity of excellent milk, similar cows would also be welcome. Normally, breeders obtain the animals they want by mating one favoured individual with another. Yet sexual reproduction produces variation among animals, so the offspring are always a little different from the parents. If it were possible to reproduce an animal without using sex, then the offspring would be identical to its single parent: a clone. Any useful characteristics in the parent would then be found in its genetically identical offspring.

With plants the application was obvious: tomatoes, strawberries, and carrots can all be cloned from individuals judged successful by farmer and consumer – and have been. It is harder to clone animals, yet soon another scientific development made cloning even more attractive: genetic engineering. Much time and money has been invested in making transgenic animals: creatures that contain one or more genes from another species, particularly humans. The Roslin Institute, with its commercial links to the pharmaceutical company PPL Therapeutics, was interested in making sheep with genes that altered the composition of the milk, so that it contained valuable medicines. Clones of such sheep would be guaranteed to have the same ability, and the investment would be secure.

The basis of cloning is that all the cells of an organism, with the exception of the sex cells, contain a full set of genes. A liver cell, for example, contains all the genes for making a brain, the skin, the skeleton, and indeed every other part of the body, yet when a liver cell reproduces it only ever makes other liver cells. It is as if all the other genes it contains were permanently switched off. Therefore, in order to grow an animal from a single cell, a way had to be found to switch back on every gene.

Early cloning attempts

Early cloning experiments, unsurprisingly, used cells taken from an embryo. The method followed was always this: take the nucleus (where the genes are found) out of a cell and then inject it into a fertilized egg – one that has been prepared by having its own nucleus removed. Success came in 1952 in Philadelphia, Pennsylvania, when Robert Briggs and Tom King took a frog embryo, separated out all the cells, and inserted each nucleus into a prepared egg. Twenty-seven tadpoles developed, each genetically identical. It was a world first: an animal had been experimentally cloned.

Frogs are not economically important; mammals are. If a sheep or cow could be cloned after its excellence had been established, in other words when it was fully developed, the technique would be highly lucrative. However, efforts to clone mammals were at first unsuccessful. Then, in the mid-1980s scientists at the University of Wisconsin, funded by the US beef giant WR Grace and Company, made a breakthrough – they managed to clone cow embryo cells, with the cloned embryos growing into adults. The same procedure was followed: take the nucleus from an embryo cell, inject it into a prepared egg, and look for signs of development. If all went well the growing egg, now itself an embryo, would be implanted into a surrogate mother and after the normal gestation period the cow would be born. Venture capitalists saw an opportunity here, related to the beef industry's requirements for productive, disease-resistant cows. Yet while the technique worked, the cloned cows were expensive. The quality of American beef was good enough using ordinary breeding techniques. Cloning cattle was an expensive luxury and within just a few years, research money for cloning was once more in short supply.

Recent experiments

Researchers at the Roslin Institute had meanwhile been developing their interest in transgenic sheep. Sheep embryos were being injected with human genes, and some of these genes were finding their way into the sheep genetic apparatus. One such gene caused the sheep to produce in their milk the drug alpha-1 antitrypsin, used in treating some lung diseases. However, the technique is hit-and-miss: the sheep embryos only incorporate the human genes occasionally. Yet if it were possible to clone transgenic sheep, especially from those individuals with a proven drug-producing history, then the offspring would be guaranteed to contain the gene, and there would be no need for those gene injections with their low success rates. Ian Wilmut had already had success with cloning from embryonic cells, but believed that it should be possible to use adult cells instead. He argued that all the genes contained within an adult nucleus could be reactivated; it was just a matter of finding the right method. Oddly enough, a period of starvation was found to produce the desired effect. Cells taken from a sheep's udder were starved for a short period and this produced in the nucleus a change: the genes became active again. Egg cells were prepared by having their own nuclei removed and replaced by the udder nuclei. Out of 277 eggs that received the nuclei, just 29 developed into embryos, all of which were implanted in surrogate mothers. Fourteen pregnancies began, but most miscarried; only one pregnancy went through to term – this was Dolly.

Ethical issues

It is no exaggeration to say that the scientific world was astonished by the achievement. Scientists' widespread feeling had been that cloning from adult mammals was impossible; indeed, throughout the long-running but sporadic debate about the ethics of cloning, running since the 1970s, scientific commentators tended to downplay the possibility of cloning from adults. In any event, with the attention of the media focused on the concept of human cloning, scientists have had little opportunity to explain that Dolly is not simply an example of scientists in white coats 'playing God' but might constitute instead a serious medical advance.

Following the birth of Dolly, the public debate focused entirely on this question: will humans be cloned? The prospect of dictators cloning themselves and of women giving birth to their father were all discussed as serious possibilities. One reader, writing to the UK newspaper *The Times*, suggested that if his son, who had died in a car accident, were cloned 'he would be able to resume his relationship with my wife and myself and our younger son in a meaningful way and our family would be complete again'. Yet a clone of a person would have their own personality, wrought by the environment. They would have their own identity. In reality no-one could clone themselves and predict the outcome, any more than one can predict the future. Controlling the outcome of human cloning, in any civilized society, would most likely be illegal, as human clones would have the same rights as any other human. The scientific reasons commonly given for cloning humans all fail when considered alongside the social and ethical problems. However, if research into human cloning gets under way, there are useful applications that involve the cloning of tissues, not individuals. Cloned bone marrow, genetically identical to the patient in need, would save lives. More lives would be saved if whole organs could be grown, genetically matched to someone with heart or kidney disease. For the moment research in such areas is banned in the UK. In the USA federal funds cannot be used for human embryo research, but private laboratories have greater freedom. Research into mammal cloning, if not human cloning, is bound to continue. The debate too will continue, and will raise the most profound of questions about human and animal rights, about the question of personal identity, and about the purposes and methods of science. Meanwhile, Dolly the sheep thrives in her pen in Scotland, the centre of attention, but a reminder that the end of the century has seen the arrival of another troubling scientific development.

cloud Standard types of cloud. The height and nature of a cloud can be deduced from its name. Cirrus clouds are at high levels and have a wispy appearance. Stratus clouds form at low level and are layered. Middle-level clouds have names beginning with 'alto'. Cumulus clouds, ball or cottonwool clouds, occur over a range of height.

habitat of the larvae is in the nests of animals, feeding on remains of hair and feathers, but they have adapted to human households and can cause considerable damage, for example, the common clothes moth *Tineola bisselliella*.

cloud water vapour condensed into minute water particles that float in masses in the atmosphere. Clouds, like fogs or mists, which occur at lower levels, are formed by the cooling of air containing water vapour, which generally condenses around tiny dust particles.

Clouds are classified according to the height at which they occur and their shape. **Cirrus** and **cirrostratus** clouds occur at around 10 km/33,000 ft. The former, sometimes called mares'-tails, consist of minute specks of ice and appear as feathery white wisps, while **cirrostratus** clouds stretch across the sky as a thin white sheet. Three types of cloud are found at 3–7 km/10,000–23,000 ft: **cirrocumulus**, **altocumulus**, and **altostratus**. **Cirrocumulus** clouds occur in small or large rounded tufts, sometimes arranged in the pattern called mackerel sky. **Altocumulus** clouds are similar, but larger, while **altostratus** clouds, also arranged in lines. **Altostratus** clouds are like heavy cirrostratus clouds and may stretch across the sky as a grey sheet. **Stratocumulus** clouds are generally lower, occurring at 2–6 km/6,500–20,000 ft. They are dull grey clouds that give rise to a leaden sky that may not yield rain. Two types of clouds, **cumulus** and **cumulonimbus**, are placed in a special category because they are produced by daily ascending air currents, which take moisture into the cooler regions of the atmosphere. Cumulus clouds have a flat base generally at 1.4 km/4,500 ft where condensation begins, while the upper part is dome-shaped and extends to about 1.8 km/6,000 ft. Cumulonimbus clouds have their base at much the same level, but extend much higher, often up to over 6 km/20,000

ft. Short heavy showers and sometimes thunder may accompany them. **Stratus** clouds, occurring below 1–2.5 km/3,000–8,000 ft, have the appearance of sheets parallel to the horizon and are like high fogs.

In addition to their essential role in the water cycle, clouds are important in the regulation of radiation in the Earth's atmosphere. They reflect short-wave radiation from the Sun, and absorb and re-emit long-wave radiation from the Earth's surface.

cloud chamber apparatus for tracking ionized particles. It consists of a vessel fitted with a piston and filled with air or other gas, saturated with water vapour. When the volume of the vessel is suddenly expanded by moving the piston outwards, the vapour cools and a cloud of tiny droplets forms on any nuclei, dust, or ions present. As fast-moving ionizing particles collide with the air or gas molecules, they show as visible tracks.

Much information about interactions between such particles and radiations has been obtained from photographs of these tracks.

The system has been improved upon in recent years by the use of liquid hydrogen or helium instead of air or gas (see *particle detector*). The cloud chamber was devised in 1897 by Charles Thomson Rees Wilson (1869–1959) at Cambridge University.

clove dried, unopened flower bud of the clove tree. A member of the myrtle family, the tree is a native of the Maluku Islands, Indonesia. Cloves are used for flavouring in cookery and confectionery. Oil of cloves, which has tonic qualities and relieves wind, is used in medicine. The aroma of cloves is also shared by the leaves, bark, and fruit of the tree. (*Eugenia caryophyllus*, family Myrtaceae.)

clover any of an Old World group of low-growing leguminous plants (see *legume*), usually with leaves consisting of three leaflets and small flowers in dense heads. Sweet clover refers to various species belonging to the related genus *Melilotus*. (True clover genus *Trifolium*, family Leguminosae.)

club moss or **lycophod** any of a group of mosslike plants that do not produce seeds but reproduce by spores. They are related to the ferns and horsetails. (Order Lycopodiales, family Pteridophyta.)

These plants have a wide distribution, but were far more numerous in Palaeozoic times, especially the Carboniferous period

CLOUD CATALOGUE

<http://covis.atmos.uiuc.edu/guide/clouds/html/cloud.home.html>

Illustrated guide to how clouds form and to the various different types. The site contains plenty of images and a glossary of key terms.

(363–290 million years ago), when members of the group were large trees. The species that exist now are all small in size.

clubroot disease affecting cabbages, turnips, and allied plants of the Cruciferae family. It is caused by a ϕ slime mould, *Plasmodiophora brassicae*. This attacks the roots of the plant, which send out knotty outgrowths. Eventually the whole plant decays.

clubshell or **watering-pot shell** bivalve shelled mollusc. It is her-maphrodite and usually lives on corals and rocks.

classification Clubshells are in genus *Clavagella*, order Pholadomyoidea, class Bivalvia, phylum Mollusca.

Clumber spaniel breed of medium-sized gundog (a dog trained to aid in hunting) that takes its name from Clumber Park, Nottinghamshire, the estate of the dukes of Newcastle who imported the dogs into England from France probably in the late 18th century. Its thick, soft coat is white with lemon-coloured flecks. One of the largest spaniels, it weighs up to 36 kg/80 lb.

clusec unit for measuring the power of a vacuum pump.

Cluster a ϕ European Space Agency project to study the interaction of the solar wind with the Earth's ϕ magnetosphere from an array of four identical satellites. Cluster works in conjunction with *SOHO* (Solar and Heliospheric Observatory).

clutch any device for disconnecting rotating shafts, used especially in a car's transmission system. In a car with a manual gearbox, the driver depresses the clutch when changing gear, thus disconnecting the engine from the gearbox.

The clutch consists of two main plates, a pressure plate and a driven plate, which is mounted on a shaft leading to the gearbox. When the clutch is engaged, the pressure plate presses the driven plate against the engine ϕ flywheel, and drive goes to the gearbox. Depressing the clutch springs the pressure plate away, freeing the driven plate. Cars with automatic transmission have no clutch. Drive is transmitted from the flywheel to the automatic gearbox by a liquid coupling or ϕ torque converter.

cm symbol for centimetre.

CMOS (abbreviation for *complementary metal-oxide semiconductor*) family of integrated circuits (chips) widely used in building electronic systems.

CMYK (abbreviation for *cyan-magenta-yellow-black*) four-colour separation used in most (subtractive) colour printing processes. Representation on computer screens normally uses the additive ϕ RGB method and so conversion is usually necessary on output for printing either on colour printers or as separations.

CNC abbreviation for ϕ computer numerical control.

CNO cycle in astrophysics, alternative name for ϕ carbon cycle.

coachwood tree *Ceratopetalum apetalum* with light, easily worked timber, found in gullies in E Australia.

coal black or blackish mineral substance formed from the compaction of ancient plant matter in tropical swamp conditions. It is used as a fuel and in the chemical industry. Coal is classified according to the proportion of carbon it contains. The main types are ϕ anthracite (shiny, with about 90% carbon), **bituminous coal** (shiny and dull patches, about 75% carbon), and **lignite** (woody, grading into peat, about 50% carbon). Coal burning is one of the main causes of ϕ acid rain.

coal gas gas produced when coal is destructively distilled or heated out of contact with the air. Its main constituents are methane, hydrogen, and carbon monoxide. Coal gas has been superseded by ϕ natural gas for domestic purposes.

coal mining extraction of coal from the Earth's crust. Coal mines may be opencast ϕ adit, or deepcast. The least expensive is opencast but this may result in scars on the landscape.

coal tar black oily material resulting from the destructive distillation of bituminous coal.

Further distillation of coal tar yields a number of fractions: light oil, middle oil, heavy oil, and anthracene oil; the residue is called pitch. On further fractionation a large number of substances are obtained, about 200 of which have been isolated. They are used as dyes and in medicines.

coastal erosion the erosion of the land by the constant battering of the sea's waves. This produces two effects. The first is a hydraulic effect, in which the force of the wave compresses air pockets in coastal rocks and cliffs, and the air then expands explosively. The second is the effect of ϕ corrosion, in which rocks and pebbles are flung against the cliffs, wearing them away. Frost shattering (or freeze-thaw), caused by the expansion of frozen seawater,

clutch The clutch consists of two main plates: a drive plate connected to the engine crankshaft and a driven plate connected to the wheels. When the clutch is disengaged, the drive plate does not press against the driven plate. When the clutch is engaged, the two plates are pressed into contact and the rotation of the crankshaft is transmitted to the wheels.

coastal erosion Typical features of coastal erosion: from the initial cracks in less resistant rock through to arches, stacks, and stumps that can occur as erosion progresses.

ter in cavities, and biological weathering, caused by the burrowing of rock-boring molluscs, also result in the breakdown of the rock.

In areas where there are beaches, the waves cause longshore drift, in which sand and stone fragments are carried parallel to the shore, causing buildups (sandspits) in some areas and beach erosion in others.

coastal protection measures taken to prevent coastal erosion. Many stretches of coastline are so severely affected by erosion that beaches are swept away, threatening the livelihood of seaside resorts, and buildings become unsafe.

To reduce erosion, several different forms of coastal protection may be employed. Structures such as sea walls attempt to prevent waves reaching the cliffs by deflecting them back to sea. Such structures are expensive and of limited success. Adding sediment (beach nourishment) to make a beach wider causes waves to break early so that they have less power when they reach the cliffs. Wooden or concrete barriers called groynes may also be constructed at right angles to the beach in order to block the movement of sand along the beach (longshore drift).

coati or *comimundi* any of several species of carnivores of the genus *Nasua*, in the same family, Procyonidae, as the raccoons. A coati is a good climber and has long claws, a long tail, a good sense of smell, and a long, flexible piglike snout used for digging. Coatis live in packs in the forests of South and Central America.

The common coati *Nasua nasua* of South America is about 60 cm/2 ft long, with a tail about the same length.

coaxial cable electric cable that consists of a solid or stranded central conductor insulated from and surrounded by a solid or braided conducting tube or sheath. It can transmit the high-frequency signals used in television, telephone, and other telecommunications transmissions.

cobalt German *Kobalt* 'evil spirit' hard, lustrous, grey, metallic element, symbol Co, atomic number 27, relative atomic mass 58.933. It is found in various ores and occasionally as a free metal, sometimes in metallic meteorite fragments. It is used in the preparation of magnetic, wear-resistant, and high-strength alloys; its compounds are used in inks, paints, and varnishes.

The isotope Co-60 is radioactive (half-life 5.3 years) and is produced in large amounts for use as a source of gamma rays in industrial radiography, research, and cancer therapy. Cobalt was named in 1730 by Swedish chemist Georg Brandt (1694-1768); the name

derives from the fact that miners considered its ore malevolent because it interfered with copper production.

cobalt-60 radioactive (half-life 5.3 years) isotope produced by neutron radiation of cobalt in heavy-water reactors, used in large amounts for gamma rays in cancer therapy, industrial radiography, and research, substituting for the much more costly radium.

cobalt chloride CoCl_2 , compound that exists in two forms: the hydrated salt ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$), which is pink, and the anhydrous salt, which is blue. The anhydrous form is used as an indicator because it turns pink if water is present. When the hydrated salt is gently heated the blue anhydrous salt is reformed.

cobalt ore cobalt is extracted from a number of minerals, the main ones being *smaltite*, $(\text{CoNi})\text{As}_2$; *linnaeite*, Co_3S_4 ; *cobaltite*, CoAsS ; and *glauco-dot*, $(\text{CoFe})\text{AsS}$.

All commercial cobalt is obtained as a by-product of other metals, usually associated with other ores, such as copper. Congo (formerly Zaire) is the largest producer of cobalt, and it is obtained there as a byproduct of the copper industry. Other producers include Canada and Morocco. Cobalt is also found in the manganese nodules that occur on the ocean floor, and was successfully refined in 1988 from the Pacific Ocean nodules, although this process has yet to prove economic.

COBOL (acronym for *common business-oriented language*) high-level computer-programming language, designed in the late 1950s for commercial data-processing problems; it has become the major language in this field. COBOL features powerful facilities for file handling and business arithmetic. Program instructions written in this language make extensive use of words and look very much like English sentences. This makes COBOL one of the easiest languages to learn and understand.

cobra any of several poisonous snakes, especially the genus *Naja*, of the family Elapidae, found in Africa and southern Asia, species of which can grow from 1 m/3 ft to over 4.3 m/14 ft. The neck stretches into a hood when the snake is alarmed. Cobra venom contains nerve toxins powerful enough to kill humans.

The Indian cobra *Naja naja* is about 1.5 m/5 ft long, and found over most of southern Asia. Some individuals have 'spectacle' markings on the hood. The hamadryad *N. hannah* of southern and southeast Asia can be 4.3 m/14 ft or more, and eats snakes. The ringhals *Hemachatus hemachatus* of S Africa and the black-necked cobra

N. nigricollis, of the African savanna are both about 1 m/3 ft long. Both are able to spray venom towards the eyes of an attacker.

coca South American shrub belonging to the coca family, whose dried leaves are the source of the drug cocaine. It was used as a holy drug by the Andean Indians. (*Erythroxylon coca*, family Erythroxylaceae.)

cocaine alkaloid $C_{17}H_{21}NO_4$ extracted from the leaves of the coca tree. It has limited medical application, mainly as a local anaesthetic agent that is readily absorbed by mucous membranes (lining tissues) of the nose and throat. It is both toxic and addictive. Its use as a stimulant is illegal. Crack is a derivative of cocaine.

Cocaine was first extracted from the coca plant in Germany in the 19th century. Most of the world's cocaine is produced from coca grown in Peru, Bolivia, Colombia, and Ecuador. Estimated annual production totals 215,000 tonnes, with most of the processing done in Colombia. Long-term use may cause mental and physical deterioration.

coccolithophorid microscopic, planktonic marine alga, which secretes a calcite shell. The shells (coccoliths) of coccolithophores are a major component of deep sea ooze. Coccolithophores were particularly abundant during the late Cretaceous period and their remains form the northern European chalk deposits, such as the white cliffs of Dover.

coccus (plural cocci) member of a group of globular bacteria, some of which are harmful to humans. The cocci contain the subgroups streptococci, where the bacteria associate in straight chains, and staphylococci, where the bacteria associate in branched chains.

cochineal red dye obtained from the cactus-eating Mexican scale insect *Dactylopius coccus*, used in colouring food and fabrics.

cochlea part of the inner ear. It is equipped with approximately 10,000 hair cells, which move in response to sound waves and thus stimulate nerve cells to send messages to the brain. In this way they turn vibrations of the air into electrical signals.

cockatiel Australian parrot *Nymphicus hollandicus*, about 20 cm/8 in long, with greyish or yellow plumage, yellow cheeks, a long tail, and a crest like a cockatoo. Cockatiels are popular as pets and aviary birds.

cockatoo any of several crested parrots, especially of the genus *Cacatua*, family Psittacidae, of the order Psittaciformes. They usually have light-coloured plumage with tinges of red, yellow, or orange on the face, and an erectile crest on the head. They are native to Australia, New Guinea, and nearby islands.

There are about 17 species, one of the most familiar being the sulphur-crested cockatoo *C. galerita* of Australia and New Guinea, about 50 cm/20 in long, white with a yellow crest and dark beak.

cockchafer or *maybug* European beetle *Melolontha melolontha*, of the scarab family, up to 3 cm/1.2 in long, with clumsy, buzzing flight, seen on early summer evenings. Cockchafers damage trees by feeding on the foliage and flowers.

cocker spaniel breed of small gundog developed in Britain for hunting woodcock (hence its name). It stands about 40 cm/15 in tall and weighs about 14 kg/30 lb. The American cocker is recognized as distinct from the English breed but both have a long, dense coat, which may be a solid colour (red, gold, black) or bi-coloured (black and white).

cockle any of over 200 species of bivalve mollusc with ribbed, heart-shaped shells. Some are edible and are sold in W European markets.

cock-of-the-rock South American bird of the genus *Rupicola*. It belongs to the family Cotingidae, which also includes the cotingas and umbrella birds. There are two species: *R. peruviana*, the Andean cock-of-the-rock, and *R. rupicola*, the Guyanese cock-of-the-rock. The male has brilliant orange plumage including the head crest, the female is a duller brown. Males display at a communal breeding area.

cockroach The so-called Australian cockroach *Periplaneta australasiae*. Mostly of African origin, cockroaches have become a cosmopolitan pest, infesting in particular kitchens and food stores, and often being linked to outbreaks of food poisoning. Premaphotos Wildlife

cockroach any of numerous insects of the family Blattellidae, distantly related to mantises and grasshoppers. There are 3,500 species, mainly in the tropics. They have long antennae and biting mouthparts. They can fly, but rarely do so.

The common cockroach, or black-beetle *Blattella orientalis*, is found in human dwellings, is nocturnal, omnivorous, and contaminates food. The German cockroach *Blattella germanica* and American cockroach *Periplaneta americana* are pests in kitchens, bakeries, and warehouses. In Britain only two innocuous species are native, but several have been introduced with imported food and have become severe pests. They are very difficult to eradicate. Cockroaches have a very high resistance to radiation, making them the only creatures likely to survive a nuclear holocaust.

COCKROACHES

<http://www.ex.ac.uk/~gjlramel/blatodea.html>

General information about the cockroach from its original arrival on Earth to the present day. Includes life history, its relationship with humans, and even how to keep a cockroach as a pet!

cocktail effect the effect of two toxic, or potentially toxic, chemicals when taken together rather than separately. Such effects are known to occur with some mixtures of drugs, with the active ingredient of one making the body more sensitive to the other.

This sometimes occurs because both drugs require the same enzyme to break them down. Chemicals such as pesticides and food additives are only ever tested singly, not in combination with other chemicals that may be consumed at the same time, so no allowance is made for cocktail effects.

'Gulf War syndrome' may have resulted from the cocktail effect of an anti-nerve gas drug and two different insecticides.

coconut fruit of the coconut palm, which grows throughout the lowland tropics. The fruit has a large outer husk of fibres, which is removed and used to make coconut matting and ropes. Inside this is the nut which is exported to temperate countries. Its hard shell contains white flesh and clear coconut milk, both of which are tasty and nourishing. (*Cocos nucifera*, family Arecaceae.)

The white flesh of the coconut can be eaten fresh, or it can be dried before extracting the oil which makes up nearly two-thirds of it. The oil is used to make soap and margarine and in cooking; the remains are used in cattle feed.

cocoon pupa-case of many insects, especially of moths and silkworms. This outer web or ball is spun from the mouth by caterpillars before they pass into the chrysalis state.

cod any fish of the family Gadidae, especially the Atlantic cod, *Gadus morhua* found in the N Atlantic and Baltic. It is brown to grey with spots, white below, and can grow to 1.5 m fl.

The main cod fisheries are in the North Sea, and off the coasts of Iceland and Newfoundland, Canada. Much of the catch is salted and dried. Formerly one of the cheapest fish, decline in numbers from overfishing has made it one of the most expensive.

COD abbreviation for chemical oxygen demand, a measure of water and effluent quality.

code the expression of an algorithm in a programming language. The term is also used as a verb, to describe the act of programming.

codec device that codes and decodes an analogue stream to or from digital data. It is used in applications such as remote broadcast-quality voiceovers recorded in a remote studio and transmitted via codecs and Integrated Services Digital Network (ISDN) lines to a central studio for final mixing.

codeine opium derivative that provides analgesia in mild to moderate pain. It also suppresses the cough centre of the brain. It is an alkaloid, derived from morphine but less toxic and addictive.

codominance in genetics, the failure of a pair of alleles, controlling a particular characteristic, to show the classic recessive-dominant relationship. Instead, aspects of both alleles may show in the phenotype.

The snapdragon shows codominance in respect to colour. Two alleles, one for red petals and the other for white, will produce a pink colour if the alleles occur together as a heterozygous form.

codon in genetics, a triplet of bases (see base pair) in a molecule of DNA or RNA that directs the placement of a particular amino acid during the process of protein (polypeptide) synthesis. There are 64 codons in the genetic code.

coefficient the number part in front of an algebraic term, signifying multiplication. For example, in the expression $4x^2 + 2xy - x$, the coefficient of x^2 is 4 (because $4x^2$ means $4 \times x^2$), that of xy is 2, and that of x is -1 (because $-1 \times x = -x$).

In general algebraic expressions, coefficients are represented by letters that may stand for numbers; for example, in the equation $ax^2 + bx + c = 0$, a , b , and c are coefficients, which can take any number.

coefficient of relationship the probability that any two individuals share a given gene by virtue of being descended from a common ancestor. In sexual reproduction of diploid species, an individual shares half its genes with each parent, with its offspring, and (on average) with each sibling, but only a quarter (on average) with its grandchildren or its siblings' offspring; an eighth with its great-grandchildren, and so on.

In certain species of insects (for example honey bees), females have only one set of chromosomes (inherited from the mother), so that sisters are identical in genetic make-up; this produces a difference of coefficients. These coefficients are important in calculations of inclusive fitness.

coelacanth large dark brown to blue-grey fish that lives in the deep waters (200 m/650 ft) of the western Indian Ocean around the Comoros Islands. They can grow to about 2 m/6 ft in length, and weigh up to 73 kg/160 lb. They have bony, overlapping scales, and muscular lobe (limblike) fins sometimes used like oars when swimming and for balance while resting on the sea floor. They feed on other fish, and give birth to live young rather than shedding eggs as most fish do. Coelacanth fossils exist dating back over 400 million years and coelacanths were believed to be extinct until one was caught in 1938 off the coast of South Africa. For this reason they are sometimes referred to as 'living fossils'.

classification Coelacanths belong to the animal phylum Chordata, superclass Pisces (fish), class Sarcopterygii, subclass

Crossopterygii, order Actinistia or coelacanthiformes, represented by a single family Latimeriidae. There is only one known surviving species of coelacanth, *Latimeria chalumnae*. Coelacanths are now threatened, and have been listed as endangered by CITES since 1991.

Nature's oddities are more than good theories. They are material for probing the limits of interesting theories about life's history and meaning.

STEPHEN JAY GOULD US palaeontologist and writer.

The Panda's Thumb 1980

coelenterate any freshwater or marine organism of the phylum Coelenterata, having a body wall composed of two layers of cells. They also possess stinging cells. Examples are jellyfish, hydra, and coral.

coeliac disease disease in which the small intestine fails to digest and absorb food. The disease can appear at any age but has a peak incidence in the 30-50 age group; it is more common in women. It is caused by an intolerance to gluten (a constituent of wheat, rye and barley) and characterized by diarrhoea and malnutrition. Treatment is by a gluten-free diet.

coelom in all but the simplest animals, the fluid-filled cavity that separates the body wall from the gut and associated organs, and allows the gut muscles to contract independently of the rest of the body.

coevolution evolution of those structures and behaviours within a species that can best be understood in relation to another species. For example, insects and flowering plants have evolved together; insects have produced mouthparts suitable for collecting pollen or drinking nectar, and plants have developed chemicals and flowers that will attract insects to them.

Coevolution occurs because both groups of organisms, over millions of years, benefit from a continuing association, and will evolve structures and behaviours that maintain this association.

coffee drink made from the roasted and ground beanlike seeds found inside the red berries of any of several species of shrubs, originally native to Ethiopia and now cultivated throughout the tropics. It contains a stimulant, caffeine. (Genus *Coffea*, family Rubiaceae.)

cultivation The shrub, naturally about 5 m/17 ft high, is pruned to about 2 m/7 ft; it is fully fruit-bearing in 5 or 6 years, and lasts for 30 years. Coffee grows best on frost-free hillsides with moderate rainfall. The world's largest producers are Brazil, Colombia, and Côte d'Ivoire; others include Indonesia (Java), Ethiopia, India, Hawaii, and Jamaica. In recent years the world coffee market has suffered from over-supply, and in the early 1990s the price of coffee was well below the cost of production.

history Coffee drinking began in Arab regions in the 14th century but did not become common in Europe until three hundred years later, when the first coffee houses were opened in Vienna, and soon after in Paris and London. In the American colonies, coffee became the substitute for tea when tea was taxed by the British.

coffee machine on the Internet, the coffee machine at Cambridge University, England, whose supplies may be monitored via the World Wide Web. It derives from an idea originally developed at a US university, where the Coke machine was some distance from the programming lab. A system of switches was installed so that a programmer could check the machine's supply of Cokes and their temperature before going to collect a drink.

cognition in psychology, a general term covering the functions involved in synthesizing information - for example, perception (seeing, hearing, and so on), attention, memory, and reasoning.

cognitive therapy or **cognitive behaviour therapy** treatment for emotional disorders such as depression and anxiety states. It encourages the patient to challenge the distorted and unhelpful

thinking that is characteristic of depression, for example. The treatment may include behaviour therapy.

coherence in physics, property of two or more waves of a beam of light or other electromagnetic radiation having the same frequency and the same phase, or a constant phase difference.

cohesion in physics, a phenomenon in which interaction between two surfaces of the same material in contact makes them cling together (with two different materials the similar phenomenon is called adhesion). According to kinetic theory, cohesion is caused by attraction between particles at the atomic or molecular level. Surface tension, which causes liquids to form spherical droplets, is caused by cohesion.

coil in medicine, another name for an intrauterine device.

coke clean, light fuel produced, along with town gas, when coal is strongly heated in an airtight oven. Coke contains 90% carbon and makes a useful domestic and industrial fuel (used, for example in the iron and steel industries).

The process was patented in England 1622, but it was only in 1709 that Abraham Darby devised a commercial method of production.

cola or **kola** any of several tropical trees, especially *Cola acuminata*. In W Africa the nuts are chewed for their high caffeine content, and in the West they are used to flavour soft drinks. (Genus *Cola*, family Sterculiaceae.)

cold, common minor disease of the upper respiratory tract, caused by a variety of viruses. Symptoms are headache, chill, nasal discharge, sore throat, and occasionally cough. Research indicates that the virulence of a cold depends on psychological factors and either a reduction or an increase of social or work activity, as a result of stress, in the previous six months.

There is little immediate hope of an effective cure since the viruses transform themselves so rapidly.

cold-blooded of animals, dependent on the surrounding temperature; see poikilothermy.

cold dark matter theory in cosmology, a theory in which the bulk of the matter in the universe is in the form of dark, unseen material consisting of slow-moving particles. The gravitational clumping of this dark matter in the early universe is may have led to the formation of clusters and superclusters of galaxies.

cold fusion in nuclear physics, the fusion of atomic nuclei at room temperature. If cold fusion were possible it would provide a limitless, cheap, and pollution-free source of energy, and it has therefore been the subject of research around the world.

In 1989, Martin Fleischmann (1927–) and Stanley Pons (1943–) of the University of Utah, USA, claimed that they had achieved cold fusion in the laboratory, but their results could not be substantiated. The University of Utah announced in 1998 that they would allow the cold fusion patent to elapse, given that the work of Pons and Fleischmann has never been reproduced.

An important scientific innovation rarely makes its way by gradually winning over and converting its opponents: it rarely happens that Saul becomes Paul. What does happen is that its opponents gradually die out, and that the growing generation is familiarized with the ideas from the beginning.

MAX PLANCK German physicist.

In G Holton *Thematic Origins of Scientific Thought* 1973, *Scientific Autobiography* 1949

cold-working method of shaping metal at or near atmospheric temperature.

coleoptile the protective sheath that surrounds the young shoot tip of a grass during its passage through the soil to the surface.

Although of relatively simple structure, most coleoptiles are very sensitive to light, ensuring that seedlings grow upwards.

colic spasmodic attack of pain in the abdomen, usually coming in waves. Colicky pains are caused by the painful muscular contraction and subsequent distension of a hollow organ; for example, the bowels, gall bladder (biliary colic), or ureter (renal colic).

Intestinal colic is due to partial or complete blockage of the intestine, or constipation; infantile colic is usually due to wind in the intestine.

colitis inflammation of the colon (large intestine) with diarrhoea (often bloody). It is usually due to infection or some types of bacterial dysentery.

collagen protein that is the main constituent of connective tissue. Collagen is present in skin, cartilage, tendons, and ligaments. Bones are made up of collagen, with the mineral calcium phosphate providing increased rigidity.

It was identified in a yeastlike fungus in 1996, the first time it has been found in a nonanimal source.

collective farm *Russian kolkhoz* farm in which a group of farmers pool their land, domestic animals, and agricultural implements, retaining as private property enough only for the members' own requirements. The profits of the farm are divided among its members. In cooperative farming, farmers retain private ownership of the land.

Collective farming was first developed in the USSR in 1917, where it became general after 1930. Stalin's collectivization drive 1929–33 wrecked a flourishing agricultural system and alienated the Soviet peasants from the land: 15 million people were left homeless, 1 million of whom were sent to labour camps and some 12 million deported to Siberia. In subsequent years, millions of those peasants forced into collectives died. Collective farming is practised in other countries; it was adopted from 1953 in China, and Israel has a large number of collective farms.

collective unconscious in psychology, a shared pool of memories, ideas, modes of thought, and so on, which, according to the Swiss psychiatrist Carl Jung, comes from the life experience of one's ancestors, indeed from the entire human race. It coexists with the personal unconscious, which contains the material of individual experience, and may be regarded as an immense depository of ancient wisdom.

Primal experiences are represented in the collective unconscious by archetypes, symbolic pictures, or personifications that appear in dreams and are the common element in myths, fairy tales, and the literature of the world's religions. Examples include the serpent, the sphinx, the Great Mother, the anima (representing the nature of woman), and the mandala (representing balanced wholeness, human or divine).

collenchyma plant tissue composed of relatively elongated cells with thickened cell walls, in particular at the corners where adjacent cells meet.

It is a supporting and strengthening tissue found in nonwoody plants, mainly in the stems and leaves.

collie any of several breeds of sheepdog originally bred in Britain. They include the border collie, the bearded collie, and the rough collie and its smooth-haired counterpart.

colligative property property that depends on the concentration of particles in a solution. Such properties include osmotic pressure (see osmosis), elevation of boiling point, depression of freezing point, and lowering of vapour pressure.

collimator (1) small telescope attached to a larger optical instrument to fix its line of sight; (2) optical device for producing a non-divergent beam of light; (3) any device for limiting the size and angle of spread of a beam of radiation or particles.

collinear in mathematics, lying on the same straight line.

collision detection in virtual reality, the ability of software to detect when two on-screen objects make contact.

collision theory Collision theory explains how chemical reactions occur and why rates of reaction differ. For a reaction to occur, particles must collide. If the collision causes a chemical change it is referred to as a fruitful collision.

collision theory theory that explains how chemical reactions take place and why rates of reaction alter. For a reaction to occur the reactant particles must collide. Only a certain fraction of the total collisions cause chemical change; these are called fruitful collisions. The fruitful collisions have sufficient energy (activation energy) at the moment of impact to break the existing bonds and form new bonds, resulting in the products of the reaction. Increasing the concentration of the reactants and raising the temperature bring about more collisions and therefore more fruitful collisions, increasing the rate of reaction.

When a catalyst undergoes collision with the reactant molecules, less energy is required for the chemical change to take place, and hence more collisions have sufficient energy for reaction to occur. The reaction rate therefore increases.

colloid substance composed of extremely small particles of one material (the dispersed phase) evenly and stably distributed in another material (the continuous phase). The size of the dispersed particles (1–1,000 nanometres across) is less than that of particles in suspension but greater than that of molecules in true solution. Colloids involving gases include aerosols (dispersions of liquid or solid particles in a gas, as in fog or smoke) and foams (dispersions of gases in liquids).

Those involving liquids include emulsions (in which both the dispersed and the continuous phases are liquids) and sols (solid particles dispersed in a liquid). Sols in which both phases contribute to a molecular three-dimensional network have a jellylike form and are known as gels; gelatin, starch 'solution', and silica gel are common examples.

Milk is a natural emulsion of liquid fat in a watery liquid; synthetic emulsions such as some paints and cosmetic lotions have chemical emulsifying agents to stabilize the colloid and stop the two phases from separating out. Colloids were first studied thoroughly by the British chemist Thomas Graham, who defined them as substances that will not diffuse through a semipermeable membrane (as opposed to what he termed crystalloids, solutions of inorganic salts, which will diffuse through).

colobus or *guereza* large tree-dwelling African monkey characterized by the almost complete suppression of the thumb. There six species divided into two groups: the black-and-white colobus and the red colobus. They live in groups and feed on fruit, leaves, flowers, and twigs.

Black-and-white colobus monkeys are slightly larger, with a head and body length of 62.5 cm/24.5 in and a long tail (80 cm/31.5 in).

classification Colobuses are in the genus *Colobus*, family Cercopithecidae, order Primates.

colon in anatomy, the main part of the large intestine, between the caecum and rectum. Water and mineral salts are absorbed from undigested food in the colon, and the residue passes as faeces towards the rectum.

colonization in ecology, the spread of species into a new habitat, such as a freshly cleared field, a new motorway verge, or a recently flooded valley. The first species to move in are called pioneers, and may establish conditions that allow other animals and plants to move in (for example, by improving the condition of the soil or by providing shade). Over time a range of species arrives and the habitat matures; early colonizers will probably be replaced, so that the variety of animal and plant life present changes. This is known as succession.

Colorado beetle or *potato beetle* North American black and yellow striped beetle that is a pest on potato crops. Although it was once a serious pest, it can now usually be controlled by using insecticides. It has also colonized many European countries.

classification Colorado beetles *Leptinotarsa decemlineata* are in the family Chrysomelidae, order Coleoptera, class Insecta, phylum Arthropoda.

colour quality or wavelength of light emitted or reflected from an object. Visible white light consists of electromagnetic radiation of various wavelengths, and if a beam is refracted through a prism, it can be spread out into a spectrum, in which the various colours correspond to different wavelengths. From long to short wavelengths (from about 700 to 400 nanometres) the colours are red, orange, yellow, green, blue, indigo, and violet.

The light entering our eyes is either reflected from the objects we see, or emitted by hot or luminous objects.

TO REMEMBER THE ADDITIVE AND SUBTRACTIVE MIXTURES OF COLOURS:

BETTER GET READY WHILE YOUR MISTRESS COMES BACK.

BLUE + GREEN + RED = WHITE (ADDITIVE) YELLOW + MAGENTA + CYAN = BLACK (SUBTRACTIVE)

emitted light Sources of light have a characteristic spectrum or range of wavelengths. Hot solid objects emit light with a broad range of wavelengths, the maximum intensity being at a wavelength which depends on the temperature. The hotter the object, the shorter the wavelengths emitted, as described by Wien's displacement law. Hot gases, such as the vapour of sodium street lights, emit light at discrete wavelengths. The pattern of wavelengths emitted is unique to each gas and can be used to identify the gas (see spectroscopy).

reflected light When an object is illuminated by white light, some of the wavelengths are absorbed and some are reflected to the eye of an observer. The object appears coloured because of the mixture of wavelengths in the reflected light. For instance, a red object absorbs all wavelengths falling on it except those in the red end of the spectrum. This process of subtraction also explains why certain mixtures of paints produce different colours. Blue and yellow paints when mixed together produce green because between them the yellow and blue pigments absorb all wavelengths except those around green. A suitable combination of three pigments – cyan (blue-green), magenta (blue-red), and yellow – can produce any colour when mixed. This fact is used in colour printing, although additional black pigment is also added.

primary colours In the light-sensitive lining of our eyeball (the retina), cells called cones are responsible for colour vision. There are three kinds of cones. Each type is sensitive to one colour only, either red, green, or blue. The brain combines the signals sent from the set of cones to produce a sensation of colour. When all cones are stimulated equally the sensation is of white light. The three colours to which the cones respond are called the **primary colours**. By mixing lights of these three colours, it is possible to produce any colour. This process is called colour mixing by addition, and is used to produce the colour on a television screen, where glowing phosphor dots of red, green, and blue combine.

complementary colours Pairs of colours that produce white light, such as yellow and blue, are called complementary colours.

classifying colours Many schemes have been proposed for classifying colours. The most widely used is the Munsell scheme, which classifies colours according to their hue (dominant wavelength), saturation (the degree of whiteness), and brightness (intensity).

colour in particle physics, a property of quarks analogous to electric charge but having three states, denoted by red, green, and blue. The colour of a quark is changed when it emits or absorbs a gluon. The term has nothing to do with colour in its usual sense. See quantum chromodynamics.

colour blindness hereditary defect of vision that reduces the ability to discriminate certain colours, usually red and green. The condition is sex-linked, affecting men more than women.

colour depth in computing, the maximum number of colours that can be displayed simultaneously in an image by a particular computer system.

The most common modes are 16, 256, 32K, 64K and 16.7 million (true colour). The greater the colour depth, the larger the size of the picture file but the more detailed and realistic the quality of the picture.

colour index in astronomy, a measure of the colour of a star made by comparing its brightness through different coloured filters. It is defined as the difference between the magnitude of the star measured through two standard photometric filters. Colour index is directly related to the surface temperature of a star and its spectral classification.

colouring food additive used to alter or improve the colour of processed foods. Colourings include artificial colours, such as tartrazine and amaranth, which are made from petrochemicals, and the 'natural' colours such as chlorophyll, caramel, and carotene. Some of the natural colours are actually synthetic copies of the naturally occurring substances, and some of these, notably the synthetically produced caramels, may be injurious to health.

Colourpoint Longhair or **Himalayan** breed of domestic long-haired cat originally developed in the 1920s in America and Sweden from a cross between Persian and Siamese cats. The

Sealpoint was one of the first varieties to be developed and has a warm cream coat with contrasting deep brown markings on the face, ears, feet, paws, and tail. It has small ears, blue eyes, and short legs.

The breed was recognized in 1955 in Europe and in the USA in 1957 where it is most widely bred. It has many varieties.

colour vision the ability of the eye to recognize different frequencies in the visible spectrum as colours. In most vertebrates, including humans, colour vision is due to the presence on the retina of three types of light-sensitive cone cell, each of which responds to a different primary colour (red, green, or blue).

Colour vision is one of the ways in which the brain can acquire knowledge of the unchanging characteristics of objects. Colours are constructs of the brain, rather than physical features of objects or their surface. They remain more or less stable, and objects remain recognizable, in spite of the continuously changing illumination in which they are seen, a phenomenon known as colour constancy.

Colt, Samuel (1814–1862)

US gunsmith who invented the revolver in 1835 that bears his name. With its rotating cylinder which turned, locked, and unlocked by cocking the hammer, the Colt was superior to other revolving pistols, and it revolutionized military tactics.

mass production for war Colt built a large factory in Hartford, Connecticut in 1854. He introduced mass-production techniques, and his weapons had interchangeable parts, making them easy to maintain and repair. During the Crimean War 1853–56 he also manufactured arms in Pimlico, London. By 1855 he had the largest private armoury in the world. When the American Civil War broke out in 1861, he supplied thousands of guns to the US government.

May Evans Picture Library

coltsfoot perennial plant belonging to the daisy family. The single yellow flower heads have many narrow rays (not petals), and the stems have large purplish scales. The large leaf, up to 22 cm/9 in across, is shaped like a horse's foot and gives the plant its name. Coltsfoot grows in Europe, N Asia, and N Africa, often on bare ground and in waste places, and has been introduced to North America. It was formerly used in medicine. (*Tussilago farfara*, family Compositae.)

colugo or **flying lemur** SE Asian climbing mammal of the genus *Cynocephalus*, order Dermoptera, about 60 cm/2 ft long including the tail. It glides between forest trees using a flap of skin that extends from head to forelimb to hindlimb to tail. It may glide 130 m/425 ft or more, losing little height. It feeds largely on buds and leaves, and rests hanging upside down under branches.

There are two species, *C. variegatus* of Indochina and Indonesia, and *C. volans* of the Philippines.

columbine any of a group of plants belonging to the buttercup family. All are perennial herbs with divided leaves and hanging flower heads with spurred petals. (Genus *Aquilegia*, family Ranunculaceae.)

The wild columbine (*Aquilegia vulgaris*), with blue flowers, has been developed by repeated crossing to produce modern garden species (*A. x hybrida*), with larger flowers and a wider range of colours. The eastern columbine (*A. canadensis*), with red flowers, is native to E North America.

columbium (Cb) former name for the chemical element niobium. The name is still used occasionally in metallurgy.

column a vertical list of numbers or terms, especially in matrices.

COM acronym for computer output on microfilm/microfiche.

coma in astronomy, the hazy cloud of gas and dust that surrounds the nucleus of a comet.

coma in medicine, a state of deep unconsciousness from which the subject cannot be roused. Possible causes include head injury, brain disease, liver failure, cerebral haemorrhage, and drug overdose.

coma in optics, one of the geometrical aberrations of a lens, whereby skew rays from an object make a comet-shaped spot on the image plane instead of meeting at a point.

combe or **coombe** steep-sided valley found on the scarp slope of a chalk escarpment. The inclusion of 'combe' in a placename usually indicates that the underlying rock is chalk.

combination in mathematics, a selection of a number of objects from some larger number of objects when no account is taken of order within any one arrangement. For example, 123, 213, and 312 are regarded as the same combination of three digits from 1234. Combinatorial analysis is used in the study of probability.

The number of ways of selecting r objects from a group of n is given by the formula:

$$n! / r!(n-r)!$$

(see ϕ factorial). This is usually denoted by nC_r .

combine in probability theory, to work out the chances of two or more events occurring at the same time.

combined cycle generation system of electricity generation that makes use of both a gas turbine and a steam turbine. Combined cycle plants are more efficient than conventional generating plants.

In combined cycle generation, the gas turbine is powered by burning gas fuel, and turns an electric generator. The exhaust gases are then used to heat water to produce steam. The steam powers a steam turbine attached to an electric generator, producing additional electricity.

combined heat and power generation (CHP generation) simultaneous production of electricity and useful heat in a power station. The heat is often in the form of hot water or steam, which can be used for local district heating or in industry. The electricity output from a CHP plant is lower than from a conventional station, but the overall efficiency of energy conversion is higher. A typical CHP plant may convert 80% of the original fuel energy into a mix of electricity and useful heat, whereas a conventional power station rarely even manages a 40% conversion rate.

combine harvester or **combine** machine used for harvesting cereals and other crops, so called because it combines the actions of reaping (cutting the crop) and threshing (beating the ears so that the grain separates).

A combine, drawn by horses, was first built in Michigan in 1836. Today's mechanical combine harvesters are capable of cutting a swath of up to 9 m/30 ft or more.

combustion burning, defined in chemical terms as the rapid combination of a substance with oxygen, accompanied by the evolution of heat and usually light. A slow-burning candle flame and the explosion of a mixture of petrol vapour and air are extreme examples of combustion.

comet small, icy body orbiting the Sun, usually on a highly elliptical path. A comet consists of a central nucleus a few kilometres

across, and has been likened to a dirty snowball because it consists mostly of ice mixed with dust. As a comet approaches the Sun its nucleus heats up, releasing gas and dust which form a tenuous coma, up to 100,000 km/60,000 mi wide, around the nucleus. Gas and dust stream away from the coma to form one or more tails, which may extend for millions of kilometres. US astronomers concluded in 1996 that there are two distinct types of comet: one rich in methanol and one low in methanol. Evidence for this comes in part from observations of the spectrum of Comet Hyakutake.

Comets are believed to have been formed at the birth of the Solar System. Billions of them may reside in a halo (the Oort cloud) beyond Pluto. The gravitational effect of passing stars pushes some towards the Sun, when they eventually become visible from Earth. Most comets swing around the Sun and return to distant space, never to be seen again for thousands or millions of years, although some, called periodic comets, have their orbits altered by the gravitational pull of the planets so that they reappear every 200 years or less. Periodic comets are thought to come from the Kuiper belt, a zone just beyond Neptune. Of the 800 or so comets whose orbits have been calculated, about 160 are periodic. The one with the shortest known period is Encke's comet, which orbits the Sun every 3.3 years. A dozen or more comets are discovered every year, some by amateur astronomers.

Comet Hale-Bopp (C/1995-O1) large and exceptionally active comet, which in March 1997 made its closest flyby to Earth since 2000 BC, coming within 190 million km/118 million mi. It has a diameter of approximately 40 km/25 mi and an extensive gas coma (when close to the Sun Hale-Bopp released 10 tonnes of gas every second). Unusually, Hale-Bopp has three tails: one consisting of dust particles, one of charged particles, and a third of sodium particles.

Comet Hale-Bopp was discovered independently in July 1995 by two amateur US astronomers, Alan Hale and Thomas Bopp.

Comet Shoemaker-Levy 9 a comet that crashed into Jupiter in July 1994. The fragments crashed into Jupiter at 60 kps/37 mps over the period 16-22 July 1994. The impacts occurred on the far side of Jupiter, but the impact sites came into view of Earth about 25 minutes later. Analysis of the impacts shows that most of the pieces were solid bodies about 1 km/0.6 mi in diameter, but that at least three of them were clusters of smaller objects.

When first sighted in 24 March 1993 by US astronomers Carolyn and Eugene Shoemaker and David Levy, it was found to consist of at least 21 fragments in an unstable orbit around Jupiter. It is believed to have been captured by Jupiter in about 1930 and fragmented by tidal forces on passing within 21,000 km/13,050 mi of the planet in July 1992.

COMET SHOEMAKER-LEVY HOME PAGE

<http://www.jpl.nasa.gov/sl9/>

Description of the comet's collision with Jupiter 1994, the first collision of two Solar System bodies ever to be observed. There is background information, latest theories about the effects of the collision, and even some animations of Jupiter and the impact.

comfort index estimate of how tolerable conditions are for humans in hot climates. It is calculated as the temperature in degrees Fahrenheit plus a quarter of the relative humidity, expressed as a percentage. If the sum is less than 95, conditions are tolerable for those unacclimatized to the tropics.

comfrey any of a group of plants belonging to the borage family, with rough, hairy leaves and small bell-shaped flowers (blue, purple-pink, or white). They are found in Europe and W Asia. (Genus *Symphytum*, family Boraginaceae.)

The European species (*Symphytum officinale*) was once used to make ointment for treating wounds and various ailments, and is still sometimes used as a poultice which is applied to the skin to treat inflammation. It grows up to 1.2 m/4 ft tall and has hairy,

Comet Hale-Bopp

BY CHARLES ARTHUR

The appearance of the Hale-Bopp comet in the skies of the northern hemisphere in February 1997 excited scientists and the public alike; but nobody could have foreseen that by the time it had disappeared from our skies, 41 people would have taken their lives because of its presence.

Comets throughout history

Comets have been viewed as harbingers of doom for thousands of years: their inexplicable appearance in an otherwise orderly sky perplexed ancient astronomers. Now they are known to be chunks of rock, dust, ice, and other chemicals, following enormously elliptical orbits around the Sun, which take them within the Earth's orbit before they swing past into the darkness of space beyond the most distant planet, Pluto. As a comet nears the Sun, its body is heated by solar radiation causing some of its constituent chemicals to boil off into space, producing the characteristic 'tail'. This tail is pushed away from the Sun by the pressure of the 'solar wind': thus the tail's direction is not related to the direction of travel, only to the position of the Sun.

This elliptical orbit means that a comet travels through a regular path; each comet differs only in how long it takes to appear. Halley's Comet, for example, turns up every 76 years; its last visit was in 1986. In 1996, many people were disappointed when Comet Hyakutake, discovered by an amateur Japanese astronomer, turned out to be a drab show.

Hale-Bopp, also discovered by amateur astronomers, takes roughly 4,000 years to complete its orbit. It first became visible in the northern hemisphere in February 1997, because its orbit is tilted compared to ours – so that it approached from 'above' the plane of the solar system.

Ablaze in the night sky

Astronomers and the general public were delighted. 'The comet of the century', commented the scientists. It quickly became so bright that outside the light pollution of cities it was easily visible at night without telescopes or binoculars, and most notably early in the morning.

Beautiful time-lapse photographs – taken in deserts, over monuments such as Stonehenge (which was seeing the comet for at least the second time), and open country – filled newspapers, showing off its dual blue (dust) and yellow (gas) tails stretching for up to 20 million miles. It was, astronomers agreed, one of the brightest comets in the past 500 years. On the Internet, the discussion about the comet drew outlandish comments from some people – including some who said that the comet was being shadowed by a UFO that was hiding behind it in order to approach the Earth. Scientists laughed it off as the sort of misconception that can be commonplace on the global network. 'If I was in a UFO and

wanted to sneak up on earth, I wouldn't do it behind the most-watched celestial object for years', said one.

Comet Hale-Bopp grew brighter by the day. Its closest approach to the Earth was on 22 March, when it flew by just 123 million miles away from us; its closest approach to the Sun was on 1 April, when it was just 85 million miles away from it. (The Earth is 93 million miles from the Sun.)

Heaven's gate

However, on Wednesday, March 26, the idea that Hale-Bopp was simply a cosmic phenomenon all changed. It was late in the afternoon when San Diego police drove to a five-bedroom Spanish mansion at 18241 Colina Norte, after receiving two anonymous phone calls telling them to check on the residents.

They had no reason to be suspicious: anyone who knew the house had heard that it was the centre for a group of people who made their living programming Web pages for corporate customers: not unusual for San Diego.

Arriving there, the police found the front doors locked, the windows shut and blinds drawn. A side door was unlocked – and through there they found ten dead men on the floor. The bodies were already decomposing. In all, the corpses of 21 women and 18 men, passports and IDs tucked in the top pockets of their shirts, were discovered. It had been a mass suicide, timed to coincide with Hale-Bopp's closest approach to Earth.

Videotapes made by the suicides, who had dressed in matching black with crewcut hair, showed that despite the name of their business – WWW Higher Source – they were quite simply a cult. They believed their leader, who told them that the comet was really the cloak for a UFO; they believed the time had come to 'shed their earthly containers' (bodies) and regain their true identities as angels from another planet. They died in a mass suicide carried out in three waves over a period of days, using a mixture of alcohol and phenobarbital (swallowed with pudding or apple sauce) and plastic bags over their heads; the last survivors took the bags off the earlier dead and draped them with purple scarves. Each had videotaped a statement saying they were 'going to a better place'. The cult called themselves 'Heaven's Gate', and had its own Web site, which had been crammed with invisible text to give it a high profile on the Internet for anyone searching for information about UFOs. The site invited people to join them in their mission. Sadly, two more people did, committing suicide in April and May, in the belief that they would join the group in leaving on the comet.

Yet away from the obsessed, the comet brought good news to makers of binoculars and telescopes, and of camera tripods: people wanted to get pictures of the comet of the century. Undoubtedly, it fulfilled all expectations.

winged stems, lanceolate (tapering) leaves, and white, yellowish, purple, or pink flowers in drooping clusters.

Comité Consultatif International Téléphonique et Télégraphique (CCITT) international organization that determines international communications standards and protocols for data communications, including fax. It was subsumed into the International Telecommunications Union (ITU) in 1993.

Natura non nisi parendo vincitur.
Nature, to be commanded, must be obeyed.

FRANCIS BACON English politician, philosopher, and essayist.
Novum Organum 1620 Aphorism 43

command language in computing, a set of commands and the rules governing their use, by which users control a program. For example, an operating system may have commands such as SAVE and DELETE, or a payroll program may have commands for adding and amending staff records.

command line interface (CLI) in computing, a character-based interface in which a prompt is displayed on the screen at which the user types a command, followed by carriage return, at which point the command, if valid, is executed.

commensalism in biology, a relationship between two species whereby one (the commensal) benefits from the association, whereas the other neither benefits nor suffers. For example, certain species of millipede and silverfish inhabit the nests of army ants and live by scavenging on the refuse of their hosts, but without affecting the ants.

Commercial Internet eXchange (CIX) US-based international nonprofit-making organization of Internet Service Providers and other data network suppliers. It is part of the Internet's US backbone funded by commercial service providers.

Common Agricultural Policy (CAP) system of financial support for farmers in European Union (EU) countries. The most important way in which EU farmers are supported is through guaranteeing them minimum prices for part of what they produce. The CAP has been criticized for its role in creating overproduction, and consequent environmental damage, and for the high price of food subsidies. **aims** The CAP permits the member countries of the EU jointly to organize and control agricultural production within their boundaries. The objectives of the CAP were outlined in the Treaty of Rome: to increase agricultural productivity, to provide a fair standard of living for farmers and their employees, to stabilize markets, and to assure the availability of supply at a price that was reasonable to the consumer.

history The policy, applied to most types of agricultural product, was evolved and introduced between 1962 and 1967, and has since been amended to take account of changing conditions and the entry of additional member states. At the heart of the CAP is a price support system based on setting a target price for a commodity, imposing a levy on cheaper imports, and intervening to buy produce at a predetermined level to maintain the stability of the internal market. When the CAP was devised, the six member states were net importers of most essential agricultural products, and the intervention mechanism was aimed at smoothing out occasional surpluses caused by an unusually productive season.

overproduction The CAP became extremely expensive in the 1970s and 1980s due to overproduction of those agricultural products that were subsidized. In many years, far more was produced than could be sold and it had to be stored, creating 'mountains' and 'lakes' of produce. This put the CAP under intense financial and political strain, and led to mounting pressure for reform.

common denominator denominator that is a common multiple of, and hence exactly divisible by, all the denominators of a set of fractions, and which therefore enables their sums or differences to be found.

For example, $\frac{2}{3}$ and $\frac{3}{4}$ can both be converted to equivalent fractions of denominator 12, $\frac{2}{3}$ being equal to $\frac{8}{12}$ and $\frac{3}{4}$ to $\frac{9}{12}$. Hence their sum is $\frac{17}{12}$ and their difference is $\frac{1}{12}$. The lowest common denominator (lcd) is the smallest common multiple of the denominators of a given set of fractions.

common difference the difference between any number and the next in an arithmetic progression. For example, in the set 1, 4, 7, 10, ..., the common difference is 3.

common factor number that will divide two or more others without leaving a remainder. For example, 3 is a common factor of 15, 21, and 24.

common gateway interface (CGI) on the World Wide Web, a facility for adding scripts to handle user input. It allows a Web server to communicate with other programs running on the same server in order to process data input by visitors to the Web site. CGI scripts 'parse' the input data, identifying each element and feeding it to the correct program for action, normally a search engine or e-mail program. The results are then fed back to the user in the form of search results or sent e-mail.

common logarithm another name for a logarithm to the base ten.

comms program contraction of communications program.

communication in biology, the signalling of information by one organism to another, usually with the intention of altering the recipient's behaviour. Signals used in communication may be visual (such as the human smile or the display of colourful plumage in birds), auditory (for example, the whines or barks of a dog), olfactory (such as the odours released by the scent glands of a deer), electrical (as in the pulses emitted by electric fish), or tactile (for example, the nuzzling of male and female elephants).

What hath God wrought?

SAMUEL FINLEY BREESE MORSE US inventor.

First message sent on his electric telegraph 24 May 1844

communications in computing, see data communications.

Communications Decency Act 1996 rider (supplement) to the US Telecommunications Bill seeking to prohibit the transmission of indecent material to minors via the Internet.

Within hours of the bill's passage into law on 8 February 1996, suits were filed by 46 plaintiffs including the American Civil Liberties Union, Voter Telecom Watch, the Electronic Frontier Foundation, and the Center for Democracy and Technology to block the law's enforcement. On 12 June the Philadelphia federal court struck the law down with a judgement that read in part: 'Just as the strength of the Internet is chaos, so the strength of our liberty depends upon the chaos and cacophony of the unfettered speech the First Amendment (to the US Constitution) protects'. A second judgement from a New York court agreed. The government was expected to appeal both rulings to the Supreme Court.

communications program or **comms program** general-purpose program for accessing older online systems and bulletin board systems which use a command-line interface; also known as a terminal emulator.

Most operating systems include a trimmed-down comms program, but full-featured programs include facilities to store phone numbers and settings for frequently called services, address books, and the ability to write scripts to automate logging on. Popular comms programs include ProComm, Smartcom, Qmodem, and Odyssey.

communications satellite relay station in space for sending telephone, television, telex, and other messages around the world. Messages are sent to and from the satellites via ground stations. Most communications satellites are in geostationary orbit, appearing to hang fixed over one point on the Earth's surface.

The first satellite to carry TV signals across the Atlantic Ocean was *Telstar* in July 1962. The world is now linked by a system of communications satellites called Intelsat. Other satellites are used by individual countries for internal communications, or for business or military use. A new generation of satellites, called direct broadcast satellites, are powerful enough to transmit direct to small domestic aerials. The power for such satellites is produced by solar cells (see solar energy). The total energy requirement of a satellite is small; a typical communications satellite needs about 2 kW of power, the same as an electric heater.

community in ecology, an assemblage of plants, animals, and other organisms living within a circumscribed area. Communities are usually named by reference to a dominant feature such as characteristic plant species (for example, a beech-wood community), or a prominent physical feature (for example, a freshwater-pond community).

commutative operation in mathematics, an operation that is independent of the order of the numbers or symbols concerned. For example, addition is commutative: the result of adding 4 + 2 is the same as that of adding 2 + 4; subtraction is not as 4 - 2 = 2, but 2 - 4 = -2. Compare associative operation and distributive operation.

commutator device in a DC (direct-current) electric motor that reverses the current flowing in the armature coils as the armature rotates.

A DC generator, or dynamo, uses a commutator to convert the AC (alternating current) generated in the armature coils into DC. A commutator consists of opposite pairs of conductors insulated from one another, and contact to an external circuit is provided by carbon or metal brushes.

compact disc (CD) disc for storing digital information, about 12 cm/4.5 in across, mainly used for music, when it can have over an hour's playing time. The compact disc is etched by a laser beam

compensation point in biology, the point at which there is just enough light for a plant to survive. At this point all the food produced by photosynthesis is used up by respiration. For aquatic plants, the compensation point is the depth of water at which there is just enough light to sustain life (deeper water = less light = less photosynthesis).

competition in ecology, the interaction between two or more organisms, or groups of organisms (for example, species), that use a common resource which is in short supply. Competition invariably results in a reduction in the numbers of one or both competitors, and in evolution contributes both to the decline of certain species and to the evolution of adaptations.

Thus plants may compete with each other for sunlight, or nutrients from the soil, while animals may compete amongst themselves for food, water, or refuge.

compiler computer program that translates programs written in a high-level language into machine code (the form in which they can be run by the computer). The compiler translates each high-level instruction into several machine-code instructions – in a process called compilation – and produces a complete independent program that can be run by the computer as often as required, without the original source program being present.

Different compilers are needed for different high-level languages and for different computers. In contrast to using an interpreter, using a compiler adds slightly to the time needed to develop a new program because the machine-code program must be recompiled after each change or correction. Once compiled, however, the machine-code program will run much faster than an interpreted program.

complement in mathematics, the set of the elements within the universal set that are not contained in the designated set. For example, if the universal set is the set of all positive whole numbers and the designated set S is the set of all even numbers, then the complement of S (denoted S^c) is the set of all odd numbers.

complementary angles two angles that add up to 90° .

complementary medicine in medicine, systems of care based on methods of treatment or theories of disease that differ from those taught in most western medical schools. See (medicine, (alternative.

complementary metal-oxide semiconductor (CMOS) in electronics, a particular way of manufacturing integrated circuits (chips). The main advantage of CMOS chips is their low power requirement and heat dissipation, which enables them to be used in electronic watches and portable microcomputers. However, CMOS circuits are expensive to manufacture and have lower operating speeds than have circuits of the (transistor-transistor logic (TTL) family.

complementary number in number theory, the number obtained by subtracting a number from its base. For example, the complement of 7 in numbers to base 10 is 3. Complementary numbers are necessary in computing, as the only mathematical operation of which digital computers (including pocket calculators) are directly capable is addition. Two numbers can be subtracted by adding one number to the complement of the other; two numbers can be divided by using successive subtraction (which, using complements, becomes successive addition); and multiplication can be performed by using successive addition.

complementation in genetics, the interaction that can occur between two different mutant alleles of a gene in a (diploid organism, to make up for each other's deficiencies and allow the organism to function normally.

completing the square method of converting a quadratic expression such as $x^2 + px + q$ into a perfect square by adding $\frac{p^2}{4}$ and subtracting $\frac{p^2}{4}$ in order to solve the quadratic equation $x^2 + px + q = 0$. The steps are:

$$\begin{aligned}x^2 + px &= -q \\x^2 + px + \frac{p^2}{4} &= \frac{p^2}{4} - q\end{aligned}$$

$$(x^2 + \frac{p}{2})^2 = \frac{p^2}{4} - q$$

$$x + \frac{p}{2} = \pm \sqrt{\frac{p^2}{4} - q}$$

$$x = -\frac{p}{2} \pm \sqrt{\frac{p^2}{4} - q}$$

complex in psychology, a group of ideas and feelings that have become repressed because they are distasteful to the person in whose mind they arose, but are still active in the depths of the person's unconscious mind, continuing to affect his or her life and actions, even though he or she is no longer fully aware of their existence. Typical examples include the (Oedipus complex and the (inferiority complex.

complex number in mathematics, a number written in the form $a + ib$, where a and b are (real numbers and i is the square root of -1 (that is, $i^2 = -1$); i used to be known as the 'imaginary' part of the complex number. Some equations in algebra, such as those of the form $x^2 + 5 = 0$, cannot be solved without recourse to complex numbers, because the real numbers do not include square roots of negative numbers.

The sum of two or more complex numbers is obtained by adding separately their real and imaginary parts, for example:

$$(a + bi) + (c + di) = (a + c) + (b + d)i$$

Complex numbers can be represented graphically on an Argand diagram, which uses rectangular (Cartesian) coordinates in which the x -axis represents the real part of the number and the y -axis the imaginary part. Thus the number $z = a + bi$ is plotted as the point (a, b) . Complex numbers have applications in various areas of science, such as the theory of alternating currents in electricity.

complex number A complex number can be represented graphically as a line whose end-point coordinates equal the real and imaginary parts of the complex number. This type of diagram is called an Argand diagram after the French mathematician Jean Argand (1768-1822) who devised it.

component in physics, one of two or more vectors, normally at right angles to each other, that add together to produce the same effect as a single resultant vector. Any (vector quantity, such as force, velocity, or electric field, can be resolved into components chosen for ease of calculation. For example, the weight of a body resting on a slope can be resolved into two force components (see (resolution of forces); one normal to the slope and the other parallel to the slope.

COM port (contraction of **communication port**) on a personal computer (PC), one of the serial (ports through which (data communications take place. PCs may have up to four COM ports. However, these cannot all be used simultaneously as COM1 and COM3 share an (interrupt, as do COM2 and COM4. A modem added to a machine with a mouse on COM1 must be attached to COM2 or COM4.

Compositae daisy family, comprising dicotyledonous flowering plants characterized by flowers borne in composite heads (see (capitulum). It is the largest family of flowering plants, the majority being herbaceous. Birds seem to favour the family for use in nest 'decoration', possibly because many species either repel or kill insects (see (pyrethrum). Species include the daisy and dandelion; food plants such as the artichoke, lettuce, and safflower; and the garden varieties of chrysanthemum, dahlia, and zinnia.

composite in industry, any purpose-designed engineering material created by combining materials with complementary properties into a composite form. Most composites have a structure in which one component consists of discrete elements, such as fibres, dispersed in a continuous matrix. For example, lengths of asbestos, glass, or carbon steel, or 'whiskers' (specially grown crystals a few millimetres long) of substances such as silicon carbide may be dispersed in plastics, concrete, or steel.

composite function in mathematics, a function made up of two or more other functions carried out in sequence, usually denoted by $*$ or $^{\wedge}$, as in the relation $(f * g) x = f(g(x))$.

Usually, composition is not commutative: $(f * g)$ is not necessarily the same as $(g * f)$.

compost organic material decomposed by bacteria under controlled conditions to make a nutrient-rich natural fertilizer for use in gardening or farming. A well-made compost heap reaches a high temperature during the composting process, killing most weed seeds that might be present.

compound chemical substance made up of two or more elements bonded together, so that they cannot be separated by physical means. Compounds are held together by ionic or covalent bonds.

compound document in Windows, a document containing elements that have been created using other programs. Usually managed through a word processor, such a document might include a table created in a spreadsheet and pictures created in a drawing program. These items may be linked using object linking and embedding (OLE), so that any changes made to the table in the word processor will also be made to the original table developed in the spreadsheet.

Compressed Serial Line Internet Protocol in computing, protocol usually abbreviated to CSLIP.

compression in computing, see data compression.

compressor machine that compresses a gas, usually air, commonly used to power pneumatic tools, such as road drills, paint sprayers, and dentist's drills.

Reciprocating compressors use pistons moving in cylinders to compress the air. Rotary compressors use a varied rotor moving eccentrically inside a casing. The air compressor in jet and gas

turbine engines consists of a many-varied rotor rotating at high speed within a fixed casing, where the rotor blades slot between fixed, or stator, blades on the casing.

Compton effect in physics, the increase in wavelength (loss of energy) of a photon by its collision with a free electron (Compton scattering). The Compton effect was first demonstrated with X-rays and provided early evidence that electromagnetic waves consisted of particles – photons – which carried both energy and momentum. It is named after US physicist Arthur Compton.

Compulink Information eXchange (CIX) London-based electronic conferencing system founded in 1987. Owned by Frank and Sylvia Thornley, CIX is the oldest and largest native British conferencing system. In 1996 it had approximately 16,000 users, including most of the country's technology journalists.

CompuServe large (US-based) public online information service. It is widely used for electronic mail and bulletin boards, as well as gateway access to large periodical databases.

CompuServe was established in 1979. It is easier to use than the Internet and most computer hardware and software suppliers provide support for their products on CompuServe. Worldwide subscribers to CompuServe have risen from half a million in 1988 to about 5.2 million in 1997. CompuServe started moving some of its services to the World Wide Web in 1996 and was taken over by rival America Online in 1997.

COMPUTER MUSEUM

<http://www.net.org/>

Well-designed interactive museum, examining the history, development, and future of computer technology. As well as plenty of illustrations and detailed explanations, it is possible to change your route through the museum by indicating whether you are a kid, student, adult, or educator.

computer programmable electronic device that processes data and performs calculations and other symbol-manipulation tasks. There are three types: the digital computer, which manipulates information coded as binary numbers (see binary number

computer A mainframe computer. Functionally, it has the same component parts as a microcomputer, but on a much larger scale. The central processing unit is at the hub, and controls all the attached devices.

Computer: chronology

| | | | |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1614 | John Napier invented logarithms. | 1963 | The first minicomputer was built by Digital Equipment (DEC). The first electronic calculator was built by Bell Punch Company. |
| 1615 | William Oughtred invented the slide rule. | 1964 | Launch of IBM System/360, the first compatible family of computers. John Kemeny and Thomas Kurtz of Dartmouth College invented BASIC (Beginner's All-purpose Symbolic Instruction Code), a computer language similar to FORTRAN. |
| 1623 | Wilhelm Schickard (1592-1635) invented the mechanical calculating machine. | 1965 | The first supercomputer, the Control Data CD6600, was developed. |
| 1645 | Blaise Pascal produced a calculator. | 1971 | The first microprocessor, the Intel 4004, was announced. |
| 1672-74 | Gottfried Leibniz built his first calculator, the Stepped Reckoner. | 1974 | CLIP-4, the first computer with a parallel architecture, was developed by John Backus at IBM. |
| 1801 | Joseph-Marie Jacquard developed an automatic loom controlled by punch cards. | 1975 | Altair 8800, the first personal computer (PC), or microcomputer, was launched. |
| 1820 | The first mass-produced calculator, the Arithmometer, was developed by Charles Thomas de Colmar (1785-1870). | 1981 | The Xerox Star system, the first WIMP system (acronym for windows, icons, menus, and pointing devices), was developed by IBM. |
| 1822 | Charles Babbage completed his first model for the difference engine. | 1984 | Apple launched the Macintosh computer. |
| 1830s | Babbage created the first design for the analytical engine. | 1985 | The Immos T414 transporter, the first 'off-the-shelf' microprocessor for building parallel computers, was announced. |
| 1890 | Herman Hollerith developed the punched-card ruler for the US census. | 1988 | The first optical microprocessor, which uses light instead of electricity, was developed. |
| 1936 | Alan Turing published the mathematical theory of computing. | 1989 | Wafer-scale silicon memory chips, able to store 200 million characters, were launched. |
| 1938 | Konrad Zuse constructed the first binary calculator, using Boolean algebra. | 1990 | Microsoft released Windows 3, a popular windowing environment for PCs. |
| 1939 | US mathematician and physicist J.V. Atanasoff (1903-1995) became the first to use electronic means for mechanizing arithmetical operations. | 1992 | Philips launched the CDD (Compact Disc Interactive) player, based on CD audio technology, to provide interactive multimedia programs for the home user. |
| 1943 | The Colossus electronic code-breaker was developed at Bletchley Park, England. The Harvard University Mark I or Automatic Sequence Controlled Calculator (partly financed by IBM) became the first program-controlled calculator. | 1993 | Intel launched the Pentium chip containing 3.1 million transistors and capable of 100 MIPS (millions of instructions per second). The Personal Digital Assistant (PDA), which recognizes user's handwriting, went on sale. |
| 1946 | ENIAC (acronym for electronic numerator, integrator, analyser, and computer), the first general purpose, fully electronic digital computer, was completed at the University of Pennsylvania, USA. | 1995 | Intel launched the Pentium Pro microprocessor (formerly codenamed P6). |
| 1948 | Manchester University (England) Mark I, the first stored-program computer, was completed. William Shockley of Bell Laboratories invented the transistor. | 1996 | IBM's computer Deep Blue beat grand master Gary Kasparov at chess, the first time a computer has beaten a human grand master. |
| 1951 | Launch of Ferranti Mark I, the first commercially produced computer. Whirlwind, the first real-time computer, was built for the US air-defence system. Grace Murray Hopper of Remington Rand invented the compiler computer program. | 1997 | In the USA, an attempt to bring legislation to control the Internet, intended to prevent access to sexual material, is rejected as unconstitutional. |
| 1952 | EDVAC (acronym for electronic discrete variable computer) was completed at the Institute for Advanced Study, Princeton, USA (by John Von Neumann and others). | | |
| 1953 | Magnetic core memory was developed. | | |
| 1958 | The first integrated circuit was constructed. | | |

system); the analogue computer, which works with continuously varying quantities; and the hybrid computer, which has characteristics of both analogue and digital computers.

There are four types of digital computer, corresponding roughly to their size and intended use. **Microcomputers** are the smallest and most common, used in small businesses, at home, and in schools. They are usually single-user machines. **Minicomputers** are found in medium-sized businesses and university departments. They may support from around 10 to 200 users at once. **Mainframes**, which can often service several hundred users simultaneously, are found in large organizations, such as national companies and government departments. **Supercomputers** are mostly used for highly complex scientific tasks, such as analysing the results of nuclear physics experiments and weather forecasting.

We do not need to have an infinity of different machines doing different jobs. A single one will suffice. The engineering problem of producing various machines for various jobs is replaced by the office work of 'programming' the universal machine to do these jobs.

ALAN MATHISON TURING English mathematician.

Quoted in A Hodges *Alan Turing: The Enigma of Intelligence* 1985

computer-aided design use of computers to create and modify design drawings; see CAD.

computer-aided manufacturing use of computers to regulate production processes in industry; see CAM.

computer art art produced with the help of a computer.

Since the 1950s the aesthetic use of computers has been increasingly evident in most artistic disciplines, including film animation, architecture, and music. Computer graphics has been the most developed area, with the 'paint-box' computer liberating artists from the confines of the canvas. It is now also possible to programme computers in advance to generate graphics, music, and sculpture, according to 'instructions' which may include a preprogrammed element of unpredictability. In this last function, computer technology has been seen as a way of challenging the elitist nature of art by putting artistic creativity within relatively easy reach of anyone owning a computer.

computer-assisted learning use of computers in education and training; see CAL.

computer-assisted reporting use of computers to do journalistic research. At its simplest, computer-assisted reporting involves searching an online database for basic information such as addresses and phone numbers. At their most sophisticated, computer systems allow journalists to sift through large quantities of

data to find patterns of behaviour or connections that would not be visible by other means.

computer crime broad term applying to any type of crime committed via a computer, including unauthorized access to files. Most computer crime is committed by disgruntled former employees or subcontractors. Examples include the releasing of viruses, hacking, and computer fraud. Many countries, including the USA and the UK, have specialized law enforcement units to supply the technical knowledge needed to investigate computer crime.

Computer Emergency Response Team (CERT) team of engineers based at Carnegie-Mellon University in Pittsburgh, Pennsylvania, USA, that issues security advice and helps resolve emergencies on the Internet by providing technical expertise.

In 1996 the US government announced the formation of a national emergency response team.

computer engineer job classification for computer personnel. A computer engineer repairs and maintains computer hardware.

computer game or **video game** any computer-controlled game in which the computer (sometimes) opposes the human player. Computer games typically employ fast, animated graphics on a VDU (visual display unit) and synthesized sound.

Commercial computer games became possible with the advent of the microprocessor in the mid-1970s and rapidly became popular as amusement-arcade games, using dedicated chips. Available games range from chess to fighter-plane simulations.

Some of the most popular computer games in the early 1990s were id Software's *Wolfenstein 3D* and *Doom*, which were designed to be played across networks including the Internet. A whole subculture built up around those particular games, as users took advantage of id's help to create their own additions to the game.

The computer games industry has been criticized for releasing many violent games with little intellectual content.

computer generation any of the five broad groups into which computers may be classified: first generation the earliest computers, developed in the 1940s and 1950s, made from valves and wire circuits; second generation from the early 1960s, based on transistors and printed circuits; third generation from the late 1960s, using integrated circuits and often sold as families of computers, such as the IBM 360 series; fourth generation using microprocessors, large-scale integration (LSI), and sophisticated programming languages, still in use in the 1990s; and fifth generation based on parallel processing and very large-scale integration, currently under development.

computer graphics use of computers to display and manipulate information in pictorial form. Input may be achieved by scanning an image, by drawing with a mouse or stylus on a graphics tablet, or by drawing directly on the screen with a light pen.

The output may be as simple as a pie chart, or as complex as an animated sequence in a science-fiction film, or a seemingly three-dimensional engineering blueprint. The drawing is stored in the computer as raster graphics or vector graphics.

Vector graphics are stored in the computer memory by using geometric formulas. They can be transformed (enlarged, rotated, stretched, and so on) without loss of picture resolution. It is also possible to select and transform any of the components of a vector-graphics display because each is separately defined in the computer memory. In these respects vector graphics are superior to raster graphics. They are typically used for drawing applications, allowing the user to create and modify technical diagrams such as designs for houses or cars.

Raster graphics are stored in the computer memory by using a map to record data (such as colour and intensity) for every pixel that makes up the image. When transformed (enlarged, rotated, stretched, and so on), raster graphics become ragged and suffer loss of picture resolution, unlike vector graphics. They are typically used for painting applications, which allow the user to create artwork on a computer screen much as if they were painting on paper or canvas.

Computer graphics are increasingly used in computer-aided design (CAD), and to generate models and simulations in engineering, meteorology, medicine and surgery, and other fields of science.

computerized axial tomography medical technique, usually known as CAT scan, for noninvasive investigation of disease or injury.

computer-mediated communication umbrella term for all types of communication via computers, such as electronic conferencing and chat.

Computer Misuse Act British law passed in 1990 which makes it illegal to hack into computers (see hacking). The first prosecution under the Act was that of British hacker Paul Bedworth, who in 1993 was acquitted on the grounds that he was addicted to computing.

computer numerical control control of machine tools, most often milling machines, by a computer. The pattern of work for the machine to follow, which often involves performing repeated sequences of actions, is described using a special-purpose programming language.

computer operator job classification for computer personnel. Computer operators work directly with the computer, running the programs, changing discs and tapes, loading paper into printers, and ensuring all data security procedures are followed.

computer output on microfilm/microfiche (COM) technique for producing computer output in very compact, photographically reduced form (microform).

computer personnel people who work with or are associated with computers. In a large computer department the staff may work under the direction of a **data processing manager**, who supervises and coordinates the work performed. Computer personnel can be broadly divided into two categories: those who run and maintain existing applications programs (programs that perform a task for the benefit of the user) and those who develop new applications.

Personnel who run existing applications programs: **data control staff** receive information from computer users (for instance, from the company's wages clerks), ensure that it is processed as required, and return it to them in processed form; **data preparation staff**, or **keyboard operators**, prepare the information received by the data control staff so that it is ready for processing by computer. Once the information has been typed at the keyboard of a VDU (or at a key-to-disc or key-to-tape station), it is placed directly onto a medium such as disc or tape; **computer operators** work directly with computers, running the programs, changing discs and tapes, loading paper into printers, and ensuring that all data security procedures are followed; **computer engineers** repair and maintain computer hardware; **file librarians**, or **media librarians**, store and issue the data files used by the department; an **operations manager** coordinates all the day-to-day activities of these staff. Personnel who develop new applications: **systems analysts** carry out the analysis of an existing system (see systems analysis), whether already computerized or not, and prepare proposals for a new system; **programmers** write the software needed for new systems.

Computer Professionals for Social Responsibility (CPSR) US organization advocating the responsible use of computers. Based in Washington DC, it was one of the first organizations to oppose President Reagan's Strategic Defense Initiative on the grounds that the many billions of lines of code it would take to program it could never be debugged successfully.

computer program coded instructions for a computer; see program.

computer simulation representation of a real-life situation in a computer program. For example, the program might simulate the flow of customers arriving at a bank. The user can alter variables, such as the number of cashiers on duty, and see the effect.

More complex simulations can model the behaviour of chemical reactions or even nuclear explosions. The behaviour of solids and liquids at high temperatures can be simulated using quantum simulation. Computers also control the actions of machines - for example, a flight simulator models the behaviour of real aircraft

and allows training to take place in safety. Computer simulations are very useful when it is too dangerous, time consuming, or simply impossible to carry out a real experiment or test.

computer-supported collaborative work (CSCW) work undertaken by individuals who, using computers, are able to function together as a group on a project despite being geographically separated. The technology to facilitate CSCW is still under development. Early initiatives include video and data conferencing so that two users can talk on the telephone while simultaneously viewing a document in progress. Changes made by either participant affect both participants' displays.

computer terminal the device whereby the operator communicates with the computer; see *terminal*.

Computer Underground Digest widely distributed e-zine covering such issues as hacking, freedom of speech, and security risks.

computing device any device built to perform or help perform computations, such as the abacus, slide rule, or computer.

The earliest known example is the abacus. Mechanical devices with sliding scales (similar to the slide rule) date from ancient Greece. In 1642, French mathematician Blaise Pascal built a mechanical adding machine and in 1671 German mathematician Gottfried Leibniz produced a machine to carry out multiplication. The first mechanical computer, the analytical engine, was designed by British mathematician Charles Babbage in 1835. For the subsequent history of computing, see *computer*.

concave of a surface, curving inwards, or away from the eye. For example, a bowl appears concave when viewed from above. In geometry, a concave polygon is one that has an interior angle greater than 180°. Concave is the opposite of *convex*.

concave lens lens that possesses at least one surface that curves inwards. It is a diverging lens, spreading out those light rays that have been refracted through it. A concave lens is thinner at its centre than at its edges, and is used to correct short-sightedness.

Common forms include the biconcave lens (with both surfaces curved inwards) and the plano-concave (with one flat surface and one concave). The whole lens may be further curved overall, making a *convexo-concave* or diverging meniscus lens, as in some lenses used for corrective purposes.

concave mirror curved mirror that reflects light from its inner surface. It may be either circular or parabolic in section. A concave mirror converges light rays to form a reduced, inverted, real image in front, or an enlarged, upright, virtual image seemingly behind it, depending on how close the object is to the mirror.

Only a parabolic concave mirror has a true, single-point principal focus for parallel rays. For this reason, parabolic mirrors are used as reflectors to focus light in telescopes, or to focus microwaves in satellite communication systems. The reflector behind a spot lamp or car headlamp is parabolic.

concentration in chemistry, the amount of a substance (solute) present in a specified amount of a solution. Either amount may be specified as a mass or a volume (liquids only). Common units used are moles per cubic decimetre, grams per cubic decimetre, grams per 100 cubic centimetres, and grams per 100 grams.

The term also refers to the process of increasing the concentration of a solution by removing some of the substance (solvent) in which the solute is dissolved. In a **concentrated solution**, the solute is present in large quantities. Concentrated brine is around 30% sodium chloride in water; concentrated caustic soda (caustic liquor) is around 40% sodium hydroxide; and concentrated sulphuric acid is 98% acid.

concentration gradient change in the concentration of a substance from one area to another. Particles, such as sugar molecules, in a fluid move over time so that they become evenly distributed throughout the fluid. In particular, they move from an area of high concentration to an area of low concentration; that is, they diffuse along the concentration gradient (see *diffusion*).

This explains why oxygen in the lungs will diffuse into the blood

supply. The oxygen molecules are more concentrated in the lungs than they are in the capillaries surrounding the alveoli (air sacs). As it diffuses along the concentration gradient, oxygen will tend to pass into the blood. Gas exchange therefore depends on the maintenance of a concentration gradient, so that oxygen will continue to diffuse across the respiratory surface.

concentric circles two or more circles that share the same centre.

conceptacle flask-shaped cavities found in the swollen tips of certain brown seaweeds, notably the wracks, *Fucus*. The gametes are formed within them and released into the water via a small pore in the conceptacle, known as an ostiole.

conch name applied to various shells, but especially to the fountain shell, a species of gastropod mollusc in the order Mesogastropoda.

conchology branch of zoology that studies molluscs with reference to their shells.

Concorde the only supersonic airliner, which cruises at Mach 2, or twice the speed of sound, about 2,170 kph/1,350 mph. Concorde, the result of Anglo-French cooperation, made its first flight 1969 and entered commercial service seven years later. It is 62 m/202 ft long and has a wing span of nearly 26 m/84 ft. Developing Concorde cost French and British taxpayers £2 billion.

concrete building material composed of cement, stone, sand, and water. It has been used since Egyptian and Roman times. Since the late 19th century, it has been increasingly employed as an economical alternative to materials such as brick and wood, and has been combined with steel to increase its tension capacity.

Reinforced concrete and prestressed concrete are strengthened by combining concrete with another material, such as steel rods or glass fibres. The addition of carbon fibres to concrete increases its conductivity. The electrical resistance of the concrete changes with increased stress or fracture, so this 'smart concrete' can be used as an early indicator of structural damage.

concurrent lines two or more lines passing through a single point; for example, the diameters of a circle are all concurrent at the centre of the circle.

concussion temporary unconsciousness resulting from a blow to the head. It is often followed by amnesia for events immediately preceding the blow.

condensation conversion of a vapour to a liquid. This is frequently achieved by letting the vapour come into contact with a cold surface. It is the process by which water vapour turns into fine water droplets to form cloud.

Condensation in the atmosphere occurs when the air becomes completely saturated and is unable to hold any more water vapour. As air rises it cools and contracts – the cooler it becomes the less water it can hold. Rain is frequently associated with warm weather fronts because the air rises and cools, allowing the water vapour to condense as rain. The temperature at which the air becomes saturated is known as the dew point. Water vapour will not condense in air if there are not enough condensation nuclei (particles of dust, smoke or salt) for the droplets to form on. It is then said to be supersaturated. Condensation is an important part of the water cycle.

condensation in organic chemistry, a reaction in which two organic compounds combine to form a larger molecule, accompanied by the removal of a smaller molecule (usually water). This is also known as an addition-elimination reaction. Polyamides (such as nylon) and polyesters (such as Terylene) are made by condensation polymerization.

condensation number in physics, the ratio of the number of molecules condensing on a surface to the total number of molecules touching that surface.

condensation polymerization polymerization reaction in which one or more monomers, with more than one reactive func-

tional group, combine to form a polymer with the elimination of water or another small molecule.

condenser laboratory apparatus used to condense vapours back to liquid so that the liquid can be recovered. It is used in distillation and in reactions where the liquid mixture can be kept boiling without the loss of solvent.

condenser in electronic circuits, a former name for a capacitor.

condenser in optics, a lens or combination of lenses with a short focal length used for concentrating a light source onto a small area, as used in a slide projector or microscope substage lighting unit. A condenser can also be made using a concave mirror.

conditioning in psychology, two major principles of behaviour modification.

In classical conditioning, described by Russian psychologist Ivan Pavlov, a new stimulus can evoke an automatic response by being repeatedly associated with a stimulus that naturally provokes that response. For example, the sound of a bell repeatedly associated with food will eventually trigger salivation, even if sounded without food being presented. In operant conditioning, described by US psychologists Edward Lee Thorndike (1874-1949) and B F Skinner, the frequency of a voluntary response can be increased by following it with a reinforcer or reward.

School yourself to demureness and patience. Learn to inure yourself to drudgery in science. Learn, compare, collect the facts.

IVAN PAVLOV Russian physiologist.

Bequest to the Academic Youth of Soviet Russia 27 Feb 1936

condom or **sheath** or **prophylactic** barrier contraceptive, made of rubber, which fits over an erect penis and holds in the sperm produced by ejaculation. It is an effective means of preventing pregnancy if used carefully, preferably with a spermicide. A condom with spermicide is 97% effective; one without spermicide is 85% effective as a contraceptive. Condoms can also give some protection against sexually transmitted diseases, including AIDS.

In 1996 the European Union agreed a standard for condoms, which is 17 cm/6.7 in long; although the width can be variable, a regular width was agreed as 5.2 cm/2 in.

condor name given to two species of birds in separate genera. The Andean condor *Vultur gryphus*, has a wingspan up to 3 m/10 ft, weighs up to 13 kg/28 lb, and can reach up to 1.2 m/3.8 ft in length. It is black, with some white on the wings and a white frill at the base of the neck. It lives in the Andes at heights of up to 4,500 m/14,760 ft, and along the South American coast, and feeds mainly on carrion. The Californian condor *Gymnogyps californianus* is a similar bird, with a wingspan of about 3 m/10 ft. It feeds entirely on carrion, and is on the verge of extinction.

The Californian condor lays only one egg at a time and may not breed every year. In 1994, only 89 Californian condors remained, of which only four were in the wild. It became the subject of a special conservation effort, and by July 1995 the number had increased to 104.

conductance ability of a material to carry an electrical current, usually given the symbol G . For a direct current, it is the reciprocal of resistance: a conductor of resistance R has a conductance of $1/R$. For an alternating current, conductance is the resistance R divided by the impedance Z : $G = R/Z$. Conductance was formerly expressed in reciprocal ohms (or mhos); the SI unit is the siemens (S).

conduction, electrical flow of charged particles through a material giving rise to electric current. Conduction in metals involves the flow of negatively charged free electrons. Conduction in gases and some liquids involves the flow of ions that carry positive charges in one direction and negative charges in the other. Conduction in a semiconductor such as silicon involves the flow of electrons and positive holes.

TO REMEMBER THE PRINCIPLES OF HEAT TRANSFER:

CONDUCTION – IMAGINE A LINE OF PASSENGERS ON A BUS BEING ASKED TO MOVE DOWN BY THE CONDUCTOR, EACH PASSENGER CAUSING THE NEXT TO BUSTLE ALONG (ANALOGY FOR THE MOVEMENT/VIBRATION OF ATOMS THAT IS PASSED ALONG, CAUSING HEAT TO BE TRANSFERRED) **CONVECTION** – CONSIDER VECTOR, A DISEASE-CARRYING INSECT, FOR EXAMPLE A MOSQUITO, WHICH TRAVELS IN SWARMS (VERY MUCH LIKE THE MOVEMENT OF CONVECTION CURRENTS) **RADIATION** – HEAT RADIATION IS A FORM OF RADIATION – (THINK OF NUCLEAR FALLOUT OR THE SUN'S RADIATION) AND THUS TRAVELS IN WAVES UNDETECTED UNTIL THEY FALL UPON ANOTHER BODY

conduction, heat flow of heat energy through a material without the movement of any part of the material itself (compare convection, electrical). Heat energy is present in all materials in the form of the kinetic energy of their vibrating molecules, and may be conducted from one molecule to the next in the form of this mechanical vibration. In the case of metals, which are particularly good conductors of heat, the free electrons within the material carry heat around very quickly.

conductivity, thermal (unit $W\ m^{-1}\ K^{-1}$) measure of how well a material conducts heat. A good conductor, such as a metal, has a high conductivity; a poor conductor, called an insulator, has a low conductivity. See also ϕ -value.

conductor any material that conducts heat or electricity (as opposed to an insulator, or nonconductor). A good conductor has a high electrical or heat conductivity, and is generally a substance rich in free electrons such as a metal. A poor conductor (such as the nonmetals, glass and porcelain) has few free electrons. Carbon is exceptional in being nonmetallic and yet (in some of its forms) a relatively good conductor of heat and electricity. Substances such as silicon and germanium, with intermediate conductivities that are improved by heat, light, or impurities, are known as semiconductors.

cone in botany, the reproductive structure of the conifers and cycads; also known as a strobilus. It consists of a central axis surrounded by numerous, overlapping, scalelike, modified leaves

cone The western yellow or ponderosa pine *Pinus ponderosa* var. *arizonica* exhibits the needlelike leaves and cones typical of gymnosperms. These are female cones which have shed their seeds; male cones are smaller and shed vast quantities of pollen into the air. Premaphotos Wildlife

(sporophylls) that bear the reproductive organs. Usually there are separate male and female cones, the former bearing pollen sacs containing pollen grains, and the larger female cones bearing the ovules that contain the ova or egg cells. The pollen is carried from male to female cones by the wind (anemophily). The seeds develop within the female cone and are released as the scales open in dry atmospheric conditions, which favour seed dispersal.

In some groups (for example, the pines) the cones take two or even three years to reach maturity. The cones of junipers have fleshy cone scales that fuse to form a berrylike structure. One group of angiosperms, the alders, also bear conelike structures; these are the woody remains of the short female catkins, and they contain the alder fruits.

cone The volume and surface area of a cone are given by formulae involving a few simple dimensions.

cone in geometry, a solid or surface consisting of the set of all straight lines passing through a fixed point (the vertex) and the points of a circle or ellipse whose plane does not contain the vertex.

A circular cone of perpendicular height, with its apex above the centre of the circle, is known as a **right circular cone**; it is generated by rotating an isosceles triangle or framework about its line of symmetry. A right circular cone of perpendicular height h and base of radius r has a volume $V = \frac{1}{3}\pi r^2 h$.

The distance from the edge of the base of a cone to the vertex is called the slant height. In a right circular cone of slant height l , the curved surface area is πrl , and the area of the base is πr^2 . Therefore the total surface area $A = \pi rl + \pi r^2 = \pi r(l + r)$.

cone in zoology, type of light-sensitive cell found in the retina of the eye.

config.sys in computing, the configuration file used by the MS-DOS and OS/2 operating systems. It is read when the system is booted.

configuration in chemistry, the arrangement of atoms in a molecule or of electrons in atomic orbitals.

configuration in computing, the way in which a system, whether it be hardware and/or software, is set up. A minimum configuration is often referred to for a particular application, and this will usually include a specification of processor, disc and memory size, and peripherals required.

congenital disease in medicine, a disease that is present at birth. It is not necessarily genetic in origin; for example, congenital herpes may be acquired by the baby as it passes through the mother's birth canal.

conger any large marine eel of the family Congridae, especially the genus *Conger*. Conger eels live in shallow water, hiding in crevices during the day and active by night, feeding on fish and

crabs. They are valued for food and angling.

conglomerate in geology, coarse-grained clastic sedimentary rock, composed of rounded fragments (clasts) of pre-existing rocks cemented in a finer matrix, usually sand.

The fragments in conglomerates are pebble- to boulder-sized, and the rock can be regarded as the lithified equivalent of gravel. A bed of conglomerate is often associated with a break in a sequence of rock beds (an unconformity), where it marks the advance of the sea over an old eroded landscape. An oligomict conglomerate contains one type of pebble; a polymict conglomerate has a mixture of pebble types. If the rock fragments are angular, it is called a breccia.

congruent in geometry, having the same shape and size, as applied to two-dimensional or solid figures. With plane congruent figures, one figure will fit on top of the other exactly, though this may first require rotation and/or rotation of one of the figures.

conic section curve obtained when a conical surface is intersected by a plane. If the intersecting plane cuts both extensions of the cone, it yields a hyperbola; if it is parallel to the side of the cone, it produces a parabola. Other intersecting planes produce circles or ellipses.

The Greek mathematician Apollonius wrote eight books with the title *Conic Sections*, which superseded previous work on the subject by Aristarchus and Euclid.

conic section The four types of curve that may be obtained by cutting a single or double right-circular cone with a plane (two-dimensional surface).

conidium (plural *conidia*) asexual spore formed by some fungi at the tip of a specialized hypha or conidiophore. The conidiophores grow erect, and cells from their ends root off and separate into conidia, often forming long chains. Conidia easily become detached and are dispersed by air movements.

conifer any of a large number of cone-bearing trees or shrubs. They are often pyramid-shaped, with leaves that are either scaled or needle-shaped; most are evergreen. Conifers include pines, spruces, firs, yews, junipers, monkey puzzles, and larches. (Order Coniferales.)

Conifers belong to the gymnosperm or naked-seed-bearing group of plants. The reproductive organs are the male and female cones, and pollen is scattered in the wind. The seeds develop in the female cones. The processes of reaching maturity, fertilization, and seed ripening may take several years. Most conifers grow quickly and can survive in poor soil, on steep slopes, and in short growing seasons. Coniferous forests are widespread in Scandinavia and

upland areas of the UK such as the Scottish Highlands, and are often planted in afforestation schemes. Conifers also grow in woodland.

conjugate in mathematics, a term indicating that two elements are connected in some way; for example, $(a + ib)$ and $(a - ib)$ are conjugate complex numbers.

conjugate angles two angles that add up to 360° .

conjugation in biology, the bacterial equivalent of sexual reproduction. A fragment of the ϕ DNA from one bacterium is passed along a thin tube, the pilus, into another bacterium.

conjugation in organic chemistry, the alternation of double (or triple) and single carbon-carbon bonds in a molecule - for example, in penta-1,3-diene, $H_2C=CH-CH=CH_2$. Conjugation imparts additional stability as the double bonds are less reactive than isolated double bonds.

conjunction in astronomy, the alignment of two celestial bodies as seen from Earth. A ϕ superior planet (or other object) is in conjunction when it lies behind the Sun. An ϕ inferior planet (or other object) comes to inferior conjunction when it passes between the Earth and the Sun; it is at **superior conjunction** when it passes behind the Sun.

Planetary conjunction takes place when a planet is closely aligned with another celestial object, such as the Moon, a star, or another planet.

Because the orbital planes of the inferior planets are tilted with respect to that of the Earth, they usually pass either above or below the Sun at inferior conjunction. If they line up exactly, a ϕ transit will occur.

conjunctiva membrane covering the front of the vertebrate eye. It is continuous with the epidermis of the eyelids, and lies on the surface of the cornea.

conjunctivitis inflammation of the conjunctiva, the delicate membrane that lines the inside of the eyelids and covers the front of the eye. Symptoms include redness, swelling, and a watery or pus-filled discharge. It may be caused by infection, allergy, or other irritant.

connective tissue in animals, tissue made up of a noncellular substance, the ϕ extracellular matrix, in which some cells are embedded. Skin, bones, tendons, cartilage, and adipose tissue (fat) are the main connective tissues. There are also small amounts of connective tissue in organs such as the brain and liver, where they maintain shape and structure.

conodont extinct eel-like organism 520-240 million years old. Several thousand species have been described, ranging from 1-40 cm/0.4-15.8 in in length. They were predators, and, following the discovery of a large fossil in South Africa in 1995, are believed to be the first vertebrates. This fossil of a 40-cm/15.8-in conodont shows fossilized soft tissue including muscle and eyes. It has eye muscles, an exclusively vertebrate feature, and 'real teeth'.

Conodont fossils consist mainly of teeth, and are often abundant, especially in Upper ϕ Cambrian and ϕ Triassic limestone. They were first discovered by Russian naturalist Christian Pander (1794-1865).

Conservation must come before recreation.

PRINCE OF WALES CHARLES Heir to the throne of Great Britain and Northern Ireland.

The Times 5 July 1989

conservation in the life sciences, action taken to protect and preserve the natural world, usually from pollution, overexploitation, and other harmful features of human activity. The late 1980s saw a great increase in public concern for the environment, with membership of conservation groups, such as ϕ Friends of the Earth,

Conservation: chronology

- 1627** Last surviving aurochs, long-horned wild cattle that previously roamed Europe, southwest Asia, and North Africa, became extinct in Poland.
- 1664** A Dutch mandate drawn up to protect forest in Cape Colony, South Africa.
- 1681** The last dodo died on the island of Mauritius.
- 1764** The British established forest reserves on Tobago, after deforestation in Barbados and Jamaica resulted in widespread soil erosion.
- 1769** The French passed conservation laws in Mauritius.
- 1868** First laws passed in the UK to protect birds.
- 1943** The International Union for Conservation of Nature and Natural Resources (IUCN) was founded, with its sister organization, the World Wildlife Fund (WWF).
- 1970** The Man and the Biosphere Programme was initiated by UNESCO, providing for an international network of biosphere reserves.
- 1971** The Convention on Wetlands of International Importance (especially concerned with wildfowl habitat) signed in Ramsar, Iran, and started a List of Wetlands of International Importance.
- 1972** The Convention Concerning the Protection of the World Cultural and Natural Heritage adopted in Paris, France, providing for the designation of World Heritage Sites.
- 1972** The UN Conference on the Human Environment held in Stockholm, Sweden, led to the creation of the UN Environment Programme (UNEP).
- 1973** The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) signed in Washington, DC.
- 1974** The world's largest protected area, the Greenland National Park covering 97 million hectares, created.
- 1980** The World Conservation Strategy launched by the IUCN, with the WWF and UNEP, showed how conservation contributes to development.
- 1982** The first herd of ten Arabian oryx bred from a 'captive breeding' programme released into the wild in Oman. The last wild oryx had been killed in 1972.
- 1986** The first 'Red List' of endangered animal species compiled by IUCN.
- 1989** International trade in ivory banned under CITES legislation in an effort to protect the African elephant from poachers.
- 1992** The UN convened the 'Earth Summit' in Rio de Janeiro, Brazil, to discuss global planning for a sustainable future. The Convention on Biological Diversity and the Convention on Climate Change were opened for signing.
- 1993** The Convention on Biological Diversity came into force.
- 1995** The Arabian oryx conservation programme (began 1962), the most successful attempt at reintroducing zoo-bred animals to the wild, came to an end as the last seven animals were flown from the USA to join the 228-strong herd in Oman.
- 1996** The World Wide Fund for Nature had 5 million members in 28 countries.
- 1997** The world ban on the ivory trade was lifted in June 1997 at the tenth CITES convention. Trade is scheduled to resume in 1999 with Zimbabwe, Botswana, and Namibia the only countries allowed to export.

ϕ Greenpeace, and the US Sierra Club, rising sharply. Globally the most important issues include the depletion of atmospheric ozone by the action of ϕ chlorofluorocarbons (CFCs), the build-up of carbon dioxide in the atmosphere (thought to contribute to an intensification of the ϕ greenhouse effect), and ϕ deforestation.

conservation of energy in chemistry, the principle that states that in a chemical reaction, the total amount of energy in the system remains unchanged.

For each component there may be changes in energy due to change of physical state, changes in the nature of chemical bonds, and either an input or output of energy. However, there is no net gain or loss of energy.

conservation of mass in chemistry, the principle that states that in a chemical reaction the sum of all the masses of the substances involved in the reaction (reactants) is equal to the sum of all of the masses of the substances produced by the reaction (products) – that is, no matter is gained or lost.

conservation of momentum in mechanics, a law that states that total momentum is conserved (remains constant) in all collisions, providing no external resultant force acts on the colliding bodies. The principle may be expressed as an equation used to solve numerical problems: total momentum before collision = total momentum after collision.

console in computing, a combination of keyboard and screen (also described as a terminal). For a multiuser system, such as UNIX, there is only one system console from which the system can be administered, while there may be many user terminals. See also games console.

constant in mathematics, a fixed quantity or one that does not change its value in relation to variables. For example, in the algebraic expression $y^2 = 5x - 3$, the numbers 3 and 5 are constants. In physics, certain quantities are regarded as universal constants, such as the speed of light in a vacuum.

constantan or *eureka* high-resistance alloy of approximately 40% nickel and 60% copper with a very low coefficient of thermal expansion (measure of expansion on heating). It is used in electrical resistors.

constant composition, law of in chemistry, the law that states that the proportions of the amounts of the elements in a pure compound are always the same and are independent of the method by which the compound was produced.

constellation one of the 88 areas into which the sky is divided for the purposes of identifying and naming celestial objects. The first

CONSTELLATIONS AND THEIR STARS

<http://www.vol.it/mirror/constellations/>

Notes on the constellations (listed alphabetically, by month, and by popularity), plus lists of the 25 brightest stars and the 32 nearest stars, and photographs of the Milky Way.

Constellations

| Constellation | Abbreviation | Popular name(s) |
|------------------|------------------|---------------------|
| Andromeda | And | – |
| Antlia Ant | Airpump | – |
| Apus Aps | Bird of Paradise | – |
| Aquarius | Aqr | Water-Bearer |
| Aquila Aql | Eagle | – |
| Ara Ara | Altar | – |
| Aries Ari | Ram | – |
| Auriga Aur | Charioteer | – |
| Bootes Boo | Herdsmen | – |
| Caelum | Cae | Chisel |
| Camelopardalis | Cam | Giraffe |
| Cancer Cnc | Crab | – |
| Canes Venatici | CVn | Hunting Dogs |
| Canis Major | CMa | Great Dog |
| Canis Minor | CMi | Little Dog |
| Capricornus | Cap | Goat, Sea-Goat |
| Carina | Car | Keel |
| Cassiopeia | Cas | – |
| Centaurus | Cen | Centaur |
| Cepheus | Cep | – |
| Cetus | Cet | Whale |
| Chamaeleon | Cha | Chameleon |
| Circinus | Cir | Compasses |
| Columba | Col | Dove |
| Coma Berenices | Com | Berenice's Hair |
| Corona Australis | CrA | Southern Crown |
| Corona Borealis | CrB | Northern Crown |
| Corvus | Crv | Crow, Raven |
| Crater | Crz | Cup |
| Cruce | Cru | Southern Cross |
| Cygnus | Cyn | Swan |
| Delphinus | Del | Dolphin |
| Dorado | Dor | Goldfish, Swordfish |
| Draco | Dra | Dragon |
| Equuleus | Equ | Filly, Foal |
| Eridanus | Eri | River |
| Fornax | For | Furnace |
| Gemini | Gem | Twins |
| Grus | Gru | Crane |
| Hercules | Her | – |
| Horologium | Hor | Clock |
| Hydra | Hya | Sea Serpent |
| Hydrus | Hyl | Watersnake |
| Indus | Ind | Indian |

| Constellation | Abbreviation | Popular name(s) |
|---------------------|--------------|--------------------|
| Lacerta | Lac | Lizard |
| Leo | Leo | Lion |
| Leo Minor | LMi | Little Lion |
| Lepus | Lep | Hare |
| Libra | Lib | Scales |
| Lupus | Lup | Wolf |
| Lynx | Lyn | – |
| Lyra | Lyr | Lyre, Harp |
| Mensa | Men | Table, Mountain |
| Microscopium | Mic | Microscope |
| Monoceros | Mon | Unicorn |
| Musca | Mus | Southern Fly |
| Norma | Nor | Rule, Straightedge |
| Octans | Oct | Octant |
| Ophiuchus | Oph | Serpent-Bearer |
| Orion | Ori | – |
| Pavo | Pav | Peacock |
| Pegasus | Peg | Flying Horse |
| Persaeus | Per | – |
| Phoenix | Phe | – |
| Pictor | Pic | Painter, Easel |
| Pisces | Psc | Fishes |
| Piscis Austrinus | PsA | Southern Fish |
| Puppis | Pup | Poop |
| Pyxis | Pyx | Compass |
| Reticulum | Ret | Net |
| Sagitta | Sge | Arrow |
| Sagittarius | Sgr | Archer |
| Scorpius | Sco | Scorpion |
| Sculptor | Scl | – |
| Scutum | Sct | Shield |
| Serpens | Ser | Serpent |
| Sextans | Sex | Sextant |
| Taurus | Tau | Bull |
| Telescopium | Tel | Telescope |
| Triangulum | Tri | Triangle |
| Triangulum Australe | TrA | Southern Triangle |
| Tucana | Tuc | Toucan |
| Ursa Major | UMa | Big Dipper |
| Ursa Minor | UMi | Little Dipper |
| Vela | Vel | Sail |
| Virgo | Vir | Virgin |
| Volans | Vol | Flying Fish |
| Vulpecula | Vul | Fox |

constellations were simple, arbitrary patterns of stars in which early civilizations visualized gods, sacred beasts, and mythical heroes.

The constellations in use today are derived from a list of 48 known to the ancient Greeks, who inherited some from the Babylonians. The current list of 88 constellations was adopted by the International Astronomical Union, astronomy's governing body, in 1930.

constipation in medicine, the infrequent emptying of the bowel. The intestinal contents are propelled by peristaltic contractions of the intestine in the digestive process. The faecal residue collects in the rectum, distending it and promoting defecation. Constipation may be due to illness, alterations in food consumption, stress, or as an adverse effect of certain drugs. An increased intake of dietary fibre (see *fibre, dietary*) can alleviate constipation. Laxatives may be used to relieve temporary constipation but they should not be used routinely.

contact force force or push produced when two objects are pressed together and their surface atoms try to keep them apart. Contact forces always come in pairs – for example, the downwards force exerted on a floor by the sole of a person's foot is matched by an equal upwards force exerted by the floor on that sole.

contact lens lens, made of soft or hard plastic, that is worn in contact with the cornea and conjunctiva of the eye, beneath the eyelid, to correct defective vision. In special circumstances, contact lenses may be used as protective shells or for cosmetic purposes, such as changing eye colour.

The earliest use of contact lenses in the late 19th century was protective, or in the correction of corneal malformation. It was not until the 1930s that simplification of fitting technique by taking eye impressions made general use possible. Recent developments are a type of soft lens that can be worn for lengthy periods without removal, and a disposable soft lens that needs no cleaning but should be discarded after a week of constant wear.

contact process the main industrial method of manufacturing the chemical sulphuric acid. Sulphur dioxide (produced by burning sulphur) and air are passed over a hot (450°C) catalyst of vanadium (V) oxide. The sulphur trioxide produced is absorbed in concentrated sulphuric acid to make fuming sulphuric acid (oleum), which is then diluted with water to give concentrated sulphuric acid (98%). Unreacted gases are recycled.

content provider organization or individual who creates intellectual property, such as information databases, which may be distributed via traditional media or via the World Wide Web.

context-sensitive help type of help built into software that displays information related to the particular function in use.

continent any one of the seven large land masses of the Earth, as distinct from the oceans. They are Asia, Africa, North America, South America, Europe, Australia, and Antarctica. Continents are constantly moving and evolving (see *plate tectonics*). A continent does not end at the coastline; its boundary is the edge of the shallow continental shelf, which may extend several hundred kilometres out to sea.

At the centre of each continental mass lies a shield or *craton*, a deformed mass of old (metamorphic) rocks dating from Precambrian times. The shield is thick, compact, and solid (the Canadian Shield is an example), having undergone all the mountain-building activity it is ever likely to, and is usually worn flat. Around the shield is a concentric pattern of fold mountains, with older ranges, such as the Rockies, closest to the shield, and

continental drift The continents are slowly shifting their positions, driven by fluid motion beneath the Earth's crust. Over 200 million years ago, there was a single large continent called Pangaea. By 200 million years ago, the continents had started to move apart. By 50 million years ago, the continents were approaching their present positions.

younger ranges, such as the coastal ranges of North America, farther away. This general concentric pattern is modified when two continental masses have drifted together and they become welded with a great mountain range along the join, the way Europe and N Asia are joined along the Urals. If a continent is torn apart, the new continental edges have no fold mountains; for instance, South America has fold mountains (the Andes) along its western flank, but none along the east where it tore away from Africa 200 million years ago.

continental drift in geology, the theory that, about 250–200 million years ago, the Earth consisted of a single large continent (*Pangaea*), which subsequently broke apart to form the continents known today. The theory was proposed 1912 by German meteorologist Alfred Wegener, but such vast continental movements could not be satisfactorily explained until the study of *plate tectonics* in the 1960s.

The term 'continental drift' is not strictly correct, since land masses do not drift through the oceans. The continents form part of a plate, and the amount of crust created at divergent plate margins must equal the amount of crust destroyed at subduction zones.

continental shelf the submerged edge of a continent, a gently sloping plain that extends into the ocean. It typically has a gradient of less than 1°. When the angle of the sea bed increases to 1°–5° (usually several hundred kilometres away from land), it becomes known as the *continental slope*.

continuity in mathematics, property of functions of a real variable that have an absence of 'breaks'. A function *f* is said to be continuous at a point *a* if $\lim_{x \rightarrow a} f(x) = f(a)$.

continuous data data that can take any of an infinite number of values between whole numbers and so may not be measured completely accurately. This type of data contrasts with *discrete data*, in which the variable can only take one of a finite set of values. For

To remember the seven continents:

EAT AN ASPIRIN AFTER A NIGHT-TIME SNACK

EUROPE, ANTARCTICA, ASIA, AFRICA, AUSTRALIA, NORTH AMERICA, SOUTH AMERICA (THE SECOND LETTER IN THE FIRST THREE 'A' WORDS HELPS TO REMEMBER THE 'A' CONTINENTS)

example, the sizes of apples on a tree form continuous data, whereas the numbers of apples form discrete data.

continuous variation the slight difference of an individual character, such as height, across a sample of the population. Although there are very tall and very short humans, there are also many people with an intermediate height. The same applies to weight. Continuous variation can result from the genetic make-up of a population, or from environmental influences, or from a combination of the two.

continuum in mathematics, a set that is infinite and everywhere continuous, such as the set of points on a line.

I have continued my work on the continuum problem last summer and I finally succeeded in proving the consistency of the continuum hypothesis (even the generalized form) with respect to generalized set theory. But for the time being please do not tell anyone of this.

KURT GÖDEL Austrian-born US mathematician.
Letter to his teacher Karl Menger 1937

contouring in computer graphics, a technique for enhancing the outline of a particular shape. This technique is used in applications such as mapping (see animation, computer), where a computer following the contours of an object (pixel) by pixel can be much more precise than a human.

contraceptive any drug, device, or technique that prevents pregnancy. The contraceptive pill (the pill) contains female hormones that interfere with egg production or the first stage of pregnancy. The 'morning-after' pill can be taken up to 72 hours after unprotected intercourse. Barrier contraceptives include condoms (sheaths) and diaphragms, also called caps or Dutch caps; they prevent the sperm entering the cervix (neck of the womb).

Intrauterine devices, also known as IUDs or coils, cause a slight inflammation of the lining of the womb; this prevents the fertilized egg from becoming implanted. See also family planning.

Other contraceptive methods include sterilization (women) and vasectomy (men); these are usually nonreversible. 'Natural' methods include withdrawal of the penis before ejaculation (coitus interruptus), and avoidance of intercourse at the time of ovulation (rhythm method). These methods are unreliable and normally only used on religious grounds. A new development is a sponge impregnated with spermicide that is inserted into the vagina. The use of any contraceptive (birth control) is part of family planning. The effectiveness of a contraceptive method is often given as a percentage. To say that a method has 95% effectiveness means that, on average, out of 100 healthy couples using that method for a year, 95 will not conceive.

contractile root in botany, a thickened root at the base of a corm, bulb, or other organ that helps position it at an appropriate level in the ground. Contractile roots are found, for example, on the corms of plants of the genus *Crocus*. After they have become anchored in the soil, the upper portion contracts, pulling the plant deeper into the ground.

contractile vacuole tiny organelle found in many single-celled fresh-water organisms. It slowly fills with water, and then contracts, expelling the water from the cell.

Fresh-water protozoa such as *Amoeba* absorb water by the process of osmosis, and this excess must be eliminated. The rate of vacuole contraction slows as the external salinity is increased, because the osmotic effect weakens; marine protozoa do not have a contractile vacuole.

control in biology, the process by which a tissue, an organism, a population, or an ecosystem maintains itself in a balanced, stable state. Blood sugar must be kept at a stable level if the brain is to function properly, and this steady-state is maintained by an interaction between the liver, the hormone insulin, and a detector system in the pancreas.

In the ecosystem, the activities of the human race are endangering the balancing mechanisms associated with the atmosphere in general and the greenhouse effect in particular.

control bus in computing, the electrical pathway, or bus, used to communicate control signals.

control character in computing, any character produced by depressing the control key (Ctrl) on a keyboard at the same time as another (usually alphabetical) key. The control characters form the first 32 ASCII characters and most have specific meanings according to the operating system used. They are also used in combination to provide formatting control in many word processors, although the user may not enter them explicitly.

control experiment essential part of a scientifically valid experiment, designed to show that the factor being tested is actually responsible for the effect observed. In the control experiment all factors, apart from the one under test, are exactly the same as in the test experiments, and all the same measurements are carried out. In drug trials, a placebo (a harmless substance) is given alongside the substance being tested in order to compare effects.

control total in computing, a validation check in which an arithmetic total of a specific field from a group of records is calculated. This total is input together with the data to which it refers. The program recalculates the control total and compares it with the one entered to ensure that no entry errors have been made.

control unit the component of the central processing unit that decodes, synchronizes, and executes program instructions.

convection heat energy transfer that involves the movement of a fluid (gas or liquid). Fluid in contact with the source of heat expands and tends to rise within the bulk of the fluid. Cooler fluid sinks to take its place, setting up a convection current. This is the principle of natural convection in many domestic hot-water systems and space heaters.

convection current current caused by the expansion of a liquid or gas as its temperature rises. The expanded material, being less dense, rises above colder and therefore denser material. Convection currents arise in the atmosphere above warm land masses or seas, giving rise to sea breezes and land breezes, respectively. In some heating systems, convection currents are used to carry hot water upwards in pipes.

Convection currents in the viscous rock of the Earth's mantle help to drive the movement of the rigid plates making up the Earth's surface (see plate tectonics).

conventional current direction in which an electric current is considered to flow in a circuit. By convention, the direction is that in which positive-charge carriers would flow - from the positive terminal of a cell to its negative terminal. It is opposite in direction to the flow of electrons. In circuit diagrams, the arrows shown on symbols for components such as diodes and transistors point in the direction of conventional current flow.

convergence in mathematics, the property of a series of numbers in which the difference between consecutive terms gradually decreases. The sum of a converging series approaches a limit as the number of terms tends to infinity.

What can be more curious than that the hand of a man, formed for grasping, that of a mole for digging, [...] and the wing of a bat, should all be constructed on the same pattern, and should include the same bones, in the same relative positions?

CHARLES DARWIN British naturalist.
On the Origin of Species 1859

convergent evolution in biology, the independent evolution of similar structures in species (or other taxonomic groups) that are not closely related, as a result of living in a similar way. Thus, birds and bats have wings, not because they are descended from a com-

convergent evolution Convergent evolution produced the superficially similar streamlined bodies of the dolphin and penguin. Despite their very different evolutionary paths – one as a mammal, the other as a bird – both have evolved and adapted to the aquatic environment they now inhabit.

mon winged ancestor, but because their respective ancestors independently evolved flight.

converging lens lens that converges or brings to a focus those light rays that have been refracted by it. It is a ϕ convex lens, with at least one surface that curves outwards, and is thicker towards the centre than at the edge. Converging lenses are used to form real images in many optical instruments, such as cameras and projectors. A converging lens that forms a virtual, magnified image may be used as a ϕ magnifying glass or to correct ϕ long-sightedness.

converse in mathematics, the reversed order of a conditional statement; the converse of the statement 'if a , then b ' is 'if b , then a '. The converse does not always hold true; for example, the converse of 'if $x = 3$, then $x^2 = 9$ ' is 'if $x^2 = 9$, then $x = 3$ ', which is not true, as x could also be -3 .

convertiplane ϕ vertical takeoff and landing craft (VTOL) with rotors on its wings that spin horizontally for takeoff, but tilt to spin in a vertical plane for forward flight.

At takeoff it looks like a two-rotor helicopter, with both rotors facing skywards. As forward speed is gained, the rotors tilt slowly forward until they are facing directly ahead. There are several different forms of convertiplane. The LTV-Hillier-Ryan XC-142, designed in the USA, had wings, carrying the four engines and propellers, that rotated. The German VC-400 had two rotors on each of its wingtips. Neither of these designs went into production. A Bell/Boeing design, the V-22 Osprey, uses a pair of tilting engines, with propellers 11.5 m/38 ft across, mounted at the end of the wings. It was originally intended to carry about 50 passengers direct to city centres. Crashes of two prototypes led to design changes 1994, but the project continues.

convex of a surface, curving outwards, or towards the eye. For example, the outer surface of a ball appears convex. In geometry, the term is used to describe any polygon possessing no interior angle greater than 180° . Convex is the opposite of ϕ concave.

convex lens lens that possesses at least one surface that curves outwards. It is a ϕ converging lens, bringing rays of light to a focus.

A convex lens is thicker at its centre than at its edges, and is used to correct long-sightedness.

Common forms include the **biconvex** lens (with both surfaces curved outwards) and the **plano-convex** (with one flat surface and one convex). The whole lens may be further curved overall, making a **concavo-convex** or converging meniscus lens, as in some lenses used in corrective eyewear.

convex mirror curved mirror that reflects light from its outer surface. It diverges reflected light rays to form a reduced, upright, virtual image. Convex mirrors give a wide field of view and are therefore particularly suitable for car wing mirrors and surveillance purposes in shops.

conveyor device used for transporting materials. Widely used throughout industry is the conveyor belt, usually a rubber or fabric belt running on rollers. Trough-shaped belts are used, for example in mines, for transporting ores and coal. **Chain conveyors** are also used in coal mines to remove coal from the cutting machines. Overhead endless chain conveyors are used to carry components and bodies in car-assembly works. Other types include **bucket conveyors** and **screw conveyors**, powered versions of the ϕ Archimedes screw.

convolvulus or **bindweed** any of a group of plants belonging to the morning-glory family. They are characterized by their twining stems and by their petals, which are joined into a funnel-shaped tube. (Genus *Convolvulus*, family Convolvulaceae.)

convulsion series of violent contractions of the muscles over which the patient has no control. It may be associated with loss of consciousness. Convulsions may arise from any one of a number of causes, including brain disease (such as ϕ epilepsy), injury, high fever, poisoning, and electrocution.

cookie on the World Wide Web, a short piece of text that a Web site stores in a Cookies folder or a cookie.txt file on the user's computer, either for tracking or configuration purposes, for example, to improve the targeting of banner advertisements. Cookies can also store user preferences and passwords. The cookie is sent back to

the server when the browser requests a new page.

Cookies are derived from 'magic cookies', the identification tokens used by some UNIX systems.

Originally, a cookie was an aphorism or short, witty saying obtained by typing 'cookie' at a computer's main system prompt. A cookie was then chosen at random – like a 'fortune cookie' – from a database called a 'cookie file'.

cookie recipe urban legend that circulates around the Net. The story is about a protagonist who ate some delicious cookies for dessert after a meal in a fancy department store or restaurant. When asked for the recipe, the waiter refuses, but finally relents saying it will cost 'two fifty'. When the bill comes, the protagonist discovers the restaurant has charged \$250. Feeling stung, he/she posts the recipe to the Net to ensure the maximum distribution (and therefore revenge) possible. A cookie recipe is attached.

coolabah Australian riverside tree *Eucalyptus microtheca* of the myrtle family Myrtaceae. It is common in the inland and usually associated with areas subject to occasional inundation.

coonhound breed of large hound developed from European hounds imported into Virginia, USA, at the start of the 17th century, and used for hunting various types of small game. It has a short black coat with red markings on muzzle, chest, and feet; long drooping ears; and a long tail. It stands up to 68 cm/27 in tall.

cooperative farming system in which individual farmers pool their resources (excluding land) to buy commodities such as seeds and fertilizers, and services such as marketing. It is a system of farming found throughout the world and is particularly widespread in Denmark and the ex-Soviet republics. In a cooperative farm, land is also held in common.

coordinate in geometry, a number that defines the position of a point relative to a point or axis (reference line). Cartesian coordinates define a point by its perpendicular distances from two or more axes drawn through a fixed point mutually at right angles to each other. Polar coordinates define a point in a plane by its distance from a fixed point and direction from a fixed line.

coordinate geometry or *analytical geometry* system of geometry in which points, lines, shapes, and surfaces are represented by algebraic expressions. In plane (two-dimensional) coordinate geometry, the plane is usually defined by two axes at right angles to each other, the horizontal *x*-axis and the vertical *y*-axis, meeting at O, the origin. A point on the plane can be represented by a pair of Cartesian coordinates, which define its position in terms of its distance along the *x*-axis and along the *y*-axis from O. These distances are respectively the *x* and *y* coordinates of the point.

Lines are represented as equations; for example, $y = 2x + 1$ gives a straight line, and $y = 3x^2 + 2x$ gives a parabola (a curve). The graphs of varying equations can be drawn by plotting the coordinates of points that satisfy their equations, and joining up the points. One of the advantages of coordinate geometry is that geometrical solutions can be obtained without drawing but by manipulating algebraic expressions. For example, the coordinates of the point of intersection of two straight lines can be determined by finding the unique values of *x* and *y* that satisfy both of the equations for the lines, that is, by solving them as a pair of simultaneous equations. The curves studied in simple coordinate geometry are the conic sections (circle, ellipse, parabola, and hyperbola), each of which has a characteristic equation.

coot freshwater bird of the genus *Fulica* in the rail family, order Gruiformes. Coots are about 38 cm/1.2 ft long, and mainly black. They have a white bill, extending up the forehead in a plate, and big feet with four lobed toes.

copepod crustacean of the subclass Copepoda, mainly microscopic and found in plankton.

coplanar in geometry, describing lines or points that all lie in the same plane.

copper orange-pink, very malleable and ductile, metallic element, symbol Cu (from Latin *cuprum*), atomic number 29, relative atom-

cartesian coordinates

polar coordinates

coordinate Coordinates are numbers that define the position of points in a plane or in space. In the Cartesian coordinate system, a point in a plane is charted based upon its location along intersecting horizontal and vertical axes. In the polar coordinate system, a point in a plane is defined by its distance from a fixed point and direction from a fixed line.

ic mass 63.546. It is used for its durability, pliability, high thermal and electrical conductivity, and resistance to corrosion.

It was the first metal used systematically for tools by humans; when mined and worked into utensils it formed the technological basis for the Copper Age in prehistory. When alloyed with tin it forms bronze, which is stronger than pure copper and may hold a sharp edge; the systematic production and use of this alloy was the basis for the prehistoric Bronze Age. Brass, another hard copper alloy, includes zinc. The element's name comes from the Greek for Cyprus (*Kyprios*), where copper was mined.

COPPER PAGE

<http://www.copper.org/>

guide to copper and copper alloys, providing a wealth of information ranging from a historical overview of the copper industry to a database of literary resources about copper technology.

copper(II) carbonate CuCO_3 green solid that readily decomposes to form black copper(II) oxide on heating.

It dissolves in dilute acids to give blue solutions with effervescence caused by the giving off of carbon dioxide.

Copernicus, Nicolaus (1473–1543)

Latinized form of Mikolaj Kopernik Polish astronomer who believed that the Sun, not the Earth, is at the centre of the Solar System, thus defying the Christian church doctrine of the time. For 30 years, he worked on the hypothesis that the rotation and the orbital motion of the Earth are responsible for the apparent movement of the heavenly bodies. His great work *De revolutionibus orbium coelestium* On the Revolutions of the Heavenly Spheres was the important first step to the more accurate picture of the Solar System built up by Tycho Brahe, Kepler, Galileo, and later astronomers.

Copernicus proposed replacing Ptolemy's ideas with a model in which the planets (including the Earth) orbited a centrally situated Sun. He proposed that the Earth described one full orbit of the Sun in a year, whereas the Moon orbited the Earth. The Earth rotated

daily about its axis (which was inclined at 23.5° to the plane of orbit), thus accounting for the apparent daily rotation of the sphere of the fixed stars.

This model was a distinct improvement on the Ptolemaic system for a number of reasons. It explained why the planets Mercury and Venus displayed only 'limited motion'; their orbits were inside that of the Earth's. Similarly, it explained that the planets Mars, Jupiter, and Saturn

displayed such curious patterns in their movements ('retrograde motion', loops, and kinks) because they travel in outer orbits at a slower pace than the Earth. The movement of the Earth on its axis accounted for the precession of the equinoxes, previously discovered by Hipparchus.

Copernicus' model represents a complete reformation of astronomy by replacing the anthropocentric view of the universe with the heliocentric viewpoint. Unable to free himself from the constraints of classical thinking, however, Copernicus was able to imagine only circular planetary orbits. This forced him to retain the system of epicycles, with the Earth revolving around a centre that revolved around another centre, which in turn orbited the Sun. Kepler rescued the model by introducing the concept of elliptical orbits. Copernicus also held to the notion of spheres, in which the planets were supposed to travel. It was Brahe who finally rid astronomy of that concept.

French mathematician, encyclopedist, and theoretical physicist. In association with Denis Diderot, he helped plan the great *Encyclopédie*, for which he also wrote the 'Discours préliminaire' 1751. He framed several theorems and principles – notably d'Alembert's principle – in dynamics and celestial mechanics, and devised the theory of partial differential equations.

The principle that now bears his name was first published in his *Traité de dynamique* 1743, and was an extension of the third of Isaac Newton's laws of motion. D'Alembert maintained that the law was valid not merely for a static body, but also for mobile bodies. Within a year he had found a means of applying the principle to the theory of equilibrium and the motion of fluids. Using also the theory of partial differential equations, he studied the properties of sound, and air compression, and also managed to relate his principle to an investigation of the motion of any body in a given figure.

Mary Evans Picture Library

copper ore any mineral from which copper is extracted, including native copper, Cu; chalcocite, Cu₂S; chalcophyllite, CuFeS₂; bornite, Cu₅FeS₄; azurite, Cu₃(CO₃)₂(OH)₂; malachite, Cu₂(CO₃)₂(OH)₂; and chrysocolla, CuSiO₃·2H₂O.

Native copper and the copper sulphides are usually found in veins associated with igneous intrusions. Chrysocolla and the carbonates are products of the weathering of copper-bearing rocks. Copper was one of the first metals to be worked, because it occurred in native form and needed little refining. Today the main producers are the USA, Russia, Kazakhstan, Georgia, Uzbekistan, Armenia, Zambia, Chile, Peru, Canada, and Congo (formerly Zaire).

copper(II) oxide CuO black solid that is readily reduced to copper by carbon, carbon monoxide, or hydrogen if heated with any of these.

It is usually made in the laboratory by heating copper(II) carbonate, nitrate, or hydroxide.

Copper(II) oxide is a typical basic oxide, dissolving readily in most dilute acids.

copper(II) sulphate CuSO₄ substance usually found as a blue, crystalline, hydrated salt CuSO₄·5H₂O (also called blue vitriol). It is made from the action of dilute sulphuric acid on copper(II) oxide, hydroxide, or carbonate.

When the hydrated salt is heated gently it loses its water of crystallization and the blue crystals turn to a white powder. The

reverse reaction is used as a chemical test for water.

coppicing woodland management practice of severe pruning where trees are cut down to near ground level at regular intervals, typically every 3–20 years, to promote the growth of numerous shoots from the base.

This form of forestry was once commonly practised in Europe, principally on hazel and chestnut, to produce large quantities of thin branches for firewood, fencing, and so on; alder, eucalyptus, maple, poplar, and willow were also coppiced. The resulting thickets were known as a coppice or copse. See also pollarding.

coprocessor in computing, an additional processor that works with the main central processing unit to carry out a specific function. The two most common coprocessors are the mathematical coprocessor, used to speed up calculations, and the graphic coprocessor, used to improve the handling of graphics.

copulation act of mating in animals with internal fertilization. Male mammals have a penis or other organ that is used to introduce spermatozoa into the reproductive tract of the female. Most birds transfer sperm by pressing their cloacas (the openings of their reproductive tracts) together.

copy protection techniques used to prevent illegal copying of computer programs. Copy protection is not as common as it used to be because it also prevents legal copying (for backup purposes). Alternative techniques to prevent illegal use include dongles, passwords and the need to uninstall a program before it can be installed on another machine.

coral marine invertebrate of the class Anthozoa in the phylum Cnidaria, which also includes sea anemones and jellyfish. It has a

coral atoll The formation of a coral atoll by the gradual sinking of a volcanic island. The reefs fringing the island build up as the island sinks, eventually producing a ring of coral around the spot where the island sank.

skeleton of lime (calcium carbonate) extracted from the surrounding water. Corals exist in warm seas, at moderate depths with sufficient light. Some coral is valued for decoration or jewellery, for example, Mediterranean red coral *Corallum rubrum*.

Corals live in a symbiotic relationship with microscopic algae (zooxanthellae), which are incorporated into the soft tissue. The algae obtain carbon dioxide from the coral polyps, and the polyps receive nutrients from the algae. Corals also have a relationship to the fish that rest or take refuge within their branches, and which excrete nutrients that make the corals grow faster. The majority of corals form large colonies although there are species that live singly. Their accumulated skeletons make up large coral reefs and atolls. The Great Barrier Reef, to the NE of Australia, is about 1,600 km/1,000 mi long, has a total area of 20,000 sq km/7,700 sq mi, and adds 50 million tonnes of calcium to the reef each year. The world's reefs cover an estimated 620,000 sq km/240,000 sq mi.

Coral reefs provide a habitat for a diversity of living organisms. In 1997, some 93,000 species were identified. One third of the world's marine fishes live in reefs. The world's first global survey of coral reefs, carried out in 1997, found around 95% of reefs had experienced some damage from overfishing, pollution, dynamiting, poisoning, and the dragging of ships' anchors.

diseases Since the 1990s, coral reefs have been destroyed by previously unknown diseases. The white plague attacked 17 species of coral in the Florida Keys, USA, in 1995. The rapid wasting disease, discovered in 1997, affects coral reefs from Mexico to Trinidad. In the Caribbean, the fungus *Aspergillus* attacks sea fans, a soft coral. It was estimated in 1997 that around 90% of the coral around the Galapagos islands had been destroyed as a result of 'bleaching', a whitening of coral reefs which occurs when the coloured algae evacuate the coral. This happens either because the corals produce toxins that are harmful to the algae or because they do not produce

sufficient nutrients. Without the algae, the coral crumbles and dies away. Bleaching is widespread all over the Caribbean and the Indo-Pacific.

coralroot any leafless orchid of the genus *Corallorhiza*, having branched coral-colored roots and small yellowish or purplish flowers. These orchids are either parasitic on the roots of other plants, or saprophytes, living on decaying organic matter.

coral snake venomous snake. *Elaps corallinus* is a typical specimen; it occurs in the tropical forests of South America, and its small body, less than 1 m/3.3 ft in length, is ringed with coral-red. It is highly poisonous.

classification Coral snakes are in the family Elapidae, suborder Serpentes, order Squamata, class Reptilia.

coral tree any of several tropical trees with bright red or orange flowers and producing a very lightweight wood. (Genus *Erythrina*, family Fabaceae.)

Corba (acronym for *Common object request broker architecture*) in computing, agreed specification that enables software components or 'objects' from different suppliers running on different computers using different operating systems to interoperate with one another. Corba has been extended via the Internet Inter-ORB Protocol (IIOP) to work over the Internet. Corba is promulgated as a standard by the Object Management Group (OMG).

cord unit for measuring the volume of wood cut for fuel. One cord equals 128 cubic feet (3.456 cubic metres), or a stack 8 feet (2.4 m) long, 4 feet (1.2 m) wide, and 4 feet high.

cordillera group of mountain ranges and their valleys, all running in a specific direction, formed by the continued convergence of two tectonic plates (see plate tectonics) along a line. The term is applied especially to the principal mountain belt of a continent. The Andes of South America are an example.

core in earth science, the innermost part of Earth. It is divided into an outer core, which begins at a depth of 2,898 km/1,800 mi, and an inner core, which begins at a depth of 4,982 km/3,095 mi. Both parts are thought to consist of iron-nickel alloy. The outer core is liquid and the inner core is solid.

The fact that seismic shear waves (see seismic wave) disappear at the mantle-outer core boundary indicates that the outer core is molten, since shear waves cannot travel through fluid. Scientists infer the iron-nickel rich composition of the core from Earth's density and its moment of inertia. The temperature of the core, as estimated from the melting point of iron at high pressure, is thought to be at least 4,000°C/7,232°F, but remains controversial. Earth's magnetic field is believed to be the result of the motions involving the inner and outer cores.

Corel Canadian software company founded in 1983 by British citizen Michael Cowpland. Its drawing program Corel Draw led the market from its first release. Corel bought the desktop publishing package Ventura Publisher 1995 and then the word processor WordPerfect 1996.

corgi breed of dog. See Welsh corgi.

coriander pungent fresh herb belonging to the parsley family, native to Europe and Asia; also a spice made from its dried ripe seeds. The spice is used commercially as a flavouring in meat products, bakery goods, tobacco, gin, liqueurs, chilli, and curry powder. Both are commonly used in cooking in the Middle East, India, Mexico, and China. (*Coriandrum sativum*, family Umbelliferae.)

Coriolis effect the effect of the Earth's rotation on the atmosphere and on all objects on the Earth's surface. In the northern hemisphere it causes moving objects and currents to be deflected to the right; in the southern hemisphere it causes deflection to the left. The effect is named after its discoverer, French mathematician Gaspard de Coriolis (1792-1843).

cork light, waterproof outer layers of the bark covering the branches and roots of almost all trees and shrubs. The cork oak (*Quercus suber*), a native of S Europe and N Africa, is cultivated in Spain and Portugal; the exceptionally thick outer layers of its bark provide the cork that is used commercially.

WELCOME TO CORAL FOREST

<http://www.blacktop.com/coralforest/>

Site dedicated to explaining the importance of coral reefs for the survival of the planet. It is an impassioned plea on behalf of the world's endangered coral reefs and includes a full description of their biodiversity, maps of where coral reefs are to be found (no less than 109 countries), and many photos.

corm Corms, found in plants such as the gladiolus and crocus, are underground storage organs. They provide the food for growth during adverse conditions such as cold or drought.

corm short, swollen, underground plant stem, surrounded by protective scale leaves, as seen in the genus *Crocus*. It stores food, provides a means of vegetative reproduction, and acts as a perennating organ.

During the year, the corm gradually withers as the food reserves are used for the production of leafy, flowering shoots formed from axillary buds. Several new corms are formed at the base of these shoots, above the old corm.

cormorant any of various diving seabirds, mainly of the genus *Phalacrocorax*, order Pelecaniformes, about 90 cm/3 ft long, with webbed feet, a long neck, hooked beak, and glossy black plumage. Cormorants generally feed on fish and shellfish, which they catch by swimming and diving under water, sometimes to a considerable depth. They collect the food in a pouch formed by the dilatable skin at the front of the throat. Some species breed on inland lakes and rivers.

P. carbo has a bright shiny head and neck, with bluish-black feathers, speckled with white. The general colour above is a greenish black, the throat white, and the bill and feet are dark grey. It is found in all parts of the world in coastal regions.

There are about 30 species of cormorant worldwide, including a flightless form *Nannopterum harrisi* in the Galápagos Islands; the shag, or green cormorant, *P. aristotelis*; and the small European cormorant, *Halietor pygmaeus*, which is a freshwater bird. The guanay cormorant *P. bougainvillae*, of the Peruvian coast, is the main producer of the guanano of those regions.

corn general term for the main cereal crop of a region – for example, wheat in the UK, oats in Scotland and Ireland, maize in the USA. Also, another word for maize.

corncrake or landrail bird *Crex crex* of the rail family Rallidae, order Gruiformes. About 25 cm/10 in long, the bill and tail are short, the legs long and powerful, and the toes have sharp claws. It is drably coloured, shy, and has a persistent rasping call. The corncrake can swim and run easily, but its flight is heavy. It lives in meadows and crops in temperate regions, but has become rare where mechanical methods of cutting corn are used.

cornea transparent front section of the vertebrate eye. The cornea is curved and behaves as a fixed lens, so that light entering the eye is partly focused before it reaches the lens.

There are no blood vessels in the cornea and it relies on the fluid in the front chamber of the eye for nourishment. Further protection for the eye is provided by the conjunctiva. In humans, diseased or

opaque parts may be replaced by grafts of corneal tissue from a donor.

cornflower native European and Asian plant belonging to the same genus as the cornpinks but distinguished from them by its deep azure-blue flowers. Formerly a common weed in N European wheat fields, it is now widely grown in gardens as a herbaceous plant with flower colours ranging from blue through shades of pink and purple to white. (*Centaurea cyanus*, family Compositae.)

cornified layer the upper layer of the skin where the cells have died, their cytoplasm being replaced by keratin, a fibrous protein also found in nails and hair. Cornification gives the skin its protective waterproof quality.

corolla collective name for the petals of a flower. In some plants the petal margins are partly or completely fused to form a corolla tube, for example in bindweed *Convolvulus arvensis*.

corona faint halo of hot (about 2,000,000°C/3,600,000°F) and tenuous gas around the Sun, which boils from the surface. It is visible at solar eclipses or through a coronagraph, an instrument that blocks light from the Sun's brilliant disc. Gas flows away from the corona to form the solar wind.

Corona Australis or **Southern Crown** small constellation of the southern hemisphere, located near the constellation Sagittarius. It is similar in size and shape to Corona Borealis but is not as bright.

Corona Borealis or **Northern Crown** small but easily recognizable constellation of the northern hemisphere, between Hercules and Boötes, traditionally identified with the jewelled crown of Ariadne that was cast into the sky by Bacchus in Greek mythology. Its brightest star is Alphecca (or Gemma), which is 78 light years from Earth.

It contains several variable stars. R Coronae Borealis is normally fairly constant in brightness but fades at irregular intervals and stays faint for a variable length of time. T Coronae Borealis is normally faint, but very occasionally blazes up and for a few days may be visible to the naked eye. It is a recurrent nova.

coronary artery disease Latin *corona* 'crown', from the arteries encircling the heart condition in which the fatty deposits of atherosclerosis form in the coronary arteries that supply the heart muscle, narrowing them and restricting the blood flow.

These arteries may already be hardened (arteriosclerosis). If the heart's oxygen requirements are increased, as during exercise, the blood supply through the narrowed arteries may be inadequate, and the pain of angina results. A heart attack occurs if the blood supply to an area of the heart is cut off, for example because a blood clot (thrombus) has blocked one of the coronary arteries. The subsequent lack of oxygen damages the heart muscle (infarct), and if a large area of the heart is affected, the attack may be fatal. Coronary artery disease tends to run in families and is linked to smoking, lack of exercise, and a diet high in saturated (mostly animal) fats, which tends to increase the level of blood cholesterol. It is a common cause of death in many industrialized countries; older men are the most vulnerable group. The condition is treated with drugs or bypass surgery.

Coronella genus of snakes inhabiting Europe, Asia, and America. All are harmless.

corpuscular theory hypothesis about the nature of light championed by Isaac Newton, who postulated that it consists of a stream of particles or corpuscles. The theory was superseded at the beginning of the 19th century by English physicist Thomas Young's wave theory. Quantum theory and wave mechanics embody both concepts.

corpus luteum glandular tissue formed in the mammalian ovary after ovulation from the Graafian follicle, a group of cells associated with bringing the egg to maturity. It secretes the hormone progesterone in anticipation of pregnancy.

After the release of an egg the follicle enlarges under the action of luteinizing hormone, released from the pituitary. The corpus luteum secretes the hormone progesterone, which maintains the

uterus well ready for pregnancy. If pregnancy occurs, the corpus luteum continues to secrete progesterone until the fourth month; if pregnancy does not occur the corpus luteum breaks down.

corrosion the grinding away of solid rock surfaces by particles carried by water, ice, and wind. It is generally held to be the most significant form of erosion. As the eroding particles are carried along they become eroded themselves due to the process of attrition.

correlation the degree of relationship between two sets of information. If one set of data increases at the same time as the other, the relationship is said to be positive or direct. If one set of data increases as the other decreases, the relationship is negative or inverse. Correlation can be shown by plotting a best-fit line on a scatter diagram.

In statistics, such relations are measured by the calculation of coefficients of correlation. These generally measure correlation

correlation Scattergraphs showing different kinds of correlation. In this way, a causal relationship between two variables may be proved or disproved, provided there are no hidden factors.

on a scale with 1 indicating perfect positive correlation, 0 no correlation at all, and -1 perfect inverse correlation. Correlation coefficients for assumed linear relations include the Pearson product moment correlation coefficient (known simply as the correlation coefficient), Kendall's tau correlation coefficient, or Spearman's rho correlation coefficient, which is used in nonparametric statistics (where the data are measured on ordinal rather than interval scales). A high correlation does not always indicate dependence between two variables; it may be that there is a third (unstated) variable upon which both depend.

correspondence in mathematics, the relation between two sets where an operation on the members of one set maps some or all of them onto one or more members of the other. For example, if A is the set of members of a family and B is the set of months in the year, A and B are in correspondence if the operation is: '...has a birthday in the month of...'

corresponding angles a pair of equal angles lying on the same side of a transversal (a line that cuts through two or more lines in the same plane), and making an interior and exterior angle with the intersected lines.

corrie (Welsh *cwm*; French, North American *cirque*) Scottish term for a steep-sided hollow in the mountainside of a glaciated area. The weight and movement of the ice has ground out the bottom and worn back the sides. A corrie is open at the front, and its sides and back are formed of corries. There may be a lake in the bottom, called a tarn.

A corrie is formed as follows: (1) snow accumulates in a hillside hollow (enlarging the hollow by nivation), and turns to ice; (2) the hollow is deepened by abrasion and plucking; (3) the ice in the corrie rotates under the influence of gravity, deepening the hollow still further; (4) since the ice is thinner and moves more slowly at the foot of the hollow, a rock lip forms; (5) when the ice melts, a lake or tarn may be formed in the corrie. The steep back wall may be severely weathered by freeze-thaw, weathering providing material for further abrasion.

corrosion in chemistry, the eating away and eventual destruction of metals and alloys by chemical attack. The rusting of ordinary iron and steel is the most common form of corrosion. Rusting takes place in moist air, when the iron combines with oxygen and water to form a brown-orange deposit of rust (hydrated iron oxide). The rate of corrosion is increased where the atmosphere is polluted with sulphur dioxide. Salty road and air conditions accelerate the rusting of car bodies.

Corrosion is largely an electrochemical process, and acidic and salty conditions favour the establishment of electrolytic cells on the metal, which cause it to be eaten away. Other examples of corrosion include the green deposit that forms on copper and bronze, called verdigris, a basic copper carbonate. The tarnish on silver is a corrosion product, a film of silver sulphide.

corrosion in earth science, an alternative name for dissolution, the process by which water dissolves rocks such as limestone.

corruption of data introduction or presence of errors in data. Most computers use a range of verification and validation routines to prevent corrupt data from entering the computer system or detect corrupt data that are already present.

cortex in biology, the outer part of a structure such as the brain, kidney, or adrenal gland. In botany the cortex includes nonspecialized cells lying just beneath the surface cells of the root and stem.

corticosteroid any of several steroid hormones secreted by the cortex of the adrenal glands; also synthetic forms with similar properties. Corticosteroids have anti-inflammatory and immunosuppressive effects and may be used to treat a number of conditions, including rheumatoid arthritis, severe allergies, asthma, some skin diseases, and some cancers. Side effects can be serious, and therapy must be withdrawn very gradually.

The two main groups of corticosteroids include glucocorticoids (cortisone, hydrocortisone, prednisone, and dexamethasone), which are essential to carbohydrate, fat, and protein metabolism, and to the body's response to stress; and mineralocorticoids

(aldosterone, fluorocortisone), which control the balance of water and salt in the body.

corticotrophin-releasing hormone (CRH) hormone produced by the hypothalamus that stimulates the adrenal glands to produce the steroid cortisol, essential for normal metabolism. CRH is also produced by the placenta and a surge in CRH may trigger the beginning of labour.

cortisol hormone produced by the adrenal glands. It plays a role in helping the body combat stress and is at its highest level in the blood at dawn.

cortisone natural corticosteroid produced by the adrenal gland, now synthesized for its anti-inflammatory qualities and used in the treatment of rheumatoid arthritis.

Cortisone was discovered by Tadeus Reichstein of Basel, Switzerland, and put to practical clinical use for rheumatoid arthritis by Philip Hench (1896–1965) and Edward Kendall (1886–1972) in the USA (all three shared a Nobel prize 1950).

A product of the adrenal gland, it was first synthesized from a constituent of ox bile, and is now produced commercially from a Mexican yam and from a by-product of the sisal plant. It is used for treating allergies and certain cancers, as well as rheumatoid arthritis. The side effects of cortisone steroids include muscle wasting, fat redistribution, diabetes, bone thinning, and high blood pressure.

corundum native aluminium oxide, Al_2O_3 , the hardest naturally occurring mineral known apart from diamond (corundum rates 9 on the Mohs' scale of hardness); lack of cleavage also increases its durability. Its crystals are barrel-shaped prisms of the trigonal system. Varieties of gem-quality corundum are **ruby** (red) and **sapphire** (any colour other than red, usually blue). Poorer-quality and synthetic corundum is used in industry, for example as an abrasive.

Corundum forms in silica-poor igneous and metamorphic rocks. It is a constituent of emery, which is metamorphosed bauxite.

cosecant in trigonometry, a function of an angle in a right-angled triangle found by dividing the length of the hypotenuse (the longest side) by the length of the side opposite the angle. Thus the cosecant of an angle A , usually shortened to cosec A , is always greater than (or equal to) 1. It is the reciprocal of the sine of the angle, that is, cosec $A = 1/\sin A$.

cosine in trigonometry, a function of an angle in a right-angled triangle found by dividing the length of the side adjacent to the angle by the length of the hypotenuse (the longest side). It is usually shortened to cos.

the cosine rule states that

$$a^2 = b^2 + c^2 - 2bc \cos A$$

cosine rule The cosine rule is a rule of trigonometry that relates the sides and angles of triangles. It can be used to find a missing length or angle in a triangle.

cosine rule in trigonometry, a rule that relates the sides and angles of triangles. The rule has the formula:

$$a^2 = b^2 + c^2 - 2bc \cos A$$

where a , b , and c are the sides of the triangle, and A is the angle opposite a .

cosmic background radiation or 3° radiation electromagnetic radiation left over from the original formation of the universe in the Big Bang around 15 billion years ago. It corresponds to an overall background temperature of $3K$ ($-270^\circ C$ – $-454^\circ F$), or $3^\circ C$ above absolute zero. In 1992 the Cosmic Background Explorer satellite, COBE, detected slight 'ripples' in the strength of the background radiation that are believed to mark the first stage in the formation of galaxies.

Cosmic background radiation was first detected in 1965 by US physicists Arno Penzias (1933–) and Robert Wilson (1936–), who in 1978 shared the Nobel Prize for Physics for their discovery.

cosmic radiation streams of high-energy particles from outer space, consisting of protons, alpha particles, and light nuclei, which collide with atomic nuclei in the Earth's atmosphere, and produce secondary nuclear particles (chiefly mesons, such as pions and muons) that shower the Earth.

Those of low energy seem to be galactic in origin, and those of high energy of extragalactic origin. The galactic particles may come from supernova explosions or pulsars. At higher energies, other sources are necessary, possibly the giant jets of gas which are emitted from some galaxies.

cosmid fragment of DNA from the human genome inserted into a bacterial cell. The bacterium replicates the fragment along with its own DNA. In this way the fragments are copied for a gene library. Cosmids are characteristically 40,000 base pairs in length. The most commonly used bacterium is *Escherichia coli*. A yeast artificial chromosome works in the same way.

cosmogony Greek 'universe' and 'creation' study of the origin and evolution of cosmic objects, especially the Solar System.

cosmological principle in astronomy, a hypothesis that any observer anywhere in the universe has the same view that we

$$\begin{aligned} \cosine \beta &= \frac{\text{adjacent}}{\text{hypotenuse}} \\ &= \frac{BC}{AB} \end{aligned}$$

cosine The cosine of angle β is equal to the ratio of the length of the adjacent side to the length of the hypotenuse (the longest side, opposite to the right angle).

BRIEF HISTORY OF COSMOLOGY

<http://www-history.mcs.st-and.ac.uk/~history/HistTopics/Cosmology.html>

Based at St Andrews University, Scotland, a site chronicling the history of cosmology from the time of the Babylonians to the Hubble Space Telescope. It includes links to the biographies of the key historical figures responsible for the advancement of the subject, and in addition has a brief list of references for further reading.

have; that is, that the universe is not expanding from any centre but all galaxies are moving away from one another.

cosmology branch of astronomy that deals with the structure and evolution of the universe as an ordered whole. Its method is to construct 'model universes' mathematically and compare their large-scale properties with those of the observed universe.

Modern cosmology began in the 1920s with the discovery that the universe is expanding, which suggested that it began in an explosion, the Big Bang. An alternative – now discarded – view, the steady-state theory, claimed that the universe has no origin, but is expanding because new matter is being continually created.

cosmonaut term used in the West for any astronaut from the former Soviet Union.

Cosmos name used from the early 1960s for nearly all Soviet artificial satellites. Over 2,300 Cosmos satellites had been launched by mid 1995.

Our loyalties are to the species and the planet. We speak for Earth. Our obligation to survive is owed not just to ourselves but also to that Cosmos, ancient and vast, from which we spring.

CARL SAGAN US astronomer.
Cosmos 1980

CoSy (contraction of *conferencing system*) command-line interface electronic conferencing software developed at the University of Guelph in the Canadian province of Ontario. It is used on London's Compulink Information eXchange (CIX) service and for the Open University's conferencing, as well as many others worldwide.

cotangent in trigonometry, a function of an angle in a right-angled triangle found by dividing the length of the side adjacent to the angle by the length of the side opposite it. It is usually written as cotan, or cot and it is the reciprocal of the tangent of the angle, so that $\cot A = 1/\tan A$, where A is the angle in question.

cotangent The cotangent of angle β is equal to the ratio of the length of the adjacent side to the length of the opposite side.

cot death or *sudden infant death syndrome* (SIDS) death of an apparently healthy baby, almost always during sleep. It is most common in the winter months, and strikes more boys than girls. The cause is not known but risk factors that have been identified include prematurity, respiratory infection, overheating, and sleeping position.

There was a 60% reduction in the number of cot deaths in the UK in the first nine months of 1993, following a massive advertising campaign advising parents to put their babies to sleep on their backs, ensure they do not overheat, and avoid smoking near them. Earlier, in New Zealand (1991), where the cot death rate had been the highest in the world, the rate was halved by a similar campaign.

cotoneaster any of a group of shrubs or trees found in Europe and Asia, belonging to the rose family and closely related to the hawthorn and medlar. The fruits, though small and unpalatable, are usually bright red and conspicuous, often surviving through the winter. Some of the shrubs are cultivated for their attractive appearance. (Genus *Cotoneaster*, family Rosaceae.)

cotton tropical and subtropical herbaceous plant belonging to the mallow family. Fibres surround the seeds inside the ripened fruits, or bolls, and these are spun into yarn for cloth. (Genus *Gossypium*, family Malvaceae.)

The fibres are separated from the seeds in a machine called a cotton gin. The seeds are used to produce cooking oil and livestock feed, and the pigment gossypol may be useful as a male contraceptive in a modified form. Cotton disease (byssinosis), caused by cotton dust, affects the lungs of those working in the industry.

Cotton production uses 50% of world pesticides and represents 5% of world agricultural output.

cotton gin machine that separates cotton fibres from the seed boll. Production of the gin (then called an engine) by US inventor Eli Whitney in 1793 was a milestone in textile history.

The modern gin consists of a roller carrying a set of circular saws. These project through a metal grill in a hopper containing the seed bolls. As the roller rotates, the saws pick up the cotton fibres, leaving the seeds behind.

cotton grass or *bog cotton* any grasslike plant of a group belonging to the sedge family. White tufts cover the fruiting heads in mid-summer; these break off and are carried long distances on the wind. Cotton grass is found in wet places throughout the Arctic and temperate regions of the northern hemisphere, most species growing in acid bogs. (Genus *Eriophorum*, family Cyperaceae.)

cotton spinning creating thread or fine yarn from the cotton plant by spinning the raw fibre contained within the seed-pods. The fibre is separated from the pods by a machine called a cotton gin. It is then cleaned and the fibres are separated out (carding). Finally the fibres are drawn out to the desired length and twisted together to form strong thread.

cotton stainer any plant-feeding bug of the family Pyrrhocoridae that pierces and stains cotton bolls; see also *Chemiptera*.

cottonwood any of several North American poplar trees with seeds topped by a thick tuft of silky hairs. The eastern cottonwood (*Populus deltoides*), growing to 30 m/100 ft, is native to the eastern USA. The name 'cottonwood' is also given to the downy-leaved Australian tree *Bedfordia salicina*. (True cottonwood genus *Populus*, family Salicaceae.)

cotton-worm caterpillar of the owl moth, closely allied to the army worm. Cotton-worms are found in both North and South America, where they ravage the cotton crops whilst ignoring other plants.

classification The cotton-worm *Aletia xylinæ* is in the family Noctuidae, order Lepidoptera, class Insecta, phylum Arthropoda.

cotyledon structure in the embryo of a seed plant that may form a 'leaf' after germination and is commonly known as a seed leaf. The number of cotyledons present in an embryo is an important character in the classification of flowering plants (angiosperms).

Monocotyledons (such as grasses, palms, and lilies) have a single cotyledon, whereas dicotyledons (the majority of plant species) have two. In seeds that also contain endosperm (nutritive tissue), the cotyledons are thin, but where they are the primary food-storing tissue, as in peas and beans, they may be quite large. After germination the cotyledons either remain below ground (hypogeal) or, more commonly, spread out above soil level (epigeal) and become the first green leaves. In gymnosperms there may be up to a dozen cotyledons within each seed.

couch grass European grass that spreads rapidly by underground stems. It is considered a troublesome weed in North America, where it has been introduced. (*Agropyron repens*, family Gramineae.)

cougar another name for the *puma*, a large North American cat.

coulomb SI unit (symbol C) of electrical charge. One coulomb is the quantity of electricity conveyed by a current of one ampere in one second.

Coulomb, Charles Augustin de (1736–1806) French scientist, inventor of the torsion balance for measuring the force of electric and magnetic attraction. The coulomb was named after him. In the fields of structural engineering and friction, Coulomb greatly influenced and helped to develop engineering in the 19th century.

Coulomb's law of 1787 states that the force between two electric charges is proportional to the product of the charges and inversely proportional to the square of the distance between them.

count rate in physics, the number of particles emitted per unit time by a radioactive source. It is measured by a counter, such as a Geiger counter, or ratemeter.

couple in mechanics, a pair of forces acting on an object that are equal in magnitude and opposite in direction, but do not act along the same straight line. The two forces produce a turning effect or moment that tends to rotate the object; however, no single resultant (unbalanced) force is produced and so the object is not moved from one position to another.

The moment of a couple is the product of the magnitude of either of the two forces and the perpendicular distance between those forces. If the magnitude of the force is F newtons and the distance is d metres then the moment, in newton-metres, is given by:

$$\text{moment} = Fd$$

couple Two equal but opposite forces (F) will produce a turning effect on a rigid body, provided that they do not act through the same straight line. The turning effect, or moment, is equal to the magnitude of one of the turning forces multiplied by the perpendicular distance (d) between those two forces.

courgette small variety of marrow, belonging to the gourd family. It is cultivated as a vegetable and harvested before it is fully mature, at 15–20 cm/6–8 in. In the USA and Canada it is known as a zucchini. (*Cucurbita pepo*, family Cucurbitaceae.)

courtship behaviour exhibited by animals as a prelude to mating. The behaviour patterns vary considerably from one species to another, but are often ritualized forms of behaviour not obviously related to courtship or mating (for example, courtship feeding in birds).

Courtship ensures that copulation occurs with a member of the opposite sex of the right species. It also synchronizes the partners' readiness to mate and allows each partner to assess the suitability of the other.

Cousteau, Jacques Yves (1910–1997) French oceanographer who pioneered the invention of the aqualung 1943 and techniques in underwater filming. In 1951 he began the first of many research voyages in the ship *Calypso*. His film and television documentaries and books established him as a household name.

covalent bond chemical bond produced when two atoms share one or more pairs of electrons (usually each atom contributes an electron). The bond is often represented by a single line drawn between the two atoms. Covalently bonded substances include hydrogen (H_2), water (H_2O), and most organic substances.

cowfish type of boxfish.

cow parsley or *keck* tall perennial plant belonging to the carrot family, found in Europe, N Asia, and N Africa. It grows up to 1 m/3 ft tall and has pinnate leaves (leaflets growing either side of a stem), hollow furrowed stems, and heads of delicate white flowers. (*Anthriscus sylvestris*, family Umbelliferae.)

cowrie marine snail of the family Cypridae, in which the interior or spiral form is concealed by a double outer lip. The shells are hard, shiny, and often coloured. Most cowries are shallow-water forms, and are found in many parts of the world, particularly the tropical Indo-Pacific. Cowries have been used as ornaments and fertility charms, and also as currency, for example the Pacific money cowrie *Cypraea moneta*.

cow shark species of shark. Cow sharks have six or seven gill openings, are about 5 m/16.5 ft long, and are found in most parts of the oceans.

classification Cow sharks are in family Hexanchidae, order Hexanchiformes, subclass Elasmobranchii, class Chondrichthyes.

cowslip European plant related to the primrose, with several small deep-yellow fragrant flowers growing from a single stem. It is native to temperate regions of the Old World. The oxlip (*Primula elatior*) is also closely related. (*Primula veris*, family Primulaceae.)

covalent bond The formation of a covalent bond between two hydrogen atoms to form a hydrogen molecule (H_2), and between two hydrogen atoms and an oxygen atom to form a molecule of water (H_2O). The sharing means that each atom has a more stable arrangement of electrons (its outer electron shells are full).

cowrie Although most species of cowrie are tropical, there are several European species. This European cowrie *Trivia monacha* is one of two species which can be found along the coast of the British Isles; they are likely to be found only at low water during periods of spring tides. Premaphotos Wildlife

coyote wild dog *Canis latrans*, in appearance like a small wolf, living in North and Central America. Its head and body are about 90 cm/3 ft long and brown, flecked with grey or black. Coyotes live in open country and can run at 65 kph/40 mph. Their main foods are rabbits and rodents. Although persecuted by humans for over a century, the species is very successful.

coyup South American water rodent *Myocastor coypus*, about 60 cm/2 ft long and weighing up to 9 kg/20 lb. It has a scaly, ratlike tail, webbed hind feet, a blunt-muzzled head, and large orange incisors. The fur ('nutria') is reddish brown. It feeds on vegetation, and lives in burrows in rivers and lake banks.

Taken to Europe and then to North America to be farmed for their fur, many escaped or were released. In Britain, coypus escaped from fur farms and became established on the Norfolk Broads where their adult numbers reached 5,000. They destroyed crops and local vegetation, and undermined banks and dykes. After a 10-year campaign they were eradicated in 1989 at a cost of over £2 million. In 1993 escaped coypu in Louisiana, USA, were causing serious damage to coastal marshland.

CP/M (abbreviation for *control program/monitor or control program for microcomputers*) one of the earliest operating systems for microcomputers. It was written by Gary Kildall, who founded Digital Research. In the 1970s it became a standard for microcomputers based on the Intel 8080 and Zilog Z80 8-bit microprocessors. In the 1980s it was superseded by Microsoft's QMS-DOS, written for Intel's 16-bit 8086/88 microprocessors.

CPSR abbreviation for QComputer Professionals for Social Responsibility.

CPU in computing, abbreviation for Qcentral processing unit.

crab any decapod (ten-legged) crustacean of the division Brachyura, with a broad, rather round, upper body shell (carapace) and a small Qabdomen tucked beneath the body. Crabs are related to lobsters and crayfish. Mainly marine, some crabs live in

CRAB

Female crabs can only mate just after moulting, when their shells are still soft. This is a vulnerable time, particularly for female paddle crabs, as some large male paddle crabs are cannibalistic. Most males, however, are keener to mate than to eat. Having found a female that is about to moult, the male paddle crab carries her around until she is ready, then mates with her and protects her until her shell hardens again.

fresh water or on land. They are alert carnivores and scavengers. They have a typical sideways walk, and strong pincers on the first pair of legs, the other four pairs being used for walking. Periodically, the outer shell is cast to allow for growth. The name 'crab' is sometimes used for similar arthropods, such as the horse-shoe crab, which is neither a true crab nor a crustacean.

crab apple any of 25 species of wild apple trees, native to temperate regions of the northern hemisphere. Numerous varieties of cultivated apples have been derived from *Malus pumila*, the common native crab apple of SE Europe and central Asia. The fruit of native species is smaller and more bitter than that of cultivated varieties and is used in crab-apple jelly. (Genus *Malus*, family Rosaceae.)

crab louse human pubic Qlouse.

classification The crab louse *Phthirus pubis* is in suborder Anoplura, order Phthiraptera, class Insecta, phylum Arthropoda.

Crab nebula cloud of gas 6,000 light years from Earth, in the constellation QTaurus. It is the remains of a star that according to Chinese records, exploded as a Qsupernova observed as a brilliant point of light on 4 July 1054. At its centre is a Qpulsar that flashes 30 times a second. It was named by Lord Rosse after its crablike shape.

crack street name for a chemical derivative (bicarbonate) of cocaine in hard, crystalline lumps; it is heated and inhaled (smoked) as a stimulant. Crack was first used in San Francisco in the early 1980s, and is highly addictive.

Its use has led to numerous deaths, but it is the fastest-growing sector of the illegal drug trade, since it is less expensive than cocaine.

cracker a hacker (see Qhacking); the term distinguishes criminal hacking ('cracking') from those who explore to satisfy their intellectual curiosity. The term is used much less than most hackers would like.

crab Crabs have adapted to many habitats. This *Sesarma* species crab from Kenya, E Africa, is adapted to the muddy tidal regions dominated by mangroves. Premaphotos Wildlife

cracking reaction in which a large alkane molecule is broken down by heat into a smaller alkane and a small alkene molecule. The reaction is carried out at a high temperature (600°C or higher) and often in the presence of a catalyst. Cracking is a commonly used process in the petrochemical industry.

It is the main method of preparation of alkenes and is also used to manufacture petrol from the higher-boiling-point fractions that are obtained by fractional distillation (fractionation) of crude oil.

crag in previously glaciated areas, a large lump of rock that a glacier has been unable to wear away. As the glacier passed up and over the crag, weaker rock on the far side was largely protected from erosion and formed a tapering ridge, or tail, of debris.

An example of a crag-and-tail feature is found in Edinburgh in Scotland; Edinburgh Castle was built on the crag (Castle Rock), which dominates the city beneath.

crake any of several small birds of the family Rallidae, order Gruliformes, related to the plover.

cranberry any of several trailing evergreen plants belonging to the heath family, related to bilberries and blueberries. They grow in marshy places and bear small, acid, crimson berries, high in vitamin C content, used for making sauce and jelly. (Genus *Vaccinium*, family Ericaceae.)

crane in engineering, a machine for raising, lowering, or placing in position heavy loads. The three main types are the jib crane, the overhead travelling crane, and the tower crane. Most cranes have the machinery mounted on a revolving turntable. This may be mounted on trucks or be self-propelled, often being fitted with caterpillar tracks.

The main features of a jib crane are a power winch, a rope or cable, and a movable arm or jib. The cable, which carries a pulley block, hangs from the end of the jib and is wound up and down by the winch. The overhead travelling crane, chiefly used in workshops, consists of a fixed horizontal arm, along which runs a trolley carrying the pulley block. Tower cranes, seen on large building sites, have a long horizontal arm able to revolve on top of a tall tower. The arm carries the trolley.

Cranes can also be mounted on barges or large semisubmersibles for marine construction work.

crane in zoology, a large, wading bird of the family Gruidae, order Gruliformes, with long legs and neck, short powerful wings, a naked or tufted head, and unwebbed feet. The hind toe is greatly elevated, and has a sharp claw. Cranes are marsh- and plains-dwelling birds, feeding on plants as well as insects and small animals. They fly well and are usually migratory. Their courtship includes frenzied, leaping dances. They are found in all parts of the world except South America.

The common crane *Grus grus* is still numerous in many parts of Europe, and winters in Africa and India. It stands over 1 m/3ft high. The plumage of the adult bird is grey, varied with black and white, with a red patch of bare skin on the head and neck. All cranes have suffered through hunting and loss of wetlands; the population of the North American whooping crane *G. americana* fell to 21 wild birds in 1944. Through careful conservation, numbers have now risen after 200.

crane fly or *daddy-longlegs* any fly of the family Tipulidae, with long, slender, fragile legs. They look like giant mosquitoes, but the adults are quite harmless. The larvae live in soil or water.

cranesbill any of a group of plants containing about 400 species. The plants are named after the long beaklike protrusion attached to the seed vessels. When ripe, this splits into coiling spirals which jerk the seeds out, helping to scatter them. (Genus *Geranium*, family Geraniaceae.)

cranium the dome-shaped area of the vertebrate skull that protects the brain. It consists of eight bony plates fused together by sutures (immovable joints). Fossil remains of the human cranium have aided the development of theories concerning human evolution.

The cranium has been studied as a possible indicator of intelligence or even of personality. The Victorian argument that a large

cranium implies a large brain, which in turn implies a more profound intelligence, has been rejected.

crank handle bent at right angles and connected to the shaft of a machine; it is used to transmit motion or convert reciprocating (backwards-and-forwards or up-and-down) movement into rotary movement, or vice versa.

Although similar devices may have been employed in antiquity and as early as the 1st century in China and the 8th century in Europe, the earliest recorded use of a crank in a water-raising machine is by Arab mathematician al-Jazari in the 12th century. Not until the 15th century, however, did the crank become fully assimilated into developing European technology.

crankshaft essential component of piston engines that converts the up-and-down (reciprocating) motion of the pistons into useful rotary motion. The car crankshaft carries a number of cranks. The pistons are connected to the cranks by connecting rods and bearings; when the pistons move up and down, the connecting rods force the offset crank pins to describe a circle, thereby rotating the crankshaft.

crater bowl-shaped depression in the ground, usually round and with steep sides. Craters are formed by explosive events such as the eruption of a volcano, the explosion of bomb, or the impact of a meteorite.

The Moon has more than 300,000 craters over 1 km/6 mi in diameter, formed by meteorite bombardment; similar craters on Earth have mostly been worn away by erosion. Craters are found on many other bodies in the Solar System.

Studies at the Jet Propulsion Laboratory in California, USA, have shown that craters produced by impact or by volcanic activity have distinctive shapes, enabling astronomers to distinguish likely methods of crater formation on planets in the Solar System. Unlike volcanic craters, impact craters have a raised rim and central peak and are almost always circular, irrespective of the meteorite's angle of incidence.

We used to think that if we knew one, we knew two, because one and one are two. We are finding that we must learn a great deal more about 'and'.

ARTHUR STANLEY EDDINGTON British astrophysicist.

Attributed remark

craton or *shield* core of a continent, a vast tract of highly deformed metamorphic rock around which the continent has been built. Intense mountain-building periods shook these shield areas in Precambrian times before stable conditions set in.

Cratons exist in the hearts of all the continents, a typical example being the Canadian Shield.

crawler on the World Wide Web, automated indexing software that scours the Web for new or updated sites. See also *bot*, *spider*, and *agent*.

crayfish freshwater decapod (ten-limbed) crustacean belonging to several families structurally similar to, but smaller than, the lobster. Crayfish are brownish-green scavengers and are found in all parts of the world except Africa. They are edible, and some species are farmed.

Accurate reckoning - the entrance into the knowledge of all existing things and all obscure secrets.

ARHMS THE SCRIBE Ancient Egyptian Scribe.

Rhind Papyrus

creationism theory concerned with the origins of matter and life, claiming, as does the Bible in Genesis, that the world and humanity were created by a supernatural Creator, not more than 6,000 years ago. It was developed in response to Darwin's theory of

crayfish The spectacular blue mountain crayfish *Euastacus ontanus* inhabits clear, swiftly-flowing mountain streams in the subtropical forests of 5 Queensland, Australia. Premaphotos Wildlife

evolution; it is not recognized by most scientists as having a factual basis.

After a trial 1981-82 a US judge ruled unconstitutional an attempt in Arkansas schools to enforce equal treatment of creationism and evolutionary theory. In Alabama from 1996 all biology textbooks must contain a statement that evolution is a controversial theory and not a proven fact.

Creative Labs name of the US and British subsidiaries of the parent computing company Creative Technology, which was founded in Singapore in 1981. Creative Labs manufactures the leading sound card, the SoundBlaster, which it markets alongside the Internet telephony, video, and multimedia products that make up the company's product range.

By the company claimed 20 million users of its products and had 4,400 staff worldwide, 400 of them in research and development.

creep in civil and mechanical engineering, the property of a solid, typically a metal, under continuous stress that causes it to deform below its yield point (the point at which any elastic solid normally stretches without any increase in load or stress). Lead, tin, and zinc, for example, exhibit creep at ordinary temperatures, as seen in the movement of the lead sheeting on the roofs of old buildings.

Copper, iron, nickel, and their alloys also show creep at high temperatures.

creeper any small, short-legged passerine bird of the family Certhidae. They spiral with a mouselike movement up tree trunks, searching for insects and larvae with their thin, down-curved beaks.

The brown creeper *Certhia familiaris* is 12 cm/5 in long, brown above, white below, and is found across North America and Eurasia.

creosote black, oily liquid derived from coal tar, used as a wood preservative. Medicinal creosote, which is transparent and oily, is derived from wood tar.

crescent curved shape of the Moon when it appears less than half illuminated. It also refers to any object or symbol resembling the crescent Moon. Often associated with Islam, it was first used by the Turks on their standards after the capture of Constantinople in 1453, and appears on the flags of many Muslim countries. The Red Crescent is the Muslim equivalent of the Red Cross.

cress any of several plants of the cress family, characterized by a pungent taste. The common European garden cress (*Lepidium sativum*) is cultivated worldwide. (Genera include *Lepidium*, *Cardamine*, and *Arabis*; family Cruciferae.)

Cretaceous Latin *creta* 'chalk' period of geological time approximately 144.2-65 million years ago. It is the last period of the Mesozoic era, during which angiosperm (seed-bearing) plants evolved, and dinosaurs reached a peak before their extinction at the end of the period. The north European chalk, which forms the white cliffs of Dover, was deposited during the latter half of the Cretaceous.

crevasse deep crack in the surface of a glacier; it can reach several metres in depth. Crevasses often occur where a glacier flows over the break of a slope, because the upper layers of ice are unable to stretch and cracks result. Crevasses may also form at the edges of glaciers owing to friction with the bedrock.

Crick, Francis Harry Compton (1916-)

English molecular biologist. From 1949 he researched the molecular structure of DNA, and the means whereby characteristics are transmitted from one generation to another. For this work he was awarded a Nobel prize (with Maurice Wilkins and James Watson) in 1962.

Using Wilkins's and others' discoveries, Crick and Watson postulated that DNA consists of a double helix consisting of two parallel chains of alternate sugar and phosphate groups linked by pairs of organic bases. They built molecular models which also explained how genetic information could be coded - in the sequence of organic bases. Crick and Watson published their work on the proposed structure of DNA in 1953. Their model is now generally accepted as correct.

Mary Evans Picture Library

cricket in zoology, an insect belonging to any of various families, especially the Gryllidae, of the order Orthoptera. Crickets are related to grasshoppers. They have somewhat flattened bodies and long antennae. The males make a chirping noise by rubbing together special areas on the forewings. The females have a long needlelike

cricket Most crickets are drably coloured in brown, grey, or black - this Kenyan species *Rhincogryllus lepidus* is an exception. Its bright livery is probably an example of aposematic (warning) coloration. Premaphotos Wildlife

egg-laying organ (ovipositor). There are around 900 species known worldwide.

Crinoidea class of echinoderms containing about 600 living species and more than 2,000 fossil forms; the extinct crinoids are commonly called stone lilies, and the existing species sea lilies and feather stars.

Crinoids retain many primitive features, notably in the use of the hydraulic water-vascular system for powering the capture and transportation of food rather than for locomotion. Uniquely amongst living echinoderms, the mouth is on the upper surface. Food particles are collected by the waving arms, and directed to the mouth along food grooves lined with cilia. Most of the living species are non-sessile (free-living), although a stalked stage may occur in development.

classification Crinoidea is in phylum Echinodermata.

crith unit of mass used for weighing gases. One crith is the mass of one litre of hydrogen gas (H_2) at standard temperature and pressure.

critical angle in optics, for a ray of light passing from a denser to a less dense medium (such as from glass to air), the smallest angle of incidence at which the emergent ray grazes the surface of the denser medium – at an angle of refraction of 90° .

When the angle of incidence is less than the critical angle, the ray passes out (is refracted) into the less dense medium; when the angle of incidence is greater than the critical angle, the ray is reflected back into the denser medium (see total internal reflection).

critical angle The critical angle is the angle at which light from within a transparent medium just grazes the surface of the medium. In the diagram, the red beam is at the critical angle. Blue beams escape from the medium, at least partially. Green beams are totally reflected from the surface.

critical density in cosmology, the minimum average density that the universe must have for it to stop expanding at some point in the future.

The precise value depends on Hubble's constant and so is not fixed, but it is approximately between 10^{-29} and 2×10^{-29} g/cm³, equivalent to a few hydrogen atoms per cubic metre. The density parameter (symbol Ω) is the ratio of the actual density to the critical density. If $\Omega < 1$, the universe is open and will expand forever (see heat death). If $\Omega > 1$, the universe is closed and the expansion will eventually halt, to be followed by a contraction (see Big Crunch). Current estimates from visible matter in the universe indicate that Ω is about 0.01, well below critical density, but unseen dark matter may be sufficient to raise Ω to somewhere between 0.1 and 2.

critical mass in nuclear physics, the minimum mass of fissile material that can undergo a continuous chain reaction. Below this mass, too many neutrons escape from the surface for a chain reaction to carry on; above the critical mass, the reaction may accelerate into a nuclear explosion.

critical path analysis procedure used in the management of complex projects to minimize the amount of time taken. The analysis shows which subprojects can run in parallel with each other, and which have to be completed before other subprojects can follow on.

By identifying the time required for each separate subproject and the relationship between the subprojects, it is possible to produce a planning schedule showing when each subproject should be started and finished in order to complete the whole project most efficiently. Complex projects may involve hundreds of subprojects, and computer applications packages for critical path analysis are widely used to help reduce the time and effort involved in their analysis.

critical reaction in a nuclear reactor, a self-sustaining chain reaction in which the number of neutrons being released by the fission of uranium-235 nuclei and the number of neutrons being absorbed by uranium-238 nuclei and by control rods are balanced. If balance is not achieved the reaction will either slow down and cease to generate enough power, or will build up and go out of control, as in a nuclear explosion. Control rods are used to adjust the rate of reaction and maintain balance.

critical temperature temperature above which a particular gas cannot be converted into a liquid by pressure alone. It is also the temperature at which a magnetic material loses its magnetism (the Curie temperature or point).

CRO abbreviation for cathode-ray oscilloscope.

crocodile large scaly-skinned reptile with a long, low cigar-shaped body and short legs. Crocodiles can grow up to 7 m/23 ft in length, and have long, powerful tails that propel them when swimming. They are found near swamps, lakes, and rivers in Asia, Africa, Australia, and Central America, where they are often seen floating in the water like logs, with only their nostrils, eyes, and ears above the surface. They are fierce hunters and active mainly at night. Young crocodiles eat worms and insects, but as they mature they add frogs and small fish to their diet. Adult crocodiles will attack animals the size of antelopes and even, occasionally, people. They can live up to 100 years and are related to the alligator and the smaller cayman.

behaviour In some species, the female lays over 100 hard-shelled eggs in holes or nest mounds of vegetation, which she guards until the eggs hatch, before carrying the hatchlings down to the water in her mouth. When in the sun, crocodiles cool themselves by opening their mouths wide, which also enables scavenging birds to pick their teeth. They can stay underwater for long periods, but must surface to breathe. The nostrils can be closed underwater. They ballast themselves with stones to adjust their buoyancy. Crocodiles have remained virtually unchanged for 200 million years.

types of crocodile There are 15 species of crocodile, all of them endangered, found in tropical parts of Africa, Asia, Australia, and Central America. The largest is the saltwater (indopacific) crocodile *Crocodylus porosus*, which can grow to 7 m/23 ft or more, and is found in E India, Australia, and the W Pacific, in both freshwater and saltwater habitats. The Nile crocodile *C. niloticus* is found in Africa and reaches 6 m/20 ft. The American crocodile *C. acutus*, about 4.6 m/15 ft long, is found from S Florida to Ecuador. The

CROCODILE

Over short distances on land, the crocodile can move at 48 kmph/30 mph, lifting itself up on its legs like a lizard. In the water, it can move at 32 kmph/20 mph.

ogavial, or gharial, *Gavialis gangeticus* is sometimes placed in a family of its own. It is an Indian species that grows to 6.5 m/21 ft or more, and has a very long narrow snout specialized for capturing and eating fish. The Cuban crocodile *C. rhombifer* has a short snout, grows up to 3.5 m/11.5 ft, and lives in freshwater swamps in Cuba. Morelet's crocodile *C. moreletii* is found in Central America, where it is overhunted, and grows up to 3.5 m/11.5 ft. Johnston's crocodile *C. johnsoni* is an Australian crocodile that feeds mainly on fish and reaches up to 3 m/9.75 ft in length. The Siamese crocodile *C. siamensis* is probably found only in captivity and grows up to 4 m/13 ft in length. The Philippine crocodile *C. mindorensis* is found in the Philippine Islands and grows to just under 3 m/9.75 ft. The mugger *C. palustris* is an Indian crocodile resembling the Nile crocodile but smaller, reaching up to 4 m/13 ft. The Orinoco crocodile *C. intermedius* grows up to 6 m/19.5 ft. False gharial *Tomistoma schlegelii* is found in rivers in India and Indochina and grows up to 4 m/13 ft. African slender-snouted crocodile *C. cataphractus* grows up to 4 m/13 ft and is found in western and central Africa. Dwarf crocodile *Osteoleaemus tetraspis* reaches only 2 m/6.6 ft in length and is found in the tropical forests of west and central Africa. New Guinea crocodile *C. novaeguineae* reaches 7 m/23 ft in length.

Differences between crocodiles and alligators Crocodiles differ from alligators in that they have a narrower, more pointed snout and their fourth tooth on the lower jaw can always be seen, even when their mouth is shut. On average, they are larger.

Classification Crocodiles are in the phylum Chordata, subphylum Vertebrata, class Reptilia, subclass Archosauria, order Crocodylia. There are 13 species in the Crocodylidae family, including the Nile crocodile (*Crocodylus niloticus*) and the saltwater crocodile (*C. porosus*).

The crocodile cannot turn its head. Like science, it must always go forward with all-devouring jaws.

PETER KAPITZA Russian physicist.
In A SVE Rutherford 1933

Crocodylia order of the class Reptilia that includes crocodiles, alligators, gavials, and caimans.

There are about 20 living species in three families. The Gavialidae family includes only the ogavial, a fish-eating reptile found in India. The Alligatoridae family includes two living species of alligators and several caimans. The Crocodylidae family contains the true crocodiles, comprising rather less than a dozen species ranging over Africa, Asia, northern Australia, and tropical America. The Indian crocodile, known as the mugger and erroneously as the alligator, ranges over India, Sri Lanka, Myanmar, and Malaysia. It is a freshwater variety inhabiting only rivers, lakes, and marshes, and in its characteristics most nearly approaches the caiman and the alligator.

crocus any of a group of plants belonging to the iris family, with single yellow, purple, or white flowers and narrow, pointed leaves. They are native to northern parts of the Old World, especially S Europe and Asia Minor. (Genus *Crocus*, family Iridaceae.)

During the dry season of the year crocuses remain underground in the form of a corm (underground storage organ), and produce fresh shoots and flowers in spring or autumn. At the end of the season of growth new corms are produced. Several species are cultivated as garden plants, the familiar mauve, white, and orange forms being varieties of *Crocus vernus*, *C. versicolor*, and *C. aureus*. The saffron crocus *C. sativus* belongs to the same genus. The so-called autumn crocus or meadow saffron (*Colchicum autumnale*) is not a true crocus but belongs to the lily family.

Crohn's disease or *regional ileitis* chronic inflammatory bowel disease. It tends to flare up for a few days at a time, causing diarrhoea, abdominal cramps, loss of appetite, weight loss, and mild fever. The cause of Crohn's disease is unknown, although stress may be a factor.

Crohn's disease may occur in any part of the digestive system but usually affects the small intestine. It is characterized by ulcer-

ation, abscess formation, small perforations, and the development of adhesions binding the loops of the small intestine. Affected segments of intestine may constrict, causing obstruction, or may perforate. It is treated by surgical removal of badly affected segments, and by corticosteroids. Mild cases respond to rest, bland diet, and drug treatment. Crohn's disease first occurs most often in adults aged 20-40.

crop in birds, the thin-walled enlargement of the digestive tract between the oesophagus and stomach. It is an effective storage organ especially in seed-eating birds; a pigeon's crop can hold about 500 cereal grains. Digestion begins in the crop, by the moistening of food. A crop also occurs in insects and annelid worms.

crop in computing, to cut away unwanted portions of a picture. The term comes from traditional manual methods of layout and paste-up; cropping is an option made available via photo-finishing and graphics software.

crop circle circular area of flattened grain found in fields especially in SE England, with increasing frequency every summer since 1980. More than 1,000 such formations were reported in the UK in 1991. The cause is unknown.

Most of the research into crop circles has been conducted by dedicated amateur investigators rather than scientists. Physicists who have studied the phenomenon have suggested that an electromagnetic whirlwind, or 'plasma vortex', can explain both the crop circles and some UFO sightings, but this does not account for the increasing geometrical complexity of crop circles, nor for the fact that until 1990 they were unknown outside the UK. Crop circles began to appear in the USA only after a US magazine published an article about them. A few people have confessed publicly to having made crop circles that were accepted as genuine by investigators.

crop rotation system of regularly changing the crops grown on a piece of land. The crops are grown in a particular order to utilize and add to the nutrients in the soil and to prevent the build-up of insect and fungal pests. Including a legume crop, such as peas or beans, in the rotation helps build up nitrate in the soil, because the roots contain bacteria capable of fixing nitrogen from the air.

A simple seven-year rotation, for example, might include a three-year ley followed by two years of wheat and then two years of barley, before returning the land to temporary grass once more. In this way, the cereal crops can take advantage of the build-up of soil fertility that occurs during the period under grass. In the 18th century, a four-year rotation was widely adopted with autumn-sown cereal, followed by a root crop, then spring cereal, and ending with a leguminous crop. Since then, more elaborate rotations have been devised with two, three, or four successive cereal crops, and with the root crop replaced by a cash crop such as sugar beet or potatoes, or by a legume crop such as peas or beans.

crossbill species of finch, genus *Loxia*, family Fringillidae, order Passeriformes, in which the hooked tips of the upper and lower beak cross one another, an adaptation for extracting the seeds from conifer cones. The red or common crossbill *Loxia curvirostra* is found in parts of Eurasia and North America, living chiefly in pine forests.

The parrot crossbill *L. pyropsittacus* of Europe, and the white-winged crossbill *L. leucoptera* of N Asia and North America, feed on pine and larch respectively.

crossing over in biology, a process that occurs during meiosis. While the chromosomes are lying alongside each other in pairs, each partner may twist around the other and exchange corresponding chromosomal segments. It is a form of genetic recombination, which increases variation and thus provides the raw material of evolution.

cross-linking in chemistry, lateral linking between two or more long-chain molecules in a polymer. Cross-linking gives the polymer a higher melting point and makes it harder. Examples of cross-linked polymers include Bakelite and vulcanized rubber.

cross-posting on USENET, the practice of sending a message to more than one newsgroup. A small amount of cross-posting is acceptable if the message is on a topic that is relevant to more than

one newsgroup. For example, a message about top tennis player André Agassi's personal life might be posted to both rec.sport.tennis and alt.showbiz.gossip. Large amounts of cross-posting are called spam (see *Spamming*) and may lead to flames and the attention of the CancelMoose.

cross-section the surface formed when a solid is cut through by a plane at right angles to its axis.

croup inflammation of the larynx in small children, with harsh, difficult breathing and hoarse coughing. Croup is most often associated with viral infection of the respiratory tract.

crow any of 35 species of omnivorous birds in the genus *Corvus*, family Corvidae, order Passeriformes, which also includes crows, jays, and magpies. Crows are usually about 45 cm/1.5 ft long, black, with a strong bill feathered at the base. The tail is long and graduated, and the wings are long and pointed, except in the jays and magpies, where they are shorter. Crows are considered to be very intelligent. The family is distributed throughout the world, though there are very few species in eastern Australia or South America. The common crows are *C. brachyrhynchos* in North America, and *C. corone* in Europe and Asia.

crowfoot any of several white-flowered aquatic plants belonging to the buttercup family, with a touch of yellow at the base of the petals. The divided leaves are said to resemble the feet of a crow. (Genus *Ranunculus*, family Ranunculaceae.)

CRT abbreviation for cathode-ray tube.

crude oil the unrefined form of petroleum.

crumple zone region at the front and rear of a motor vehicle that is designed to crumple gradually during a collision, so reducing the risk of serious injury to passengers. The progressive crumpling absorbs the kinetic energy of the vehicle more gradually than a rigid structure would, thereby diminishing the forces of deceleration acting on the vehicle and on the people inside.

crust the outermost part of the structure of Earth, consisting of two distinct parts, the oceanic crust and the continental crust. The oceanic crust is on average about 10 km/6.2 mi thick and consists mostly of basaltic types of rock. By contrast, the continental crust is largely made of granite and is more complex in its structure. Because of the movements of plate tectonics, the oceanic crust is in no place older than about 200 million years. However, parts of the continental crust are over 3 billion years old.

Beneath a layer of surface sediment, the oceanic crust is made up of a layer of basalt, followed by a layer of gabbro. The composition of the oceanic crust overall shows a high proportion of silicon and magnesium oxides, hence named sima by geologists. The continental crust varies in thickness from about 40 km/25 mi to 70 km/45 mi, being deeper beneath mountain ranges. The surface layer consists of many kinds of sedimentary and igneous rocks. Beneath lies a zone of metamorphic rocks built on a thick layer of granodiorite. Silicon and aluminum oxides dominate the composition and the name sial is given to continental crustal material.

crustacean one of the class of arthropods that includes crabs, lobsters, shrimps, woodlice, and barnacles. The external skeleton is made of protein and chitin hardened with lime. Each segment bears a pair of appendages that may be modified as sensory feelers (antennae), as mouthparts, or as swimming, walking, or grasping structures.

crust The crust of the Earth is made up of plates with different kinds of margins. In mid-ocean, there are constructive plate margins, where magma wells up from the Earth's interior, forming new crust. On continent-continent margins, mountain ranges are flung up by the collision of two continents. At an ocean-continent destructive margin, ocean crust is forced under the denser continental crust, forming an area of volcanic instability.

Crux constellation of the southern hemisphere, popularly known as the Southern Cross, the smallest of the 88 constellations but one of the brightest, and one of the best known as it is represented on the flags of Australia and New Zealand. Its brightest stars are Alpha Crucis (or Acrux), a δ double star about 400 light years from Earth, and Beta Crucis (or Mimosa).

Near Beta Crucis lies a glittering star cluster known as the Jewel Box, named by John Herschel. The constellation also contains the Coalsack, a dark nebula silhouetted against the bright starry background of the Milky Way.

cryogenics science of very low temperatures (approaching absolute zero), including the production of very low temperatures and the exploitation of special properties associated with them, such as the disappearance of electrical resistance (δ superconductivity).

Low temperatures can be produced by the Joule-Thomson effect (cooling a gas by making it do work as it expands). Gases such as oxygen, hydrogen, and helium may be liquefied in this way, and temperatures of 0.3K can be reached. Further cooling requires magnetic methods; a magnetic material, in contact with the substance to be cooled and with liquid helium, is magnetized by a strong magnetic field. The heat generated by the process is carried away by the helium. When the material is then demagnetized, its temperature falls; temperatures of around 10⁻³K have been achieved in this way. At temperatures near absolute zero, materials can display unusual properties. Some metals, such as mercury and lead, exhibit superconductivity. Liquid helium loses its viscosity and becomes a 'superfluid' when cooled to below 2K; in this state it flows up the sides of its container. Cryogenics has several practical applications. **Cryotherapy** is a process used in eye surgery, in which a freezing probe is briefly applied to the outside of the eye to repair a break in the retina. Electronic components called δ Josephson junctions, which could be used in very fast computers, need low temperatures to function. Magnetic levitation (δ maglev) systems must be maintained at low temperatures. Food can be frozen for years, and freezing eggs, sperm and pre-embryos is now routine. In September 1996 South African researchers resuscitated a rat's heart that had been frozen to -196°C.

CRYONICS FREQUENTLY ASKED QUESTION LIST

<http://www.cs.cmu.edu/afs/cs/user/tsf/Public-Mail/cryonics/html/overview.html>

Answers to all the questions you could possibly ask about the controversial practice of cryonics. If, after reading this, you are tempted to give it a go, be warned. Of the sixty people who have been suspended, forty have been thawed out and buried, as the cryonics companies they had paid went bankrupt.

cryolite rare granular crystalline mineral (sodium aluminium fluoride), Na₃AlF₆, used in the electrolytic reduction of δ bauxite to aluminium. It is chiefly found in Greenland.

cryptogam obsolete name applied to the lower plants. It included the algae, liverworts, mosses, and ferns (plus the fungi and bacteria in very early schemes of classification). In such classifications seed plants were known as δ phanerogams.

cryptography science of creating and reading codes; for example, those produced by the Enigma coding machine used by the Germans in World War II and those used in commerce by banks encoding electronic fund-transfer messages, business firms sending computer-conveyed memos between headquarters, and in the growing field of electronic mail. The breaking and decipherment of such codes is known as 'cryptanalysis'. No method of encrypting is completely unbreakable, but decoding can be made extremely complex and time consuming.

CRYPTOGRAPHY

<http://rschp2.anu.edu.au:8080/crypt.html>

Introduction to the whys and wherefores of encrypting messages, particularly within an Internet framework. The author introduces various common encrypting systems and explains their relative weaknesses. The site also includes a good page on public-key cryptography which is becoming increasingly important as more and more information is transmitted electronically.

cryptosporidium waterborne parasite that causes disease in humans and other animals. It has been found in drinking water in the UK and USA, causing diarrhoea, abdominal cramps, vomiting, and fever, and can be fatal in people with damaged immune systems, such as AIDS sufferers or those with leukaemia. Just 30 cryptosporidia are enough to cause prolonged diarrhoea.

Conventional filtration and chlorine disinfection are ineffective at removing the parasite. Slow sand filtration is the best method of removal, but the existing systems were dismantled in the 1970s because of their slowness.

crystal substance with an orderly three-dimensional arrangement of its atoms or molecules, thereby creating an external surface of clearly defined smooth faces having characteristic angles between them. Examples are table salt and quartz.

Each geometrical form, many of which may be combined in one crystal, consists of two or more faces – for example, dome, prism, and pyramid. A mineral can often be identified by the shape of its crystals and the system of crystallization determined. A single crystal can vary in size from a submicroscopic particle to a mass some 30 m/100 ft in length. Crystals fall into seven crystal systems or groups, classified on the basis of the relationship of three or four imaginary axes that intersect at the centre of any perfect, undistorted crystal.

crystallization formation of crystals from a liquid, gas, or solution.

crystallography the scientific study of crystals. In 1912 it was found that the shape and size of the repeating atomic patterns (unit cells) in a crystal could be determined by passing X-rays through a sample. This method, known as δ X-ray diffraction, opened up an entirely new way of 'seeing' atoms. It has been found that many substances have a unit cell that exhibits all the symmetry of the whole crystal; in table salt (sodium chloride, NaCl), for instance, the unit cell is an exact cube.

Many materials were not even suspected of being crystals until they were examined by X-ray crystallography. It has been shown that purified biomolecules, such as proteins and DNA, can form crystals, and such compounds may now be studied by this method. Other applications include the study of metals and their alloys, and of rocks and soils.

CRYSTALLOGRAPHY AND MINERALOGY

<http://www.iuamsc.indiana.edu/docs/crystmin.htm>

Understand the shapes and symmetries of crystallography, with these interactive drawings of cubic, tetrahedral, octahedral, and dodecahedral solids (just drag your mouse over the figures to rotate them).

CSCW abbreviation for δ computer-supported collaborative work.

CSH abbreviation for corticotrophin-releasing hormone.

CSLIP (abbreviation for *Compressed Serial Line Internet Protocol*) in computing, newer version of δ SLIP allowing slightly faster dial-up connections to the Internet.

CT scanner medical device used to obtain detailed X-ray pictures of the inside of a patient's body. See *☞* CAT scan.

CTS/RTS (abbreviation for *Clear To Send/Ready To Send*) in computing, hardware handshaking (see *handshake*) used in high-speed modems. In most communications software this is an option that can be toggled on or off. The alternative, software handshaking, is considered less reliable at high speeds.

cu abbreviation for **cubic** (measure).

CUA (abbreviation for *common user access*) standard designed by Microsoft to ensure that identical actions, such as saving a file or accessing help, can be carried out using the same keystrokes in any piece of software. For example, in programs written to the CUA standard, help is always summoned by pressing the F1 function key. New programs should be easier to use because users will not have to learn new commands to perform standard tasks.

cube in geometry, a regular solid figure whose faces are all squares. It has 6 equal-area faces and 12 equal-length edges.

If the length of one edge is l , the volume V of the cube is given by:

$$V = l^3$$

and its surface area A by:

$$A = 6l^2$$

cube to multiply a number by itself and then by itself again. For example, 5 cubed = $5^3 = 5 \times 5 \times 5 = 125$. The term also refers to a number formed by cubing; for example, 1, 8, 27, 64 are the first four cubes.

cubic centimetre (or metre) the metric measure of volume, corresponding to the volume of a cube whose edges are all 1 cm (or 1 metre) in length.

cubic decimetre metric measure (symbol dm^3) of volume corresponding to the volume of a cube whose edges are all 1 dm (10 cm) long; it is equivalent to a capacity of one litre.

cubic equation any equation in which the largest power of x is x^3 . For example, $x^3 + 3x^2y + 4y^2 = 0$ is a cubic equation.

cubic measure measure of volume, indicated either by the word 'cubic' followed by a linear measure, as in 'cubic foot', or the word 'cubed' after a linear measure, as in 'metre cubed'.

cubit earliest known unit of length, which originated between 2800 and 2300 BC. It is approximately 50.5 cm/20.6 in long, which is about the length of the human forearm measured from the tip of the middle finger to the elbow.

cuboid six-sided three-dimensional prism whose faces are all rectangles. A brick is a cuboid.

cuckoo species of bird, any of about 200 members of the family Cuculidae, order Cuculiformes, especially the Eurasian cuckoo *Cuculus canorus*, whose name derives from its characteristic call. Somewhat hawklike, it is about 33 cm/1.1 ft long, bluish-grey and barred beneath (females are sometimes reddish), and typically has a long, rounded tail. Cuckoos feed on insects, including hairy caterpillars that are distasteful to most birds. It is a 'brood parasite', laying its eggs singly, at intervals of about 48 hours, in the nests of small insectivorous birds. As soon as the young cuckoo hatches, it ejects all other young birds or eggs from the nest and is tended by its 'foster parents' until fledging. American species of cuckoo hatch and rear their own young.

The North American roadrunner *Geococcyx californianus* is a member of the cuckoo family, and the yellow-billed cuckoo, *Coccyzus americanus*, incubates its own eggs.

cuckoo flower or *lady's smock* perennial meadow plant of northern temperate regions. From April to June it bears pale lilac flowers, which later turn white. (*Cardamine pratensis*, family Cruciferae.)

cuckoo-pint or *lords-and-ladies* perennial European plant, a wild arum. It has large arrow-shaped leaves that appear in early spring and flower-bearing stalks enclosed by a bract, or spathe (specialized leaf). The bright red berrylike fruits, which are poisonous, appear in late summer. (*Arum maculatum*, family Araceae.)

cuckoo spit the frothy liquid surrounding and exuded by the larvae of the *☞* frog hopper.

cuckoo-spit insect another name for *☞* frog hopper.

cucumber trailing annual plant belonging to the gourd family, producing long, green-skinned fruit with crisp, translucent, edible flesh. Small cucumbers, called gherkins, usually the fruit of *Cucurbitaceae*.)

There are about 735 species belonging to the cucumber family.

cultivar variety of a plant developed by horticultural or agricultural techniques. The term derives from 'cultivated variety'.

culture in biology, the growing of living cells and tissues in laboratory conditions.

cumin seedlike fruit of the herb cumin, which belongs to the carrot family. It has a bitter flavour and is used as a spice in cooking. (*Cuminum cyminum*, family Umbelliferae.)

cumulative frequency in statistics, the total frequency of a given value up to and including a certain point in a set of data. It is used to draw the cumulative frequency curve, the ogive.

cuprite Cu_2O ore (copper(I) oxide), found in crystalline form or in earthy masses. It is red to black in colour, and is often called ruby copper.

cupronickel copper alloy (75% copper and 25% nickel), used in hardware products and for coinage.

curare black, resinous poison extracted from the bark and juices of various South American trees and plants. Originally used on arrowheads by Amazonian hunters to paralyse prey, it blocks nerve stimulation of the muscles. Alkaloid derivatives (called curarines) are used in medicine as muscle relaxants during surgery.

curie former unit (symbol Ci) of radioactivity, equal to 3.7×10^{10} *☞* becquerels. One gram of radium has a radioactivity of about one curie. It was named after French physicist Pierre Curie.

Curie temperature the temperature above which a magnetic material cannot be strongly magnetized. Above the Curie temperature, the energy of the atoms is too great for them to join together to form the small areas of magnetized material, or *☞* domains, which combine to produce the strength of the overall magnetization.

curing method of preserving meat by soaking it in salt (sodium chloride) solution, with saltpetre (sodium nitrate) added to give the meat its pink colour and characteristic taste. The nitrates in cured meats are converted to nitrites and nitrosamines by bacteria, and these are potentially carcinogenic to humans.

curium synthesized, radioactive, metallic element of the *actinide* series, symbol Cm, atomic number 96, relative atomic mass 247. It is produced by bombarding plutonium or americium with neutrons. Its longest-lived isotope has a half-life of 1.7×10^7 years.

curlew wading bird of the genus *Numenius* of the sandpiper family, Scolopacidae, order Charadriiformes. The curlew is between 36 cm/14 in and 55 cm/1.8 ft long, and has pale brown plumage with dark bars and mainly white underparts, long legs, and a long, thin, downcurved bill. It feeds on a variety of insects and other invertebrates. Several species live in N Europe, Asia, and North America. The name derives from its haunting flutlike call.

One species, the Eskimo curlew, is almost extinct, never having recovered from relentless hunting in the late 19th century.

currant berry of a small seedless variety of cultivated grape (*Vitis vinifera*). Currants are grown on a large scale in Greece and California and are dried for use in cooking and baking. Because of the similarity of the fruit, the name 'currant' is also given to several species of shrubs (genus *Ribes*, family Grossulariaceae).

Curie, Marie (1867-1934)

(born *Manya Skłodowska*) Polish scientist who, with husband Pierre Curie, discovered in 1898 two new radioactive elements in pitchblende ores: polonium and radium. They isolated the pure elements in 1902. Both scientists refused to take out a patent on their discovery and were jointly awarded the Nobel Prize for Physics 1903, with Henri Becquerel. Marie Curie was also awarded the Nobel Prize for Chemistry 1911.

From 1896 the Curies worked together on radioactivity, building on the results of Wilhelm Röntgen (who had discovered X-rays) and Becquerel (who had discovered that similar rays are emitted by uranium salts). Marie Curie discovered that thorium emits radiation and found that the mineral pitchblende was even more radioactive than could be accounted for by any uranium and thorium content. In July 1898, the Curies announced the discovery of polonium, followed by the discovery of radium five months later. They eventually prepared 1 g/0.04 oz of pure radium chloride - from 8 tonnes of waste pitchblende from Austria.

They also established that beta rays (now known to consist of electrons) are negatively charged particles. In 1910 with André Debierne (1874-1949), who had discovered actinium in pitchblende 1899, Marie Curie isolated pure radium metal in 1911.

Curie, Pierre (1859-1906) French scientist. He shared the Nobel Prize for Physics 1903 with his wife Marie Curie and Henri Becquerel. From 1896 the Curies had worked together on radioactivity, discovering two radioactive elements.

Mary Evans Picture Library

current flow of a body of water or air, or of heat, moving in a definite direction. Ocean currents are fast-flowing currents of seawater generated by the wind or by variations in water density between two areas. They are partly responsible for transferring heat from the Equator to the poles and thereby evening out the global heat imbalance. There are three basic types of ocean current: **drift currents** are broad and slow-moving; **stream currents** are narrow and swift-moving; and **upwelling currents** bring cold, nutrient-rich water from the ocean bottom.

Stream currents include the Gulf Stream and the Japan (or Kuroshio) Current. Upwelling currents, such as the Gulf of Guinea Current and the Peru (Humboldt) current, provide food for plankton, which in turn supports fish and sea birds. At approximate five-to-eight-year intervals, the Peru Current that runs from the Antarctic up the W coast of South America, turns warm, with heavy rain and rough seas, and has disastrous results (as in 1982-83) for Peruvian wildlife and for the anchovy industry. The phenomenon is called El Niño (Spanish 'the Child') because it occurs towards Christmas.

current directory in a computer's file system, the directory in which the user is positioned. As users move around a computer system, opening, reading, writing, and storing files, they navigate through that computer's directory structure. Most file commands are assumed to apply to the files in the current directory.

In DOS, adding the command 'prompt \$P\$' to the 'autoexec.bat' file sets the computer to display the name and path of the current

directory at the system prompt. On an FTP (file transfer protocol) site, the command 'pwd' will print the name of the current directory on the remote machine.

current, electric see *electric current*.

cursor on a computer screen, the symbol that indicates the current entry position (where the next character will appear). It usually consists of a solid rectangle or underline character, flashing on and off.

curve in geometry, the locus of a point moving according to specified conditions. The circle is the locus of all points equidistant from a given point (the centre). Other common geometrical curves are the ellipse, parabola, and hyperbola, which are also produced when a cone is cut by a plane at different angles.

Many curves have been invented for the solution of special problems in geometry and mechanics - for example, the cissoid (the inverse of a parabola) and the cycloid.

cuscus tree-dwelling marsupial found in Australia, New Guinea, and Sulawesi. There are five species, all about the size of a cat. They have a prehensile tail and an opposable big toe.

Phalanger spilocus is known as the spotted cuscus or tiger cat; *P. ursinus* and *P. celebensis* are natives of the Celebes. **classification** Cuscuses are in genus *Phalanger*, in the family Phalangeridae (possums), order Marsupialia, class Mammalia.

CU-SeeMe in computing, software that enables videoconferencing across the Internet. Developed by US computer scientist Richard Cogger, CU-SeeMe was bought in 1996 by US videoconferencing specialist White Pine Software of Nashua, New Hampshire, and is now a commercial product.

Early experiments with CU-SeeMe included broadcasts by the North American Space Agency (NASA) of live and prerecorded video footage of shuttle missions, New Year parties held at cybercafes around the world, and live hook-ups between schools.

cusp point where two branches of a curve meet and the tangents to each branch coincide.

custard apple any of several large edible heart-shaped fruits produced by a group of tropical trees and shrubs which are often cultivated. Bullock's heart (*Annona reticulata*) produces a large dark-brown fruit containing a sweet reddish-yellow pulp; it is a native of the West Indies. (Family Annonaceae.)

cuticle the horny noncellular surface layer of many invertebrates such as insects; in botany, the waxy surface layer on those parts of plants that are exposed to the air, continuous except for stomata and lenticels. All types are secreted by the cells of the epidermis. A cuticle reduces water loss and, in arthropods, acts as an exoskeleton.

cutting technique of vegetative propagation involving taking a section of root, stem, or leaf and treating it so that it develops into a new plant.

*He that uses many words for the explaining of any subject,
doth, like the cuttle fish, hide himself for the most part in his
own ink.*

JOHN RAY English naturalist.
On the Creation

cuttlefish any of a family, Sepiidae, of squidlike cephalopods with an internal calcareous shell (cuttlebone). The common cuttle *Sepia officinalis* of the Atlantic and Mediterranean is up to 30 cm/1 ft long. It swims actively by means of the fins into which the sides of its oval, flattened body are expanded, and jerks itself backwards by shooting a jet of water from its 'siphon'.

It is capable of rapid changes of colour and pattern. The large head has conspicuous eyes, and the ten arms are provided with suckers. Two arms are very much elongated, and with them the

cuttlefish seizes its prey. It has an ink sac from which a dark fluid can be discharged into the water, distracting predators from the cuttle itself. The dark brown pigment sepia is obtained from the ink sacs of cuttlefish.

cutworm common name for the larva of many species of owlet-moth. They cut off the young shoots of cultivated plants. They are related to the army-worm and cotton-worm.

classification Cutworms belong to several genera, including *Agrotis*, *Prodenia*, and *Euxoa* in the family Noctuidae, class Insecta, phylum Arthropoda.

CWIS in computing, abbreviation for campus-wide information service.

cwt symbol for hundredweight, a unit of weight equal to 112 pounds (50.802 kg); 100 lb (45.36 kg) in the USA.

cyanamide process process used in the manufacture of calcium cyanamide (CaCN_2), a colourless crystalline powder used as a fertilizer under the tradename Nitrolime. Calcium carbide is reacted with nitrogen in an electric furnace.

The calcium cyanamide reacts with water in the soil to form the ammonium ion and calcium carbonate. The ammonium is then oxidized to nitrate, which is taken up by plants. Calcium cyanamide can also be converted commercially into ammonia.

cyanide CN^- ion derived from hydrogen cyanide (HCN), and any salt containing this ion (produced when hydrogen cyanide is neutralized by alkalis), such as potassium cyanide (KCN). The principal cyanides are potassium, sodium, calcium, mercury, gold, and copper. Certain cyanides are poisons.

cyanobacteria (singular *cyanobacterium*) alternative name for blue-green algae.

cyanocobalamin chemical name for vitamin B_{12} , which is normally produced by microorganisms in the gut. The richest sources are liver, fish, and eggs. It is essential to the replacement of cells, the maintenance of the myelin sheath which insulates nerve fibres, and the efficient use of folic acid, another vitamin in the B complex. Deficiency can result in pernicious anaemia (defective production of red blood cells), and possible degeneration of the nervous system.

cybercafe coffeehouse equipped with public-access Internet terminals. Typically, users pay a small sum to use the terminals for short periods. Cafes usually supply brief tutorials for newcomers. By 1996 many major cities around the world had such cafes. There were more than 1,200 cybercafes in 78 countries by the end of 1997.

CyberCash in computing, one of several schemes for electronic money that can be used to trade on the Internet. Founded in 1994, CyberCash uses the RSA encryption algorithm to protect customer financial information in transit.

The system stores customers' payment information, such as credit card numbers, in an electronic wallet, software which is downloaded from the company's site on the World Wide Web. When a customer wishes to buy something at a commercial Web site, the site generates a payment request, the customer adds a payment method, and the CyberCash server authenticates the transaction. Future plans are to add electronic cheques and cash or debit cards to the choice of payment instruments. See also eDigitalCash.

cyberlaw in computing, relatively new field of Internet and computer law. Still being defined, the field includes new areas such as the responsibility of Internet Service Providers and bulletin-board system operators for the material that passes through or is stored on their systems and the framework for international electronic commerce, and a new look at traditional areas such as intellectual property rights and copyright and censorship.

cybernetics Greek *kubernan* 'to steer' science concerned with how systems organize, regulate, and reproduce themselves, and

also how they evolve and learn. In the laboratory, inanimate objects are created that behave like living systems. Applications range from the creation of electronic artificial limbs to the running of the fully automated factory where decisionmaking machines operate up to managerial level.

Cybernetics was founded and named in 1947 by US mathematician Norbert Wiener. Originally, it was the study of control systems using feedback to produce automatic processes.

We should take care not to make the intellect our god; it has, of course, powerful muscles, but no personality.

ALBERT EINSTEIN German-born US physicist.

Out of My Later Life

cyberpunk in computing, term coined by US science-fiction writer and editor Gardner Dozois for a particular type of modern science fiction that combines high-technology landscapes with countercultural social and political ideas. Leading writers in this genre include William Gibson, Bruce Sterling, Pat Cadigan, Greg Bear, and Rudy Rucker.

cybersex in computing, online sexual fantasy spun by two or more participants via live, online chat. Futurists hypothesize about a future where 'virtual' sex will take place in virtual reality via body suits and other hardware input devices. In 1996, however, cybersex is limited to text-based systems such as IRC (Internet Relay Chat) or the shared worlds created in MUDs (Multiuser dungeons) and MOOs (MUD, object-oriented), both shared role-playing game worlds.

cyberspace the imaginary, interactive 'worlds' created by networked computers; often used interchangeably with 'virtual world'. The invention of the word 'cyberspace' is generally credited to US science-fiction writer William Gibson (1948–) and his first novel *Neuromancer* 1984.

As well as meaning the interactive environment encountered in a virtual reality system, cyberspace is 'where' the global community of computer-linked individuals and groups lives. From the mid-1980s, the development of computer networks and telecommunications, both international (such as the Internet) and local (such as the services known as 'bulletin board' or conferencing systems), made possible the instant exchange of messages using electronic mail and electronic conferencing systems directly from the individual's own home.

cycad any of a group of plants belonging to the Cycnospores, whose seeds develop in cones. Some are superficially similar to palms, others to ferns. Their large cones contain fleshy seeds. There are ten genera and about 80–100 species, native to tropical and subtropical countries. Cycads were widespread during the Mesozoic era (245–65 million years ago). (Order Cycadales.)

The stems of many species yield an edible starchy substance resembling $\text{C}_2\text{H}_5\text{O}$. In 1993 cycads were discovered to be pollinated by insects, not by wind as had been previously thought; their cones produce heat that vaporizes a sweet minty odour to attract insects to a supply of nectarlike liquid.

cyclamate derivative of cyclohexylsulphamic acid, formerly used as an artificial sweetener, 30 times sweeter than sugar. It was first synthesized 1937.

Its use in foods was banned in the USA and the UK from 1970, when studies showed that massive doses caused cancer in rats.

cyclamen any of a group of perennial plants belonging to the primrose family, with heart-shaped leaves and petals that are pruned at the base and bent back, away from the centre of the downward-facing flower. The flowers are usually white or pink, and several species are cultivated. (Genus *Cyclamen*, family Primulaceae.)

cycle in physics, a sequence of changes that moves a system away from, and then back to, its original state. An example is a vibration that moves a particle first in one direction and then in the opposite

direction, with the particle returning to its original position at the end of the vibration.

cyclic compound any of a group of organic chemicals that have rings of atoms in their molecules, giving them a closed-chain structure.

cyclic polygon in geometry, a polygon in which each vertex (corner) lies on the circumference of a circle.

cyclic quadrilateral four-sided figure with all four of its vertices lying on the circumference of a circle. The opposite angles of cyclic quadrilaterals add up to 180° , and are therefore said to be supplementary; each external angle (formed by extending a side of the quadrilateral) is equal to the opposite interior angle.

Cycliophora invertebrate phylum containing only one known species *Symbion pandora*. The phylum was discovered in 1995. *S. pandora* are minute (347 μm) bottle-shaped invertebrates living amongst the mouthparts of lobsters. They have threadlike cilia for gathering food and are attached by an adhesive disc. They have a reproductive cycle consisting of both asexual and sexual forms. The cycliophoran's nearest known relatives are bryozoans.

cyclodextrin ring-shaped α -glucose molecule chain created in 1993 at Osaka University, Japan. Cyclodextrins are commonly used in food additives, and can also be used as capsules to deliver drugs, as cutters to separate ions and molecules, and as catalysts for chemical reactions.

They generally consist of 6–8 glucose molecules linked together in a ring, leaving a central hole of 0.45–0.8 nanometres, which can hold a small molecule such as benzene. They can be joined together to form tubes even smaller than DNA, the length and width of which can be controlled. They could hypothetically be used in the production of large scale integrated computer systems.

cycloid in geometry, a curve resembling a series of arches traced out by a point on the circumference of a circle that rolls along a straight line. Its applications include the study of the motion of wheeled vehicles along roads and tracks.

cyclone alternative name for a δ depression, an area of low atmospheric pressure. A severe cyclone that forms in the tropics is called a tropical cyclone or δ hurricane.

cyclotron circular type of particle δ accelerator.

Cygnus large prominent constellation of the northern hemisphere, represented as a swan. Its brightest star is first-magnitude Alpha Cygni or δ Deneb.

Beta Cygni (Albireo) is a yellow and blue δ double star, visible through small telescopes. The constellation contains the North America nebula (named after its shape), the Veil nebula (the remains of a δ supernova that exploded about 50,000 years ago), Cygnus A (apparently a double galaxy, a powerful radio source, and the first radio star to be discovered), and the X-ray source Cygnus X-1, thought to mark the position of a black hole. The area is rich in high luminosity objects, nebulae, and clouds of obscuring matter. Deneb marks the tail of the swan, which is depicted as lying along the Milky Way. Some of the brighter stars form the Northern Cross, the upright being defined by Alpha, Gamma, Eta, and Beta, and the crosspiece by Delta, Gamma, and Epsilon Cygni.

cylinder in computing, combination of the tracks on all the platters making up a hard drive or fixed disc that can be accessed without moving the read/write heads.

cylinder The volume and area of a cylinder are given by simple formulae relating the dimensions of the cylinder.

cylinder in geometry, a tubular solid figure with a circular base. In everyday use, the term applies to a **right cylinder**, the curved surface of which is at right angles to the base.

The volume V of a cylinder is given by the formula $V = \pi r^2 h$, where r is the radius of the base and h is the height of the cylinder. Its total surface area A has the formula $A = 2\pi r(h + r)$, where $2\pi r h$ is the curved surface area, and $2\pi r^2$ is the area of both circular ends.

cymbidium genus of generally epiphytic orchids found in Africa, Asia, and Australia, producing numerous showy flowers. The three Australian species are popular subjects for hybridization.

cyberpunk (contraction of 'c δ ipher' and 'c δ yperpunk') in computing, a passionate believer in the importance of free access to strong encryption on the Net, in the interests of guarding privacy and free speech.

cypress any of a group of coniferous trees or shrubs containing about 20 species, originating from temperate regions of the northern hemisphere. They have tiny scalelike leaves and cones made up of woody, wedge-shaped scales containing an aromatic δ resin. (Genera *Cupressus* and *Chamaecyparis*, family Cupressaceae.)

cystic fibrosis hereditary disease involving defects of various tissues, including the sweat glands, the mucous glands of the bronchi (air passages), and the pancreas. The sufferer experiences repeated chest infections and digestive disorders and generally fails to thrive. In 1989 a gene for cystic fibrosis was identified by teams of researchers in Michigan, USA, and Toronto, Canada. This discovery enabled the development of a screening test for carriers; the disease can also be detected in the unborn child.

inheriting the disease One person in 22 is a carrier of the disease. If two carriers have children, each child has a one-in-four chance of having the disease, so that it occurs in about one in 2,000 pregnancies. Around 10% of newborns with cystic fibrosis develop an intestinal blockage (meconium ileus) which requires surgery.

treatment Cystic fibrosis was once universally fatal at an early age; now, although there is no definitive cure, treatments have

cycloid The cycloid is the curve traced out by a point on a circle as it rolls along a straight line. The teeth of gears are often cut with faces that are arcs of cycloids so that there is rolling contact when the gears are in use.

raised both the quality and expectancy of life. Results in 1995 from a four-year US study showed that the painkiller ibuprofen, available over the counter, slowed lung deterioration in children by almost 90% when taken in large doses.

Management of cystic fibrosis is by diets and drugs, physiotherapy to keep the chest clear, and use of antibiotics to combat infection and minimize damage to the lungs. Some sufferers have benefited from heart-lung transplants.

gene therapy In 1993, UK researchers (at the Imperial Cancer Research Fund, Oxford, and the Wellcome Trust, Cambridge) successfully introduced a corrective version of the gene for cystic fibrosis into the lungs of mice with induced cystic fibrosis, restoring normal function (in 1992, US researchers had introduced such a gene into the lungs of healthy laboratory rats, greatly improving the prospect of a cure). Trials in human subjects began in 1993, and the cystic fibrosis defect in the nasal cavities of three patients in the USA was successfully corrected, though a later trial was halted after a patient became ill following a dose of the genetically altered virus. Patients treated by gene therapy administered in the form of a nasal spray were showing signs of improvement following a preliminary trial in 1996. Cystic fibrosis is seen as a promising test case for gene therapy. It is the commonest fatal hereditary disease amongst white people.

cystitis inflammation of the bladder, usually caused by bacterial infection, and resulting in frequent and painful urination. It is more common in women. Treatment is by antibiotics and copious fluids with vitamin C.

cytochrome protein responsible for part of the process of respiration by which food molecules are broken down in aerobic organisms. Cytochromes are part of the electron transport chain, which uses energized electrons to reduce molecular oxygen (O_2) to oxygen ions (O^{2-}). These combine with hydrogen ions (H^+) to form water (H_2O), the end product of aerobic respiration. As electrons

are passed from one cytochrome to another, energy is released and used to make ATP.

cytokine in biology, chemical messenger that carries information from one cell to another, for example the lymphokines.

cytokinin plant hormone that stimulates cell division. Cytokinins affect several different aspects of plant growth and development, but only if auxin is also present. They may delay the process of senescence, or ageing, break the dormancy of certain seeds and buds, and induce flowering.

cytology the study of cells and their functions. Major advances have been made possible in this field by the development of electron microscopes.

cytoplasm the part of the cell outside the nucleus. Strictly speaking, this includes all the organelles (mitochondria, chloroplasts, and so on), but often cytoplasm refers to the jellylike matter in which the organelles are embedded (correctly termed the cytosol). The cytoplasm is the site of protein synthesis.

In many cells, the cytoplasm is made up of two parts: the **ectoplasm** (or **plasmagel**), a dense gelatinous outer layer concerned with cell movement, and the **endoplasm** (or **plasmalol**), a more fluid inner part where most of the organelles are found.

cytoskeleton in a living cell, a matrix of protein filaments and tubules that occurs within the cytosol (the liquid part of the cytoplasm). It gives the cell a definite shape, transports vital substances around the cell, and may also be involved in cell movement.

cytotoxic drug any drug used to kill the cells of a malignant tumour; it may also damage healthy cells. Side effects include nausea, vomiting, hair loss, and bone-marrow damage. Some cytotoxic drugs are also used to treat other diseases and to suppress rejection in transplant patients.

D

dab small marine flatfish of the flounder family, especially the genus *Limanda*. Dabs live in the North Atlantic and around the coasts of Britain and Scandinavia.

Species include *L. limanda* which grows to about 40 cm/16 in, and the American dab *L. proboscidea*, which grows to 30 cm/12 in. Both have both eyes on the right side of their bodies. The left, or blind, side is white, while the rough-scaled right side is light-brown or grey, with dark-brown spots.

DAC abbreviation for digital-to-analogue converter.

dace freshwater fish *Leuciscus leuciscus* of the carp family. Common in England and mainland Europe, it is silvery and grows up to 30 cm/1 ft.

dachshund German 'badger-dog' small dog of German origin, bred originally for digging out badgers. It has a long body and short legs. Several varieties are bred: standard size (up to 10 kg/22 lb), miniature (5 kg/11 lb or less), long-haired, smooth-haired, and wire-haired.

daddy-longlegs popular name for a crane fly.

Daedalus in space travel, a futuristic project proposed by the British Interplanetary Society to send a robot probe to nearby stars. The probe, 20 times the size of the Saturn V moon rocket, would be propelled by thermonuclear fusion; in effect, a series of small hydrogen-bomb explosions. Interstellar cruise speed would be about 40,000 km/25,000 mi per second.

daffodil any of several Old World species of bulbous plants belonging to the amaryllis family, characterized by their trumpet-shaped yellow flowers which appear in spring. The common daffodil of northern Europe (*Narcissus pseudonarcissus*) has large yellow flowers and grows from a large bulb. There are numerous cultivated forms in which the colours range from white to deep orange. (Genus *Narcissus*, family Amaryllidaceae.)

DAGUERREIAN SOCIETY

<http://abell.austinc.edu/dag/home.html>

Information about the process involved in this early form of photography, 19th- and 20th-century texts about it, an extensive bibliography of related literature, plenty of daguerreotypes to look at, and information about this society itself can be found here.

daguerreotype in photography, a single-image process using mercury vapour and an iodine-sensitized silvered plate; it was invented by Louis Daguerre 1838.

dahlia any of a group of perennial plants belonging to the daisy family, comprising 20 species and many cultivated forms. Dahlias are stocky plants with tuberous roots and showy flowers that come in a wide range of colours. They are native to Mexico and Central America. (Genus *Dahlia*, family Compositae.)

daisy any of numerous species of perennial plants belonging to the daisy family, especially the field daisy of Europe and North

America (*Chrysanthemum leucanthemum*) and the English common daisy (*Bellis perennis*), with a single white or pink flower rising from a rosette of leaves. (Family Compositae.)

daisy bush any of several Australian and New Zealand shrubs with flowers like daisies and felted or hollylike leaves. (Genus *Olearia*, family Compositae.)

daisywheel printing head in a computer printer or typewriter that consists of a small plastic or metal disc made up of many spokes (like the petals of a daisy). At the end of each spoke is a character in relief. The daisywheel is rotated until the spoke bearing the required character is facing an inked ribbon, then a hammer strikes the spoke against the ribbon, leaving the impression of the character on the paper beneath.

The daisywheel can be changed to provide different typefaces; however, daisywheel printers cannot print graphics nor can they print more than one typeface in the same document. For these reasons, they are rapidly becoming obsolete.

DALMATIAN CLUB OF AMERICA

<http://www.cet.com/~bholland/dca/>

Absolute must for Dalmatian lovers. The site is filled with information about the history of the breed, the breed standard, shows, veterinary advice, and many tips for owners. There is a comprehensive listing of other Dalmatian sites and a useful bibliography. This well-organized site even has a search engine.

Dalmatian breed of dog, about 60 cm/24 in tall, with a distinctive smooth white coat with spots that are black or brown. Dalmatians are born white; the spots appear later. They were formerly used as coach dogs, running beside horse-drawn carriages to fend off highwaymen.

DALMATIAN

Three out of ten dalmatian dogs suffer from some form of hearing disability, and 8% of all dalmatians are entirely deaf. Their beautiful spotty coats are caused by intense inbreeding, which has the side-effect of increasing genetic disorders – such as deafness.

Dalton, John (1766–1844)

English chemist who proposed the theory of atoms, which he considered to be the smallest parts of matter. He produced the first list of relative atomic masses in 'Absorption of Gases' 1805 and put forward the law of partial pressures of gases (Dalton's law).

Mary Evans Picture Library

dam structure built to hold back water in order to prevent flooding, to provide water for irrigation and storage, and to provide

concrete gravity dam

arch dam

buttress dam

dam There are two basic types of dam: the gravity dam and the arch dam. The gravity dam relies upon the weight of its material to resist the forces imposed upon it; the arch dam uses an arch shape to take the forces in a horizontal direction into the sides of the river valley. The largest dams are usually embankment dams. Buttress dams are used to hold back very wide rivers or lakes.

hydroelectric power. The biggest dams are of the earth- and rock-fill type, also called embankment dams. Early dams in Britain, built before and about 1800, had a core made from puddled clay (clay which has been mixed with water to make it impermeable). Such dams are generally built on broad valley sites. Deep, narrow gorges dictate a concrete dam, where the strength of reinforced concrete can withstand the water pressures involved.

concrete dams A valuable development in arid regions, as in parts of Brazil, is the underground dam, where water is stored on a solid rock base, with a wall to ground level, so avoiding rapid evaporation. Many concrete dams are triangular in cross section, with their vertical face pointing upstream. Their sheer weight holds them in position, and they are called **gravity dams**. They are no longer favoured for very large dams, however, because they are expensive and time-consuming to build. Other concrete dams are built in the shape of an arch, which transfers the horizontal force into the sides of the river valley; the **arch dam** derives its strength from the arch shape, just as an arch bridge does, and has been widely used in the 20th century. They require less construction material than other dams and are the strongest type.

buttress dams are used when economy of construction is important or foundation conditions preclude any other type. The upstream portion of a buttress dam may comprise series of cantilevers, slabs, arches or domes supported from the back by a line of buttresses. They are usually made from reinforced and pre-stressed concrete.

earth dams Earth dams have a watertight core wall, formerly made of puddle clay but nowadays constructed of concrete. Their construction is very economical even for very large structures. **Rock-fill dams** are a variant of the earth dam in which dumped rock takes the place of compacted earth fill.

major dams Rogun (Tajikistan) is the world's highest at 335 m/1,099 ft. New Cornelia Tailings (USA) is the world's biggest in volume, 209 million cu m/7.4 billion cu ft. Owen Falls (Uganda) has the world's largest reservoir capacity, 204.8 billion cu m/7.2 trillion cu ft. Itaipu (Brazil/Paraguay) is the world's most powerful, producing 12,700 megawatts of electricity. The Three Gorges Dam on the Chang Jiang was officially inaugurated in 1994 and is due for completion 2009. A treaty between Nepal and India, ratified by Nepal in 1996, included plans to construct the 315-m/1,035-ft Pancheshwar dam.

In 1997 there were approximately 40,000 large dams (more than 15 m in height) and 800,000 small ones worldwide.

damask textile of woven linen, cotton, wool, or silk, with a reversible figured pattern. It was first made in the city of Damascus, Syria.

damper any device that deadens or lessens vibrations or oscillations; for example, one used to check vibrations in the strings of a piano. The term is also used for the movable plate in the flue of a stove or furnace for controlling the draught.

damselfly long, slender, colourful dragonfly of the suborder Zygoptera, with two pairs of similar wings that are generally held vertically over the body when at rest, unlike those of other dragonflies.

damselfly As in all members of the suborder Zygoptera, this common blue damselfly *Enallagma cyathigerum* male holds his wings closed above his back. Dragonflies (suborder Anisoptera) hold their wings out to their sides at 90 degrees to the body when at rest, and are generally stouter than damselflies. *Premaphotos Wildlife*

damson cultivated variety of plum tree, distinguished by its small oval edible fruits, which are dark purple or blue-black in colour. (*Prunus domestica* var. *instittia*.)

dandelion common plant throughout Europe and Asia, belonging to the same family as the daisy. The stalk rises from a rosette of leaves that are deeply indented like a lion's teeth, hence the name (from French *dent de lion*). The flower heads are bright yellow, and

the fruit is covered with fine hairs, known as the dandelion 'clock'. (*Taraxacum officinale*, family Compositae.)

The milky juice of the dandelion has laxative properties (causing the bowels to empty), and the young leaves are sometimes eaten in salads. In the Russian species (*Taraxacum koksaghyz*), the juice forms an industrially usable latex, relied upon especially during World War II when Malaysian rubber supplies were blocked by the Japanese (see also *crubber*).

Dandie Dinmont breed of *terrier* that originated in the Scottish border country. It is about 25 cm/10 in tall, short-legged and long-bodied, with drooping ears and a long tail. Its hair, about 5 cm/2 in long, can be greyish or yellowish. It is named after the character Dandie Dinmont in Walter Scott's novel *Guy Mannering* 1815.

darcy c.g.s. unit (symbol D) of permeability, used mainly in geology to describe the permeability of rock (for example, to oil, gas, or water).

dark cloud in astronomy, a cloud of cold dust and gas seen in silhouette against background stars or an *CHII* region.

dark matter matter that, according to current theories of cosmology, makes up 90–99% of the mass of the universe but so far remains undetected. Dark matter, if shown to exist, would explain many currently unexplained gravitational effects in the movement of galaxies.

Theories of the composition of dark matter include unknown atomic particles (cold dark matter) or fast-moving neutrinos (hot dark matter) or a combination of both.

In 1993 astronomers identified part of the dark matter in the form of stray planets and brown dwarfs, and possibly, stars that have failed to light up. These objects are known as MACHOs (massive astrophysical compact halo objects) and, according to US astronomers 1996, make up approximately half of the dark matter in the Milky Way's halo.

DARPANET early US computer network. See *CHARPANET*.

dasyure any marsupial of the family Dasyuridae, also known as a 'native cat', found in Australia and New Guinea. Various species

DARWIN, CHARLES ROBERT

The English naturalist Charles Darwin, who developed the theory of evolution, was once told by his father: 'You care for nothing but shooting, dogs, and rat-catching, and you will be a disgrace to yourself and all your family'.

have body lengths from 25 cm/10 in to 75 cm/2.5 ft. Dasyures have long, bushy tails and dark coats with white spots. They are agile, nocturnal carnivores, able to move fast and climb.

DAT abbreviation for *digital audio tape*.

data (singular *datum*) facts, figures, and symbols, especially as stored in computers. The term is often used to mean raw, unprocessed facts, as distinct from information, to which a meaning or interpretation has been applied.

... mathematics is a natural and a fundamental language. It may well be that it's a property of human beings, that only human beings can think maths. But I think it's probably true that any intelligence in the universe would have this language as well. So maybe it's even greater than – no, not greater than, but more universal than – the human race.

ERIK CHRISTOPHER ZEEMAN English mathematician.
L. Wolpert and A. Richards *A Passion for Science* 1988

database in computing, a structured collection of data, which may be manipulated to select and sort desired items of information. For example, an accounting system might be built around a database containing details of customers and suppliers. In larger computers, the database makes data available to the various programs that need it, without the need for those programs to be aware of

Darwin, Charles Robert (1809–1882)

English naturalist who developed the modern theory of evolution and proposed, with Alfred Russel Wallace, the principle of natural selection. After research in South America and the Galápagos Islands as naturalist on HMS Beagle 1831–36, Darwin published *On the Origin of Species by Means of Natural Selection or the Preservation of Favoured Races in the Struggle for Life* 1859. This book explained the evolutionary process through the principles of natural selection and aroused bitter controversy because it disagreed with the literal interpretation of the Book of Genesis in the Bible.

Darwin's work marked a turning point in many of the sciences, including physical anthropology and palaeontology. But, before the voyage of the Beagle, Darwin, like everyone else at that time, did not believe in the mutability of species. In South America, he saw fossil remains of giant sloths and other animals now extinct, and on the Galápagos Islands he found a colony of finches that he could divide into at least 14

similar species, none of which existed on the mainland. It was obvious to him that one type must have evolved into many others, but how they did so eluded him. Two years after his return he read Malthus's 'An Essay on the Principle of Population' 1798, which proposed that the human population was growing too fast for it to be adequately fed, and that something would have to reduce it, such as war or natural disaster. This work inspired Darwin to see that the same principle could be applied to animal populations.

Darwin's theory of natural selection concerned the variation existing between members of a sexually reproducing population. Those members with variations better fitted to the environment would be more likely to survive and breed, subsequently passing on these favourable characteristics to their offspring. He avoided the issue of human evolution, however, remarking at the end of *The Origin of Species* that 'much light will be thrown on the origin of man and his history'. It was not until his publication of *The Descent of Man and Selection in Relation to Sex* 1871, that Darwin argued that people evolved just like other organisms. He did not seek the controversy he caused but his ideas soon caught the public imagination. The popular press soon published articles about the 'missing link' between humans and apes.

Darwin also made important discoveries in many other areas, including the fertilization mechanisms of plants, the classification of barnacles, and the formation of coral reefs. He was the first to propose a link between coral reefs and volcanic islands. His ideas remain the primary theory of atoll growth formation.

Mary Evans Picture Library

how the data are stored. The term is also sometimes used for simple record-keeping systems, such as mailing lists, in which there are facilities for searching, sorting, and producing records.

There are three main types (or 'models') of database: hierarchical, network, and relational, of which relational is the most widely used. In a **relational database** data are viewed as a collection of linked tables. A **free-text database** is one that holds the unstructured text of articles or books in a form that permits rapid searching.

A collection of databases is known as a **databank**. A database-management system (DBMS) program ensures that the integrity of the data is maintained by controlling the degree of access of the applications programs using the data. Databases are normally used by large organizations with mainframes or minicomputers.

A telephone directory stored as a database might allow all the people whose names start with the letter B to be selected by one program, and all those living in Chicago by another.

database program Databases are usually created using a database program that enables a user to define the database structure by selecting the number of fields, naming those fields, and allocating the type and amount of data that will valid for each field. Data programs also determine how data can be viewed on screen or extracted into files.

data bus in computing, the electrical pathway, or ϕ bus, used to carry data between the components of the computer.

data capture collecting information for computer processing and analysis. Data may be captured automatically – for example, by a ϕ sensor that continuously monitors physical conditions such as temperature – or manually; for example, by reading electricity meters.

data communications sending and receiving data via any communications medium, such as a telephone line. The term usually implies that the data are digital (such as computer data) rather than analogue (such as voice messages). However, in the ISDN (ϕ Integrated Services Digital Network) system, all data – including voices and video images – are transmitted digitally.

See also ϕ telecommunications.

data compression in computing, techniques for reducing the amount of storage needed for a given amount of data. They include word tokenization (in which frequently used words are stored as shorter codes), variable bit lengths (in which common characters are represented by fewer ϕ bits than less common ones), and run-length encoding (in which a repeated value is stored once along with a count).

In lossless compression the original file is retrieved unchanged after decompression. Some types of data (sound and pictures) can be stored by lossy compression where some detail is lost during compression, but the loss is not noticeable. Lossy compression allows a greater level of compression. The most popular compression program is ϕ KZIP, widely available as ϕ shareware.

data dictionary in computing, a file that holds data about data – for example, lists of files, number of records in each file, and types of fields. Data dictionaries are used by database software to enable access to the data; they are not normally accessible to the user.

Data Encryption Standard (DES) in computing, widely used US government standard for encryption, adopted in 1977 and recertified for five more years 1993. DES was developed by IBM and adopted as a government standard by the National Security Agency. It is a private-key system, so that the sender and recipient encrypt and decrypt the message using the same key.

This means that a secure way has to be found to send the key from one party to the other; any third party who has the key can decrypt the encoded transmissions. Concerns over the long-term security of DES in the face of increasingly available cheap hardware have been somewhat mitigated by new techniques such as triply encrypted DES.

data flow chart diagram illustrating the possible routes that data can take through a system or program; see ϕ flow chart.

DataGlove in ϕ virtual reality, a glove wired to the computer that allows it to take input from a user's hand gestures. Sensors in the glove detect the wearer's hand movements, and transmit these to the computer in a digital format which the computer can interpret.

DataGlove is a trademark of VPL Research; the general term for such devices is **wired glove**.

data logging in computing, the process, usually automatic, of capturing and recording a sequence of values for later processing and analysis by computer. For example, the level in a water-storage tank might be automatically logged every hour over a seven-day period, so that a computer could produce an analysis of water use. The monitoring is carried out through ϕ sensors or similar instruments, connected to the computer via an interface.

The computer logging the data samples the readings at regular time intervals. Data is analysed either continuously (displayed on a changing screen display or as a graph on a ϕ plotter) or at the end of the logging period.

data mining analysis of computer data to determine trends. It is used by retailers to find out those items often purchased together. For example, one supermarket chain found that purchases of nappies and beer were linked, and so increased sales by putting beer next to nappies. Store 'loyalty cards' enable retailers to profile customers' week-by-week shopping against their age, sex, and address.

data preparation preparing data for computer input by transferring it to a machine-readable medium. This usually involves typing the data at a keyboard (or at a ϕ key-to-disc or key-to-tape station) so that it can be transferred directly to tapes or discs. Various methods of direct data capture, such as ϕ bar codes, ϕ optical mark recognition (OMR), and ϕ optical character recognition (OCR), have been developed to reduce or eliminate lengthy data preparation before computer input.

data processing (DP) or electronic data processing (EDP) use of computers for performing clerical tasks such as stock control, payroll, and dealing with orders. DP systems are typically ϕ batch systems, running on mainframe computers.

data processing cycle For data to be processed the following cycle of operations must be undergone: data are collected, then input into a computer where they are processed to produce the output. As the output may also be the input of a subsequent process the process is deemed cyclical. Whilst being processed data may undergo other operations such as storage and ϕ validation.

data protection safeguarding of information about individuals stored on computers, to protect privacy.

data recovery in computing, any of several possible procedures for restoring a computer system and its data after a system crash, burglary, or other damage. The first line of defence in any computer system is ϕ backups.

Every system fails at some point, and typically the data on the system is more valuable than the hardware on which it resides. The best course of action depends on the cause of the damage, which may be due to an outside agent, such as a virus, or a simple mistake, such as accidentally deleting important files. Some antivirus software comes with tools to assist users to clean up their systems; for deleted files, utility software such as Norton Utilities may be able to restore ('undelete') the data. In worse cases, specialists may still be able to restore the information by reading the hard disc's platters directly.

data security in computing, precautions taken to prevent the loss or misuse of data, whether accidental or deliberate. These include measures that ensure that only authorized personnel can gain entry to a computer system or file, and regular procedures for storing and 'backing up' data, which enable files to be retrieved or recreated in the event of loss, theft, or damage.

A number of ϕ verification and ϕ validation techniques may also be used to prevent data from being lost or corrupted by misprocessing.

Encryption involves the translation of data into a form that is meaningless to unauthorized users who do not have the necessary decoding software.

Passwords can be chosen by, or issued to, individual users. These secret words (or combinations of alphanumeric characters) may have to be entered each time a user logs on to a computer system or attempts to access a particular protected file within the system.

Physical access to the computer facilities can be restricted by locking entry doors and storage cabinets.

Master files (files that are updated periodically) can be protected by storing successive versions, or generations, of these files and of the transaction files used to update them. The most recent version of the master file may then be recreated, if necessary, from a previous generation. It is common practice to store the three most recent versions of a master file (often called the grandfather, father, and son generations).

Direct-access files are protected by making regular dumps, or back-up copies. Because the individual records in direct-access files are constantly being accessed and updated, specific generations of these files cannot be said to exist. The files are therefore dumped at fixed time intervals onto a secure form of backing store. A record, or log, is also kept of all the changes made to a file between security dumps.

Fireproof safes are used to store file generations or sets of security dumps, so that the system can be restarted on a new computer in the event of a fire in the computer department.

Write-protect mechanisms on discs or tapes allow data to be read but not deleted, altered, or overwritten. For example, the protective case of a 3½-inch floppy disc has a write-protect tab that can be slid back with the tip of a pencil or pen to protect the disc's contents.

data terminator or rogue value in computing, a special value used to mark the end of a list of input data items. The computer must be able to detect that the data terminator is different from the input data in some way – for instance, a negative number might be used to signal the end of a list of positive numbers, or 'XXX' might be used to terminate the entry of a list of names.

date palm tree, also known as the date palm. The female tree produces the brown oblong fruit, dates, in bunches weighing 9–11 kg/20–25 lb. Dates are an important source of food in the Middle East, being rich in sugar; they are dried for export. The tree also supplies timber and materials for baskets, rope, and animal feed. (Genus *Phoenix*.)

The most important species is *Phoenix dactylifera*; native to northern Africa, southwest Asia, and parts of India, it grows up to 25 m/80 ft high. A single bunch can contain as many as 1,000 dates. Their juice is made into a kind of wine.

dating science of determining the age of geological structures, rocks, and fossils, and placing them in the context of geological time. The techniques are of two types: relative dating and absolute dating. **Relative dating** can be carried out by identifying fossils of creatures that lived only at certain times (marker fossils), and by looking at the physical relationships of rocks to other rocks of a known age.

Absolute dating is achieved by measuring how much of a rock's radioactive elements have changed since the rock was formed, using the process of radiometric dating.

datura any of a group of plants belonging to the nightshade family, such as the thorn apple, with handsome trumpet-shaped blooms. They have narcotic (pain-killing and sleep-inducing) properties. (Genus *Datura*, family Solanaceae.)

daughterboard in computing, small printed circuit board that plugs into a motherboard to give it new capabilities.

David Dunlap Observatory Canadian observatory at Richmond Hill, Ontario, operated by the University of Toronto, with a 1.88-m/74-in reflector, the largest optical telescope in Canada, opened in 1935.

day time taken for the Earth to rotate once on its axis. The **solar day** is the time that the Earth takes to rotate once relative to the Sun. It is divided into 24 hours, and is the basis of our civil day. The **sidereal day** is the time that the Earth takes to rotate once relative

to the stars. It is 3 minutes 56 seconds shorter than the solar day, because the Sun's position against the background of stars as seen from Earth changes as the Earth orbits it.

Thought is only a flash between two long nights, but this flash is everything.

JULES HENRI POINCARÉ French mathematician.

dayflower any plant of the genus *Commelina* of the spiderwort family. All have pointed leaves and creeping stems that form roots. The flowers, usually blue, open in the morning and wither by day's end throughout the summer and fall.

dBASE family of microcomputer programs used for manipulating large quantities of data; also, a related fourth-generation language. The first version, dBASE II, was published by Ashton-Tate in 1981; it has since become the basis for a recognized standard for database applications, known as xBase.

DBS in computing, abbreviation for ϕ direct broadcast system.

DC in physics, abbreviation for *direct current* (electricity).

DCC abbreviation for ϕ digital compact cassette.

DCE (abbreviation for *data communications equipment*) in computing, another name for a ϕ modem.

DDE in computing, abbreviation for ϕ dynamic data exchange, a form of communication between processes used in Microsoft Windows.

DDT abbreviation for *dichloro-diphenyl-trichloroethane* ($\text{Cl}_2\text{C}_6\text{H}_4\text{CH}(\text{Cl})\text{CCl}_3$) insecticide discovered in 1939 by Swiss chemist Paul Müller. It is useful in the control of insects that spread malaria, but resistant strains develop. DDT is highly toxic and persists in the environment and in living tissue. Its use is now banned in most countries, but it continues to be used on food plants in Latin America.

deadly nightshade another name for ϕ belladonna, a poisonous plant.

deafness partial or total deficit of hearing in either ear. Of assistance are hearing aids, lip-reading, a cochlear implant in the ear in combination with a special electronic processor, sign language, and 'cued speech' (manual clarification of ambiguous lip movement during speech).

Conductive deafness is due to faulty conduction of sound inwards from the external ear, usually due to infection (see ϕ otitis), or a hereditary abnormality of the bones of the inner ear (see ϕ otosclerosis).

Perceptive deafness may be inborn or caused by injury or disease of the cochlea, auditory nerve, or the hearing centres in the brain. It becomes more common with age.

deamination removal of the amino group ($-\text{NH}_2$) from an unwanted ϕ amino acid. This is the nitrogen-containing part, and it is converted into ammonia, uric acid, or urea (depending on the type of animal) to be excreted in the urine.

In vertebrates, deamination occurs in the ϕ liver.

death cessation of all life functions, so that the molecules and structures associated with living things become disorganized and indistinguishable from similar molecules found in nonliving things. In medicine, a person is pronounced dead when the brain ceases to control the vital functions, even if breathing and heartbeat are maintained artificially.

medical definition Death used to be pronounced with the permanent cessation of heartbeat, but the advent of life-support equipment has made this point sometimes difficult to determine. For removal of vital organs in transplant surgery, the World Health Organization in 1968 set out that a potential donor should exhibit

no brain-body connection, muscular activity, blood pressure, or ability to breathe spontaneously.

religious belief In religious belief, death may be seen as the prelude to rebirth (as in Hinduism and Buddhism); under Islam and Christianity, there is the concept of a day of judgement and consignment to heaven or hell; Judaism concentrates not on an after-life but on survival through descendants who honour tradition.

death cap fungus of the Amanita group, the most poisonous mushroom known. The fruiting body, or mushroom, has a scaly white cap and a collarlike structure (volva) near the base of the stalk. (*Amanita phalloides*, family Agaricaceae.)

death's-head moth largest British hawk moth with downy wings measuring 13 cm/5 in from tip to tip, and its thorax is marked as though with a skull.

When it is at rest it sometimes gives out a squeaking noise, produced probably by rubbing the palpi (sense organs close to the mouthparts) upon the proboscis.

The caterpillar is about 10 cm/4 in long and is brightly coloured. It feeds on potato plants.

classification Hawk moths *Acherontia atropos* are in the family Sphingidae in order Lepidoptera, class Insecta, phylum Arthropoda.

deathwatch beetle any wood-boring beetle of the family Anobiidae, especially *Xestobium rufovillosum*. The larvae live in oaks and willows, and sometimes cause damage by boring in old furniture or structural timbers. To attract the female, the male beetle produces a ticking sound by striking his head on a wooden surface, and this is taken by the superstitious as a warning of approaching death.

debt-for-nature swap agreement under which a proportion of a country's debts are written off in exchange for a commitment by the debtor country to undertake projects for environmental protection. Debt-for-nature swaps were set up by environment groups in the 1980s in an attempt to reduce the debt problem of poor countries, while simultaneously promoting conservation.

Most debt-for-nature swaps have concentrated on setting aside areas of land, especially tropical rainforest, for protection and have involved private conservation foundations. The first swap took place in 1987, when a US conservation group bought \$650,000 of Bolivia's national debt from a bank for \$100,000, and persuaded the Bolivian government to set aside a large area of rainforest as a nature reserve in exchange for never having to pay back the money owed. Other countries participating in debt-for-nature swaps are the Philippines, Costa Rica, Ecuador, and Poland. However, the debtor country is expected to ensure that the area of land remains adequately protected, and in practice this does not always happen. The practice has also produced complaints of neocolonialism.

debugging finding and removing errors, or bugs, from a computer program or system.

DEC (acronym for *Digital Equipment Corporation*) US computer manufacturer. DEC was founded by US computer engineers, Kenneth Olsen and Harlan Anderson, and was the first minicomputer manufacturer. It became the world's second largest computer manufacturer, after IBM, but made huge losses in the early 1990s. DEC's most successful computers were the PDP-11 and the VAX (Virtual Address eXtension). The former was used in the creation of the UNIX operating system.

The original aim was to make the first small computers for engineering and departmental use, and the PDP (Programmed Data Processor) range became known as minicomputers to contrast them with giant mainframes. The success of its 32-bit VAX minis in the 1980s made DEC one of the world's largest computer manufacturers. The company - now called Digital - has still to recover, but has developed the world's fastest microprocessor, the Alpha chip, and has a popular search engine called AltaVista on the Internet's World Wide Web.

decagon in geometry, a ten-sided polygon.

decay, radioactive see radioactive decay.

Decca navigation system radio-based aid to marine navigation, available in many parts of the world. The system consists of a master radio transmitter and two or three secondary transmitters situated within 100-200 km/60-120 mi from the master. The signals from the transmitters are detected by the ship's navigation receiver, and slight differences (phase differences) between the master and secondary transmitter signals indicate the position of the receiver. It was first used 1944 for the D-Day landings.

decibel unit (symbol dB) of measure used originally to compare sound intensities and subsequently electrical or electronic power outputs; now also used to compare voltages. An increase of 10 dB is equivalent to a 10-fold increase in intensity or power, and a 20-fold increase in voltage. The decibel scale is used for audibility measurements, as one decibel, representing an increase of about 25%, is about the smallest change the human ear can detect. A whisper has an intensity of 20 dB; 140 dB (a jet aircraft taking off nearby) is the threshold of pain.

The difference in decibels between two levels of intensity (or power) I_1 and I_2 is $10 \log_{10}(I_1/I_2)$; a difference of 1 dB thus corresponds to a change of about 25%. For two voltages V_1 and V_2 , the difference in decibels is $20 \log_{10}(V_1/V_2)$; 1 dB corresponding in this case to a change of about 12%.

Decibel scale

The decibel scale is used primarily to compare sound intensities although it can be used to compare voltages.

| Decibels | Typical sound |
|----------|---------------------------------------|
| 0 | threshold of hearing |
| 10 | rattle of leaves in gentle breeze |
| 10 | quiet whisper |
| 20 | average whisper |
| 20-50 | quiet conversation |
| 40-45 | hotel, theatre (between performances) |
| 50-65 | loud conversation |
| 65-70 | traffic on busy street |
| 65-90 | train |
| 75-80 | factory (light/medium work) |
| 90 | heavy traffic |
| 90-100 | thunder |
| 110-140 | jet aircraft at take-off |
| 130 | threshold of pain |
| 140-190 | space rocket at take-off |

deciduous of trees and shrubs, that shed their leaves at the end of the growing season or during a dry season to reduce transpiration (the loss of water by evaporation).

Most deciduous trees belong to the angiosperms, plants in which the seeds are enclosed within an ovary, and the term 'deciduous tree' is sometimes used to mean 'angiosperm tree', despite the fact that many angiosperms are evergreen, especially in the tropics, and a few gymnosperms, plants in which the seeds are exposed, are deciduous (for example, larches). The term broad-leaved is now preferred to 'deciduous' for this reason.

decimal fraction a fraction in which the denominator is any higher power of 10. Thus $\frac{51}{10}$, $\frac{51}{100}$, and $\frac{51}{1000}$ are decimal fractions and are normally expressed as 0.3, 0.51, and 0.023. The use of decimals greatly simplifies addition and multiplication of fractions, though not all fractions can be expressed exactly as decimal fractions.

The regular use of the decimal point appears to have been introduced about 1585, but the occasional use of decimal fractions can be traced back as far as the 12th century.

decimal number system or **denary number system** the most commonly used number system, to the base ten. Decimal numbers do not necessarily contain a decimal point; 563, 5.63, and -563 are all decimal numbers. Other systems are mainly used in computing and include the binary number system, octal number system, and hexadecimal number system.

Decimal numbers may be thought of as written under column headings based on the number ten. For example, the number 2,567 stands for 2 thousands, 5 hundreds, 6 tens, and 7 ones. Large decimal numbers may also be expressed in floating-point notation.

decimal point the dot dividing a decimal number's whole part from its fractional part (the digits to the left of the point are unit digits). It is usually printed on the line but hand written above the line, for example 3.5. Some European countries use a comma to denote the decimal point, for example 3,56.

decision table in computing, a method of describing a procedure for a program to follow, based on comparing possible decisions and their consequences. It is often used as an aid in systems design.

The top part of the table contains the conditions for making decisions (for example, if a number is negative rather than positive and is less than 1), and the bottom part describes the outcomes when those conditions are met. The program either ends or repeats the operation.

declarative programming computer programming that does not describe how to solve a problem, but rather describes the logical structure of the problem. It is used in the programming language PROLOG. Running such a program is more like proving an assertion than following a procedure.

declination in astronomy, the coordinate on the celestial sphere (imaginary sphere surrounding the Earth) that corresponds to latitude on the Earth's surface. Declination runs from 0° at the celestial equator to 90° at the north and south celestial poles.

decoder in computing, an electronic circuit used to select one of several possible data pathways. Decoders are, for example, used to direct data to individual memory locations within a computer's immediate access memory.

decomposer in biology, any organism that breaks down dead matter. Decomposers play a vital role in the ecosystem by freeing important chemical substances, such as nitrogen compounds, locked up in dead organisms or excrement. They feed on some of the released organic matter, but leave the rest to filter back into the soil as dissolved nutrients, or pass in gas form into the atmosphere, for example as nitrogen and carbon dioxide.

The principal decomposers are bacteria and fungi, but earthworms and many other invertebrates are often included in this group. The nitrogen cycle relies on the actions of decomposers.

decomposition process whereby a chemical compound is reduced to its component substances. In biology, it is the destruction of dead organisms either by chemical reduction or by the action of decomposers, such as bacteria and fungi.

decompression sickness illness brought about by a sudden and substantial change in atmospheric pressure. It is caused by a too rapid release of nitrogen that has been dissolved into the bloodstream under pressure; when the nitrogen forms bubbles it causes the bends. The condition causes breathing difficulties, joint and muscle pain, and cramps, and is experienced mostly by deep-sea divers who surface too quickly.

After a one-hour dive at 30 m/100 ft, 40 minutes of decompression are needed, according to US Navy tables.

decontamination factor in radiological protection, a measure of the effectiveness of a decontamination process. It is the ratio of the original contamination to the remaining radiation after decontamination: 1,000 and above is excellent; 10 and below is poor.

decrepitation in crystallography, unusual features that accompany the thermal decomposition of some crystals, such as lead(II) nitrate. When these are heated, they spit and crackle and may jump out of the test tube before they decompose.

dedicated computer computer built into another device for the purpose of controlling or supplying information to it. Its use has increased dramatically since the advent of the microprocessor: washing machines, digital watches, cars, and video recorders all now have their own processors.

A dedicated system is a general-purpose computer system confined to performing only one function for reasons of efficiency or convenience. A word processor is an example.

Deep Blue name given to the IBM chess-playing computer that first defeated a human grandmaster, the Russian Gary Kasparov, in 1996.

The architect and principal designer of Deep Blue is Feng-Hsiung Hsu, who joined IBM in 1989. Deep Blue's award-winning precursor, Deep Thought, was developed by Hsu and other graduate students at Carnegie-Mellon University in Pittsburgh. In 1988 it was the first computer to achieve a grandmaster rating.

KASPAROV V. DEEP BLUE - THE REMATCH

<http://www.chess.ibm.com/>

Official site of the team that produced the first computer able to beat a world chess champion. This is a complete account of the tussle between Deep Blue and Gary Kasparov. There are some thought provoking articles on the consequences of Deep Blue's victory. There is also some video footage of the games.

deep-sea trench another term for ocean trench.

deer any of various ruminant, even-toed, hoofed mammals belonging to the family Cervidae. The male typically has a pair of antlers, shed and regrown each year. Most species of deer are forest-dwellers and are distributed throughout Eurasia and North America, but are absent from Australia and Africa south of the Sahara.

deerhound breed of large, rough-coated dog, formerly used in Scotland for hunting and killing deer. Slim and long-legged, it grows to 75 cm/30 in or more, usually with a bluish-grey coat.

default in computing, a factory setting for user-configurable options. Default settings appear in all areas of computing, from the on-screen colour scheme in a graphical user interface to the directories where software programs store data.

defibrillation use of electrical stimulation to restore a chaotic heartbeat to a rhythmic pattern. In fibrillation, which may occur in most kinds of heart disease, the heart muscle contracts irregularly; the heart is no longer working as an efficient pump. Paddles are applied to the chest wall, and one or more electric shocks are delivered to normalize the beat.

In patients suffering with arrhythmia, implantable defibrillators are inserted into the chest with leads threading through veins into the right side of the heart. The first was implanted in 1980 and by 1996 around 50,000-80,000 had been implanted worldwide.

In nature there are neither rewards nor punishments - there are consequences.

ROBERT INGERSOLL US lawyer and orator.
Lectures and Essays, "Some Reasons Why"

deforestation destruction of forest for timber, fuel, charcoal burning, and clearing for agriculture and extractive industries, such as mining, without planting new trees to replace those lost (reafforestation) or working on a cycle that allows the natural forest to regenerate. Deforestation causes fertile soil to be blown away or washed into rivers, leading to soil erosion, drought, flooding, and loss of wildlife. It may also increase the carbon dioxide content of the atmosphere and intensify the greenhouse effect, because there are fewer trees absorbing carbon dioxide from the air for photosynthesis.

Many people are concerned about the rate of deforestation as great damage is being done to the habitats of plants and animals.

Deforestation ultimately leads to famine, and is thought to be partially responsible for the flooding of lowland areas – for example, in Bangladesh – because trees help to slow down water movement.

defragmentation program or disc optimizer in computing, a program that rearranges data on disc so that files are not scattered in many small sections. See also *fragmentation*.

degaussing neutralization of the magnetic field around a body by encircling it with a conductor through which a current is maintained. Ships were degaussed in World War II to prevent them from detonating magnetic mines.

degeneration in biology, a change in the structure or chemical composition of a tissue or organ that interferes with its normal functioning. Examples of degeneration include fatty degeneration, fibroid degeneration (cirrhosis), and calcareous degeneration, all of which are part of natural changes that occur in old age.

The causes of degeneration are often unknown. Heredity often has a role in the degeneration of organs; for example, fibroid changes in the kidney can be seen in successive generations. Defective nutrition and continued stress on particular organs can cause degenerative changes. Alcoholism can result in cirrhosis of the liver and tuberculosis causes degeneration of the lungs.

de Gennes, Pierre-Gilles 1932 French physicist who worked on liquid crystals and polymers. He showed how mathematical models, developed for studying simpler systems, are applicable to such complicated systems. He won the Nobel Prize for Physics in 1991.

It had been known for a long time that liquid crystals scatter light in an unusual way but all early explanations failed. De Gennes found the explanation in the special way that the molecules of a liquid crystal are arranged. According to de Gennes, the molecules are arranged in a similar way to the molecules of a magnet, so that they point in the same direction. De Gennes found similar analogies between the behaviour of molecules in magnetic materials and polymers. This led to the formulation of laws from which simple relations between different properties of polymers can be deduced. In this way, predictions can be made about unknown properties – predictions which have been confirmed by experiment.

degree in mathematics, a unit (symbol °) of measurement of an angle or arc. A circle or complete rotation is divided into 360°. A degree may be subdivided into 60 minutes (symbol ′), and each minute may be subdivided in turn into 60 seconds (symbol ″).

Temperature is also measured in degrees, which are divided on a decimal scale. See *°Celsius*, and *°Fahrenheit*.

A degree of latitude is the length along a meridian such that the difference between its north and south ends subtend an angle of 1° at the centre of the Earth. A degree of longitude is the length between two meridians making an angle of 1° at the centre of the Earth.

dehydration in chemistry, the removal of water from a substance to give a product with a new chemical formula; it is not the same as drying.

There are two types of dehydration. For substances such as hydrated copper sulphate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) that contain *water* of crystallization, dehydration means removing this water to leave the anhydrous substance. This may be achieved by heating, and is reversible.

Some substances, such as ethanol, contain the elements of water (hydrogen and oxygen) joined in a different form. Dehydrating agents such as concentrated sulphuric acid will remove these elements in the ratio 2:1.

dehydration process to preserve food. Moisture content is reduced to 10–20% in fresh produce, and this provides good protection against moulds. Bacteria are not inhibited by drying, so the quality of raw materials is vital.

The process was developed commercially in France about 1795 to preserve sliced vegetables, using a hot-air blast. The earliest large-scale application was to starch products such as pasta, but after 1945 it was extended to milk, potatoes, soups, instant coffee, and prepared baby and pet foods. A major benefit to food manufacturers is reduction of weight and volume of the food products, thus lowering distribution cost.

Deimos one of the two moons of Mars. It is irregularly shaped, 15 × 12 × 11 km/9 × 7.5 × 7 mi, orbits at a height of 24,000 km/15,000 mi every 1.26 days, and is not as heavily cratered as the other moon, Phobos. Deimos was discovered in 1877 by US astronomer Asaph Hall (1829–1907), and is thought to be an asteroid captured by Mars's gravity.

delete remove or erase. In computing, the deletion of a character removes it from the file; the deletion of a file normally means removing its directory entry, rather than actually deleting it from the disc. Many systems now have an undelete facility that allows the restoration of the directory entry. While deleted files may not have been removed from the disc, they can be overwritten.

deliquescence phenomenon of a substance absorbing so much moisture from the air that it ultimately dissolves in it to form a solution.

Deliquescent substances make very good drying agents and are used in the bottom chambers of *desiccators*. Calcium chloride (CaCl_2) is one of the commonest.

delirium in medicine, a state of acute confusion in which the subject is incoherent, frenzied, and out of touch with reality. It is often accompanied by delusions or hallucinations.

Delirium may occur in feverish illness, some forms of mental illness, brain disease, and as a result of drug or alcohol intoxication. In chronic alcoholism, attacks of *delirium tremens* (DTs), marked by hallucinations, sweating, trembling, and anxiety, may persist for several days.

Delphi in computing, text-based UK and US national online information service. In 1992, Delphi was the first national US service to open a gateway to the Internet. Founded 1982 as the world's first online encyclopedia, Delphi was bought by News International 1993, and launched its UK service in 1994. In 1996 the US arm of Delphi was sold back to one of its original owners. The UK service continues in the hands of News International.

delphinium any of a group of plants containing about 250 species, including the butterfly or Chinese delphinium (*Delphinium grandiflorum*), an Asian form and one of the ancestors of the garden delphinium. Most species have blue, purple, or white flowers on a long spike. (Genus *Delphinium*, family Ranunculaceae.)

delta tract of land at a river's mouth, composed of silt deposited as the water slows on entering the sea. Familiar examples of large deltas are those of the Mississippi, Ganges and Brahmaputra, Rhône, Po, Danube, and Nile; the shape of the Nile delta is like the Greek letter *delta* Δ, and thus gave rise to the name.

The arcuate delta of the Nile is only one form. Others are bird-foot deltas, like that of the Mississippi which is a seaward extension of the river's levee system; and tidal deltas, like that of the Mekong, in which most of the material is swept to one side by sea currents.

Delta rocket US rocket used to launch many scientific and communications satellites since 1960, based on the Thor ballistic missile. Several increasingly powerful versions produced as satellites became larger and heavier. Solid-fuel boosters were attached to the first stage to increase lifting power.

delta wing aircraft wing shaped like the Greek letter *delta* Δ. Its design enables an aircraft to pass through the sound barrier with little effect. The supersonic airliner *Concorde* and the US *space shuttle* have delta wings.

dementia mental deterioration as a result of physical changes in the brain. It may be due to degenerative change, circulatory disease, infection, injury, or chronic poisoning. Senile dementia, a progressive loss of mental faculties such as memory and orientation, is typically a disease process of old age, and can be accompanied by *depression*.

Dementia is distinguished from *amentia*, or severe congenital mental insufficiency.

demo or demonstration software in computing, preview version of software that allows users to try out the main features of a par-

ticular program before buying it. Especially common among shareware producers, demo software usually blocks some features of the full version, so that a demo database might be able to handle only a small number of records.

The word 'demo' is also used to refer to fancy graphics and sound routines which are created by young programmers to demonstrate their skills to friends, admirers, and potential employers such as computer game publishers.

demodulation in radio, the technique of separating a transmitted audio frequency signal from its modulated radio carrier wave. At the transmitter, the audio frequency signal (representing speech or music, for example) may be made to modulate the amplitude (AM broadcasting) or frequency (FM broadcasting) of a continuously transmitted radio-frequency carrier wave. At the receiver, the signal from the aerial is demodulated to extract the required speech or sound component. In early radio systems, this process was called detection. See *modulation*.

Demon Internet in computing, Britain's first and largest mass-market Internet Service Provider. Founded 1992 by English hardware salesman Cliff Stanford with 200 founding subscribers who each paid £120 in advance for a year's service, Demon set the price (£10 a month plus VAT) for Internet access in the UK. By 1996, Demon Internet had 65,000 customers.

demonstration software in computing, see *demo*.

denaturation irreversible changes occurring in the structure of proteins such as enzymes, usually caused by changes in pH or temperature, by radiation or chemical treatments. An example is the heating of egg albumen resulting in solid egg white.

The enzymes associated with digestion and metabolism become inactive if given abnormal conditions. Heat will damage their complex structure so that the usual interactions between enzyme and substrate can no longer occur.

dendrite part of a nerve cell or neuron. The dendrites are slender filaments projecting from the cell body. They receive incoming messages from many other nerve cells and pass them on to the cell body.

If the combined effect of these messages is strong enough, the cell body will send an electrical impulse along the axon (the thread-like extension of a nerve cell). The tip of the axon passes its message to the dendrites of other nerve cells.

dendrochronology or **tree-ring dating** analysis of the annual rings of trees to date past events by determining the age of timber. Since annual rings are formed by variations in the water-conducting cells produced by the plant during different seasons of the year, they also provide a means of establishing past climatic conditions in a given area.

Samples of wood are obtained by driving a narrow metal tube into a tree to remove a core extending from the bark to the centre. Samples taken from timbers at an archaeological site can be compared with a master core on file for that region or by taking cores from old living trees; the year when they were felled can be determined by locating the point where the rings of the two samples correspond and counting back from the present.

Moisture levels will affect growth, the annual rings being thin in dry years, thick in moist ones, although in Europe ring growth is most affected by temperature change and insect defoliation.

In North America, studies are now extremely extensive, covering many wood types, including sequoia, juniper, and sagebrush. Sequences of tree rings extending back over 8,000 years have been obtained for the southwest USA and northern Mexico by using cores from the bristle-cone pine *Pinus aristata* of the White Mountains, California, which can live for over 4,000 years in that region. The dryness of the southwest USA has preserved wood in its archaeological sites. In wet temperate regions, wood is usually absorbed by soil acidity so that this dating technique cannot be used.

Deneb or **Alpha Cygni** brightest star in the constellation *cygnus*, and the 19th brightest star in the night sky. It is one of the greatest supergiant stars known, with a true luminosity of about

60,000 times that of the Sun. Deneb is about 1,800 light years from Earth.

The name Deneb is derived from the Arabic word for tail.

denier unit used in measuring the fineness of yarns, equal to the mass in grams of 9,000 metres of yarn. Thus 9,000 metres of 15 denier nylon, used in nylon stockings, weighs 15 g/0.5 oz, and in this case the thickness of thread would be 0.00425 mm/0.0017 in. The term is derived from the French silk industry; the *denier* was an old French silver coin.

denitrification process occurring naturally in soil, where bacteria break down nitrates to give nitrogen gas, which returns to the atmosphere.

denominator in mathematics, the bottom number of a fraction, so called because it names the family of the fraction. The top number, or numerator, specifies how many unit fractions are to be taken.

density measure of the compactness of a substance; it is equal to its mass per unit volume and is measured in kg per cubic metre/lb per cubic foot. Density is a scalar quantity. The average density D of a mass m occupying a volume V is given by the formula:

$$D = m/V$$

Relative density is the ratio of the density of a substance to that of water at 4°C/32.2°F.

In photography, density refers to the degree of opacity of a negative; in population studies, it is the quantity or number per unit of area; in electricity, current density is the amount of current passing through a cross-sectional area of a conductor (usually given in amperes per sq in or per sq cm).

density wave in astrophysics, a concept proposed to account for the existence of spiral arms in galaxies. In the density wave theory, stars in a spiral galaxy move in elliptical orbits in such a way that they crowd together in waves of temporarily enhanced density that appear as spiral arms. The idea was first proposed by Swedish astronomer Bertil Lindblad in the 1920s and developed by US astronomers C C Lin and Frank Shu in the 1960s.

dental caries in medicine, another name for *decay*.

dental formula way of showing the number of teeth in an animal's mouth. The dental formula consists of eight numbers separated by a line into two rows. The four above the line represent the teeth on one side of the upper jaw, starting at the front. If this reads 2 1 2 3 (as for humans) it means two incisors, one canine, two premolars, and three molars (see *tooth*). The numbers below the line represent the lower jaw. The total number of teeth can be calculated by adding up all the numbers and multiplying by two.

dentistry care and treatment of the teeth and gums. Orthodontics deals with the straightening of the teeth for aesthetic and clinical reasons, and periodontics with care of the supporting tissue (bone and gums).

The bacteria that start the process of dental decay are normal, nonpathogenic members of a large and varied group of microorganisms present in the mouth. They are strains of oral streptococci, and it is only in the presence of sucrose (from refined sugar) in the mouth that they become damaging to the teeth. *Fluoride* in the water supply has been one attempted solution to prevent decay,

DENTISTRY NOW

[http://www.DentistryNow.com/
Mainpage.htm#Main Part](http://www.DentistryNow.com/Mainpage.htm#MainPart)

Canadian-based site that includes an index of dentists worldwide. There is also an index of university courses where dentistry can be studied. In addition, there is a section on common dental problems and a good site for kids called 'tooth fairy' to introduce them to the importance of cleaning their teeth.

and in 1979 a vaccine was developed from a modified form of the bacterium *Streptococcus mutans*.

dentition type and number of teeth in a species. Different kinds of teeth have different functions; a grass-eating animal will have large molars for grinding its food, whereas a meat-eater will need powerful canines for catching and killing its prey. The teeth that are less useful to an animal's lifestyle may be reduced in size or missing altogether. An animal's dentition is represented diagrammatically by a dental formula.

Young children have **deciduous dentition**, popularly known as 'milk teeth', the first ones erupting at about six months of age. **Mixed dentition** is present from the ages of about six (when the first milk teeth are shed) to about 12. **Permanent dentition** (up to 32 teeth) is usually complete by the mid-teens, although the third molars (wisdom teeth) may not appear until around the age of 21.

herbivore (sheep)

dental formula $\begin{matrix} i & c & pm & m \\ 0 & 0 & 3 & 3 \\ 3 & 0 & 3 & 3 \end{matrix}$

carnivore (dog)

dental formula $\begin{matrix} i & c & pm & m \\ 3 & 1 & 4 & 2 \\ 3 & 1 & 4 & 2 \end{matrix}$

dentition The dentition and dental formulae of a typical herbivore (sheep) and carnivore (dog). The dog has long pointed canines for puncturing and gripping its prey and has modified premolars and molars (carnassials) for shearing flesh. In the sheep, by contrast, there is a wide gap, or diastema, between the incisors, developed for cutting through blades of grass, and the grinding premolars and molars; the canines are absent.

denudation natural loss of soil and rock debris, blown away by wind or washed away by running water, laying bare the rock below. Over millions of years, denudation causes a general lowering of the landscape.

deodar Himalayan deciduous tree, often planted as a rapid-growing ornamental. Its fragrant, durable wood is valuable as timber. (*Cedrus deodara*, family Pinaceae.)

deoxyribonucleic acid full name of DNA.

depolarizer oxidizing agent used in dry-cell batteries that converts hydrogen released at the negative electrode into water. This prevents the build-up of gas, which would otherwise impair the efficiency of the battery. Manganese(IV) oxide is used for this purpose.

depression or *cyclone* or *low* in meteorology, a region of low atmospheric pressure. In mid latitudes a depression forms as warm, moist air from the tropics mixes with cold, dry polar air, producing warm and cold boundaries (fronts) and unstable weather – low cloud and drizzle, showers, or fierce storms. The warm air, being less dense, rises above the cold air to produce the area of low pressure on the ground. Air spirals in towards the centre of the depression in an anticlockwise direction in the northern hemisphere, clockwise in the southern hemisphere, generating winds up to gale force. Depressions tend to travel eastwards and can remain active for several days.

depression in medicine, an emotional state characterized by sadness, unhappy thoughts, apathy, and dejection. Sadness is a normal response to major losses such as bereavement or unemployment. After childbirth, postnatal depression is common. However, clinical depression, which is prolonged or unduly severe, often requires treatment, such as antidepressant medication, cognitive therapy, or, in very rare cases, electroconvulsive therapy (ECT), in which an electrical current is passed through the brain.

Periods of depression may alternate with periods of high optimism, over-enthusiasm, and confidence. This is the manic phase in a disorder known as manic depression or bipolar disorder. A manic depressive state is one in which a person switches repeatedly from one extreme to the other. Each mood can last for weeks or months. Typically, the depressive state lasts longer than the manic phase.

a typical depression showing low pressure at the centre

depression

derivative or *differential coefficient* in mathematics, the limit of the gradient of a chord linking two points on a curve as the distance between the points tends to zero; for a function of a single variable, $y = f(x)$, it is denoted by $f'(x)$, $Df(x)$, or dy/dx , and is equal to the gradient of the curve.

dermatitis inflammation of the skin (see eczema), usually related to allergy. Dermatitis refers to any skin disorder and may be caused by contact or systemic problems.

dermatology medical speciality concerned with the diagnosis and treatment of skin disorders.

derrick simple lifting machine consisting of a pole carrying a block and tackle. Derricks are commonly used on ships that carry freight. In the oil industry the tower used for hoisting the drill pipes is known as a derrick.

derris climbing leguminous plant (see legume) of southeast Asia. Its roots contain rotenone, a strong insecticide. (*Derris elliptica*, family Fabaceae.)

DES in computing, abbreviation for Data Encryption Standard.

desalination removal of salt, usually from sea water, to produce fresh water for irrigation or drinking. Distillation has usually been

the method adopted, but in the 1970s a cheaper process, using certain polymer materials that filter the molecules of salt from the water by reverse osmosis, was developed.

Desalination plants occur along the shores of the Middle East where fresh water is in short supply.

DESCARTES, RENÉ

<http://www.knight.org/advent/cathen/04744b.htm>

Extensive treatment of the life and philosophical, scientific, and mathematical achievements of Renatus Cartesius. The restless travels of the young savant are described before a detailed discussion of his contribution to learning.

Descartes, René (1596–1650)

French philosopher and mathematician. He believed that commonly accepted knowledge was doubtful because of the subjective nature of the senses, and attempted to rebuild human knowledge using as his foundation the dictum *cogito ergo sum* ('I think, therefore I am'). He also believed that the entire material universe could be explained in terms of mathematical physics, and founded coordinate geometry as a way of defining and manipulating geometrical shapes by means of algebraic expressions. Cartesian coordinates, the means by which points are represented in this system, are named after him. Descartes also established the science of optics, and helped to shape contemporary theories of astronomy and animal behaviour.

Descartes identified the 'thinking thing' (*res cogitans*), or mind, with the human soul or consciousness; the body, though somehow interacting with the soul, was a physical machine, secondary to, and in principle separable from, the soul. He held that everything has a cause; nothing can result from nothing. He believed that, although all matter is in motion, matter does not move of its own accord; the initial impulse comes from God. He also postulated two quite distinct substances: spatial substance, or matter, and thinking substance, or mind. This is called 'Cartesian dualism', and it preserved him from serious controversy with the church.

*Cogito, ergo sum.
I think, therefore I am.*

RENÉ DESCARTES French philosopher and mathematician.
Le discours de la méthode

desert arid area with sparse vegetation (or, in rare cases, almost no vegetation). Soils are poor, and many deserts include areas of shifting sands. Deserts can be either hot or cold. Almost 33% of the Earth's land surface is desert, and this proportion is increasing.

The **tropical desert** belts of latitudes from 5° to 30° are caused by the descent of air that is heated over the warm land and therefore has lost its moisture. Other natural desert types are the **continental**

Largest deserts in the world

| Desert | Location | Area ¹ | |
|----------------|-----------------------------|-------------------|-----------|
| | | sq km | sq mi |
| Sahara | northern Africa | 9,065,000 | 3,500,000 |
| Gobi | Mongolia/northeastern China | 1,295,000 | 500,000 |
| Patagonian | Argentina | 673,000 | 260,000 |
| Rub al-Khali | southern Arabian peninsula | 647,500 | 250,000 |
| Chihuahuan | Mexico/southwestern USA | 362,600 | 140,000 |
| Taklimakan | northern China | 362,600 | 140,000 |
| Great Sandy | northwestern Australia | 338,500 | 130,000 |
| Great Victoria | southwestern Australia | 338,500 | 130,000 |
| Kalahari | southwestern Africa | 260,000 | 100,000 |
| Kyzyl Kum | Uzbekistan | 259,000 | 100,000 |
| Thar | India/Pakistan | 259,000 | 100,000 |
| Sonoran | Mexico/southwestern USA | 181,300 | 70,000 |
| Simpson | Australia | 103,600 | 40,000 |
| Mojave | southwestern USA | 51,800 | 20,000 |

¹Desert areas are very approximate, because clear physical boundaries may not occur.

deserts, such as the Gobi, that are too far from the sea to receive any moisture; **rain-shadow deserts**, such as California's Death Valley, that lie in the lee of mountain ranges, where the ascending air drops its rain only on the windward slopes; and **coastal deserts**, such as the Namib, where cold ocean currents cause local dry air masses to descend. Desert surfaces are usually rocky or gravelly, with only a small proportion being covered with sand. Deserts can be created by changes in climate, or by the human-aided process of desertification.

Characteristics common to all deserts include irregular rainfall of less than 250 mm/19.75 in per year, very high evaporation rates often 20 times the annual precipitation, and low relative humidity and cloud cover. Temperatures are more variable; tropical deserts have a big diurnal temperature range and very high daytime temperatures (58°C/136.4°F) has been recorded at Azizia in Libya), whereas mid-latitude deserts have a wide annual range and much lower winter temperatures (in the Mongolian desert the mean temperature is below freezing point for half the year).

Desert soils are infertile, lacking in (humus and generally grey or red in colour. The few plants capable of surviving such conditions are widely spaced, scrubby and often thorny. Long-rooted plants (phreatophytes) such as the date palm and musquitte commonly grow along dry stream channels. Salt-loving plants (halophytes) such as saltbushes grow in areas of highly saline soils and near the edges of playas (dry saline lakes). Others, such as the *oxerophytes* are drought-resistant and survive by remaining leafless during the dry season or by reducing water losses with small waxy leaves. They frequently have shallow and widely branching root systems and store water during the wet season (for example, succulents and cacti with pulpy stems).

desertification spread of deserts by changes in climate, or by human-aided processes. Desertification can sometimes be reversed by special planting (marram grass, trees) and by the use of water-absorbent plastic grains, which, added to the soil, enable crops to be grown.

The processes leading to desertification include overgrazing, destruction of forest belts, and exhaustion of the soil by intensive cultivation without restoration of fertility – all of which may be prompted by the pressures of an expanding population or by concentration in land ownership. About 135 million people are directly affected by desertification, mainly in Africa, the Indian subcontinent, and South America.

desiccator airtight vessel, traditionally made of glass, in which materials may be stored either to dry them or to prevent them, once dried, from reabsorbing moisture.

The base of the desiccator is a chamber in which is placed a substance with a strong affinity for water (such as calcium chloride or silica gel), which removes water vapour from the desiccator atmosphere and from substances placed in it.

Mary Evans Picture Library

desktop in computing, a graphical representation of file systems, in which applications and files are represented by pictures (icons), which can be triggered by a single or double click with a mouse button. Such a graphical user interface can be compared with the command line interface, which is character-based.

desktop publishing (DTP) use of microcomputers for small-scale typesetting and page makeup. DTP systems are capable of producing camera-ready pages (pages ready for photographing and printing), made up of text and graphics, with text set in different typefaces and sizes. The page can be previewed on the screen before final printing on a laser printer.

A DTP program is able to import text and graphics from other packages; run text as columns, over pages, and around artwork and other insertions; enable a wide range of fonts; and allow accurate positioning of all elements required to make a page.

desktop video in computing, a videoconferencing system that can be used by an individual from a desktop computer. A desktop conferencing system needs a computer, an attached video camera, microphone, and speakers, and a telephone or network connection.

Early videoconferencing systems required such expensive equipment that participants had to gather in the room where the equipment was kept. Systems introduced in the mid-1990s, however, made videoconferencing as convenient, private, and easy to use as ordinary telephone calls.

The first desktop videoconferencing system on the Internet was *CCU-SeeMe*.

destination page in computing, page designated by a hypertext link.

detergent surface-active cleansing agent. The common detergents are made from fats (hydrocarbons) and sulphuric acid, and their long-chain molecules have a type of structure similar to that of soap molecules: a salt group at one end attached to a long hydrocarbon 'tail'. They have the advantage over soap in that they do not produce scum by forming insoluble salts with the calcium and magnesium ions present in hard water.

To remove dirt, which is generally attached to materials by means of oil or grease, the hydrocarbon 'tails' (soluble in oil or grease) penetrate the oil or grease drops, while the 'heads' (soluble in water but insoluble in grease) remain in the water and, being salts, become ionized. Consequently the oil drops become negatively charged and tend to repel one another; thus they remain in suspension and are washed away with the dirt.

Detergents were first developed from coal tar in Germany during World War I, and synthetic organic detergents were increasingly used after World War II.

Domestic powder detergents for use in hot water have alkyl benzene as their main base, and may also include bleaches and fluorescers as whiteners, perborates to free stain-removing oxygen, and water softeners. Environment-friendly detergents contain no phosphates or bleaches. Liquid detergents for washing dishes are based on epoxyethane (ethylene oxide). Cold-water detergents consist of a mixture of various alcohols, plus an ingredient for breaking down the surface tension of the water, so enabling the liquid to penetrate fibres and remove the dirt. When these surface-active agents (surfactants) escape the normal processing of sewage, they cause troublesome foam in rivers; phosphates in some detergents can also cause the excessive enrichment (eutrophication) of rivers and lakes.

determinant in mathematics, an array of elements written as a square, and denoted by two vertical lines enclosing the array. For a 2×2 matrix, the determinant is given by the difference between the products of the diagonal terms. Determinants are used to solve sets of simultaneous equations by matrix methods.

When applied to transformational geometry, the determinant of a 2×2 matrix signifies the ratio of the area of the transformed shape to the original and its sign (plus or minus) denotes whether the image is direct (the same way round) or indirect (a mirror image).

For example, the determinant of the matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bdc \begin{vmatrix} d \\ c \end{vmatrix}$$

detonator or **blasting cap** or **percussion cap** small explosive charge used to trigger off a main charge of high explosive. The relatively unstable compounds mercury fulminate and lead azide are often used in detonators, being set off by a lighted fuse or, more commonly, an electric current.

detritus in biology, the organic debris produced during the decomposition of animals and plants.

deuterium naturally occurring heavy isotope of hydrogen, mass number 2 (one proton and one neutron), discovered by Harold Urey in 1932. It is sometimes given the symbol D. In nature, about one in every 6,500 hydrogen atoms is deuterium. Combined with oxygen, it produces 'heavy water' (D_2O), used in the nuclear industry.

deuteron nucleus of an atom of deuterium (heavy hydrogen). It consists of one proton and one neutron, and is used in the bombardment of chemical elements to synthesize other elements.

developer in computing, designer of a computer system, most commonly used to mean a software developer.

developing in photography, the process that produces a visible image on exposed photographic film, involving the treatment of the exposed film with a chemical developer.

The developing liquid consists of a reducing agent that changes the light-altered silver salts in the film into darker metallic silver. The developed image is made permanent with a fixer, which dissolves away any silver salts which were not affected by light. The developed image is a negative, or reverse image: darkest where the strongest light hit the film, lightest where the least light fell. To produce a positive image, the negative is itself photographed, and the development process reverses the shading, producing the final print. Colour and black-and-white film can be obtained as direct reversal, slide, or transparency material. Slides and transparencies are used for projection or printing with a positive-to-positive process such as Cibachrome.

development in biology, the process whereby a living thing transforms itself from a single cell into a vastly complicated multicellular organism, with structures, such as limbs, and functions, such as respiration, all able to work correctly in relation to each other. Most of the details of this process remain unknown, although some of the central features are becoming understood.

Apart from the sex cells (gametes), each cell within an organism contains exactly the same genetic code. Whether a cell develops into a liver cell or a brain cell depends therefore not on which genes it contains, but on which genes are allowed to be expressed. The development of forms and patterns within an organism, and the production of different, highly specialized cells, is a problem of control, with genes being turned on and off according to the stage of development reached by the organism.

developmental psychology study of development of cognition and behaviour from birth to adulthood.

device driver in computing, small piece of software required to tell the operating system how to interact with a particular input or output device or peripheral.

Much work has been done to standardize devices and their interfaces to eliminate the need for individual device drivers. Peripherals such as CD-ROM drives, for example, work with a single standard device driver (in Microsoft Windows, MSCDEX.EXE). Other devices, such as modems and printers, still need an individual driver tailored to work with that specific model.

devil ray any of several large rays of the genera *Manta* and *Mobula*, in which two 'horns' project forwards from the sides of the huge mouth. These flaps of skin guide the plankton, on which the fish feed, into the mouth.

The largest of these rays can be 7 m/23 ft across, and weigh 1,000 kg/2,200 lb. They live in warm seas.

devil's coach horse large, black, long-bodied, omnivorous beetle *Oryctes olens*, about 3 cm/1.2 in long. It has powerful jaws and is capable of giving a painful bite. It emits an unpleasant smell when threatened.

devil's coach horse The devil's coach horse beetle (family Staphylinidae) adopts a threatening posture with its tail raised and emits an unpleasant smell when it senses danger. Premiafotos Wildlife

Devonian period of geological time 408–360 million years ago, the fourth period of the Palaeozoic era. Many desert sandstones from North America and Europe date from this time. The first land plants flourished in the Devonian period, corals were abundant in the seas, amphibians evolved from air-breathing fish, and insects developed on land.

The name comes from the county of Devon in southwest England, where Devonian rocks were first studied.

dew precipitation in the form of moisture that collects on the ground. It forms after the temperature of the ground has fallen below the dew point of the air in contact with it. As the temperature falls during the night, the air and its water vapour become chilled, and condensation takes place on the cooled surfaces.

dew point temperature at which the air becomes saturated with water vapour. At temperatures below the dew point, the water vapour condenses out of the air as droplets. If the droplets are large they become deposited on the ground as dew; if small they remain in suspension in the air and form mist or fog.

dewpond drinking pond for farm animals on arid hilltops such as chalk downs. In the UK, dewponds were excavated in the 19th century and lined with mud and clay. It is uncertain where the water comes from but it may be partly rain, partly sea mist, and only a small part dew.

dhole wild dog *Cuon alpinus* found in Asia from Siberia to Java. With head and body up to 1 m/39 in long, variable in colour but often reddish above and lighter below, the dhole lives in groups of from 3 to 30 individuals. The species is becoming rare and is protected in some areas.

Dholes can chase prey for long distances; a pack is capable of pulling down deer and cattle as well as smaller prey. They are even known to have attacked tigers and leopards.

diabase alternative name for dolerite (a form of basalt that contains very little silica), especially dolerite that has metamorphosed.

diabetes disease *diabetes mellitus* in which a disorder of the islets of Langerhans in the pancreas prevents the body producing the hormone insulin , so that sugars cannot be used properly.

Treatment is by strict dietary control and oral or injected insulin , depending on the type of diabetes.

There are two forms of diabetes: Type 1, or insulin-dependent diabetes, which usually begins in childhood (early onset) and is an

autoimmune condition; and Type 2, or noninsulin-dependent diabetes, which occurs in later life (late onset).

diagenesis in geology, the physical and chemical changes by which a sediment becomes a sedimentary rock. The main processes involved include compaction of the grains, and the cementing of the grains together by the growth of new minerals deposited by percolating groundwater.

dialler in computing, element of an Internet software package that makes the connection to the online service or Internet Service Provider. In Windows systems, this is usually the WINSOCK.DLL file, with or without a front end (part of the program that interacts with the user) to make configuration easier.

dialog box in graphical user interfaces, a small on-screen window with blanks for user input.

dial-up connection in computing, connection to an online system or Internet Service Provider made by dialling via a modem over a telephone line.

dialysis technique for removing waste products from the blood suffering chronic or acute kidney failure. There are two main methods, haemodialysis and peritoneal dialysis.

In haemodialysis, the patient's blood is passed through a pump, where it is separated from sterile dialysis fluid by a semipermeable membrane. This allows any toxic substances which have built up in the bloodstream, and which would normally be filtered out by the kidneys, to diffuse out of the blood into the dialysis fluid. Haemodialysis is very expensive and usually requires the patient to attend a specialized unit.

Peritoneal dialysis uses one of the body's natural semipermeable membranes for the same purpose. About two litres of dialysis fluid is slowly instilled into the peritoneal cavity of the abdomen, and drained out again, over about two hours. During that time toxins from the blood diffuse into the peritoneal cavity across the peritoneal membrane. The advantage of peritoneal dialysis is that the patient can remain active while the dialysis is proceeding. This is known as continuous ambulatory peritoneal dialysis (CAPD).

In the long term, dialysis is expensive and debilitating, and transplants are now the treatment of choice for patients in chronic kidney failure.

diagenesis The formation of sedimentary rock by diagenesis. Sand and other sediment grains are compacted and cemented together.

diamagnetic material a material weakly repelled by a magnet. All substances are diamagnetic but the behaviour is often masked by stronger forms of magnetism such as ferromagnetic or paramagnetic behaviour.

Diamagnetism is caused by changes in the orbits of electrons in the substance induced by the applied field. Diamagnetic materials have a small negative magnetic susceptibility.

diameter straight line joining two points on the circumference of a circle that passes through the centre of that circle. It divides a circle into two equal halves.

diamond generally colourless, transparent mineral, an allotrope of carbon. It is regarded as a precious gemstone, and is the hardest substance known (10 on the Mohs' scale). Industrial diamonds, which may be natural or synthetic, are used for cutting, grinding, and polishing.

Diamond crystallizes in the cubic system as octahedral crystals, some with curved faces and striations. The high refractive index of 2.42 and the high dispersion of light, or 'fire', account for the spectral displays seen in polished diamonds.

history Diamonds were known before 3000 BC and until their discovery in Brazil in 1725, India was the principal source of supply. Present sources are Australia, Congo (formerly Zaire), Botswana, Russia (Yakut), South Africa, Namibia, and Angola; the first two produce large volumes of industrial diamonds. Today, about 80% of the world's rough gem diamonds are sold through the De Beers Central Selling Organization in London.

sources Diamonds may be found as alluvial diamonds on or close to the Earth's surface in riverbeds or dried watercourses; on the sea bottom (off southwest Africa); or, more commonly, in diamond-bearing volcanic pipes composed of 'blue ground', kimberlite or lamproite, where the original matrix has penetrated the Earth's crust from great depths. They are sorted from the residue of crushed ground by X-ray and other recovery methods.

varieties There are four chief varieties of diamond: well-crystallized transparent stones, colourless or only slightly tinted, valued as gems; **boart**, poorly crystallized or inferior diamonds; **balas**, an industrial variety, extremely hard and tough; and **carbonado**, or industrial diamond, also called black diamond or carbon, which is opaque, black or grey, and very tough. Industrial diamonds are also produced synthetically from graphite. Some synthetic diamonds conduct heat 50% more efficiently than natural diamonds and are five times greater in strength. This is a great advantage in their use to disperse heat in electronic and telecommunication devices and in the production of laser components.

practical uses Because diamonds act as perfectly transparent windows and do not absorb infrared radiation, they were used aboard NASA space probes to Venus in 1978. The tungsten-carbide tools used in steel mills are cut with industrial diamond tools.

cutting Rough diamonds are often dull or greasy before being polished; around 50% are considered 'cuttable' (all or part of the diamond may be set into jewellery). Gem diamonds are valued by weight (carat), cut (highlighting the stone's optical properties), colour, and clarity (on a scale from internally flawless to having a large inclusion clearly visible to the naked eye). They are sawn and polished using a mixture of oil and diamond powder. The two most popular cuts are the brilliant, for thicker stones, and the marquise, for shallower ones. India is the world's chief cutting centre.

Noted rough diamonds include the Cullinan, or Star of Africa (3.106 carats, over 500 g/17.5 oz before cutting, South Africa, 1905); Excelsior (995.2 carats, South Africa, 1893); and Star of Sierra Leone (968.9 carats, Yengema, 1972).

experiments a moderate force applied to the small tips of two opposing diamonds can be used to attain extreme pressures of millions of atmospheres or more, allowing scientists to subject small amounts of material to conditions that exist deep within planet interiors.

diamondine technical term for heroin.

DIANE (acronym for *direct information access network for Europe*) collection of information suppliers, or 'hosts', for the European computer network.

diapause period of suspended development that occurs in some species of insects, characterized by greatly reduced metabolism. Periods of diapause are often timed to coincide with the winter months, and improve the insect's chances of surviving adverse conditions.

diaphragm in mammals, a thin muscular sheet separating the thorax from the abdomen. It is attached by way of the ribs at either side and the breastbone and backbone, and a central tendon. Arching upwards against the heart and lungs, the diaphragm is important in the mechanics of breathing. It contracts at each inhalation, moving downwards to increase the volume of the chest cavity, and relaxes at exhalation.

diaphragm or **cap** or **Dutch cap** barrier (contraceptive that is passed into the vagina to fit over the cervix (neck of the uterus), preventing sperm from entering the uterus. For a cap to be effective, a spermicide must be used and the diaphragm left in place for 6-8 hours after intercourse. This method is 97% effective if practised correctly.

diarrhoea frequent or excessive action of the bowels so that the faeces are liquid or semiliquid. It is caused by intestinal irritants (including some drugs and poisons), infection with harmful organisms (as in dysentery, salmonella, or cholera), or allergies.

Diarrhoea is the biggest killer of children in the world. In 1996 the World Health Organization reported that 3.1 million deaths had been caused by diarrhoeal disease during 1995. The commonest cause of dehydrating diarrhoea is human rotavirus infection, responsible for about 870,000 infant deaths annually. Dehydration as a result of diarrhoeal disease can be treated by giving a solution of salt and glucose by mouth in large quantities (to restore the electrolyte balance in the blood). Since most diarrhoea is viral in origin, antibiotics are ineffective.

diastole in biology, the relaxation of a hollow organ. In particular, the term is used to indicate the resting period between beats of the heart when blood is flowing into it.

diastolic pressure in medicine, measurement due to the pressure of blood against the arterial wall during diastole (relaxation of the heart). It is the lowest blood pressure during the cardiac cycle. The average diastolic pressure in healthy young adults is about 80 mmHg. The variation of diastolic pressure due to changes in body position and mood is greater than that of systolic pressure. Diastolic pressure is also a more accurate predictor of hypertension (high blood pressure).

diatom microscopic (algae) found in all parts of the world in either fresh or marine waters. Diatoms consist of single cells that secrete a hard cell wall made of silica. (Division Bacillariophyta.)

The cell wall of a diatom is made up of two overlapping valves known as frustules, which are impregnated with silica, and which fit together like the lid and body of a pillbox. Diatomaceous earths (diatomite) are made up of the valves of fossil diatoms, and are used in the manufacture of dynamite and in the rubber and plastics industries.

diatomic molecule molecule composed of two atoms joined together. In the case of an element such as oxygen (O₂), the atoms are identical.

dichloro-diphenyl-trichloroethane full name of the insecticide DDT.

dichotomous key method of identifying an organism. The investigator is presented with pairs of statements, for example 'flower has less than five stamens' and 'flower has five or more stamens'. By successively eliminating statements the field naturalist moves closer to a positive identification. Dichotomous keys assume a good knowledge of the subject under investigation.

dicotyledon major subdivision of the angiosperms, containing the great majority of flowering plants. Dicotyledons are characterized by the presence of two seed leaves, or cotyledons, in the embryo, which is usually surrounded by the endosperm. They generally have broad leaves with netlike veins.

diecasting form of casting in which molten metal is injected into permanent metal moulds or dies.

dielectric an insulator or nonconductor of electricity, such as rubber, glass, and paraffin wax. An electric field in a dielectric material gives rise to no net flow of electricity. However, the applied field causes electrons within the material to be displaced, creating an electric charge on the surface of the material. This reduces the field strength within the material by a factor known as the dielectric constant (or relative permittivity) of the material. Dielectrics are used in capacitors, to reduce dangerously strong electric fields, and have optical applications.

diesel engine internal-combustion engine that burns a light-weight fuel oil. The diesel engine operates by compressing air until it becomes sufficiently hot to ignite the fuel. It is a piston-in-cylinder engine, like the petrol engine, but only air (rather than an air-and-fuel mixture) is taken into the cylinder on the first piston stroke (down). The piston moves up and compresses the air until it is at a very high temperature. The fuel oil is then injected into the hot air, where it burns, driving the piston down on its power stroke. For this reason the engine is called a compression-ignition engine.

Diesel engines have sometimes been marketed as 'cleaner' than petrol engines because they do not need lead additives and produce fewer gaseous pollutants. However, they do produce high levels of the tiny black carbon particles called particulates, which are believed to be carcinogenic and may exacerbate or even cause asthma.

The principle of the diesel engine was first explained in England by Herbert Akroyd (1864-1937) in 1890, and was applied practically by Rudolf Diesel in Germany in 1892.

diesel oil lightweight fuel oil used in diesel engines. Like petrol, it is a petroleum product. When used in vehicle engines, it is also known as *derv* (diesel-engine road vehicle).

diet range of foods eaten by an animal each day; it is also a particular selection of food, or the total amount and choice of food for a specific person or people. Most animals require seven kinds of food in their diet: proteins, carbohydrates, fats, vitamins, minerals, water, and roughage. A diet that contains all of these things in the correct amounts and proportions is termed a balanced diet. The amounts and proportions required varies with different animals, according to their size, age, and lifestyle. The digestive systems of animals have evolved to meet particular needs; they have also adapted to cope with the foods available in the surroundings in which they live. The necessity of finding and processing an appropriate diet is a very basic drive in animal evolution. Dietetics is the science of feeding individuals or groups; a dietitian is a specialist in this science.

Dietary requirements may vary over the lifespan of an animal, according to whether it is growing, reproducing, highly active, or approaching death. For instance, increased carbohydrate for additional energy, or increased minerals, may be necessary during periods of growth.

An adequate diet for humans is one that supplies the body's daily nutritional needs (see nutrition), and provides sufficient energy to meet individual levels of activity. The average daily requirement for men is 2,500 calories, but this will vary with age, occupation, and weight; in general, women need fewer calories than men. The energy requirements of active children increase steadily with age, reaching a peak in the late teens. At present, about 450 million people in the world - mainly living in famine or poverty stricken areas, especially in Third World countries - subsist on fewer than 1,500 calories per day. The average daily intake in developed countries is 3,300 calories.

dietetics specialized branch of human nutrition, dealing with the promotion of health through the proper kinds and quantities of food.

Therapeutic dietetics has a large part to play in the treatment of certain illnesses, such as allergies, arthritis, and diabetes; it is sometimes used alone, but often in conjunction with drugs. The preventative or curative effects of specific diets, such as the 'grape cure' or raw vegetable diets sometimes prescribed for cancer patients, are disputed by orthodox medicine.

difference in mathematics, the result obtained when subtracting one number from another. Also, those elements of one set that are not elements of another.

difference engine mechanical calculating machine designed (and partly built in 1822) by the British mathematician Charles Babbage to produce reliable tables of life expectancy. A precursor of the analytical engine, it was to calculate mathematical functions by solving the differences between values given to variables within equations. Babbage designed the calculator so that once the initial values for the variables were set it would produce the next few thousand values without error.

differential arrangement of gears in the final drive of a vehicle's transmission system that allows the driving wheels to turn at different speeds when cornering. The differential consists of sets of bevel gears and pinions within a cage attached to the crown wheel. When cornering, the bevel pinions rotate to allow the outer wheel to turn faster than the inner.

differential The differential lies midway between the driving wheels of a motorcar. When the car is turning, the bevel pinions spin, allowing the outer wheel to turn faster than the inner wheel.

differential calculus branch of calculus involving applications such as the determination of maximum and minimum points and rates of change.

differentiation in embryology, the process by which cells become increasingly different and specialized, giving rise to more complex structures that have particular functions in the adult organism. For instance, embryonic cells may develop into nerve, muscle, or bone cells.

differentiation in mathematics, a procedure for determining the derivative or gradient of the tangent to a curve $f(x)$ at any point x .

Diffie-Hellman key exchange system in computing, the basis of public-key cryptography, proposed by researchers Whitfield Diffie and Martin Hellman 1976.

diffraction the slight spreading of a light beam into a pattern of light and dark bands when it passes through a narrow slit or past

The act of putting into your mouth what the earth has grown is perhaps your most direct interaction with the earth.

FRANCES LAPPE US ecologist.
Diet for a Small Planet pt 1

differentiation A mathematical procedure for determining the gradient, or slope, of the tangent to any curve $f(x)$ at any point x . Part of a branch of mathematics called differential calculus, it is used to solve problems involving continuously varying quantities (such as the change in velocity or altitude of a rocket), to find the rates at which these variations occur and to obtain maximum and minimum values for the quantities.

the edge of an obstruction. A **diffraction grating** is a plate of glass or metal ruled with close, equidistant parallel lines used for separating a wave train such as a beam of incident light into its component frequencies (white light results in a spectrum).

The regular spacing of atoms in crystals are used to diffract X-rays, and in this way the structure of many substances has been elucidated, including that of proteins (see X-ray diffraction). Sound waves can also be diffracted by a suitable array of solid objects.

diffusion spontaneous and random movement of molecules or particles in a fluid (gas or liquid) from a region in which they are at a high concentration to a region of lower concentration, until a uniform concentration is achieved throughout. No mechanical mixing or stirring is involved. For instance, if a drop of ink is added to water, its molecules will diffuse until their colour becomes evenly distributed throughout.

In biological systems, diffusion plays an essential role in the transport, over short distances, of molecules such as nutrients, respiratory gases, and neurotransmitters. It provides the means by which small molecules pass into and out of individual cells and microorganisms, such as amoebae, that possess no circulatory system. Diffusion of water across a semi-permeable membrane is termed osmosis.

One application of diffusion is the separation of isotopes, particularly those of uranium. When uranium hexafluoride diffuses through a porous plate, the ratio of the 235 and 238 isotopes is changed slightly. With sufficient number of passages, the separation is nearly complete. There are large plants in the USA and UK for obtaining enriched fuel for fast nuclear reactors and the fissile uranium-235, originally required for the first atom bombs. Another application is the diffusion pump, used extensively in vacuum work, in which the gas to be evacuated diffuses into a chamber from which it is carried away by the vapour of a suitable medium, usually oil or mercury.

Laws of diffusion were formulated by Thomas Graham in 1829 (for gases) and Adolph Fick 1829-1901 (for solutions).

digestion process whereby food eaten by an animal is broken down mechanically, and chemically by enzymes, mostly in the stomach and intestines, to make the nutrients available for absorption and cell metabolism.

In some single-celled organisms, such as amoebae, a food particle is engulfed by the cell and digested in a vacuole within the cell.

digestive system in the body, all the organs and tissues involved in the digestion of food. In animals, these consist of the mouth, stomach, intestines, and their associated glands. The process of digestion breaks down the food by physical and chemical means into the different elements that are needed by the body for energy and tissue building and repair. Digestion begins in the mouth and is completed in the stomach; from there most nutrients are absorbed into the small intestine from where they pass through the intestinal wall into the bloodstream; what remains is stored and concentrated into faeces in the large intestine. Birds have two additional digestive organs – the crop and gizzard. In smaller, simpler animals such as jellyfish, the digestive system is simply a cavity (coelenteron or enteric cavity) with a 'mouth' into which food is taken; the digestible portion is dissolved and absorbed in this cavity, and the remains are ejected back through the mouth.

The digestive system of humans consists primarily of the alimentary canal, a tube which starts at the mouth, continues with the pharynx, oesophagus (or gullet), stomach, large and small intestines, and rectum, and ends at the anus. The food moves through this canal by peristalsis whereby waves of involuntary muscular contraction and relaxation produced by the muscles in the wall of the gut cause the food to be ground and mixed with various digestive juices. Most of these juices contain digestive enzymes, chemicals that speed up reactions involved in the breakdown of food. Other digestive juices empty into the alimentary canal from the salivary glands, gall bladder, and pancreas, which are also part of the digestive system.

The fats, proteins, and carbohydrates (starches and sugars) in foods contain very complex molecules that are broken down (see diet; nutrition) for absorption into the bloodstream: starches and complex sugars are converted to simple sugars; fats are converted to fatty acids and glycerol; and proteins are converted to amino acids and peptides. Foods such as vitamins, minerals, and water do not need to undergo digestion prior to absorption into the bloodstream. The small intestine, which is the main site of digestion and absorption, is subdivided into the duodenum, jejunum, and ileum.

diffusion Diffusion is the movement of molecules from a region of high concentration into a region of lower concentration.

digestive system The human digestive system. When food is swallowed, it is moved down the oesophagus by the action of muscles (peristalsis) into the stomach. Digestion starts in the stomach as the food is mixed with enzymes and strong acid. After several hours, the food passes to the small intestine. Here more enzymes are added and digestion is completed. After all nutrients have been absorbed, the indigestible parts pass into the large intestine and thence to the rectum. The liver has many functions, such as storing minerals and vitamins and making bile, which is stored in the gall bladder until needed for the digestion of fats. The pancreas supplies enzymes. The appendix appears to have no function in human beings.

Covering the surface of its mucous membrane lining are a large number of small prominences called villi which increase the surface for absorption and allow the digested nutrients to diffuse into small blood-vessels lying immediately under the epithelium.

DigiCash in computing, one of several competing systems for electronic money suitable for use on the Internet. Invented by Belgian-based US cryptographer David Chaum, DigiCash uses public-key cryptography techniques to assure anonymity. Trials of the system began in 1994 using software developed for Windows, UNIX, and the Mac.

digit in mathematics, any of the numbers from 0 to 9 in the decimal system. Different bases have different ranges of digits. For example, the hexadecimal system has digits 0 to 9 and A to F, whereas the binary system has two digits (or bits), 0 and 1.

digital in electronics and computing, a term meaning 'coded as numbers'. A digital system uses two-state, either on/off or high/low voltage pulses, to encode, receive, and transmit information. A digital display shows discrete values as numbers (as opposed to an analogue signal, such as the continuous sweep of a pointer on a dial).

Digital electronics is the technology that underlies digital techniques. Low-power, miniature, integrated circuits (chips) provide

the means for the coding, storage, transmission, processing, and reconstruction of information of all kinds.

digital audio tape (DAT) digitally recorded audio tape produced in cassettes that can carry up to two hours of sound on each side and are about half the size of standard cassettes. DAT players/recorders were developed in 1987. Prerecorded cassettes are copy-protected. The first DAT for computer data was introduced in 1988.

DAT machines are constructed like video cassette recorders (though they use metal audio tape), with a movable playback head, the tape winding in a spiral around a rotating drum. The tape can also carry additional information; for example, a time code for instant location of any point on the track. The music industry delayed releasing prerecorded DAT cassettes because of fears of bootlegging, but a system has now been internationally agreed whereby it is not possible to make more than one copy of any prerecorded compact disc or DAT. DAT is mainly used in recording studios for making master tapes. The system was developed by Sony.

By 1990, DATs for computer data had been developed to a capacity of around 2.5 gigabytes per tape, achieved by using helical scan recording (in which the tape covers about 90% of the total head area of the rotating drum). This enables data from the tape to be read over 200 times faster than it can be written. Any file can be located within 60 seconds.

Digestive System: Pioneering Experiments on the Digestive System

BY JULIAN ROWE

An army marches on its stomach

On 6 June 1822 at Fort Mackinac, Michigan, USA, an 18-year-old French Canadian was accidentally wounded in the abdomen by the discharge of a musket. He was brought to the army surgeon, US physician William Beaumont (1785-1853), who noted several serious wounds and, in particular, a hole in the abdominal wall and stomach. The surgeon observed that through this hole in the patient 'was pouring out the food he had taken for breakfast'.

The patient, Alexis St Martin, a trapper by profession, was serving with the army as a porter and general servant. Not surprisingly, St Martin was at first unable to keep food in his stomach. As the wound gradually healed, firm dressings were needed to retain the stomach contents. Beaumont tended his patient assiduously and tried during the ensuing months to close the hole in his stomach, without success. After 18 months, a small, protruding fleshy fold had grown to fill the aperture (fistula). This 'valve' could be opened simply by pressing it with a finger.

Digestion ... inside and outside

At this point, it occurred to Beaumont that here was an ideal opportunity to study the process of digestion. His patient must have been an extremely tough character to have survived the accident at all. For the next nine years he was the subject of a remarkable series of pioneering experiments, in which Beaumont was able to vary systematically the conditions under which digestion took place and discover the chemical principles involved.

Beaumont attacked the problem of digestion in two ways. He studied how various substances were actually digested in the stomach, and also how they were 'digested' outside the stomach in the digestive juices he extracted from St Martin. He found it was easy enough to drain out the digestive juices from his fortuitously wounded patient 'by placing the subject on his left side, depressing the valve within the aperture, introducing a gum elastic tube and then turning him ... on introducing the tube the fluid soon began to run.'

A typical experiment

Beaumont was basically interested in the rate and temperature of digestion, and also the chemical conditions that favoured different stages of the process of digestion. He describes a typical experiment (he performed hundreds), where (a) digestion in the stomach is contrasted (b) with artificial digestion in glass containers kept at suitable temperatures, like this:

(a) 'At 9 o'clock he breakfasted on bread, sausage, and coffee, and kept exercising. 11 o'clock, 30 minutes, stomach two-thirds empty, aspects of weather similar, thermometer 298°F, temperature of stomach $101\frac{1}{2}$ and $100\frac{3}{4}$. The appearance of contraction and dilation and alternative piston motions were distinctly observed at this examination. 12 o'clock, 20 minutes, stomach empty.'

(b) 'February 7. At 8 o'clock, 30 minutes a.m. I put twenty grains of boiled codfish into three drachms of gastric juice and placed them on the bath.'

'At 1 o'clock, 30 minutes, p.m., the fish in the gastric juice on the bath was almost dissolved, four grains only remaining: fluid opaque, white, nearly the colour of milk. 2 o'clock, the fish in the vial all completely dissolved.'

All a matter of chemistry

Beaumont's research showed clearly for the first time just what happens during digestion and that digestion, as a process, can take place independently outside the body. He wrote that gastric juice: 'so far from being inert as water as some authors assert, is the most general solvent in nature of alimentary matter - even the hardest bone cannot withstand its action. It is capable, even out of the stomach, of effecting perfect digestion, with the aid of due and uniform degree of heat (100°Fahrenheit) and gentle agitation ... I am impelled by the weight of evidence ... to conclude that the change effected by it on the aliment, is purely chemical.'

Our modern understanding of the physiology of digestion as a process whereby foods are gradually broken down into their basic components follows logically from his work. An explanation of how the digestive juices flowed in the first place came in 1889, when Russian physiologist Ivan Pavlov (1849-1936) showed that their secretion in the stomach was controlled by the nervous system. By preventing the food eaten by a dog from actually entering the stomach, he found that the secretions of gastric juices began the moment the dog started eating, and continued as long as it did so. Since no food had entered the stomach, the secretions must be mediated by the nervous system.

Later, it was found that the further digestion that takes place beyond the stomach was hormonally controlled. But it was Beaumont's careful scientific work, which was published in 1833 with the title *Experiments and Observations on the Gastric Juice and Physiology of Digestion*, that triggered subsequent research in this field.

digital camera camera that uses a charge-coupled device (CCD) to take pictures which are stored as digital data rather than on film. The output from digital cameras can be downloaded onto a computer for retouching or storage, and can be readily distributed as computer files. Leading manufacturers of digital cameras include Canon and Kodak.

digital city in computing, area in cyberspace, either text-based or graphical, that uses the model of a city to make it easy for visitors and residents to find specific types of information.

digital compact cassette (DCC) digitally recorded audio cassette that is roughly the same size as a standard cassette. It cannot be played on a normal tape recorder, though standard tapes can be played on a DCC machine; this is known as 'backwards compatibility'. The playing time is 90 minutes.

A DCC player has a stationary playback and recording head similar to that in ordinary tape decks, though the tape used is chrome video tape. The cassettes are copy-protected and can be individually programmed for playing order. Some DCC decks have a liquid-crystal digital-display screen, which can show track titles and other information encoded on the tape.

digital composition or compositing in computing, computerized film editing. Some film special effects require shots to be cut together - composited. A sequence showing an actor hanging off the edge of a skyscraper, for example, may be put together out of footage of the actor in a safe location inserted into a shot looking down the side of the skyscraper, which may itself be a model. Traditional techniques for creating such a shot involved photographing the foreground shot with the background shot playing behind it, with an inevitable degradation of quality in the background material. In digital compositing, the same footage is digitized, and the work of merging the two sequences is done by manipulating computer files. The composite image is then transferred back onto film with no loss of quality.

digital computer computing device that operates on a two-state system, using symbols that are internally coded as binary numbers (numbers made up of combinations of the digits 0 and 1); see computer.

digital data transmission in computing, a way of sending data by converting all signals (whether pictures, sounds, or words) into numeric (normally binary) codes before transmission, then recon-

verting them on receipt. This virtually eliminates any distortion or degradation of the signal during transmission, storage, or processing.

digitalis in botany, any of a group of plants belonging to the figwort family, which includes the foxgloves. The leaves of the common foxglove (*Digitalis purpurea*) are the source of the drug digitalis used in the treatment of heart disease. (Genus *Digitalis*, family Scrophulariaceae.)

digitalis in medicine, drug that increases the efficiency of the heart by strengthening its muscle contractions and slowing its rate. It is derived from the leaves of the common European woodland plant *Digitalis purpurea* (foxglove).

It is purified to digoxin, digitoxin, and lanatoside C, which are effective in cardiac regulation but induce the side effects of nausea, vomiting, and pulse irregularities. Pioneered in the late 1700s by William Withering, an English physician and botanist, digitalis was the first cardiac drug.

digital monitor in computing, display monitor using standard cathode-ray tube technology that converts a digital signal from the computer into an analogue signal for display.

Digital monitors are used to display the continuously variable range of colours offered by analogue monitors.

digital recording technique whereby the pressure of sound waves is sampled more than 30,000 times a second and the values converted by computer into precise numerical values. These are recorded and, during playback, are reconverted to sound waves.

This technique gives very high-quality reproduction. The numerical values converted by computer represent the original sound-wave form exactly and are recorded on compact disc. When this is played back by a laser, the exact values are retrieved.

When the signal is fed via an amplifier to a loudspeaker, sound waves exactly like the original ones are reproduced.

digital retouching in computing, technique for touching up digital photographs, similar to airbrushing in the analogue world. It is commonly used in the film industry to remove scratches or to cover up filming mistakes.

The retoucher points out the error to the computer and the computer calculates new colour values for the affected pixels from the colours of neighbouring pixels.

digital sampling electronic process used in telecommunications for transforming a constantly varying (analogue) signal into one composed of discrete units, a digital signal. In the creation of recorded music, sampling enables the composer, producer, or remix engineer to borrow discrete vocal or instrumental parts from other recorded work (it is also possible to sample live sound).

A telephone microphone changes sound waves into an analogue signal that fluctuates up and down like a wave. In the digitizing process the waveform is sampled thousands of times a second and each part of the sampled wave is given a binary code number (made up of combinations of the digits 0 and 1) related to the height of the wave at that point, which is transmitted along the telephone line. Using digital signals, messages can be transmitted quickly, accurately, and economically.

digital signal processor (DSP) in computing, special-purpose integrated circuit that handles voice. DSPs are used in voice modems, which add answering machine facilities to a personal computer, and also in computer dictation systems.

digital signature in computing, method of using encryption to certify the source and integrity of a particular electronic document. Because all ASCII characters look the same no matter who types them, methods have to be found to certify the origins of particular messages if they are to be legally binding for electronic commerce or other transactions. One type of digital signature commonly seen on the Net is generated by the program Pretty Good Privacy (PGP), which adds a digest of the message to the signature.

digital-to-analogue converter electronic circuit that converts a digital signal into an analogue (continuously varying) signal. Such a circuit is used to convert the digital output from a computer into

the analogue voltage required to produce sound from a conventional loudspeaker.

digital versatile disc or digital video disc (DVD) disc format for storing digital information. DVDs can hold 14 times the data stored on current CDs. Pre-recorded DVDs have a storage capacity of 4.7 gigabytes and can hold a full-length feature film. As with CDs, information is etched in the form of microscopic pits onto a plastic disc (though the pits are half the size), which is then coated with aluminium. DVDs may have two pitted surfaces per side whereas CDs have only one. The data is read optically using a laser as the disc rotates. A double layer disc can hold 4 hours of video. The Japanese company TDK produced the rewritable DVD-RAM, capable of holding 2.6 gigabytes, in 1996.

digital video interactive powerful compression system used for storing video images on computer; see DVD-I.

digitize in computing, to turn analogue signals into the binary data a computer can read. Any type of analogue signal can be digitized, including pictures, sound, video, or film. The result is files that can be manipulated, stored, or transmitted by computers.

digitizer in computing, a device that converts an analogue video signal into a digital format so that video images can be input, stored, displayed, and manipulated by a computer. The term is sometimes used to refer to a graphics tablet.

dihybrid inheritance in genetics, a pattern of inheritance observed when two characteristics are studied in succeeding generations.

The first experiments of this type, as well as in monohybrid inheritance, were carried out by Austrian biologist Gregor Mendel using pea plants.

dik-dik any of several species of tiny antelope, genus *Madoqua*, found in Africa south of the Sahara in dry areas with scattered brush. Dik-diks are about 60 cm/2 ft high and 35 cm/1.1 ft tall, and are often seen in pairs. Males have short, pointed horns. The dik-dik is so named because of its alarm call.

dilatation and curettage (D and C) common gynaecological procedure in which the cervix (neck of the womb) is widened, or dilated, giving access so that the lining of the womb can be scraped away (curettage). It may be carried out to terminate a pregnancy, treat an incomplete miscarriage, discover the cause of heavy menstrual bleeding, or for biopsy.

dill herb belonging to the carrot family, whose bitter seeds and aromatic leaves are used in cooking and in medicine. (*Anethum graveolens*, family Umbelliferae.)

dilution process of reducing the concentration of a solution by the addition of a solvent.

The extent of a dilution normally indicates the final volume of solution required. A fivefold dilution would mean the addition of sufficient solvent to make the final volume five times the original.

dimension in science, any directly measurable physical quantity such as mass (M), length (L), and time (T), and the derived units obtainable by multiplication or division from such quantities.

For example, acceleration (the rate of change of velocity) has dimensions (LT⁻²), and is expressed in such units as km s⁻². A quantity that is a ratio, such as relative density or humidity, is dimensionless.

In geometry, the dimensions of a figure are the number of measures needed to specify its size. A point is considered to have zero dimension, a line to have one dimension, a plane figure to have two, and a solid body to have three.

dimethyl sulphoxide (DMSO) (CH₃)₂SO colourless liquid used as an industrial solvent and an antifreeze. It is obtained as a by-product of the processing of wood to paper.

DIN (abbreviation for *Deutsches Institut für Normung*) German national standards body, which has set internationally accepted standards for (among other things) paper sizes and electrical connectors.

dingbat non-alphanumeric character, such as a star, bullet, or arrow. Dingbats have been combined into $\text{\textcircled{P}}$ PostScript and $\text{\textcircled{T}}$ TrueType fonts for use with word processors and graphics programs.

dingo wild dog of Australia. Descended from domestic dogs brought from Asia by Aborigines thousands of years ago, it belongs to the same species *Canis familiaris* as other domestic dogs. It is reddish brown with a bushy tail, and often hunts at night. It cannot bark.

dinitrogen oxide alternative name for $\text{\textcircled{N}}$ itrous oxide, or 'laughing gas', one of the nitrogen oxides.

Dinorwig location of Europe's largest pumped-storage hydroelectric scheme, completed 1984, in Gwynedd, North Wales. It is used as a backup to meet heavy demands for electricity. Six turbo-generators are installed, with a maximum output of some 1,880 megawatts. The working head of water for the station is 530 m/1,740 ft.

The main machine hall is twice as long as a football field and as high as a 16-storey building.

dinosaur Greek *deinos* 'terrible', *sauros* 'lizard' any of a group (sometimes considered as two separate orders) of extinct reptiles living between 205 million and 65 million years ago. Their closest living relations are crocodiles and birds. Many species of dinosaur evolved during the millions of years they were the dominant large land animals. Most were large (up to 27 m/90 ft), but some were as small as chickens. They disappeared 65 million years ago for reasons not fully understood, although many theories exist.

classification Dinosaurs are divisible into two unrelated stocks, the orders *Saurischia* ('lizard-hip') and *Ornithischia* ('bird-hip'). Members of the former group possess a reptile-like pelvis and are mostly bipedal and carnivorous, although some are giant amphibious quadrupedal herbivores. Members of the latter group have a bird-like pelvis, are mainly four-legged, and entirely herbivorous.

The *Saurischia* are divided into: *theropods* ('beast-feet'), including all the bipedal carnivorous forms with long hindlimbs and short forelimbs (*Tyrannosaurus*, *megalosaurus*); and *sauropodomorphs* ('lizard-feet forms'), including sauropods, the large quadrupedal herbivorous and amphibious types with massive limbs, long tails and necks, and tiny skulls (*diplocodus*, *brontosaurus*).

The *Ornithischia* were almost all plant-eaters, and eventually outnumbered the *Saurischia*. They are divided into four suborders: *ornithomorphs* ('bird-feet'), Jurassic and Cretaceous bipedal forms (*iguodon*) and Cretaceous hadrosaurs with duckbills; *stegosaurs* ('plated' dinosaurs), Jurassic quadrupedal dinosaurs with a double row of triangular plates along the back and spikes on the tail (*stegosaurus*); *ankylosaurs* ('armoured' dinosaurs), Cretaceous quadrupedal forms, heavily armoured with bony plates (*nodosaurus*); and *ceratopsians* ('horned' dinosaurs), Upper Cretaceous quadrupedal horned dinosaurs with very large skulls bearing a neck frill and large horns (*triceratops*).

These two main dinosaur orders form part of the superorder *Archosaurus* ('ruling reptiles'), comprising a total of five orders. The other three are *Pterosaurs* ('winged lizards'), including *pterosodactyls*, of which no examples exist today, *crocodilians*, and *birds*. All five orders are thought to have evolved from a 'stem-order', the *Thecodontia*.

species *Brachiosaurus*, a long-necked plant-eater of the sauropod group, was about 12.6 m/40 ft to the top of its head, and weighed 80 tonnes. *Compsognathus*, a meat-eater, was only the size of a chicken, and ran on its hind legs. *Stegosaurus*, an armoured plant-eater 6 m/20 ft long, had a brain only about 3 cm/1.25 in long. Not all dinosaurs had small brains. At the other extreme, the hunting dinosaur *stenonychosaurus*, 2 m/6 ft long, had a brain size comparable to that of a mammal or bird of today, stereoscopic vision, and grasping hands. Many dinosaurs appear to have been equipped for a high level of activity. *Tyrannosaurus* was a huge, two-footed, meat-eating theropod dinosaur of the Upper Cretaceous in North America and Asia. The largest carnivorous dinosaur was *Giganotosaurus carolinii*. It lived in Patagonia about 97 million years ago, was 12.5 m/41 ft long, and weighed 6-8 tonnes. Its skeleton was discovered 1995.

theories of extinction A popular theory of dinosaur extinction suggests that the Earth was struck by a giant meteorite or a swarm of comets 65 million years ago and this sent up such a cloud of debris and dust that climates were changed and the dinosaurs could not adapt quickly enough. The evidence for this includes a bed of rock rich in $\text{\textcircled{I}}$ ridium - an element rare on Earth but common in extraterrestrial bodies - dating from the time.

An alternative theory suggests that changes in geography brought about by the movements of continents and variations in sea level led to climate changes and the mixing of populations between previously isolated regions. This resulted in increased competition and the spread of disease.

archaeological findings The term 'dinosaur' was coined 1842 by Richard Owen, although there were findings of dinosaur bones as far back as the 17th century. In 1822 G. A. Mantell (1790-1852) found teeth of *iguodon* in a quarry in Sussex. The first dinosaur to be described in a scientific journal was in 1824, when William Buckland, professor of geology at Oxford University, published his finding of a 'megalosaurus or great fossil lizard' found at Stonesfield, a village northwest of Oxford, although a *megalosaurus* bone had been found in 1677.

One of the largest dinosaur species found in the UK was a *Sauropod*, *Cetiosaurus oxoniensis*, discovered in 1870 near Bletchington, north of Oxford. It was around 15 m/49 ft long, although specimens have been discovered in North Africa up to 18 m/60 ft long. In 1992 another large dinosaur, *Iguanodon bernissartensis*, was discovered near Ockley in Surrey, England, by amateur fossil hunters.

An almost complete fossil of a dinosaur skeleton was found in 1969 in the Andean foothills, South America; it had been a two-legged carnivore 2 m/6 ft tall and weighed more than 100 kg/220 lb. More than 230 million years old, it is the oldest known dinosaur. In 1982 a number of nests and eggs were found in 'colonies' in Montana, suggesting that some bred together like modern seabirds. In 1987 finds were made in China that may add much to the traditional knowledge of dinosaurs, chiefly gleaned from North American specimens. In 1989 and 1990 an articulated *Tyrannosaurus rex* was unearthed by a palaeontological team in Montana, with a full skull, one of only six known. Short stretches of dinosaur DNA were extracted in 1994 from unfossilized bone retrieved from coal deposits approximately 80 million years old.

recent discoveries The discovery of a small dinosaur was announced in China in 1996. *Sinosauropteryx* lived about 120 million years old and was 0.5 m/1.6 ft tall. It had short forelegs, a long tail, and short feathers, mainly on its neck and shoulders.

In 1997 US scientists claimed that 65 million-year-old remains discovered in the Atlantic Ocean were proof that a massive asteroid impact on Earth killed the dinosaurs. A sea-drilling expedition discovered three samples that have the signature of an asteroid impact. Previous evidence from sediment suggested that the dinosaurs did not become extinct at exactly the same time as an impact occurred. The new evidence appeared to substantiate the theories of geologists such as Walter Alvarez, who championed the theory that the dinosaurs disappeared from fossil history because of such an impact.

US palaeontologists discovered in 1997 a dinosaur wishbone in place in the skeleton of a velociraptor. This was the first time a wishbone had been found in place and scientists claimed that this constitutes strong evidence for birds having evolved from dinosaurs.

diode combination of a cold anode and a heated cathode, or the semiconductor equivalent, which incorporates a *p-n* junction; see *semiconductor diode*. Either device allows the passage of direct current in one direction only, and so is commonly used as a *\text{\textcircled{r}}*ectifier to convert alternating current (AC) to direct current (DC).

dioecious of plants with male and female flowers borne on separate individuals of the same species. Dioecism occurs, for example, in the willows *Salix*. It is a way of avoiding self-fertilization.

dioptr optical unit in which the power of a *\text{\textcircled{l}}*ens is expressed as the reciprocal of its focal length in metres. The usual convention is that convergent lenses are positive and divergent lenses negative. Short-sighted people need lenses of power about -0.7 dioptr; a typical value for long sight is about +1.5 dioptr.

diorite igneous rock intermediate in composition between mafic (consisting primarily of dark-coloured minerals) and felsic (consisting primarily of light-coloured minerals) – the coarse-grained plutonic equivalent of gabbro. Constituent minerals include quartz and amphibole or pyroxene with only minor amounts of feldspar.

dioxin any of a family of over 200 organic chemicals, all of which are heterocyclic hydrocarbons (see *cyclic compounds*).

The term is commonly applied, however, to only one member of the family, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD), a highly toxic chemical that occurs, for example, as an impurity in the defoliant Agent Orange, used in the Vietnam War, and sometimes in the weedkiller 2,4,5-T. It has been associated with a disfiguring skin complaint (chloracne), birth defects, miscarriages, and cancer.

Disasters involving accidental release of large amounts of dioxin into the environment have occurred at Seveso, Italy, and Times Beach, Missouri, USA. Small amounts of dioxins are released by the burning of a wide range of chlorinated materials (treated wood, exhaust fumes from fuels treated with chlorinated additives, and plastics) and as a side-effect of some techniques of paper-making. The possibility of food becoming contaminated by dioxins in the environment has led the European Community to decrease significantly the allowed levels of dioxin emissions from incinerators. Dioxin may be produced as a by-product in the manufacture of the bactericide hexachlorophene.

DIP abbreviation for document image processing.

diphtheria acute infectious disease in which a membrane forms in the throat (threatening death by asphyxia), along with the production of a powerful toxin that damages the heart and nerves. The organism responsible is a bacterium (*Corynebacterium diphtheriae*). It is treated with antitoxin and antibiotics.

Although its incidence has been reduced greatly by immunization, an epidemic in the former Soviet Union resulted in 47,802 cases and 1,746 deaths in 1994, and 1,500 deaths in 1995. In 1995 the World Health Organization (WHO) declared the epidemic 'an international public health emergency' after 20 linked cases were identified in other parts of Europe. The epidemic showed signs of abating in 1996, with a 59% decrease in the number of cases for the first three months, compared with the same period in 1995.

diploblastic in biology, having a body wall composed of two layers. The outer layer is the ectoderm, the inner layer is the endoderm. This pattern of development is shown by coelenterates.

diplococus plant-eating saurpoid dinosaur that lived about 145 million years ago, the fossils of which have been found in the western USA. Up to 27 m/88 ft long, most of which was neck and tail, it weighed about 11 tonnes. It walked on four elephantine legs, had nostrils on top of the skull, and peglike teeth at the front of the mouth.

diploid having paired chromosomes in each cell. In sexually reproducing species, one set is derived from each parent, the gametes, or sex cells, of each parent being haploid (having only one set of chromosomes) due to meiosis (reduction cell division).

diplomonad single-celled organisms with two nuclei and no mitochondria. They produce energy by anaerobic metabolism, such as glycolysis. The human intestinal parasite *Giardia lamblia* is a diplomonad.

dip, magnetic angle at a particular point on the Earth's surface between the direction of the Earth's magnetic field and the horizontal. It is measured using a **dip circle**, which has a magnetized needle suspended so that it can turn freely in the vertical plane of the magnetic field. In the northern hemisphere the needle dips below the horizontal, pointing along the line of the magnetic field towards its north pole. At the magnetic north and south poles, the needle dips vertically and the angle of dip is 90°. See also *angle of declination*.

dipole the uneven distribution of magnetic or electrical characteristics within a molecule or substance so that it behaves as

though it possesses two equal but opposite poles or charges, a finite distance apart.

The uneven distribution of electrons within a molecule composed of atoms of different electronegativities may result in an apparent concentration of electrons towards one end of the molecule and a deficiency towards the other, so that it forms a dipole consisting of apparently separated but equal positive and negative charges. The product of one charge and the distance between them is the dipole moment. A bar magnet has a magnetic dipole and behaves as though its magnetism were concentrated in separate north and south magnetic poles.

dipole in radio, a rod aerial, usually one half-wavelength or a whole wavelength long.

dipole, magnetic see *magnetic dipole*.

dipper or **water ouzel** any of various birds of the genus *Cinclus*, family Cinclidae, order Passeriformes, found in hilly and mountainous regions across Eurasia and North America, where there are clear, fast-flowing streams. It can swim, dive, or walk along the bottom, using the pressure of water on its wings and tail to keep it down, while it searches for insect larvae and other small animals. Both wings and tail are short, the beak is fairly short and straight, and the general colour of the bird is brown, the throat and part of the breast being white.

diprotodon extinct giant Australian marsupial. It was about the size of a large rhinoceros, with well developed incisor teeth and huge skull. It is the largest known marsupial and lived during the Pleistocene epoch.

DIP switch (abbreviation of *dual in-line package*) in computing, tiny switch that controls settings on devices such as printers and modems. The owner's manual will usually specify how DIP switches should be set.

On printers, these switches are typically used to specify which emulation to use; on modems, they set the modem to match the COM port to which it is connected. They should not need to be changed once the device has been installed and is working properly.

Diptera order consisting of the two-winged 'true' flies. The order contains some 75,000 species arranged in approximately 100 families.

Diptera is divided into three suborders. **suborder Nematocera** The adults are usually long-legged delicate flies. Their long filamentous antennae have many segments. The larvae usually have a well-defined chitinous head. The pupae are usually free and active. This suborder includes: midges, mosquitoes, gnats, and crane flies.

suborder Brachycera These are more robust flies than the nematocerans, with various types of antennae, usually made up of vari-

dip A dip circle is used to measure the angle between the direction of the Earth's magnetic field and the horizontal at any point on the Earth's surface.

ous, dissimilar segments. The larva has a less heavily chitinated head which is retractile. The pupa is usually free. This suborder includes: assassin flies, bee flies, and horse flies.

suborder Cyclorrhapha The antennae are usually of two small segments with a larger, pendulous third segment; an arista (bristle-like extension) is usually present. The palps usually consist of one segment. The larva is a maggot without a head capsule. The pupa usually has a puparium which is formed from the last-stage larval skin. This suborder includes: house flies, blowflies, botflies, tsetse flies, and fruit flies.

classification Diptera is in the subclass Pterygota, class Insecta, phylum Arthropoda.

direct access or random access type of file access. A direct-access file contains records that can be accessed by the computer directly because each record has its own address on the storage disc.

direct broadcast system (DBS) in computing, combination of a small satellite dish and receiver which allows consumers to receive television and radio broadcasts from a satellite rather than via terrestrial broadcasting towers and repeaters.

direct connection in computing, connection between two computers via cable to transfer files without the intermediary of a network or online service. Each computer must be running communications software using the same protocols for file transfers. If the computers are in the same room, they can be connected using a special type of serial cable known as a null modem cable; if they are connected via telephone lines each must have a modem so that one can dial the other.

There are several software packages designed for this purpose; the market leader is Laplink.

direct current (DC) electric current that flows in one direction, and does not reverse its flow as alternating current does. The electricity produced by a battery is direct current.

directed number a number with a positive (+) or negative (-) sign attached, for example +5 or -5. On a graph, a positive sign shows

a movement to the right or upwards; a negative sign indicates movement downwards or to the left.

direct memory access (DMA) in computing, a technique used for transferring data to and from external devices without going through the central processing unit (CPU) and thus speeding up transfer rates. DMA is used for devices such as scanners.

direct memory access channel in computing, channel used for the fast transfer of data; usually abbreviated as DMA channel.

Director in computing, multimedia software authoring tool published by Macromedia, a company of multimedia software specialists based in San Francisco, USA.

directory in computing, a list of file names, together with information that enables a computer to retrieve those files from backing storage. The computer operating system will usually store and update a directory on the backing storage to which it refers. So, for example, on each disc used by a computer a directory file will be created listing the disc's contents.

directory tree in computing, collective name for a directory and all its subdirectories.

dirigible another name for airship.

disaccharide sugar made up of two monosaccharides or simple sugars. Sucrose, $C_{12}H_{22}O_{11}$, or table sugar, is a disaccharide.

disc in astronomy, the flat, roughly circular region of a spiral or lenticular galaxy containing stars, nebulae, and dust clouds orbiting about the nucleus. Discs contain predominantly young stars and regions of star formation. The disc of our own Galaxy is seen from Earth as the band of the Milky Way.

disc or disk in computing, a common medium for storing large volumes of data (an alternative is magnetic tape). A magnetic disc is rotated at high speed in a disc-drive unit as a read/write (playback or record) head passes over its surfaces to record or read the magnetic variations that encode the data. Recently, optical discs,

directory A graphical illustration of the directory filing system on a computer. On the left hand side of the screen are the sub-directories available from the root; on the right are the files contained within the active directory.

disc A hard disc. Data is stored in sectors within cylinders and is read by a head which passes over the spinning surface of each disc.

such as ϕ CD-ROM (compact-disc read-only memory) and ϕ WORM (write once, read many times), have been used to store computer data. Data are recorded on the disc surface as etched microscopic pits and are read by a laser-scanning device. Optical discs have an enormous capacity – about 550 megabytes (million bytes) on a compact disc, and thousands of megabytes on a full-size optical disc.

Magnetic discs come in several forms: fixed **hard discs** are built into the disc-drive unit, occasionally stacked on top of one another. A fixed disc cannot be removed: once it is full, data must be deleted in order to free space or a complete new disc drive must be added to the computer system in order to increase storage capacity. In 1997, small hard drives typically stored two thousand megabytes or 2 gigabytes (GB) of data, but could store up to 9 GB or more. Arrays of such discs were also used to store minicomputer and mainframe data in RAID storage systems, replacing large fixed discs and removable hard discs.

Removable hard discs are still found in minicomputer and mainframe systems. The discs are contained, individually or as stacks (disc packs), in a protective plastic case, and can be taken out of the drive unit and kept for later use. By swapping such discs around, a single hard-disc drive can be made to provide a potentially infinite storage capacity. However, access speeds and capacities tend to be lower than those associated with large fixed hard discs. A **floppy disc** (or diskette) is the most common form of backing store for microcomputers. It is much smaller in size and capacity than a hard disc, normally holding 0.5–2 megabytes of data. The floppy disc is so called because it is manufactured from thin flexible plastic coated with a magnetic material. The earliest form of floppy disc was packaged in a card case and was easily damaged; more recent versions are contained in a smaller, rigid plastic case and are much more robust. All floppy discs can be removed from the drive unit.

disc compression technique, based on ϕ data compression, that makes hard discs and floppy discs appear to have more storage capacity than is normally available. If the data stored on a disc can be compressed to occupy half the original amount of disc space, it will appear that the disc is twice its original size. The processes of compression (to store data) and decompression (so that data can be used) are hidden from the user by the software.

Several commercial disc compression products are available, for example DoubleSpace in ϕ MS-DOS 6.0 and Stacker.

disc drive mechanical device that reads data from, and writes data to, a magnetic ϕ disc.

disc formatting in computing, preparing a blank magnetic disc in order that data can be stored on it. Data are recorded on a disc's surface on circular tracks, each of which is divided into a number of sectors. In formatting a disc, the computer's operating system adds control information such as track and sector numbers, which enables the data stored to be accessed correctly by the disc-drive unit.

Some floppy discs, called **hard-sectored discs**, are sold already formatted. However, because different makes of computer use different disc formats, discs are also sold unformatted, or **soft-sectored**, and computers are provided with the necessary utility program to format these discs correctly before they are used.

discharge in a river, the volume of water passing a certain point per unit of time. It is usually expressed in cubic metres per second (cumecs). The discharge of a particular river channel may be calculated by multiplying the channel's cross-sectional area (in square metres) by the velocity of the water (in metres per second).

discharge tube device in which a gas conducting an electric current emits visible light. It is usually a glass tube from which virtually all the air has been removed (so that it 'contains' a near vacuum).

disc drive A floppy disc drive. As the disc is inserted into the drive, its surface is exposed to the read-write head, which moves over the spinning disc surface to locate a specific track.

um), with electrodes at each end. When a high-voltage current is passed between the electrodes, the few remaining gas atoms in the tube (or some deliberately introduced ones) ionize and emit coloured light as they conduct the current along the tube. The light originates as electrons change energy levels in the ionized atoms.

By coating the inside of the tube with a phosphor, invisible emitted radiation (such as ultraviolet light) can produce visible light; this is the principle of the fluorescent lamp.

Discman Sony trademark for a portable compact-disc player; the equivalent of a Walkman, it also comes in a model with a liquid-crystal display for data discs.

disc optimizer in computing, another name for a defragmentation program, a program that gathers together files that have become fragmented for storage on different areas of a disc. See also defragmentation.

discrete data data that can take only whole-number or fractional values. The opposite is continuous data, which can take all in-between values. Examples of discrete data include frequency and population data. However, measurements of time and other dimensions can give rise to continuous data.

disease condition that disturbs or impairs the normal state of an organism. Diseases can occur in all life forms, and normally affect the functioning of cells, tissues, organs, or systems. Diseases are usually characterized by specific symptoms and signs, and can be mild and short-lasting – such as the common cold – or severe

enough to decimate a whole species – such as Dutch elm disease. Diseases can be classified as infectious or noninfectious. Infectious diseases are caused by microorganisms, such as bacteria and viruses, invading the body; they can be spread across a species, or transmitted between one or more species. All other diseases can be grouped together as noninfectious diseases. These can have many causes: they may be inherited (congenital diseases); they may be caused by the ingestion or absorption of harmful substances, such as toxins; they can result from poor nutrition or hygiene; or they may arise from injury or ageing. The causes of some diseases are still unknown.

Some diseases occur mainly in certain climates or geographical regions of the world. These are endemic diseases. For example, African sleeping sickness, which is carried by the tsetse fly, is found mainly in the very hot, humid regions of Africa. Similarly, malaria, a disease spread by mosquitoes, is usually found in or near the marsh or stagnant water which provide breeding grounds for the insect. Other diseases may be seasonal – such as influenza, which tends to occur mainly in winter, or intestinal illnesses that result from food contamination in summer.

Some age groups may be more prone to certain diseases, such as measles in children, meningitis in young adults, and coronary heart disease in the elderly. Other diseases may tend to occur only in certain racial types and are usually genetic in origin, such as sickle-cell disease which is found mainly among people of black African descent. Other diseases, such as black lung, or coal-workers' pneumoconiosis, result from occupational hazards; some of the 'new' diseases that have appeared in recent years – such as sick building syndrome and legionnaire's disease, result from modern building designs, while the cause of ME (myalgic encephalomyelitis), or chronic fatigue syndrome, is still unknown.

disinfectant agent that kills, or prevents the growth of, bacteria and other microorganisms. Chemical disinfectants include carbolic acid (phenol, used by Joseph Lister in surgery in the 1870s), ethanol, methanol, chlorine, and iodine.

dispersal phase of reproduction during which gametes, eggs, seeds, or offspring move away from the parents into other areas. The result is that overcrowding is avoided and parents do not find

CRIMEAN WAR

In the Crimean War more soldiers died from disease than in the fighting. Disease (mainly typhus, cholera, and dysentery) accounted for many of the deaths of 104,494 soldiers compared with 63,261 from wounds; 662,917 were out of action through illness compared with 150,533 wounded.

themselves in competition with their own offspring. The mechanisms are various, including a reliance on wind or water currents and, in the case of animals, locomotion. The ability of a species to spread widely through an area and to colonize new habitats has survival value in evolution.

dispersion in chemistry, the distribution of the microscopic particles of a colloid. In colloidal sulphur the dispersion is the tiny particles of sulphur in the aqueous system.

dispersion in physics, the separation of waves of different frequencies by passage through a dispersive medium, in which the speed of the wave depends upon its frequency or wavelength. In optics, the splitting of white light into a spectrum; for example, when it passes through a prism or diffraction grating. It occurs because the prism or grating bends each component wavelength through a slightly different angle. A rainbow is formed when sunlight is dispersed by raindrops.

dispersion in statistics, the extent to which data are spread around a central point (typically the arithmetic mean).

displacement activity in animal behaviour, an action that is performed out of its normal context, while the animal is in a state of stress, frustration, or uncertainty. Birds, for example, often peck at grass when uncertain whether to attack or flee from an opponent; similarly, humans scratch their heads when nervous.

displacement reaction chemical reaction in which a less reactive element is replaced in a compound by a more reactive one.

For example, the addition of powdered zinc to a solution of copper(II) sulphate displaces copper metal, which can be detected by its characteristic colour. See also electrochemical series.

display in computing, an output device that looks like a television set and displays commands to the computer and their results.

display control interface in computing, standard developed by Microsoft and Intel for the device drivers that control graphics cards.

dissection cutting apart of bodies to study their organization, or tissues to gain access to a site in surgery. Postmortem dissection was considered a sin in the Middle Ages. In the UK before 1832, hanged murderers were the only legal source of bodies, supplemented by grave-robbing (Burke and Hare were the most notorious grave robbers). The Anatomy Act of 1832 authorized the use of deceased institutionalized paupers unclaimed by next of kin, and by the 1940s bequests of bodies had been introduced.

dissociation in chemistry, the process whereby a single compound splits into two or more smaller products, which may be capable of recombining to form the reactant.

Where dissociation is incomplete (not all the compound's molecules dissociate), a chemical equilibrium exists between the compound and its dissociation products. The extent of incomplete dissociation is defined by a numerical value (dissociation constant).

distance learning form of education using technology to teach pupils who are dispersed geographically. Britain's Open University, founded in 1969, is the oldest and most successful distance-learning institution in the world, using a mixture of postal mail, television, electronic conferencing, and the Internet to offer degree courses to students all over the world. Experiments in the 1990s used videconferencing and other multimedia techniques to widen the university's range.

distance modulus in astronomy, a method of finding the distance to an object in the universe, such as a star or galaxy, using the difference between the actual and observed brightness of the object. The actual brightness is deduced from the object's type and its size. The apparent brightness is obtained by direct observation.

distance ratio in a machine, the distance moved by the input force, or effort, divided by the distance moved by the output force, or load. The ratio indicates the movement magnification achieved, and is equivalent to the machine's velocity ratio.

distance-time graph graph used to describe the motion of a body by illustrating the relationship between the distance that it travels and the time taken. Plotting distance (on the vertical axis) against time (on the horizontal axis) produces a graph the gradient of which is the body's speed. If the gradient is constant (the graph is a straight line), the body has uniform or constant speed; if the gradient varies (the graph is curved), then so does the speed and the body may be said to be accelerating or decelerating.

distemper any of several infectious diseases of animals characterized by catarrh, cough, and general weakness. Specifically, it refers to a virus disease in young dogs, also found in wild animals, which can now be prevented by vaccination. In 1988 an allied virus killed over 10,000 common seals in the Baltic and North seas.

distillation technique used to purify liquids or to separate mixtures of liquids possessing different boiling points. **Simple distillation** is used in the purification of liquids (or the separation of substances in solution from their solvents) – for example, in the production of pure water from a salt solution.

The solution is boiled and the vapours of the solvent rise into a separate piece of apparatus (the condenser) where they are cooled and condensed. The liquid produced (the distillate) is the pure solvent; the non-volatile solutes (now in solid form) remain in the distillation vessel to be discarded as impurities or recovered as required. Mixtures of liquids (such as petroleum or aqueous ethanol) are separated by **fractional distillation**, or **fractionation**. When the mixture is boiled, the vapours of its most volatile component rise into a vertical fractionating column where they condense to liquid form. However, as this liquid runs back down the column it is reheated to boiling point by the hot rising vapours of the next-most-volatile component and so its vapours ascend the column once more. This boiling-condensing process occurs repeatedly inside the column, eventually bringing about a temperature gradient along its length. The vapours of the more volatile components therefore reach the top of the column and enter the condenser for collection before those of the less volatile components. In the fractional distillation of petroleum, groups of compounds (fractions) possessing similar relative molecular masses and boiling points are tapped off at different points on the column.

The earliest-known reference to the process is to the distillation of wine in the 12th century by Adelard of Bath. The chemical retort used for distillation was invented by Muslims, and was first seen in the West about 1570.

distillation Laboratory apparatus for simple distillation. Other forms of distillation include steam distillation, in which steam is passed into the mixture being distilled, and vacuum distillation, in which air is removed from above the mixture to be distilled.

distributed processing computer processing that uses more than one computer to run an application. (Local area networks, client-server architecture, and parallel processing involve distributed processing.

distribution in statistics, the pattern of frequency for a set of data.

distributive operation in mathematics, an operation, such as multiplication, that bears a relationship to another operation, such as addition, such that $a \times (b + c) = (a \times b) + (a \times c)$. For example, $3 \times (2 + 4) = (3 \times 2) + (3 \times 4) = 18$. Multiplication may be said to be distributive over addition. Addition is not, however, distributive over multiplication because $3 + (2 \times 4) \neq (3 + 2) \times (3 + 4)$.

distributor device in the ignition system of a piston engine that distributes pulses of high-voltage electricity to the spark plugs in the cylinders. The electricity is passed to the plug leads by the tip of a rotor arm, driven by the engine camshaft, and current is fed to the rotor arm from the ignition coil. The distributor also houses the contact point or breaker, which opens and closes to interrupt the battery current to the coil, thus triggering the high-voltage pulses. With electronic ignition the distributor is absent.

dithering in computer graphics, a technique for varying the patterns of dots in an image in order to give the impression of shades of grey. Each dot, however, is of the same size and the same intensity, unlike grey scaling (where each dot can have a different shade) and photographically reproduced half-tones (where the dot size varies).

diuretic any drug that increases the output of urine by the kidneys. It may be used in the treatment of high blood pressure and to relieve oedema associated with heart, lung, kidney or liver disease, and some endocrine disorders.

diver or *loon* any of four species of marine bird of the order Gaviiformes, specialized for swimming and diving, found in northern regions of the northern hemisphere. The legs are set so far back that walking is almost impossible, but they are powerful swimmers and good flyers, and only come ashore to nest. They have straight bills, short tail-feathers, webbed feet, and long bodies; they feed on fish, crustaceans, and some water plants. During the breeding period they live inland and the female lays two eggs which hatch into down-covered chicks. Of the four species, the largest is the white-billed diver *Gavia adamsii*, an Arctic species 75 cm/2.5 ft long.

diversification in agriculture and business, the development of distinctly new products or markets. A company or farm may diversify in order to spread its risks or because its original area of operation is becoming less profitable. In the UK agricultural diversification has included offering accommodation and services to tourists—for example, bed and breakfast, camping and caravanning sites, and pony trekking.

diverticulitis inflammation of diverticula (pockets of herniation) in the large intestine. It is usually triggered by infection and causes diarrhoea or constipation, and lower abdominal pain. Usually it can be controlled by diet and antibiotics.

diving apparatus any equipment used to enable a person to spend time underwater. Diving bells were in use in the 18th century, the diver breathing air trapped in a bell-shaped chamber. This was followed by cumbersome diving suits in the early 19th century. Complete freedom of movement came with the aqualung, invented by Jacques Cousteau in the early 1940s. For work at greater depths the technique of saturation diving was developed in the 1970s in which divers live for a week or more breathing a mixture of helium and oxygen at the pressure existing on the seabed where they work (as in work on North Sea platforms and tunnel building).

The first diving suit, with a large metal helmet supplied with air through a hose, was invented in the UK by the brothers John and Charles Deane in 1828. Saturation diving was developed for working in offshore oilfields. Working divers are ferried down to the work site by a lock-out chamber. By this technique they avoid the need for lengthy periods of decompression after every dive. Slow decompression is necessary to avoid the dangerous consequences of an attack of the bends, or decompression sickness.

division basic operation of arithmetic, the inverse of multiplication.

dizziness another word for vertigo.

DLL in computing, the abbreviation for dynamic link library.

DMA channel (abbreviation for *direct memory access channel*) in computing, type of channel used for the fast transfer of data between a computer and peripherals such as CD-ROM drives. Most ISA (industry standard architecture) personal computers (PCs) have eight DMA channels, of which typically six are available for use by add-on peripherals, most of which require dedicated channels.

DNA (abbreviation for *deoxyribonucleic acid*) complex giant molecule that contains, in chemically coded form, the information needed for a cell to make proteins. DNA is a ladderlike double-stranded nucleic acid which forms the basis of genetic inheritance in all organisms, except for a few viruses that have only RNA. DNA is organized into chromosomes and, in organisms other than bacteria, it is found only in the cell nucleus.

If you want to understand function, study structure.

FRANCIS CRICK English molecular biologist.
What Mad Pursuit 1988

DNA fingerprinting or **DNA profiling** another name for genetic fingerprinting.

DNS in computing, abbreviation for domain name server.

Dobermann or **Dobermann pinscher** breed of smooth-coated dog with a docked tail, much used as a guard dog. It stands up to 70 cm/27.5 in tall, has a long head with a flat, smooth skull, and is often black with brown markings. It takes its name from the man who bred it in 19th-century Germany.

dock or **sorrel** in botany, any of a number of plants belonging to the buckwheat family. They are tall, annual or perennial herbs, often with lance-shaped leaves and small greenish flowers. Native to temperate regions, there are 30 North American and several British species. (Genus *Rumex*, family Polygonaceae.)

dock port accommodation for commercial and naval vessels, usually simple linear quays (wharfs or piers) adaptable to ships of any size, but with specialized equipment for handling bulk cargoes, refrigerated goods, container traffic, and oil tankers.

document in computing, data associated with a particular application. For example, a text document might be produced by a word processor and a graphics document might be produced with a CAD package. An OMR or OCR document is a paper document containing data that can be directly input to the computer using a document reader.

documentation in computing, the written information associated with a computer program or applications package. Documentation is usually divided into two categories: program documentation and user documentation.

Program documentation is the complete technical description of a program, drawn up as the software is written and intended to support any later maintenance or development of that program. It typically includes details of when, where, and by whom the software was written; a general description of the purpose of the software, including recommended input, output, and storage methods; a detailed description of the way the software functions, including full program listings and flow charts; and details of software testing, including sets of test data with expected results. User documentation explains how to operate the software. It typically includes a nontechnical explanation of the purpose of the software; instructions for loading, running, and using the software; instructions for preparing any necessary input data; instructions for requesting and interpreting output data; and explanations of any error messages that the program may produce.

document image processing (DIP) scanning documents for storage on CD-ROM. The scanned images are indexed electronically,

DNA: Discovery of the Structure of DNA

BY JULIAN ROWE

The first announcement

'We wish to suggest a structure for the salt of deoxyribose nucleic acid (DNA). This structure has novel features which are of considerable biological interest.'

So began a 900-word article that was published in the journal *Nature* in April 1953. Its authors were British molecular biologist Francis Crick (1916–) and US biochemist James Watson (1928–). The article described the correct structure of DNA, a discovery that many scientists have called the most important since Austrian botanist and monk Gregor Mendel (1822–1884) laid the foundations of the science of genetics. DNA is the molecule of heredity, and by knowing its structure, scientists can see exactly how forms of life are transmitted from one generation to the next.

The problem of inheritance

The story of DNA really begins with British naturalist Charles Darwin (1809–1882). When, in November 1859, he published 'On the Origin of Species by Means of Natural Selection' outlining his theory of evolution, he was unable to explain exactly how inheritance came about. For at that time it was believed that offspring inherited an average of the features of their parents. If this were so, as Darwin's critics pointed out, any remarkable features produced in a living organism by evolutionary processes would, in the natural course of events, soon disappear.

The work of Gregor Mendel, only rediscovered 18 years after Darwin's death, provided a clear demonstration that inheritance was not a 'blending' process at all. His description of the mathematical basis to genetics followed years of careful plant-breeding experiments. He concluded that each of the features he studied, such as colour or stem length, was determined by two 'factors' of inheritance, one coming from each parent. Each egg or sperm cell contained only one factor of each pair. In this way a particular factor, say for the colour red, would be preserved through subsequent generations.

Genes

Today, we call Mendel's factors genes. Through the work of many scientists, it came to be realized that genes are part of the chromosomes located in the nucleus of living cells and that DNA, rather than protein as was first thought, was a hereditary material.

The double helix

In the early 1950s, scientists realized that X-ray crystallography, a

method of using X-rays to obtain an exact picture of the atoms in a molecule, could be successfully applied to the large and complex molecules found in living cells.

It had been known since 1946 that genes consist of DNA. At King's College, London, New Zealand-British biophysicist Maurice Wilkins (1916–) had been using X-ray crystallography to examine the structure of DNA, together with his colleague, British X-ray crystallographer Rosalind Franklin (1920–1958), and had made considerable progress.

While in Copenhagen, US scientist James Watson had realized that one of the major unresolved problems of biology was the precise structure of DNA. In 1952, he came as a young postdoctoral student to join the Medical Research Council Unit at the Cavendish Laboratory, Cambridge, where Francis Crick was already working. Convinced that a gene must be some kind of molecule, the two scientists set to work on DNA.

Helped by the work of Wilkins, they were able to build an accurate model of DNA. They showed that DNA had a double helical structure, rather like a spiral staircase. Because the molecule of DNA was made from two strands, they envisaged that as a cell divides, the strands unravel, and each could serve as a template as new DNA was formed in the resulting daughter cells. Their model also explained how genetic information might be coded in the sequence of the simpler molecules of which DNA is comprised. Here for the first time was a complete insight into the basis of heredity. James Watson commented that this result was 'too pretty not to be true!'

Cracking the code

Later, working with South African-British molecular biologist Sidney Brenner (1927–), Crick went on to work out the genetic code, and so ascribe a precise function to each specific region of the molecule of DNA. These triumphant results created a tremendous flurry of scientific activity around the world. The pioneering work of Crick, Wilkins, and Watson was recognized in the award of the Nobel Prize for Physiology or Medicine in 1962.

The unravelling of the structure of DNA led to a new scientific discipline, molecular biology, and laid the foundation stones for genetic engineering – a powerful new technique that is revolutionizing biology, medicine, and food production through the purposeful adaptation of living organisms.

which provides much faster access than is possible with either paper or microform. See also optical character recognition.

document reader in computing, an input device that reads marks or characters, usually on preprepared forms and documents. Such devices are used to capture data by optical mark

recognition (OMR), optical character recognition (OCR), and mark sensing.

dodder parasitic plant belonging to the morning-glory family, without leaves or roots. The thin stem twines around the host plant, and penetrating suckers withdraw nourishment. (Genus *Cuscuta*, family Convolvulaceae.)

dodecahedron regular solid with 12 pentagonal faces and 12 vertices. It is one of the five regular polyhedra, or Platonic solids.

dodo extinct flightless bird *Raphus cucullatus*, order Columbiformes, formerly found on the island of Mauritius, but

dodecahedron A dodecahedron is a solid figure which has 12 pentagonal faces and 12 vertices. It is one of the five regular polyhedra (with all faces the same size and shape).

DODO

Most pictures of the dodo show a bird with two right legs. This is because the only person to paint a live dodo, the Belgian artist Roelandt Savery, made an elementary error in drawing the parts that he could not see.

exterminated by early settlers around 1681. Although related to the pigeons, it was larger than a turkey, with a bulky body, rudimentary wings, and short curly tail-feathers. The bill was blackish in colour, forming a horny hook at the end.

dog any carnivorous mammal of the family Canidae, including wild dogs, wolves, jackals, coyotes, and foxes. Specifically, the domestic dog *Canis familiaris*, the earliest animal descended from the wolf. Dogs were first domesticated around 14,000 years ago, and migrated with humans to all the continents. They have been selectively bred into many different varieties for use as working animals and pets.

characteristics The dog has slender legs and walks on its toes (digitigrade). The forefoot has five toes, the hind feet four, with non-retractile claws. The head is small and the muzzle pointed, but the shape of the head differs greatly in various breeds. The average life of a dog is from 10 to 14 years, though some live to be 20. The dog has a very acute sense of smell and can readily be trained, for it has a good intelligence.

wild dogs Of the wild dogs, some are solitary, such as the long-legged maned wolf *Chrysocyon brachyurus* of South America, but others hunt in groups, such as the African hunting dog *Lycanopsis* (classified as a vulnerable species) and the ϕ wolf. ϕ Jackals scavenge for food, and the raccoon dog *Nyctereutes procyonoides* of east Asia includes plant food as well as meat in its diet. The Australian wild dog is the dingoo.

DOG LOVERS' PAGE

<http://www.petnet.com.au/dogs/dogbreedindex.html>

Information on breeds, ranging from the world's smallest breed (the Chihuahua) to the tallest (the Irish Wolfhound). This Australian-based site includes photographs and details of over 100 breeds of dog.

dog in computing, reference to a cartoon published in *The New Yorker* that showed a dog poised over a computer keyboard remarking to another dog, 'On the Internet, no one knows you're a dog.' It is used to illustrate the point that the Internet gives users the opportunity to adopt a different persona, for example many women surf using a male identity.

dogbane any sometimes poisonous herbaceous North American plant of the genus *Apocynum*, with opposite leaves, small white or pink flowers, and milky juice.

dogfish any of several small sharks found in the northeast Atlantic, Pacific, and Mediterranean.

dog's mercury plant belonging to the spurge family, common in woods of Europe and southwest Asia. It grows to 30 cm/1 ft, has oval, light-green leaves, and spreads over woodland floors in patches of plants of a single sex. Male flowers are small, greenish yellow, and held on an upright spike above the leaves; female flowers droop below the upper leaves. (*Mercurialis perennis*, family Euphorbiaceae.)

dogwhelk marine mollusc, some of which live on rocky shores whilst others burrow. The shell aperture is grooved to house the inhalant siphon keeping it clear of the mud.

The common dogwhelk *Thais lapillus* is a predator of barnacles and mussels and the coloured bands in the shell are believed to be influenced by the food material. The egg capsules are attached singly in crevices and have the appearance of corn grains.

The netted dogwhelk *Nassarius reticulatus* is recognizable by the crenulations on the shell. The egg capsules are flat and are deposited in egg-class. Like the closely related thick-lipped dogwhelk *N. incrassatus*, it is a scavenger.

classification Dogwhelks are in order Neogastropoda, subclass Prosobranchia, class Gastropoda, phylum Mollusca.

dogwood any of a group of trees and shrubs belonging to the dogwood family, native to temperate regions of North America, Europe, and Asia. The flowering dogwood (*Cornus florida*) of the eastern USA is often cultivated as an ornamental for its beautiful blooms consisting of clusters of small greenish flowers surrounded by four large white or pink petal-like bracts (specialized leaves). (Genus *Cornus*, family Cornaceae.)

Heads of small white flowers, each with four petals joined as a tube, are produced in midsummer, followed by black berries. The dogwood is characteristic of lime soils in southern England, and is found over much of southern Europe. *C. sanguinea* is native to Britain and common in old hedgerows and woods. It takes its name from the redness of the twigs. The introduced red-osier dogwood (*C. sericea*) has longer twigs of a brighter red, with white berries rather than black. Various other species of dogwood are planted in gardens.

Dolby system electronic circuit that reduces the background high-frequency noise, or hiss, during replay of magnetic tape recordings. The system was developed by US engineer Raymond Dolby (1933–) in 1966.

doldrums area of low atmospheric pressure along the Equator, in the intertropical convergence zone where the northeast and southeast trade winds converge. The doldrums are characterized by calm or very light winds, during which there may be sudden squalls and stormy weather. For this reason the areas are avoided as far as possible by sailing ships.

dolerite igneous rock formed below the Earth's surface, a form of basalt, containing relatively little silica (mafic in composition).

Dolerite is a medium-grained (hypabyssal) basalt and forms in shallow intrusions, such as dykes, which cut across the rock strata, and sills, which push between beds of sedimentary rock. When exposed at the surface, dolerite weathers into spherical lumps.

dolmen prehistoric ϕ megalith in the form of a chamber built of three or more large upright stone slabs, capped by a horizontal flat stone. Dolmens are the burial chambers of Neolithic (New Stone Age) chambered tombs and passage graves, revealed by the removal of the covering burial mound. They are found in Europe and Africa, and occasionally in Asia as far east as Japan.

dolomite in mineralogy, white mineral with a rhombohedral structure, calcium magnesium carbonate (CaMg (CO₃)₂). Dolomites are common in geological successions of all ages and are often formed when limestone is changed by the replacement of the mineral calcite with the mineral dolomite.

dolphin any of various highly intelligent aquatic mammals of the family Delphinidae, which also includes porpoises. There are about 60 species. Most inhabit tropical and temperate oceans, but there are some freshwater forms in rivers in Asia, Africa, and South America. The name 'dolphin' is generally applied to species having a beaklike snout and slender body, whereas the name 'porpoise' is reserved for the smaller species with a blunt snout and stocky body. Dolphins use sound (echolocation) to navigate, to find prey, and for communication. The common dolphin *Delphinus delphis* is found in all temperate and tropical seas. It is up to 2.5 m/8 ft long, and is dark above and white below, with bands of grey, white, and yellow on the sides. It has up to 100 teeth in its jaws, which make the 15 cm/6 in 'beak' protrude forward from the rounded head. The corners of its mouth are permanently upturned, giving the appearance of a smile, though dolphins cannot actually smile. Dolphins feed on fish and squid.

river dolphins There are five species of river dolphin, two South American and three Asian, all of which are endangered. The two South American species are the Amazon river dolphin or boto *Inia geoffrensis*, the largest river dolphin (length 2.7 m/8.9 ft, weight 180 kg/396 lb) and the La Plata river dolphin *Pontoporia blainvilliei* (length 1.8 m/5.9 ft, weight 50 kg/110 lb). The tucuxi *Sotalia fluviatilis* is not a true river dolphin, but lives in the Amazon and Orinoco rivers, as well as in coastal waters.

The Asian species are the Ganges river dolphin *Platanista gangetica*, the Indus river dolphin *Platanista minor* (length 2 m/6.6 ft, weight 70 kg/154 lb) (fewer than 500 remaining), and the

Yangtze river dolphin or *baiji* *Lipotes vexillifer* (length 2 m/6.6 ft, weight 70 kg/154 lb) (fewer than 100 remaining).

As a result of living in muddy water, river dolphins' eyes have become very small. They rely on echolocation to navigate and find food. Some species of dolphin can swim at up to 56 kph/35 mph, helped by special streamlining modifications of the skin.

All dolphins power themselves by beating the tail up and down, and use the flippers to steer and stabilize. The flippers betray dolphins' land-mammal ancestry with their typical five-toed limb-bone structure. Dolphins have great learning ability and are popular performers in aquariums. The species most frequently seen is the bottle-nosed dolphin *Tursiops truncatus*, found in all warm seas, mainly grey in colour and growing to a maximum 4.2 m/14 ft. The US Navy began training dolphins for military purposes in 1962, and in 1987 six dolphins were sent to detect mines in the Persian Gulf. Marine dolphins are endangered by fishing nets, speedboats, and pollution. In 1990 the North Sea states agreed to introduce legislation to protect them.

Also known as **dolphin** is the totally unrelated true fish *Coryphaena hippurus*, up to 1.5 m/5 ft long.

dolphinfish carnivorous marine fish. Dolphinfish are large and brilliantly coloured, with hues of metallic yellow, blue, and silver; their bodies are elongated, compressed, and covered with small scales. They are usually about 2 m/6.6 ft in length and feed largely on flying fish.

classification Dolphinfish are in the genus *Coryphaena*, family Coryphaenidae, belonging to the order Perciformes, class Osteichthyes.

domain on the Internet, segment of an address that specifies an organization, its type, or its country of origin. Domain names are read backwards, starting at the end. All countries except the USA use a final two-letter code such as *ca* for Canada and *uk* for the UK. US addresses end in one of seven 'top-level' domains, which specify the type of organization: *com* (commercial), *mil* (military), *org* (usually a nonprofit-making organization), and so on.

These names are for humans; to enable mail and other messages to be sorted by machine, computers use IP (Internet protocol) numbers. To route a message, the computer looks up the domain name on a domain name server (DNS), which tells the computer the number.

In 1998 there were 30 million domains on the Internet.

domain small area in a magnetic material that behaves like a tiny magnet. The magnetism of the material is due to the movement of electrons in the atoms of the domain. In an unmagnetized sample of material, the domains point in random directions, or form closed loops, so that there is no overall magnetization of the sample. In a magnetized sample, the domains are aligned so that their magnetic effects combine to produce a strong overall magnetism.

domain name server in computing, see *name server*.

dominance in genetics, the masking of one allele (an alternative form of a gene) by another allele. For example, if a heterozygous person has one allele for blue eyes and one for brown eyes, his or her eye colour will be brown. The allele for blue eyes is described as *recessive* and the allele for brown eyes as *dominant*.

The preservation of favourable variations and the rejection of injurious variations, I call Natural Selection, or Survival of the Fittest. Variations neither useful nor injurious would not be affected by natural selection and would be left a fluctuating element.

CHARLES DARWIN British naturalist.
On the Origin of Species 1859

Dominion Astrophysical Observatory Canadian observatory near Victoria, British Columbia, the site of a 1.85-m/73-in reflector opened in 1918, operated by the National Research Council of Canada. The associated Dominion Radio Astrophysical Observatory

at Penticton, British Columbia, operates a 26-m/84-ft radio dish and an aperture synthesis radio telescope.

dongle in computing, a device which ensures the legal use of an application program. It is usually attached to the printer port of the computer (between the port and the printer cable) and the program will not run in its absence.

donkey another name for *ass*.

Doom popular computer game released in 1994. It is one of a series of games from the Texas-based company id Software, which specializes in 3-D graphics, alien monsters, and complex mazes which players must navigate to find secret treasures and hidden keys along the way. *Doom* can be played competitively over a network as well as on a single computer.

Because the company has encouraged players to create their own additional levels for *Doom* (and its other games) by releasing the necessary source code, a whole culture has grown up around *Doom* and its other games.

dopamine neurotransmitter, hydroxytyramine $C_8H_{11}NO_2$, an intermediate in the formation of adrenaline. There are special nerve cells (neurons) in the brain that use dopamine for the transmission of nervous impulses. One such area of dopamine neurons lies in the basal ganglia, a region that controls movement. Patients suffering from the tremors of Parkinson's disease show nerve degeneration in this region. Another dopamine area lies in the limbic system, a region closely involved with emotional responses. It has been found that schizophrenic patients respond well to drugs that limit dopamine excess in this area.

Doppler, Christian Johann (1803–1853)

Austrian physicist who in 1842 described the **Doppler effect** and derived the observed frequency mathematically in **Doppler's principle**.

Doppler effect change in the observed frequency (or wavelength) of waves due to relative motion between the wave source and the observer. The Doppler effect is responsible for the perceived change in pitch of a siren as it approaches and then recedes, and for the red shift of light from distant galaxies. It is named after the Austrian physicist Christian Doppler.

Dorado constellation of the southern hemisphere, represented as a goldfish. It is easy to locate, since the Large Magellanic Cloud marks its southern border. Its brightest star is Alpha Doradus, just under 200 light years from Earth.

One of the most conspicuous objects in the Large Magellanic Cloud is the 'Great Looped Nebula' that surrounds 30 Doradus.

dor beetle oval-shaped, stout beetle measuring on average 20 mm/0.8 in, and with a metallic sheen. In general, dor beetles feed on dung, mostly of herbivorous animals.

They usually build burrows almost 50 cm/19.5 in deep under an accumulation of dung. The blind end of each burrow is sealed with a portion of dung into which the female deposits a single egg. The developing larva feeds on the dung. Both adults and larvae possess stridulating (sound-producing) organs.

classification Dor beetles are in the family Geotrupidae (superorder Scarabaeoidea), order Coleoptera, class Insecta, phylum Arthropoda.

dormancy in botany, a phase of reduced physiological activity exhibited by certain buds, seeds, and spores. Dormancy can help a plant to survive unfavourable conditions, as in annual plants that pass the cold winter season as dormant seeds, and plants that form dormant buds.

For various reasons many seeds exhibit a period of dormancy even when conditions are favourable for growth. Sometimes this

dot matrix printer Characters and graphics printed by a dot matrix printer are produced by a block of pins which strike the ribbon and make up a pattern using many small dots.

dormancy can be broken by artificial methods, such as penetrating the seed coat to facilitate the uptake of water (chitting) or exposing the seed to light. Other seeds require a period of after-ripening.

dormouse small rodent, of the family Gliridae, with a hairy tail. There are about ten species, living in Europe, Asia, and Africa. They are arboreal (live in trees) and nocturnal, hibernating during winter in cold regions. They eat berries, nuts, pollen, and insects.

dorsal in vertebrates, the surface of the animal closest to the backbone. For most vertebrates and invertebrates this is the upper surface, or the surface furthest from the ground. For bipedal primates such as humans, where the dorsal surface faces backwards, then the word is 'back'.

Not all animals can be said to have a dorsal surface, just as many animals cannot be said to have a front; for example, jellyfish, anemones, and sponges do not have a dorsal surface.

dory marine fish *Zeus faber* found in the Mediterranean and Atlantic. It grows up to 60 cm/2 ft, and has nine or ten long spines at the front of the dorsal fin, and four at the front of the anal fin. It is considered to be an excellent food fish and is also known as John Dory.

The dory is olive brown or grey, with a conspicuous black spot rising with yellow on each side. A stalking predator, it shoots out its mobile jaws to catch fish.

DOS (acronym for *disc operating system*) computer operating system specifically designed for use with disc storage; also used as an alternative name for a particular operating system, QMS-DOS.

dot in computing, full stop that separates QIP addresses, sections of Qdomain names, and the hierarchies in Qnewsgroup names, as well as file names and their extensions.

dot matrix printer computer printer that produces each character individually by printing a pattern, or matrix, of very small dots. The printing head consists of a vertical line or block of either 9 or 24 printing pins. As the printing head is moved from side to side across the paper, the pins are pushed forwards selectively to strike an inked ribbon and build up the dot pattern for each character on the paper beneath.

A dot matrix printer is more flexible than a Qdaisywheel printer because it can print graphics and text in many different typefaces. It is cheaper to buy and maintain than a Qlaser printer or Qink-jet printer, and, because its pins physically strike the paper, is capable of producing carbon copies. However, it is noisy in operation and cannot produce the high-quality printing associated with the non-impact printers.

dot pitch in computing, distance between the dots which make up the picture on a computer monitor. The smaller the dot pitch, the better and finer-grained the picture.

dotterel bird *Eudromias morinellus* of the plover family, in order Charadriiformes, nesting on high moors and tundra in Europe and

Asia, and migrating south for the winter. About 23 cm/9 in long, its plumage is patterned with black, brown, and white in summer, duller in winter, but always with white eyebrows and breastband. The female is larger than the male, and mates up to five times with different partners, each time laying her eggs and leaving them in the sole care of the male, who incubates and rears the brood. Three pale-green eggs with brown markings are laid in hollows in the ground.

double bond two covalent bonds between adjacent atoms, as in the Qalkenes ($C=C$) and Qketones ($C=O$).

double click in computing, to click (press and release a Qmouse button) twice in quick succession. Double clicking on an Qicon shown on a Qgraphical user interface (GUI) is used to start an application. In most GUIs it is possible to set the maximum time interval between the two clicks.

double coconut treelike Qpalm plant, also known as *coco de mer*, of the Seychelles. It produces a two-lobed edible nut, one of the largest known fruits. (*Lodoicea maldivica*.)

double decomposition reaction between two chemical substances (usually Qsalts in solution) that results in the exchange of a constituent from each compound to create two different compounds.

For example, if silver nitrate solution is added to a solution of sodium chloride, there is an exchange of ions yielding sodium nitrate and silver chloride.

double precision in computing, a type of floating-point notation that has higher precision, that is, more significant decimal places. The term 'double' is not strictly correct, deriving from such numbers using twice as many Qbits as standard floating-point notation.

double star two stars that appear close together. Many stars that appear single to the naked eye appear double when viewed through a telescope. Some double stars attract each other due to gravity, and orbit each other, forming a genuine Qbinary star, but other double stars are at different distances from Earth, and lie in the same line of sight only by chance. Through a telescope both types look the same.

Double stars of the second kind, which are of little astronomical interest, are referred to as 'optical pairs'; those of the first as 'physical pairs' or, more usually, 'visual binaries'. They are the principal source from which is derived our knowledge of stellar masses.

dough mixture consisting primarily of flour, water, and yeast, which is used in the manufacture of bread.

The preparation of dough involves thorough mixing (kneading) and standing in a warm place to 'prove' (increase in volume) so that the Qenzymes in the dough can break down the starch from the flour into smaller sugar molecules, which are then fermented by the yeast. This releases carbon dioxide, which causes the dough to rise.

Douglas fir any of some six species of coniferous evergreen tree belonging to the pine family. The most common is *Pseudotsuga menziesii*, native to western North America and east Asia. It grows up to 60–90 m/200–300 ft in height, has long, flat, spirally-arranged needles and hanging cones, and produces hard, strong timber. *P. glauca* has shorter, bluish needles and grows to 30 m/100 ft in mountainous areas. (Genus *Pseudotsuga*, family Pinaceae.)

douroucoulis or night monkey or owl monkey nocturnal South American monkey. Its eyes are very large and its thick coat is a grey brown. Douroucoulis sleep in tree holes or thick vegetation and feed mainly on fruit and leaves, and some insects. They are the only nocturnal monkeys.

Unlike most South American monkeys, their long tails are not prehensile. The incisors in the lower jaw project forwards and they have a total of 36 teeth.

classification Douroucoulis are in the genus *Aotus* in the family Cebidae, order Primates.

doze another name for *opigeon*.

Down's syndrome condition caused by a chromosomal abnormality (the presence of an extra copy of chromosome 21), which in humans produces mental retardation; a flattened face; coarse, straight hair; and a fold of skin at the inner edge of the eye (hence the former name 'mongolism'). The condition can be detected by prenatal testing.

Those afflicted are usually born to mothers over 40 (one in 100), and in 1995 French researchers discovered a link between Down's syndrome incidence and paternal age, with men over 40 having an increased likelihood of fathering a Down's syndrome baby.

The syndrome is named after J. L. H. Down (1828–1896), an English physician who studied it. All people with Down's syndrome who live long enough eventually develop early-onset Alzheimer's disease, a form of dementia. This fact led to the discovery in 1991 that some forms of early-onset Alzheimer's disease are caused by a gene defect on chromosome 21.

DOWN'S SYNDROME WEB PAGE

<http://www.nas.com/downsyn/>

Well-organized source of information about the syndrome – with articles, essays, lists of organizations worldwide, toy catalogues, the 'Brag Book' photo gallery, and links to other helpful Web sites.

downtime in computing, time when a computer system is unavailable for use, due to maintenance or a system crash. Some downtime is inevitable on almost all systems.

dowsing ascertaining the presence of water or minerals beneath the ground with a forked twig or a pendulum. Unconscious muscular action by the dowser is thought to move the twig, usually held with one fork in each hand, possibly in response to a local change in the pattern of electrical forces. The ability has been known since at least the 16th century and, though not widely recognized by science, it has been used commercially and in archaeology.

INTRODUCTION TO DOWSING

<http://home.interstat.net/~slawcio/dowsing.html>

American Association of Dowsers site that includes all the information you might need to make some dowsing rods and how to use them.

dpi abbreviation for *dots per inch*, measure of the resolution of images produced by computer screens and printers.

Draco in astronomy, a large but faint constellation represented as a dragon coiled around the north celestial pole. Due to precession the star Alpha Draconis (Thuban) was the pole star 4,800 years ago.

This star seems to have faded, for it is no longer the brightest star in the constellation as it was at the beginning of the 17th century. Gamma Draconis is more than a magnitude brighter. It was extensively observed by James Bradley, who from its apparent changes in position discovered the aberration of starlight and nutation.

drag resistance to motion a body experiences when passing through a fluid – gas or liquid. The aerodynamic drag aircraft experience when travelling through the air represents a great waste of power, so they must be carefully shaped, or streamlined, to reduce drag to a minimum. Cars benefit from streamlining, and aerodynamic drag is used to slow down spacecraft returning from space. Boats travelling through water experience hydrodynamic drag on their hulls, and the fastest vessels are hydrofoils, whose hulls lift out of the water while cruising.

drag and drop in computing, in graphical user interfaces, feature that allows users to select a file name or icon using a mouse and move it to the name or icon representing a program so that the computer runs the program using that file as input data.

This method is convenient for computer users, as it eliminates unnecessary typing. Moving the name of a text file, for example, to a copy of a word processor will start up the word processor with that file loaded and ready for editing.

dragon name popularly given to various sorts of lizard. These include the flying dragon *Draco volans* of southeast Asia; the komodo dragon *Varanus komodoensis* of Indonesia, at over 3 m/10 ft the largest living lizard; and some Australian lizards with bizarre spines or frills.

dragonet small, spiny-rayed fish that lives in temperate and tropical seas. The males are larger and brightly coloured with filament-like rays extending from the first dorsal fin. Females are dull in colour. Dragonets have smooth bodies without scales.

The gill openings are reduced to a single small hole near the nape of the neck and the ventral fins are under the throat. The sculpin *Callionymus draco* is about 30 cm/12 in long, and is brown and white in colour; the common dragonet *C. lyra* is yellow, sapphire, and violet in hue.

classification Dragonets are in the genus *Callionymus*, order Perciformes, class Osteichthyes.

dragonfly any of numerous insects of the order Odonata, including the damselfly. They all have long narrow bodies, two pairs of almost equal-sized, glassy wings with a network of veins; short, bristly antennae; powerful, 'toothed' mouthparts; and very large compound eyes which may have up to 30,000 facets. They can fly at speeds of up to 64–96 kph/40–60 mph.

Dragonflies hunt other insects by sight, both as adults and as aquatic nymphs. The largest species have a wingspan of 18 cm/7 in, but fossils related to dragonflies have been found with wings of up to 70 cm/2.3 ft across.

DRAM (acronym for *dynamic random-access memory*) computer memory device in the form of a silicon chip commonly used to provide the immediate-access memory of microcomputers. DRAM loses its contents unless they are read and rewritten every 2 milliseconds or so. This process is called refreshing the memory. DRAM is slower but cheaper than SRAM, an alternative form of silicon-chip memory.

drawing program in computing, software that allows a user to draw freehand and create complex graphics. Additional features may include special fonts, clip art, or painting facilities that allow a user to simulate on the computer the drawing characteristics of specific real-world implements such as charcoal, watercolours, or pastels. The market-leading drawing package is Corel Draw.

dream series of events or images perceived through the mind during sleep. Their function is unknown, but Sigmund Freud saw them as wish fulfilment (nightmares being failed dreams prompted by fears of 'repressed' impulses). Dreams occur in periods of rapid eye movement (REM) by the sleeper, when the cortex of the brain

is approximately as active as in waking hours. Dreams occupy about a fifth of sleeping time.

If a high level of acetylcholine (chemical responsible for transmission of nerve impulses) is present, dreams occur too early in sleep, causing wakefulness, confusion, and depression, which suggests that a form of memory search is involved. Prevention of dreaming, by taking sleeping pills, for example, has similar unpleasant results. For the purposes of (allegedly) foretelling the future, dreams fell into disrepute in the scientific atmosphere of the 18th century.

drill large Old World monkey *Mandrillus leucophaeus* similar to a baboon and in the same genus as the mandrill. Drills live in the forests of Cameroon and Nigeria. Brownish-coated, black-faced, and stoutly built, with a very short tail, the male can have a head and body up to 75 cm/2.5 ft long, although females are much smaller.

drilling common woodworking and metal machinery process that involves boring holes with a drill bit. The commonest kind of drill bit is the fluted drill, which has spiral grooves around it to allow the cut material to escape. In the oil industry, rotary drilling is used to bore oil wells. The drill bit usually consists of a number of toothed cutting wheels, which grind their way through the rock as the drill pipe is turned, and mud is pumped through the pipe to lubricate the bit and flush the ground-up rock to the surface.

In rotary drilling, a drill bit is fixed to the end of a length of drill pipe and rotated by a turning mechanism, the rotary table. More lengths of pipe are added as the hole deepens. The long drill pipes are handled by lifting gear in a steel tower or derrick.

drinking water water that has been subjected to various treatments, including filtration and sterilization, to make it fit for human consumption; it is not pure water.

DRINKING WATER

Darkling beetles living in the Namib desert in Africa drink by standing on their heads at the crests of sand dunes at dawn. Mists rolling in from the coast condense to form water on their bodies; the water then trickles down into their mouths.

drive bay in computing, slot in a computer designed to hold a disc drive such as a hard drive, floppy drive, or CD-ROM drive. Like most computer components, disc drives have decreased in size. Older drives were 5 1/4 inches in size, but most newer drives are 3 1/2 inches. Kits to fit a 3 1/2 inch drive into a 5 1/4 inch bay are readily available.

driver in computing, a program that controls a peripheral device. Every device connected to the computer needs a driver program.

The driver ensures that communication between the computer and the device is successful.

For example, it is often possible to connect many different types of printer, each with its own special operating codes, to the same type of computer. This is because driver programs are supplied to translate the computer's standard printing commands into the special commands needed for each printer.

dromedary variety of Arabian camel. The dromedary or one-humped camel has been domesticated since 400 BC. During a long

period without water, it can lose up to one-quarter of its body weight without ill effects.

drop-down list in computing, in a graphical user interface, a list of options that hangs down from a blank space in a dialog box or other on-screen form when a computer awaits user input.

To select one of the choices, highlight it and click. The list will disappear and the selected item will appear in the blank. If the list is longer than the space available, small arrows and a scroll bar will appear on the right-hand side.

drug any of a range of substances, natural or synthetic, administered to humans and animals as therapeutic agents: to diagnose, prevent, or treat disease, or to assist recovery from injury. Traditionally many drugs were obtained from plants or animals; some minerals also had medicinal value. Today, increasing numbers of drugs are synthesized in the laboratory.

Drugs are administered in various ways, including: orally, by injection, as a lotion or ointment, as a pessary, by inhalation, or by transdermal patch.

A miracle drug is any drug that will do what the label says it will do.

ERIC HODGINS

Episode

drug, generic any drug produced without a brand name that is identical to a branded product. Usually generic drugs are produced when the patent on a branded drug has expired, and are cheaper than their branded equivalents.

drug misuse illegal use of drugs for nontherapeutic purposes. Under the UK Misuse of Drugs regulations drugs used illegally include: narcotics, such as heroin, morphine, and the synthetic opioids; barbiturates; amphetamines and related substances; benzodiazepine tranquilizers; cocaine, LSD, and cannabis. Designer drugs, for example ecstasy, are usually modifications of the amphetamine molecule, altered in order to evade the law as well as for different effects, and may be many times more powerful and dangerous. Crack, a highly toxic derivative of cocaine, became available to drug users in the 1980s. Some athletes misuse drugs such as ephedrine and anabolic steroids.

Sources of traditional drugs include the 'Golden Triangle' (where Myanmar, Laos, and Thailand meet), Mexico, Colombia, China, and the Middle East.

drupe fleshy fruit containing one or more seeds which are surrounded by a hard, protective layer – for example cherry, almond, and plum. The wall of the fruit (pericarp) is differentiated into the outer skin (exocarp), the fleshy layer of tissues (mesocarp), and the hard layer surrounding the seed (endocarp).

The coconut is a drupe, but here the pericarp becomes dry and fibrous at maturity. Blackberries are an aggregate fruit composed of a cluster of small drupes.

dry-cleaning method of cleaning textiles based on the use of volatile solvents, such as trichloroethene (trichloroethylene), that dissolve grease. No water is used. Dry-cleaning was first developed in France 1849.

Some solvents are known to damage the ozone layer and one, tetrachloroethene (perchloroethylene), is toxic in water and gives off toxic fumes when heated.

dry ice solid carbon dioxide (CO₂), used as a refrigerant. At temperatures above -79°C/-110.2°F, it sublimates (turns into vapour without passing through a liquid stage) to gaseous carbon dioxide.

dry rot infection of timber in damp conditions by fungi (see fungus), such as *Merulius lacrymans*, that form a threadlike surface. Whittish at first, the fungus later reddens as reproductive spores are formed. Tentacles from the fungus also work their way into the timber, making it dry-looking and brittle. Dry rot spreads rapidly through a building.

DROMEDARY CAMEL

http://www.seaworld.org/animal_bytes/dromedary_camelab.html

Illustrated guide to the dromedary camel including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

Commonly abused drugs

The two main laws about drugs are the Medicines Act and the Misuse of Drugs Act. The Medicines Act controls the way medicines are made and supplied. The Misuse of Drugs Act bans the non-medical use of certain drugs. The Misuse of Drugs Act places drugs in different classes – A, B, and C. The penalties for offences involving a drug depend on the class it is in and will also vary according to individual circumstances. Class A drugs carry the highest penalty, class C the lowest.

| Name | Source | Forms and appearance | Legal position | Methods of use ¹ |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Amphetamine (also called speed, uppers, whizz, billy, sulphate) | a totally synthetic product | powder form, tablets and capsules | class B, schedule 2 controlled substance | taken orally in drink or licking off the finger, sniffed, smoked, dissolved in water for injecting |
| Anabolic steroids | synthetic products designed to imitate certain natural hormones within the human body | capsules and tablets, liquid | not controlled | injections; also taken orally |
| Cannabis (also called dope, grass, hash, ganja, shit, blow, weed) | plants of the genus <i>Cannabis sativa</i> | herbal: dried plant material, similar to a coarse cut tobacco (marijuana); resin: blocks of various colours and texture (hashish); oil: extracted from resin, with a distinctive smell | class B, schedule 1 controlled substance | smoked in a variety of ways, can be put into cooking or made into a drink, occasionally eaten on its own |
| Cocaine (also called coke, charlie, snow, white lady) | leaves of the coca bush, <i>Erythroxylum coca</i> | white crystalline powder, very rarely in paste form | class A, schedule 2 controlled substance | sniffed; injected, smoked (paste) |
| Crack and freebase cocaine (also called rock, wash, cloud nine, base, freebase) | derived from cocaine hydrochloride | crystals (crack cocaine); powder (freebase cocaine) | class A, schedule 2 controlled substances | smoking |
| Ecstasy (also called disco burgers, Dennis the Menace, diamonds, New Yorkers, E, Adam, XTC, Fantasy, Doves, rubbero and custard (red and yellow capsules)) | a totally synthetic product | tablets and capsules; rarely, powder; ecstasy is not always available in pure form, which increases the risks | class A, schedule 1 | orally; occasionally injections |
| Heroin (also called smack, junk, H, skag, brown, horse, gravy) | from raw opium produced by the opium poppy | powder | class A, schedule 2 controlled substance | smoking, injections, also sniffed or taken orally |
| Lysergic acid diethylamide (LSD) (also called acid, trips, tab, bloters, dots) | derived from ergot (a fungus of certain cereal grains) | colourless crystals; for street use, mainly impregnated into squares of blotted paper or into squares of clear gelatine, or into tiny pills | class A, schedule 1 controlled substance | orally (paper squares and pills); under the eyelid (gelatine squares) |
| Magic (hallucinogenic) mushrooms (also called shrooms, mushies) | natural mushrooms (mainly fly agaric and liberty cap) | several varieties; identification is difficult | possession and eating of fresh mushrooms is not an offence; preparation is ¹ | eaten; infused to make a drink |
| Methadone (also called doll, dolly, red rock, tootsie roll, phy-amps, phy (ampoules)) | a totally synthetic product | powder, tablets, ampoules, tincture, mixture | class A, schedule 2 controlled substance | orally; injections |
| Methylamphetamine (also called ice, meth, crystal, glass, ice-cream (crystal form), meth, methedrine (powder or tablets)) | a totally synthetic drug, closely related to amphetamine sulphate | crystals or, less commonly, tablets or powder | class B, schedule 2 controlled substance | burning crystals and inhaling the fumes; drinking, sniffing, licking off the finger (powder and tablets) |
| Nitrites (poppers) (also called nitro, nitrite) | various synthetic volatile chemicals | in small glass bottles under trade names of Liquid Gold, Hi-Tech, Rave, Locker Room, Ram, Rush, etc | controlled by the Medicines Act | inhalation |
| Solvents (also called glue, gas, can, cog (depending on substance and container)) | domestic and commercial products | liquid petroleum gases (LPGs): aerosols, camping gas cylinders, lighter gas refills; liquid solvents: fire extinguisher fluid, corrective fluids, certain paints and removers, nail polish and remover, anti-freeze, petrol; solvent-based glues: impact adhesives used for wood, plastic, laminate surfaces, vinyl floor tiles | not controlled | sprayed into the mouth and inhaled (LPGs), sniffing |
| Tranquillizers (also called tranx, barbs, barbies, blockers, tues, traffic lights, golf balls (tranquillizers); jellies, jelly beans, M&Ms, rugby balls (temazepam in jelly capsules)) | pharmaceutical drugs aimed at treating patients with problems of anxiety, insomnia, and depression, based on benzodiazepine or barbiturate | tablets or capsules | benzodiazepine-based: class C controlled substances; barbiturate-based: class B controlled substances | taken orally or injected |

¹ Preparation (such as crushing, slicing, drying, etc) is punishable as an offence relating to psilocin and psilocybin – the active ingredients of most hallucinogenic mushrooms, both class A, schedule 1 controlled substances.

| Effects of use | Adverse effects | Tolerance potential | Habituation potential | Withdrawal effects | Overdose potential |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| increased energy, strength, concentration, euphoria and elation; suppression of appetite, wakefulness | increased blood pressure with risk of stroke; diarrhoea or increased urination; disturbance of sleep patterns; weight loss; depression; paranoia; psychosis | tolerance develops rapidly | physical dependence: rare; psychological dependence: common | mental agitation, depression, panic | fatal overdose possible, even at low doses |
| increase in body bulk and muscle growth; feelings of stamina and strength | bone growth abnormalities; hypertension and heart disease; liver and kidney malfunction; hepatitis; sexual abnormalities and impotence | tolerance may develop | no physical dependence; profound psychological dependence | sudden collapse of muscle strength and stamina; irritability, violent mood swings | overdose can lead to collapse, convulsions, coma, and death |
| relaxation, feelings of happiness, congeniality, increased concentration, sexual arousal | impaired judgement; loss of short-term memory; dizziness; confusion; anxiety; paranoia; potential for cancer and breathing disorders | tolerance develops rapidly | true physical dependence: rare; psychological dependence: common | disturbed sleep patterns; anxiety, panic | it is not thought possible to overdose fatally |
| feelings of energy, strength, exhilaration, confidence, talkativeness | agitation, panic, feelings of being threatened; damage to nasal passages; exhaustion, weight loss; collapsed veins; ulceration; delusions; violence | tolerance develops rapidly | strong physical and psychological dependence | severe cravings; feelings of anxiety and panic; depression | it is possible to overdose fatally |
| elation and euphoria, feelings of power, strength, and well-being | depression, feelings of being threatened; paranoia, psychosis; violence | some tolerance develops | strong physical and psychological dependence | severe depression; aggression, panic; risk of suicide | overdose can lead to coma and death |
| feelings of euphoria, energy, stamina, sociability, sexual arousal | mood swings; nausea and vomiting, overheating, dehydration, convulsions, sudden death | tolerance develops | physical dependence: none; psychological dependence: low | no physical symptoms; irritability, depression | overdose can lead to coma and death |
| feelings of euphoria, inner peace, freedom from fear and deprivation | depressed breathing, severe constipation, nausea and vomiting; effect on general state of health, lower immunity, vein collapse and ulceration; risk of infection from needles | tolerance develops rapidly | profound physical and psychological dependence | sweating, flu-like symptoms 'going cold turkey'; severe cravings; professional assistance necessary | overdose can lead to coma and death |
| hallucinations | risk of accident while hallucinating; flashbacks; risk of developing a latent psychiatric disorder | tolerance develops and disappears rapidly | no physical dependence; some psychological dependence | no physical effect; few psychological effects | it is not thought possible to overdose |
| hallucinations; feelings of euphoria, well-being, gaiety | long-term mental problems; risk of poisoning | tolerance develops rapidly | no dependence | few withdrawal effects | little overdose potential |
| feelings of relaxation, bodily warmth, freedom from pain and worry | sweating, nausea, itching, tiredness; disruption of menstrual cycle in women | tolerance develops slowly | strong physical and psychological dependence | fever, flu-like symptoms; diarrhoea; aggression | overdose can lead to respiratory depression, collapse, coma, and death |
| feelings of euphoria, great strength and energy, sustained for long periods without rest or food | increased blood pressure with risk of stroke and heart failure, diarrhoea or increased urination, disturbance of sleep, hallucinations, aggression, psychosis, delusions, paranoia | tolerance develops rapidly | physical dependence: not uncommon; psychological dependence: profound | severe cravings; depression; fear; panic and mental agitation | serious risk of fatal overdose, even at very low levels |
| feelings of excitement and exhilaration; sexual arousal and increased sensitivity of sexual organs | nausea and vomiting; headaches and dizziness; skin problems; damage to vision if touches the eyes; poisonous if swallowed | tolerance develops quickly | no significant physical or psychological dependence | no significant effects | little risk of overdose |
| deep intoxication, hallucinations, excitability | over-stimulation of the heart, and death; asphyxiation from swelling of throat tissues or inhalation of vomit, problems with speech, balance, short-term memory, cognitive skills; possible personality changes | tolerance may develop | no physical dependence; strong psychological dependence | no physical symptoms; anxiety and mood swings | overdose can lead to collapse, coma, and death |
| in higher doses: feelings of euphoria, elimination of fear and feeling of deprivation | violent mood swings, bizarre sexual behaviour, deep depression, disorientation, lethargy | tolerance develops rapidly | profound physical and psychological tolerance | confusion, headaches, depression; sudden withdrawal may lead to convulsions and death | overdose can lead to convulsions, depression of breathing, collapse, coma, and death |

DSP in computing, abbreviation for digital signal processor.

DTP abbreviation for desktop publishing.

dbnium synthesized, radioactive, metallic element of the transactinide series, symbol Db, atomic number 105, relative atomic mass 261. Six isotopes have been synthesized, each with very short (fractions of a second) half-lives. Two institutions claim to have been the first to produce it: the Joint Institute for Nuclear Research in Dubna, Russia, 1967; and the University of California at Berkeley, USA, who disputed the Soviet claim, 1970. Its temporary name was unnilpentium.

duck any of about 50 species of short-legged waterbirds with webbed feet and flattened bills, of the family Anatidae, order Anseriformes, which also includes the larger geese and swans. Ducks were domesticated for eggs, meat, and feathers by the ancient Chinese and the ancient Maya (see *poultry*). Most ducks live in fresh water, feeding on worms and insects as well as vegetable matter. They are generally divided into dabbling ducks and diving ducks.

anatomy The three front toes of a duck's foot are webbed and the hind toe is free; the legs are scaly. The broad rounded bill is skin-covered with a bony tip provided with little plates (lamellae) through which the duck is able to strain its food from water and mud.

species of duck The mallard *Anas platyrhynchos*, 58 cm/1.9 ft, found over most of the northern hemisphere, is the species from which all domesticated ducks originated. The male (drake) has a glossy green head, brown breast, grey body, and yellow bill. The female (duck) is speckled brown, with a duller bill. The male moults and resembles the female for a while just after the breeding season. There are many other species of duck including teal, *oider*, mandarin duck, *üngeranser*, muscovy duck, pintail duck, *öshelduck*, and *öshoveler*. They have different-shaped bills according to their diet and habitat; for example, the shoveler has a wide spade-shaped bill for scooping insects off the surface of water.

duck-billed platypus another name for the *öplatypus*.

duckweed any of a family of tiny plants found floating on the surface of still water throughout most of the world, except the polar regions and tropics. Each plant consists of a flat, circular, leaflike structure 0.4 cm/0.15 in or less across, with a single thin root up to 15 cm/6 in long below. (Genus chiefly *Lemna*, family Lemnaceae.)

The plants bud off new individuals and soon cover the surface of the water. Flowers rarely appear, but when they do, they are extremely small and are found in a pocket at the edge of the plant.

ductile material material that can sustain large deformations beyond its elastic limit (see *öelasticity*) without fracture. Metals are very ductile, and may be pulled out into wires, or hammered or rolled into thin sheets without breaking. Compare *öbrittle material*.

ductless gland alternative name for a *öndocrine gland*.

dugong marine mammal *Dugong dugong* of the order Sirenia (sea cows), found in the Red Sea, the Indian Ocean, and western Pacific. It can grow to 3.6 m/11 ft long, and has a tapering body with a notched tail and two fore-flippers. It has a very long hind gut (30 m/98 ft in adults) which functions similarly to the rumen in *öruminants*. It is largely herbivorous, feeding mostly on sea grasses and seaweeds, and is thought to have given rise to the mermaid myth.

Previously thought to be the only truly herbivorous marine mammal, Australian research 1995 showed that some dugongs eat sea squirts, which make up 25.5% of the wet weight of faeces from dugongs in Moreton Bay, eastern Australia.

duiker *Afrikaans* diver any of several antelopes of the family Bovidae, common in Africa. Duikers are shy and nocturnal, and grow to 30–70 cm/12–28 in tall.

duikerbok small African antelope with crested head, large muzzle, and short, conical horns in the males only.

classification Duikerboks are in genus *Cephalophus* in the family Bovidae (cattle and antelopes) of order Artiodactyla.

dulse any of several edible red seaweeds, especially *Rhodomenia palmata*, found on middle and lower shores of the north Atlantic. They may have a single broad blade up to 30 cm/12 in long rising directly from the holdfast which attaches them to the sea floor, or may be palmate (with five lobes) or fan-shaped. The frond is tough and dark red, sometimes with additional small leaflets at the edge.

Dumas, Jean Baptiste André (1800–1884)

French chemist. He made contributions to organic analysis and synthesis, and to the determination of atomic weights (relative atomic masses) through the measurement of vapour densities. In 1833, Dumas worked out an absolute method for the estimation of the amount of nitrogen in an organic compound, which still forms the basis of modern methods of analysis. He went on to correct the atomic masses of 30 elements – half the total number known at that time – referring to the hydrogen value as 1.

In 1826, Dumas began working on atomic theory, and concluded that 'in all elastic fluids observed under the same conditions, the molecules are placed at equal distances' – that is, they are present in equal numbers. His theory of substitution in organic compounds, which he proved by experiments, established that atoms of apparently opposite electrical charge replaced each other. This refuted the dualistic theory of chemistry proposed by Swedish chemist Jöns Berzelius.

Studying blood, Dumas showed that urea is present in the blood of animals from which the kidneys have been removed, proving that one of the functions of the kidneys is to remove urea from the blood, not to produce it.

Mary Evans Picture Library

dumb terminal in computing, a terminal that has no processing capacity of its own. It works purely as a means of access to a main *öcentral* processing unit. Compare with a *öpersonal* computer used as an intelligent terminal – for example in *öclient-server* architecture.

dump in computing, the process of rapidly transferring data to external memory or to a printer. It is usually done to help with debugging (see *öbug*) or as part of an error-recovery procedure designed to provide *ödata* security. A *öscreen* dump makes a printed copy of the current screen display.

dune mound or ridge of wind-drifted sand common on coasts and in sandy deserts. Loose sand is blown and bounced along by the wind, up the windward side of a dune. The sand particles then fall to rest on the lee side, while more are blown up from the windward side. In this way a dune moves gradually downwind.

In sandy deserts, the typical crescent-shaped dune is called a *barchan*. Seif dunes are longitudinal and lie parallel to the wind direction, and star-shaped dunes are formed by irregular winds.

dung waste matter excreted by living animals. Dung may also serve as a marker through the addition of scents from the anal glands, whether for determining territorial boundaries or as an indication of status within a group.

Some animals, such as rabbits, may reingest dung immediately

barchans with
weak wind

barchans with
strong wind

irregular winds

seif dunes on
bare rock, parallel
to wind direction

dune The shape of a dune indicates the prevailing wind pattern. Crescent-shaped dunes form in sandy desert with winds from a constant direction. Seif dunes form on bare rocks, parallel to the wind direction. Irregular star dunes are formed by variable winds.

after excretion and continue digesting it, a process known as refection. In addition to being broken down by bacteria, animal dung provides food for many invertebrates, especially beetles and flies, and provides a habitat for certain species of fungi and plants such as stinging nettles.

dunlin small gregarious shore bird *Calidris alpina* of the sandpiper family Scolopacidae, order Charadriiformes, about 18 cm/7 in long, nesting on moors and marshes in the far northern regions of Eurasia and North America. Chestnut above and black below in summer, it is greyish in winter; the bill and feet are black.

Dunnite US high explosive named after Major Dunn, its developer; also called 'Explosive D'. Made of ammonium picrate powder, it was relatively insensitive, and so was widely used in armour-piercing shells as it withstood the shock of impact against armour without detonating, allowing the shell to pierce the armour before the fuse initiated the explosive.

dunnock or **hedge sparrow** European bird *Prunella modularis* family Prunellidae, similar in size and colouring to the sparrow, but

with a slate-grey head and breast, and more slender bill. It is characterized in the field by a hopping gait, with continual twitches of the wings whilst feeding. It nests in bushes and hedges.

duodecimal system system of arithmetic notation using 12 as a base, at one time considered superior to the decimal number system in that 12 has more factors (2, 3, 4, 6) than 10 (2, 5).

It is now superseded by the universally accepted decimal system.

duodenum in vertebrates, a short length of alimentary canal found between the stomach and the small intestine. Its role is in digesting carbohydrates, fats, and proteins. The smaller molecules formed are then absorbed, either by the duodenum or the ileum.

Entry of food to the duodenum is controlled by the pyloric sphincter, a muscular ring at the outlet of the stomach. Once food has passed into the duodenum it is mixed with bile released from the gall bladder and with a range of enzymes secreted from the pancreas, a digestive gland near the top of the intestine. The bile neutralizes the acidity of the gastric juices passing out of the stomach and aids fat digestion.

duplex or **echo** in printing, the ability to print on both sides of the page; in computer communications, setting that toggles the ability to send and receive signals simultaneously. **Full duplex** means two-way communication is enabled; **half duplex** means it is disabled.

duralumin lightweight aluminium alloy widely used in aircraft construction, containing copper, magnesium, and manganese.

durra or **doura** grass, also known as Indian millet, grown as a cereal in parts of Asia and Africa. *Sorghum vulgare* is the chief cereal in many parts of Africa. See also *Osorghum*. (Genus *Sorghum*.)

dust bowl area in the Great Plains region of North America (Texas to Kansas) that suffered extensive wind erosion as the result of drought and poor farming practice in once-fertile soil. Much of the topsoil was blown away in the droughts of the 1930s and the 1980s.

Similar dust bowls are being formed in many areas today, noticeably across Africa, because of overcropping and overgrazing.

Dutch cap common name for a barrier method of contraception; see *diaphragm*.

Dutch elm disease disease of elm trees *Ulmus*, principally Dutch, English, and American elm, caused by the fungus *Cercosyria ulmi*. The fungus is usually spread from tree to tree by the elm-bark beetle, which lays its eggs beneath the bark. The disease has no cure, and control methods involve injecting insecticide into the trees annually to prevent infection, or the destruction of all elms in a broad band around an infected area, to keep the beetles out.

The disease was first described in the Netherlands and by the early 1930s had spread across Britain and continental Europe, as well as North America.

DVD abbreviation for *digital versatile disc* or *digital video disc*.

DVI (abbreviation for *digital video interactive*) in computing, a powerful compression and decompression system for digital video and audio. DVI enables 72 minutes of full-screen, full-motion video and its audio track to be stored on a CD-ROM. Originally developed by the US firm RCA, DVI is now owned by Intel and has active support from IBM and Microsoft. It can be used on the hard disc of a PC as well as on a CD-ROM.

Dvorak keyboard alternative keyboard layout to the normal typewriter keyboard layout (QWERTY). In the Dvorak layout the most commonly used keys are situated in the centre, so that keying is faster.

DWANGO (acronym for *Dial-up Wide Area Network Game Operation*) in computing, server that enables computer users with modems to play each other at action games such as DOOM, Duke Nukem 3D, and Monster Truck Madness without the variable delays involved in moving data over the Internet.

dye substance that, applied in solution to fabrics, imparts a colour resistant to washing. **Direct dyes** combine with the material of the fabric, yielding a coloured compound; **indirect dyes** require the presence of another substance (a mordant), with which the fabric must first be treated; **vat dyes** are colourless soluble substances that on exposure to air yield an insoluble coloured compound.

Naturally occurring dyes include indigo, madder (alizarin), logwood, and cochineal, but industrial dyes (introduced in the 19th century) are usually synthetic: acid green was developed 1835 and bright purple in 1856.

Industrial dyes include çazo dyestuffs, çacridine, çanthracene, and çaniline.

dyke in earth science, a sheet of çigneous rock created by the intrusion of magma (molten rock) across layers of pre-existing rock. (By contrast, a sill is intruded *between* layers of rock.) It may form a ridge when exposed on the surface if it is more resistant than the rock into which it intruded. A dyke is also a human-made embankment built along a coastline (for example, in the Netherlands) to prevent the flooding of lowland coastal regions.

dynamic data exchange (DDE) in computing, a form of inter-process communication used in Microsoft çWindows, providing exchange of commands and data between two applications. DDE was used principally to include live data from one application in another – for example, spreadsheet data in a word-processed report. After Windows 3.1 DDE was replaced by çobject linking and embedding.

DDE links between files rely on the files remaining in the same locations in the computer's directory.

Dynamic HTML in computing, the fourth version of hypertext markup language (çHTML), the language used to create Web pages. It is called Dynamic HTML because it enables dynamic effects to be incorporated in pages without the delays involved in downloading Java çapplets and without referring back to the server.

dynamic IP address in computing, a temporary çIP address assigned from a pool of available addresses by an çInternet Service Provider when a customer logs on to begin an online session.

Companies and other organizations which have their own networks typically have their own permanent IP addresses. Customers of a dial-up service provider, however, only need addresses for the length of time that they are actually on line. This method allows the finite number of available IP addresses to be used most efficiently.

dynamic link library (DLL) in computing, files of executable functions that can be loaded on demand in Microsoft çWindows and linked at run time. Windows itself uses DLL files for handling international keyboards, for example, and Windows word-processing programs use DLL files for functions such as spelling and hyphenation checks, and thesaurus.

dynamics or **kinetics** in mechanics, the mathematical and physical study of the behaviour of bodies under the action of forces that produce changes of motion in them.

dynamite explosive consisting of a mixture of nitroglycerine and diatomaceous earth (diatomite, an absorbent, chalklike material). It was first devised by Alfred Nobel.

dynamo simple generator or machine for transforming mechanical energy into electrical energy. A dynamo in basic form consists of a powerful field magnet between the poles of which a suitable conductor, usually in the form of a coil (armature), is rotated. The mechanical energy of rotation is thus converted into an electric current in the armature.

Present-day dynamos work on the principles described by English physicist Michael Faraday in 1830, that an electromotive force is developed in a conductor when it is moved in a magnetic field.

dyne c.g.s. unit (symbol dyn) of force. 10^5 dynes make one newton. The dyne is defined as the force that will accelerate a mass of one gram by one centimetre per second per second.

dysentery infection of the large intestine causing abdominal cramps and painful çdiarrhoea with blood. There are two kinds of dysentery: amoebic (caused by a protozoan), common in the tropics, which may lead to liver damage; and bacterial, the kind most often seen in the temperate zones.

Both forms are successfully treated with antibacterials and fluids to prevent dehydration.

DYSLEXIA

Hans Christian Andersen, the Danish writer of fairy tales, was a bad speller and was probably dyslexic.

dyslexia Greek 'bad', 'pertaining to words' malfunction in the brain's synthesis and interpretation of written information, popularly known as 'word blindness'.

Dyslexia may be described as specific or developmental to distinguish it from reading or writing difficulties which are acquired. It results in poor ability in reading and writing, though the person may excel in other areas, for example, in mathematics. A similar disability with figures is called *dyscalculia*. Acquired dyslexia may occur as a result of brain injury or disease.

dysprosium Greek *dusprositos* 'difficult to get near' silver-white, metallic element of the çlanthanide series, symbol Dy, atomic number 66, relative atomic mass 162.50. It is among the most magnetic of all known substances and has a great capacity to absorb neutrons.

It was discovered in 1886 by French chemist Paul Lecoq de Boisbaudran (1838–1912).

E

2E abbreviation for *east*.

eagle any of several genera of large birds of prey of the family Accipitridae, order Falconiformes, including the golden eagle *Aquila chrysaetos* of Eurasia and North America, which has a 2 m/6 ft wingspan. Eagles occur worldwide, usually building eyries or nests in forests or mountains, and all are fierce and powerful birds of prey. The harpy eagle is the largest eagle.

The white-headed bald eagle *Haliaeetus leucocephalus* is the symbol of the USA; rendered infertile through the ingestion of agricultural chemicals, it is now rare, except in Alaska.

Another endangered species is the Philippine eagle, sometimes called the Philippine monkey-eating eagle (although its main prey is the flying lemur). Loss of large tracts of forest, coupled with hunting by humans, have greatly reduced its numbers.

ear organ of hearing in animals. It responds to the vibrations that constitute sound, which are translated into nerve signals and passed to the brain. A mammal's ear consists of three parts: outer ear, middle ear, and inner ear. The outer ear is a funnel that collects sound, directing it down a tube to the ear drum (tympanic membrane), which separates the outer and middle ears. Sounds vibrate this membrane, the mechanical movement of which is transferred to a smaller membrane leading to the inner ear by three small bones, the auditory ossicles. Vibrations of the inner ear membrane move fluid contained in the snail-shaped cochlea, which

EAR ANATOMY

http://weber.u.washington.edu/~otoweb/ear_anatomy.html

Concise medical information on the anatomy and function of the ear. It includes separate sections on perforated eardrums and their treatment, ear tubes and their use, tinnitus, and a series of different hearing tests.

vibrates hair cells that stimulate the auditory nerve connected to the brain. There are approximately 30,000 sensory hair cells (stereocilia). Exposure to loud noise and the process of ageing damages the stereocilia, resulting in hearing loss. Three fluid-filled canals of the inner ear detect changes of position; this mechanism, with other sensory inputs, is responsible for the sense of balance.

When a loud noise occurs, muscles behind the eardrum contract automatically, suppressing the noise to enhance perception of sound and prevent injury.

earth electrical connection between an appliance and the ground. In the event of a fault in an electrical appliance, for example, involving connection between the live part of the circuit and the outer casing, the current flows to earth, causing no harm to the user.

In most domestic installations, earthing is achieved by a connection to a metal water-supply pipe buried in the ground.

Earth third planet from the Sun. It is almost spherical, flattened slightly at the poles, and is composed of three concentric layers: the core, the mantle, and the crust. About 70% of the surface (including the north and south polar icecaps) is covered with water. The Earth is surrounded by a life-supporting atmosphere and is the only planet on which life is known to exist.

mean distance from the Sun 149,500,000 km/92,860,000 mi

equatorial diameter 12,756 km/7,923 mi

circumference 40,070 km/24,900 mi

rotation period 23 hr 56 min 4.1 sec

ear The structure of the ear. The three bones of the middle ear – hammer, anvil, and stirrup – vibrate in unison and magnify sounds about 20 times. The spiral-shaped cochlea is the organ of hearing. As sound waves pass down the spiral tube, they vibrate fine hairs lining the tube, which activate the auditory nerve connected to the brain. The semicircular canals are the organs of balance, detecting movements of the head.

Earth Inside the Earth. The surface of the Earth is a thin crust about 6 km/4 mi thick under the sea and 40 km/25 mi thick under the continents. Under the crust lies the mantle about 2,900 km/1,800 mi thick and with a temperature of 1,500–3,000°C/2,700–5,400°F. The inner core is probably solid iron and nickel at about 5,000°C/9,000°F.

year (complete orbit, or sidereal period) 365 days 5 hr 48 min 46 sec. Earth's average speed around the Sun is 30 kps/18.5 mps; the plane of its orbit is inclined to its equatorial plane at an angle of 23.5°, the reason for the changing seasons

atmosphere nitrogen 78.09%; oxygen 20.95%; argon 0.93%; carbon dioxide 0.03%; and less than 0.0001% neon, helium, krypton, hydrogen, xenon, ozone, radon

surface land surface 150,000,000 sq km/57,500,000 sq mi (greatest height above sea level 8,872 m/29,118 ft Mount Everest); water surface 361,000,000 sq km/139,400,000 sq mi (greatest depth 11,034 m/36,201 ft Mariana Trench in the Pacific). The interior is thought to be an inner core about 2,600 km/1,600 mi in diameter, of solid iron and nickel; an outer core about 2,250 km/1,400 mi thick, of molten iron and nickel; and a mantle of mostly solid rock

To remember the most common elements of the planet's crust, in descending order:

ONLY SILLY ASSES IN COLLEGE STUDY PAST MIDNIGHT

OXYGEN, SILICON, ALUMINIUM, IRON, CALCIUM, SODIUM,
POTASSIUM, MAGNESIUM

about 2,900 km/1,800 mi thick, separated from the Earth's crust by the Mohorovičić discontinuity. The crust and the topmost layer of the mantle form about twelve major moving plates, some of which carry the continents. The plates are in constant, slow motion, called tectonic drift. US geophysicists announced in 1996 that they had detected a difference in the spinning time of the Earth's core and the rest of the planet; the core is spinning slightly faster.

satellite the Moon

age 4.6 billion years. The Earth was formed with the rest of the Solar System by consolidation of interstellar dust. Life began 3.5–4 billion years ago

EARTH AND MOON VIEWER

<http://www.fourmilab.ch/earthview/vplanet.html>

View a map of the Earth showing the day and night regions at this moment, or view the Earth from the Sun, the Moon, or any number of other locations. Alternatively, take a look at the Moon from the Earth or the Sun, or from above various formations on the lunar surface.

The earth only has so much bounty to offer and inventing ever larger and more notional prices for that bounty does not change its real value.

BEN ELTON English writer and comedian.
Stark, 'Dinner in Los Angeles'

earthquake abrupt motion that propagates through the Earth and along its surfaces. Earthquakes are caused by the sudden release in rocks of strain accumulated over time as a result of tectonics. The study of earthquakes is called *seismology*. Most earthquakes occur along *faults* (fractures or breaks) and *Benioff zones*. Plate tectonic movements generate the major proportion: as two plates move past each other they can become jammed. When sufficient strain has accumulated, the rock breaks, releasing a series of elastic waves (*seismic waves*) as the plates spring free. The force of earthquakes (magnitude) is measured on the *Richter scale*, and their effect (intensity) on the *Mercalli scale*. The point at which an earthquake originates is the *seismic focus* or *hypocentre*; the point on the Earth's surface directly above this is the *epicentre*.

The Alaskan (USA) earthquake of 27 March 1964 ranks as one of the greatest ever recorded, measuring 8.3 to 8.8 on the Richter scale. The 1906 San Francisco earthquake is among the most famous in history. Its magnitude was 8.3 on the Richter scale. The deadliest, most destructive earthquake in historical times is thought to have been in China in 1556. In 1987, a California earthquake was successfully predicted by measurement of underground pressure waves; prediction attempts have also involved the study of such phenomena as the change in gases issuing from the *crust*, the level of water in wells, slight deformation of the rock surface, a sequence of minor tremors, and the behaviour of animals. The possibility of earthquake prevention is remote. However, rock slippage might be slowed at movement points, or promoted at stoppage

Earth science: chronology

| | | | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10000–8000 BC | Holocene (post-glacial) period of hunters and gatherers. Harvesting and storage of wild grains in southwest Asia. Herding of reindeer in northern Eurasia. Domestic sheep in northern Iraq. | 12th–14th centuries | Expansion of European population brought more land into cultivation. Crop rotations, manuring, and new crops such as beans and peas helped increase productivity. Feudal system at its height. |
| 8000 | Neolithic revolution with cultivation of domesticated wheats and barleys, sheep, and goats in southwest Asia. Domestication of pigs in New Guinea. | 13th–14th centuries | Agricultural recession in western Europe with a series of bad harvests, famines, and pestilence. |
| 7000–6000 | Domestic goats, sheep, and cattle in Anatolia, Greece, Persia, and the Caspian basin. Planting and harvesting techniques transferred from Asia Minor to Europe. | 1347 | Black Death killed about a third of the European population. |
| 5000 | Beginning of Nile valley civilization. Millet cultivated in China. | 16th century | Decline of the feudal system in western Europe. More specialist forms of production were now possible with urban markets. Manorial estates and serfdom remained in eastern Europe. Chinese began cultivation of non-indigenous crops such as corn, sweet potatoes, potatoes, and peanuts. |
| 3400 | Flax used for textiles in Egypt. Widespread corn production in the Americas. | | Potato introduced into Europe. Norfolk crop rotation became widespread in England, involving wheat, turnips, barley and then ryegrass/clover. |
| 3200 | Records of ploughing, raking, and manuring by Egyptians. | 17th century | |
| c. 3100 | River Nile dammed during the rule of King Menes. | 1700–1845 | Agricultural revolution began in England. Two million hectares of farmland in England enclosed. Removal of open fields in other parts of Europe followed. |
| 3000 | First record of asses used as beasts of burden in Egypt. Sumerian civilization used barley as main crop with wheat, dates, flax, apples, plums, and grapes. | c. 1701 | Jethro Tull developed the seed drill and the horse-drawn hoe. |
| 2900 | Domestication of pigs in eastern Asia. | 1747 | First sugar extracted from sugar beet in Prussia. |
| 2640 | Reputed start of Chinese silk industry. | 1762 | Veterinary school founded in Lyon, France. |
| 2500 | Domestic elephants in the Indus valley. Potatoes a staple crop in Peru. | 1783 | First plough factory in England. |
| 2350 | Wine-making in Egypt. | 1785 | Cast-iron ploughshare patented. |
| 2250 | First known irrigation dam. | 1793 | Invention of the cotton gin. |
| 1600 | Important advances in the cultivation of vines and olives in Crete. | 1800 | Early threshing machines developed in England. |
| 1500 | Shadoof (mechanism for raising water) used for irrigation in Egypt. | 1820s | First nitrates for fertilizer imported from South America. |
| 1400 | Iron ploughshares in use in India. | 1830 | Reaping machines developed in Scotland and the US. Steel plough made by John Deere in Illinois, US. |
| 1300 | Aqueducts and reservoirs used for irrigation in Egypt. | 1840s | Extensive potato blight in Europe. |
| 1200 | Domestic camels in Arabia. | 1850s | Use of clay pipes for drainage well established throughout Europe. |
| 1000–500 | Evidence of crop rotation, manuring, and irrigation in India. | 1862 | First steam plough used in the Netherlands. |
| 600 | First windmills used for corn grinding in Persia. | 1850–1890s | Major developments in transport and refrigeration technology altered the nature of agricultural markets with crops, dairy products, and wheat being shipped internationally. |
| 350 | Rice cultivation well established in parts of western Africa. Hunting and gathering in the east, central, and south parts of the continent. | 1890s | Development of stationary engines for ploughing. |
| c. 300 | Use of gears to create ox-driven water wheel for irrigation. Archimedes screw used for irrigation. | 1892 | First petrol-driven tractor in the USA. |
| 100 | Cattle-drawn iron ploughs in use in China. | 1921 | First attempt at crop dusting with pesticides from an aeroplane near Dayton, Ohio, US. |
| AD 65 | <i>De Re Rustica</i> /On Rural Things, Latin treatise on agriculture and irrigation. | 1938 | First self-propelled grain combine harvester used in the USA. |
| 500 | 'Three fields in two years' rotation used in China. | 1942–62 | Huge increase in the use of pesticides, later curbed by disquiet about their effects and increasing resistance of pests to standard controls such as DDT. |
| 630 | Cotton introduced into Arabia. | 1945 onwards | Increasing use of scientific techniques, crop specialization and larger scale of farm enterprises. |
| 800 | Origins of the 'open field' system in northern Europe. | 1985 | First cases of bovine spongiform encephalopathy (BSE) recorded by UK vets. |
| 900 | 'Wheeled ploughs in use in western Europe. Horse collar, originating in China, allowed horses to be used for ploughing as well as carrying. | 1992 | Number of cases of BSE in cattle was at its peak (700 cases per week). |
| 1000 | Frisians (NW Netherlands) began to build dykes and reclaim land. Chinese began to introduce Champa rice which cropped much more quickly than other varieties. | 1995 | Increase in the use of genetic engineering with nearly 3,000 transgenic crops being field-tested. |
| 11th century | Three-field system replaced the two-field system in western Europe. Concentration on crop growing. | 1996 | Organic farming was on the increase in EU countries. The rise was 11% per year in Britain, 50% in Germany, and 40% in Italy. |
| 1126 | First artesian wells, at Artois, France. | | |
| 12th century | Increasing use of water mills and windmills. Horses replaced oxen for pulling work in many areas. | | |

points, by the extraction or injection of large quantities of water underground, since water serves as a lubricant. This would ease overall pressure.

earth science scientific study of the planet Earth as a whole. The mining and extraction of minerals and gems, the prediction of weather and earthquakes, the pollution of the atmosphere, and the forces that shape the physical world all fall within its scope of study. The emergence of the discipline reflects scientists' concern that an understanding of the global aspects of the Earth's structure and its past will hold the key to how humans affect its future, ensuring that its resources are used in a sustainable way. It is a synthesis of several traditional subjects such as geology, meteorology, oceanography, geophysics, geochemistry, and palaeontology.

Earth Summit (official name *United Nations Conference on Environment and Development*) international meetings aiming at drawing measures towards environmental protection of the world. The first summit took place in Rio de Janeiro, Brazil, in June 1992. Treaties were made to combat global warming and protect wildlife ('biodiversity') (the latter was not signed by the USA). The second Earth Summit was held in New York in June 1997 to review progress on the environment. The meeting agreed to work towards a global forest convention in 2000 with the aim of halting the destruction of tropical and old-growth forests.

The Rio summit, which cost \$23 million to stage (of which 60% was spent on security), was attended by 10,000 official delegates, 12,000 representatives of nongovernmental organizations, and 7,000 journalists.

In 1993, the Clinton administration overturned certain decisions made by George Bush at the Earth Summit. The USA, which had failed to ratify the Convention of Biological Diversity pact along with other nations, came under renewed pressure to endorse it in April 1995 after India threatened to prevent US pharmaceutical and cosmetic companies from gaining access to its natural resources.

By 1996 most wealthy nations estimated that they would exceed their emissions targets, including Spain by 24%, Australia by 25%, and the USA by 3%. Britain and Germany were expected to meet their targets.

The second summit (1997) failed to agree a new deal to address the world's escalating environmental crisis. Dramatic falls in aid to the so-called Third World countries, which the 1992 Earth Summit promised to increase, were at the heart of the breakdown. British prime minister Tony Blair condemned the USA, Japan, Canada and Australia for failing to deliver on commitments to stabilise rising emissions of climate-changing greenhouse gases. The European Community as a whole was on target to meet its stabilisation commitment because of cuts in emissions in Germany and the UK.

Deforestation was the main problem tackled at the second summit. The World Bank and the World Wide Fund for Nature signed an agreement aimed at protecting 250 million hectares/617 million acres of forest (10% of the world's forests). The importance of the issue was highlighted by the fact that deforestation progressed rapidly in developing countries since the first summit, with 15,000 sq km/9,300 sq mi a year lost in the Amazon region alone.

earthworm annelid worm of the class Oligochaeta. Earthworms are hermaphroditic and deposit their eggs in cocoons. They live by burrowing in the soil, feeding on the organic matter it contains. They are vital to the formation of humus, aerating the soil and levelling it by transferring earth from the deeper levels to the surface as castings.

EARWIG

In the 18th century, earwigs were prescribed for hearing difficulties. Dr James' *Medicinal Dictionary* of 1743, comments: 'These insects, being dried, pulverized, and mixed with the urine of a hare, are esteemed to be good for deafness, being introduced into the ear.'

earwig nocturnal insect of the order Dermaptera. The forewings are short and leathery and serve to protect the hindwings, which are large and are folded like a fan when at rest. Earwigs seldom fly. They have a pincerlike appendage in the rear. The male is distinguished by curved pincers; those of the female are straight. Earwigs are regarded as pests because they feed on flowers and fruit, but they also eat other insects, dead or alive. Eggs are laid beneath the soil, and the female cares for the young even after they have hatched. The male dies before the eggs have hatched.

Easter Island or Rapa Nui, Spanish Isla de Pascua Chilean island in the south Pacific Ocean, part of the Polynesian group, about 3,500 km/2,200 mi west of Chile; area about 166 sq km/64 sq mi; population (1994) 2,800. It was first reached by Europeans on Easter Sunday 1722. On it stand over 800 huge carved statues (*moai*) and the remains of boat-shaped stone houses, the work of Neolithic peoples from Polynesia. The chief centre is Hanga-Roa.

In 1996, following seven years of work, a New Zealand linguist, Dr Steven Fischer, deciphered a script discovered on the island. This script showed the inhabitants were the first in Oceania to write. According to Dr Fischer, the script, known as 'rongorongo', was made up of chants in Rapanui, the island's Polynesian tongue, and tell the story of creation.

The carved statues are believed to have been religious icons. However, archaeological evidence suggests that, prior to European contact, the island suffered an environmental or cultural crisis resulting in the inhabitants renouncing their earlier religious values, which caused them to damage or overturn many of the statues.

Eastman, George

(1854–1932)

US entrepreneur and inventor who founded the Eastman Kodak photographic company in 1892. He patented flexible film 1884, invented the Kodak box camera 1888, and introduced daylight-loading film in 1892. By 1900 his company was selling a pocket camera for as little as one dollar.

eau de cologne refreshing toilet water (weaker than perfume), made of alcohol and aromatic oils. Its invention is ascribed to Giovanni Maria Farina (1685–1766), who moved from Italy to Cologne 1709 to manufacture it.

EBCDIC (abbreviation for *extended binary-coded decimal interchange code*) in computing, a code used for storing and communicating alphabetic and numeric characters. It is an 8-bit code, capable of holding 256 different characters, although only 85 of these

ecdysis A bush cricket or katydid (family Tettigoniidae) sheds its skin at night in a rainforest in Costa Rica. The insect is very vulnerable to attack at this time, so it is an advantage for ecdysis to take place during the hours of darkness. Premaphotos Wildlife

Did We Save the World at Rio de Janeiro?

BY NIGEL DUDLEY

The Earth Summit

The United Nations Conference on Environment and Development – usually called UNCED or the Earth Summit – took place in Rio de Janeiro, Brazil, in June 1992. It was the largest gathering of heads of state in history and almost certainly also the largest assembly of professional environmentalists and non-governmental organizations. In a historic meeting, the world's leaders agreed two important conventions to combat environmental destruction – on climate change and biodiversity – along with a comprehensive environmental strategy called 'Agenda 21' and a carefully-worded set of 'Forest Principles'. The meeting raised high expectations. It was hailed as a new start for the environment – indeed as a step towards a safer, more equitable world. Yet did anything really change? Five years on, in June 1997, a follow-up meeting took place in New York. Some of the results make depressing reading.

The Climate Change Convention has made extremely slow progress. After agreeing targets for reducing greenhouse gases that many experts believed were too low, several of the richer countries have failed to meet even these aims, and, instead, pollution continues to increase. The Convention on Biological Diversity has, in turn, become mired in infighting about rights to genetic material and has suffered chronic underfunding: if anything, threats of widespread extinctions are greater now than they were in 1992. Debates about a global forest convention – rejected at the time of the Earth Summit – are still going on today, against a background of continuing deforestation and forest degradation. Worse still, there has been a well-orchestrated backlash against the environment, promoted by some business interests intent on preventing their short-term profits being affected by long-term environmental planning.

Decisions into practice

Yet the bad news has to be balanced by some good. While global negotiations have sometimes seemed like little more than an excuse for a handful of people to fly around the world for talking sessions, changes at the national, regional, and grassroots levels have been more encouraging. A 'Local Agenda 21' initiative has challenged community groups, non-governmental organizations, individuals, and local authorities to put the principles of the Earth Summit into practice. Literally thousands of projects have sprung up around the world, ranging from neighbourhood energy conservation schemes to community forest management and introduction of new techniques to enable resources to be used sustainably. These are important not only because of their practical impact, but because they have enabled the environmental message to be carried into thousands of schools and colleges, women's groups, religious organizations, trade unions, and so on.

Indeed, if there is one fundamental change that can be identified since the Rio meeting, it is that social issues have become much more fundamentally related to environmental concerns. Whereas early environmental projects sometimes virtually ignored people – leading to circumstances such as local people being expelled from their traditional areas to establish nature reserves – today there is increasing effort to integrate human and environmental needs, leading to stronger and more durable solutions. Rather than impose solutions from above, experience

has also shown that results are likely to be far better if local people are involved in both the planning and the management of conservation projects, instead of being left to gaze at them from the outside. Such changes make the conservationist's role more complicated, and involve some inevitable give and take, but ultimately result in ways of reducing our impact on the environment that invite general support rather than opposition.

Things are working better at a regional level as well. Although we have no global forest convention, there have been several regional initiatives to define and implement 'sustainable forest management', where timber needs are balanced with other requirements, such as biodiversity conservation, environmental services such as control of soil erosion, production of food, medicinal herbs, and a range of non-timber forest products, recreational uses of forests, and even the spiritual and religious importance of particular forests.

Global partnerships

In the absence of global leadership, local and national partnerships have been developing to fill the vacuum. Some of them are unexpected. For example, sections of the timber trade have been working with non-governmental organizations in several countries to develop 'certification of good forest management': a forest gains a certificate if it is judged to be well-managed by an independent inspector against an agreed set of standards. Consumers have the chance to buy timber that they know has been produced without damaging the environment or local human communities. Efforts are being co-ordinated by the Forest Stewardship Council, an international organization based in Mexico which had not even been thought of at Rio, and already over 5 million hectares of forest have been certified around the world.

Conditions are still getting worse

These and other similar developments are certainly signs of hope. But down at the sharp end of environmental problems, it is hard to avoid the conclusion that, for many countries, conditions are still getting worse. Almost every developing country is still losing its forests. Desertification – the creation of new deserts as a result of overgrazing, poor irrigation schemes, climate change, and forest loss – is occurring in over a hundred countries. Forest fires are increasing in intensity, particularly in the tropical moist forests that should almost never burn under natural conditions. Commercially important fish species have, in many cases, been over-caught to the extent that stocks have collapsed, and the loss of mangroves in coastal regions has resulted in a similar rapid decline in the coastal species that rely on them to provide cover for breeding. The ozone hole continues to grow, and the evidence for climate change is increasing: extreme weather events appear to be growing in strength and frequency. At the moment we stand at a crossroads. Awareness of the importance of environmental issues has never been stronger. Governments and local communities are becoming increasingly willing to take action. But at the same time, ground continues to be lost – literally – and efforts at conservation and restoration will, in the future, be played out against a backdrop of a planet that will probably be far poorer in species and habitats than it was when the 20th century began.

are defined in the standard version. It is still used in many main-frame computers, but almost all mini-and microcomputers now use ASCII code.

ebony any of a group of hardwood trees belonging to the ebony family, especially some tropical species native to Africa and Asia. (Genus chiefly *Diospyros*, family Ebenaceae.)

e-cash (contraction of *electronic cash*) generic name for new electronic money systems such as Mondex, CyberCash, and DigiCash.

eccentricity in geometry, a property of a conic section (circle, ellipse, parabola, or hyperbola). It is the distance of any point on the curve from a fixed point (the focus) divided by the distance of

that point from a fixed line (the directrix). A circle has an eccentricity of zero; for an ellipse it is less than one; for a parabola it is equal to one; and for a hyperbola it is greater than one.

ecdysis periodic shedding of the exoskeleton by insects and other arthropods to allow growth. Prior to shedding, a new soft and expandable layer is laid down underneath the existing one. The old layer then splits, the animal moves free of it, and the new layer expands and hardens.

ECG abbreviation for electrocardiogram.

echidna or *spiny anteater* toothless, egg-laying, spiny mammal of the order Monotremata, found in Australia and New Guinea. There are two species: *Tachyglossus aculeatus*, the short-nosed echidna, and the rarer *Zaglossus bruijnii*, the long-nosed echidna. They feed entirely upon ants and termites, which they dig out with their powerful claws and lick up with their prehensile tongues. When attacked, an echidna rolls itself into a ball, or tries to hide by burrowing in the earth.

echinoderm marine invertebrate of the phylum Echinodermata ('spiny-skinned'), characterized by a five-radial symmetry. Echinoderms have a water-vascular system which transports substances around the body. They include starfishes (or sea stars), brittle-stars, sea lilies, sea urchins, and sea cucumbers. The skeleton is external, made of a series of limy plates. Echinoderms generally move by using tube-feet, small water-filled sacs that can be protruded or pulled back to the body.

Echinodermata phylum of invertebrate animals, members of which are called echinoderms.

echo in computing, user input that is printed to the screen so the user can read it.

echo repetition of a sound wave, or of a radar or sonar signal, by reflection from a surface. By accurately measuring the time taken for an echo to return to the transmitter, and by knowing the speed

of a radar signal (the speed of light) or a sonar signal (the speed of sound in water), it is possible to calculate the range of the object causing the echo (echolocation).

echolocation or *biosonar* method used by certain animals, notably bats, whales, and dolphins, to detect the positions of objects by using sound. The animal emits a stream of high-pitched sounds, generally at ultrasonic frequencies (beyond the range of human hearing), and listens for the returning echoes reflected off objects to determine their exact location.

The location of an object can be established by the time difference between the emitted sound and its differential return as an echo to the two ears. Echolocation is of particular value under conditions when normal vision is poor (at night in the case of bats, in murky water for dolphins). A few species of bird can also echolocate, including cave-dwelling birds such as some species of swiftlets and the South American Oil Bird.

The frequency range of bats' echolocation calls is 20–215 kHz. Many species produce a specific and identifiable pattern of sound. Bats vary in the way they use echolocation: some emit pure sounds lasting up to 150 milliseconds, while others use a series of shorter 'chirps'. Sounds may be emitted through the mouth or nostrils depending on species.

Echolocation was first described in the 1930s, though it was postulated by Italian biologist Lazzaro Spallanzani (1729–1799).

echo sounder or *sonar device* device that detects objects under water by means of sonar – by using reflected sound waves. Most boats are equipped with echo sounders to measure the water depth beneath them. An echo sounder consists of a transmitter, which emits an ultrasonic pulse, and a receiver, which detects the pulse after reflection from the seabed. The time between transmission and receipt of the reflected signal is a measure of the depth of water. Fishing boats use echo sounders to detect shoals of fish and navies use them to find enemy submarines.

eclampsia convulsions occurring during pregnancy following pre-eclampsia.

eclipse The two types of eclipse: lunar and solar. A lunar eclipse occurs when the Moon passes through the shadow of the Earth. A solar eclipse occurs when the Moon passes between the Sun and the Earth, blocking out the Sun's light. During a total solar eclipse, when the Moon completely covers the Sun, the Moon's shadow sweeps across the Earth's surface from west to east at a speed of 3,200 kph/2,000 mph.

Solar and Lunar Eclipses

Table does not include partial eclipses of the Moon.

| Month | Day | Type of eclipse | Duration of maximum eclipse | Region for observation |
|-------------|-----|-----------------|-----------------------------|-------------------------------------------------------------------|
| 1998 | | | | |
| February | 26 | solar total | 17 hr 39 min | southern and eastern USA, Central America, northern South America |
| August | 22 | solar annular | 2 hr 7 min | Southeast Asia, Oceania, Australasia |
| 1999 | | | | |
| February | 16 | solar annular | 6 hr 35 min | southern Indian Ocean, Antarctica, Australia |
| August | 11 | solar total | 11 hr 4 min | Europe, North Africa, Arabia, western Asia |
| 2000 | | | | |
| January | 21 | lunar total | 4 hr 44 min | the Americas, Europe, Africa, western Asia |
| February | 5 | solar partial | 12 hr 50 min | Antarctica |
| July | 1 | solar partial | 19 hr 34 min | southeastern Pacific Ocean |
| July | 16 | lunar total | 13 hr 56 min | southeastern Asia, Australasia |
| July | 31 | solar partial | 2 hr 14 min | Arctic regions |
| December | 25 | solar partial | 17 hr 36 min | USA, eastern Canada, Central America, Caribbean |
| 2001 | | | | |
| January | 9 | lunar total | 20 hr 21 min | Africa, Europe, Asia |
| June | 21 | solar total | 12 hr 4 min | central and southern Africa |
| December | 14 | solar annular | 20 hr 52 min | Pacific Ocean |

eclipse passage of an astronomical body through the shadow of another.

The term is usually employed for solar and lunar eclipses, which may be either partial or total, but also, for example, for eclipses by Jupiter of its satellites. An eclipse of a star by a body in the Solar System is called an occultation.

A solar eclipse occurs when the Moon passes in front of the Sun as seen from Earth, and can happen only at new Moon. During a total eclipse the Sun's corona can be seen. A total solar eclipse can last up to 7.5 minutes. When the Moon is at its farthest from Earth it does not completely cover the face of the Sun, leaving a ring of sunlight visible. This is an annular eclipse (from the Latin word *annulus* 'ring'). Between two and five solar eclipses occur each year.

A lunar eclipse occurs when the Moon passes into the shadow of the Earth, becoming dim until emerging from the shadow. Lunar eclipses may be partial or total, and they can happen only at full Moon. Total lunar eclipses last for up to 100 minutes; the maximum number each year is three.

eclipsing binary binary (double) star in which the two stars periodically pass in front of each other as seen from Earth.

When one star crosses in front of the other the total light received on Earth from the two stars declines. The first eclipsing binary to be noticed was δ Algol.

ecliptic path, against the background of stars, that the Sun appears to follow each year as it is orbited by the Earth. It can be thought of as the plane of the Earth's orbit projected on to the celestial sphere (imaginary sphere around the Earth).

The ecliptic is tilted at about 23.5° with respect to the celestial equator, a result of the tilt of the Earth's axis relative to the plane of its orbit around the Sun.

ecliptic coordinates in astronomy, a system for measuring the position of astronomical objects on the celestial sphere with reference to the plane of the Earth's orbit, the ecliptic.

Ecliptic latitude (symbol B) is measured in degrees from the ecliptic ($B = 0^\circ$) to the north ($B = 90^\circ$) and south ($B = -90^\circ$) ecliptic poles.

Ecliptic longitude (symbol λ) is measured in degrees eastward along the ecliptic ($\lambda = 0^\circ$ to 360°) from a fixed point known as the first point of Aries or the vernal equinox. Ecliptic coordinates are often used to measure the positions of the Sun and planets with respect to the Earth.

Ecliptic latitude and longitude are sometimes known as celestial latitude and longitude or declination and ascension. The ecliptic

longitude of the Sun (solar longitude) is a convenient measure of the position of the Earth in its orbit.

WHAT THE HECK IS AN E. COLI?

<http://falcon.cc.ukans.edu/~jbrown/ecoli.html>

Explains the basics behind this bacterium, including information on the dangerous strain of the bacterium and how it developed. It contains guidelines to reduce the risk of infection. There are a number of links throughout the article to sites expanding on issues raised.

E. coli abbreviation for *Escherichia coli*.

ecology Greek *oikos* 'house' study of the relationship among organisms and the environments in which they live, including all living and nonliving components. The chief environmental factors governing the distribution of plants and animals are temperature, humidity, soil, light intensity, daylength, food supply, and interaction with other organisms. The term was coined by the biologist Ernst Haeckel in 1866.

Ecology may be concerned with individual organisms (for example, behavioural ecology, feeding strategies), with populations (for example, population dynamics), or with entire communities (for example, competition between species for access to resources in an ecosystem, or predator-prey relationships). Applied ecology is concerned with the management and conservation of habitats and the consequences and control of pollution.

We are unravelling nature like an old jumper.

PENNY KEMP English ecologist.

A Green Manifesto for the 1990s ch 4

EcoNet in computing, one of several international computer networks dedicated to environmental issues.

Ecology: chronology

| | | | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c. 325 BC | Greek scholar Theophrastus wrote about the relationship between organisms, and between organisms and their environment – the first ecological study. | 1934 | Russian ecologist G F Gause first stated the principles of competitive exclusion, related to a species' niche. |
| 1735 | Swedish naturalist Carl Linnaeus developed his system for classifying and naming plants and animals. | 1935 | British ecologist Arthur Tansley first coined the term 'ecosystem'. |
| 1798 | English cleric Thomas Malthus produced the earliest theoretical study of population dynamics. | 1938 | The coelacanth, a marine fish believed to have become extinct 65 million years ago, was 'rediscovered' in the Indian Ocean. |
| 1859 | English naturalist Charles Darwin published his 'On the Origin of Species'. | 1940 | Population biologist Charles Elton developed the idea of trophic levels in a community of organisms. |
| 1869 | German zoologist Ernst Haeckel first defined the term 'ecology'. | 1950 | The theory that natural selection may favour either individuals with high reproductive rates and rapid development (r-selection) or individuals with low reproductive rates and better competitive ability (k-selection) was first discussed. |
| 1899 | US botanist Henry Cowles published his classic paper on succession in sand dunes on Lake Michigan, USA. | 1967 | US biologists MacArthur and Wilson proposed their 'Theory of Island Biogeography' which related population and community size to island size. The theory is still widely used in the design of nature reserves today. |
| 1913 | British Ecological Society founded. | 1967 | US biologists MacArthur and Wilson proposed their 'Theory of Island Biogeography' which related population and community size to island size. The theory is still widely used in the design of nature reserves today. |
| 1915 | Ecological Society of America founded. | 1979 | English naturalist James Lovelock proposed his Gaia hypothesis, viewing the planet as a single organism. |
| 1916 | US ecologist Frederic Clements coined the phrase 'climax communities' for large areas of rather uniform vegetation which he attributed to climatic factors. | 1993 | UN Convention on Biological Diversity came into force. |
| 1926 | Russian botanist N I Vavilov published <i>Centres of Origin of Cultivated Plants</i> , concluding that there are relatively few such centres, many of which are located in mountainous areas. | | |

ecosystem in ecology, an integrated unit consisting of the community of living organisms and the nonliving, or physical, environment in a particular area. The relationships among species in an ecosystem are usually complex and finely balanced, and removal of any one species may be disastrous. The removal of a major predator, for example, can result in the destruction of the ecosystem through overgrazing by herbivores.

Ecosystems can be identified at different scales – for example, the global ecosystem consists of all the organisms living on Earth, the Earth itself (both land and sea), and the atmosphere above; a freshwater-pond ecosystem consists of the plants and animals living in the pond, the pond water and all the substances dissolved or suspended in that water, and the rocks, mud, and decaying matter that make up the pond bottom.

Energy and nutrients pass through organisms in an ecosystem in a particular sequence (see food chain): energy is captured through photosynthesis, and nutrients are taken up from the soil or water by plants; both are passed to herbivores that eat the plants and then to carnivores that feed on herbivores. These nutrients are returned to the soil through the decomposition of excrement and dead organisms, thus completing a cycle that is crucial to the stability and survival of the ecosystem.

tested by the US army in 1953, but was otherwise largely forgotten until the mid-1970s. It can be synthesized from nutmeg oil. Since 1996 chemical recipes for making the drug have been circulated on the Internet.

ECT abbreviation for electroconvulsive therapy.

ectoparasite parasite that lives on the outer surface of its host.

ectopic in medicine, term applied to an anatomical feature that is displaced or found in an abnormal position. An ectopic pregnancy is one occurring outside the womb, usually in a Fallopian tube.

ectoplasm outer layer of a cell's cytoplasm.

ectotherm 'cold-blooded' animal (see poikilothermy), such as a lizard, that relies on external warmth (ultimately from the Sun) to raise its body temperature so that it can become active. To cool the body, ectotherms seek out a cooler environment.

eczema inflammatory skin condition, a form of dermatitis, marked by dryness, rashes, itching, the formation of blisters, and the exudation of fluid. It may be allergic in origin and is sometimes complicated by infection.

eddy current electric current induced, in accordance with Faraday's laws, in a conductor located in a changing magnetic field. Eddy currents can cause much wasted energy in the cores of transformers and other electrical machines.

edelweiss perennial alpine plant belonging to the daisy family, with a white, woolly, star-shaped flower, found in the high mountains of Europe and Asia. (*Leontopodium alpinum*, family Compositae.)

edge connector in computing, an electrical connection formed by taking some of the metallic tracks on a printed circuit board to the edge of the board and using them to plug directly into a matching socket.

ECSTASY.ORG

<http://www.ecstasy.org/>

Huge clearing house for information on this popular recreational drug. Contents of this much-visited site include instructions for paramedics and hospital staff, how to get an ecstasy sample chemically assessed, how to recognise danger signs, notes on the dance drug scene, and what to do if arrested for possession. On the question of the dangers of the drug, the site is noncommittal, presenting a huge sample of contradictory scientific opinion assessing the toxicity and long-term dangers of MDMA.

ecstasy or **MDMA** (3,4-methylenedioxymethamphetamine) illegal drug in increasing use from the 1980s. It is a modified amphetamine with mild psychedelic effects, and works by depleting serotonin (a neurotransmitter) in the brain. Its long-term effects are unknown, but animal experiments have shown brain damage.

Ecstasy was first synthesized in 1914 by the Merck pharmaceutical company in Germany, and was one of eight psychedelics

EDISON, THOMAS

<http://hfm.umd.umich.edu/histories/edison/tae.html>

Short, illustrated biography of the US inventor, plus a chronology and bibliography. It includes sections on such topics as his childhood and the electric light.

Edison, Thomas Alva (1847-1931)

US scientist and inventor, whose work in the fields of communications and electrical power greatly influenced the world in which we live. With more than 1,000 patents, Edison produced his most important inventions in Menlo Park, New Jersey 1876-87, including the phonograph and the electric light bulb in 1879. He also constructed a system of electric power distribution for consumers, the telephone transmitter, and the megaphone.

telegraphy and telephony Edison's first success came in the area of telegraphy. Perceiving the need for rapid communications after the Civil War, his first invention was an automatic repeater for telegraphic messages. He then invented a tape machine called a "ticker," which communicated stock exchange prices across the country.

Turning his attention to the transmission of the human voice over long distances in 1876, he patented an electric transmitter system that proved to be less

commercially successful than the telephone of Bell and Gray, patented a few months later. Undeterred, Edison set about improving their system, culminating in his invention of the carbon transmitter, which so increased the volume of the telephone signal that it was used as a microphone in the Bell telephone.

the light bulb While experimenting with the carbon microphone in the 1870s,

Edison had toyed briefly with the idea of using a thin carbon filament as a light source in an incandescent electric lamp. He returned to the idea in 1879. His first major success came on 19 October of that year when, using carbonized sewing cotton mounted on an electrode in a vacuum (one millionth of an atmosphere), he obtained a source that remained aglow for 45 hours without overheating — a major problem with all other materials used. He and his assistants tried 6,000 other organic materials before finding a bamboo fibre that gave a bulb life of 1,000 hours. **generators and the first power stations** To produce a serious rival to gas illumination, a power source was required as well as a cheap and reliable lamp. The alternatives were either generators or heavy and expensive batteries. At that time, the best generators rarely converted more than 40% of the mechanical energy into electrical energy. Edison's first generator consisted of a drum armature of soft iron wire and a simple bi-polar magnet, and was designed to operate one arc lamp and some incandescent lamps in series.

A few months later he built a much more ambitious generator, the largest built to date; weighing 500 kg/1,103 lb and with an efficiency of 82%. Edison's team were at the forefront of development in generator technology over the next decade, during which efficiency was raised above 90%. To complete his electrical system he designed cables to carry power into the home from small (by modern standards) generating stations, and also invented an electricity meter to record its use.

the phonograph In 1877 he began the era of recorded sound by inventing the phonograph, a device in which the vibrations of the human voice were engraved by a needle on a revolving cylinder coated with tin foil.

Mary Evans Picture Library

Edge connectors are often used to connect the computer's main circuit board, or motherboard, to the expansion boards that provide the computer with extra memory or other facilities.

EDI in computing, abbreviation for ϕ electronic data interchange.

EDIFACT (acronym from *electronic data interchange for administration, commerce, and trade*) in computing, the ISO and ANSI standard system for handling EDI transactions.

editing in computing, act of creating, changing, and formatting word processor documents or pages for distribution on the World Wide Web.

EDO RAM (abbreviation for *extended data out random-access memory*) in computing, faster type of ϕ RAM introduced in the mid-1990s.

EDP in computing, abbreviation for ϕ electronic data processing.

Educational Resources Information Center in computing, database of resources for education available on the Internet. See ϕ ERIC.

edutainment (contraction of *education and entertainment*) ϕ multimedia-related term, used to describe computer software that is both educational and entertaining. Examples include educational software for children that teaches them to spell or count while playing games, and CD-ROMs about machines that contain animations showing how the machines work. Compare ϕ infotainment.

Edwards Air Force Base military USAF centre in California, situated on a dry lake bed, often used as a landing site by the Space Shuttle.

EEG abbreviation for ϕ electroencephalogram.

eel any fish of the order Anguilliformes. Eels are snakelike, with

elongated dorsal and anal fins. They include the freshwater eels of Europe and North America (which breed in the Atlantic), the marine conger eels, and the morays of tropical coral reefs.

A new species of moray eel was discovered 1995 off the coasts of Oman and Somalia. It is up to 60 cm/2 ft in length with a large black blotch around the gill openings.

eelgrass or tape grass or glass wrack any of several aquatic plants, especially *Zostera marina*. Eelgrass is found in tidal mud flats and is one of the few flowering plants to adapt to marine conditions, being completely submerged at high tide. (Genus *Zostera*, family Zosteraceae.)

eelpout freshwater fish also called a ϕ burbot.

EEPROM (acronym for *electrically erasable programmable read-only memory*) computer memory that can record data and retain it indefinitely. The data can be erased with an electrical charge and new data recorded.

Some EEPROM must be removed from the computer and erased and reprogrammed using a special device. Other EEPROM, called **flash memory**, can be erased and reprogrammed without removal from the computer.

EFF abbreviation for ϕ Electronic Frontier Foundation.

Effelsberg site, near Bonn, Germany, of the world's largest fully steerable radio telescope, the 100-m/328-ft radio dish of the Max Planck Institute for Radio Astronomy, opened in 1971.

efficiency in physics, a general term indicating the degree to which a process or device can convert energy from one form to another without loss. It is normally expressed as a fraction or percentage, where 100% indicates conversion with no loss. The efficiency of a machine, for example, is the ratio of the work done by the machine to the energy put into the machine; in practice it is

always less than 100% because of frictional heat losses. Certain electrical machines with no moving parts, such as transformers, can approach 100% efficiency.

Since the ζ mechanical advantage, or force ratio, is the ratio of the load (the output force) to the effort (the input force), and the ζ velocity ratio is the distance moved by the effort divided by the distance moved by the load, for certain machines the efficiency can also be defined as the mechanical advantage divided by the velocity ratio.

efflorescence loss of water or crystallization of crystals exposed to air, resulting in a dry powdery surface.

ETPOS (acronym for *electronic funds transfer at point of sale*), a form of electronic funds transfer.

EGA (abbreviation for *enhanced graphics array*) computer colour display system superior to ζ CGA (colour graphics adapter), providing 16 colours on screen and a resolution of 640 x 350, but not as good as ζ VGA.

egestion the removal of undigested food or faeces from the gut. In most animals egestion takes place via the anus, although the invertebrate flatworms must use the mouth because their gut has

no exit. Egestion is the last part of a complex feeding process that starts with food capture and continues with digestion and assimilation.

egg in animals, the ovum, or female ζ gamete (reproductive cell).

After fertilization by a sperm cell, it begins to divide to form an embryo. Eggs may be deposited by the female (ζ ovipary) or they may develop within her body (ζ vivipary and ζ ovovivipary). In the oviparous reptiles and birds, the egg is protected by a shell, and well supplied with nutrients in the form of yolk.

eggarmoth large reddish-brown moth with a highly developed hindwing. The length across the wings is 3.8–11.5 cm/1.5–4.5 in.

The walls of the cocoons sometimes have a smooth, shell-like appearance, hence the name.

classification The eggarmoth in the family Lasiocampidae, order Lepidoptera, class Insecta, phylum Arthropoda.

eggplant another name for ζ aubergine.

ego *Latin* 'I' in psychology, the processes concerned with the self and a person's conception of himself or herself, encompassing values and attitudes. In Freudian psychology, the term refers specifically to the element of the human mind that represents the conscious processes concerned with reality, in conflict with the ζ id (the instinctual element) and the ζ superego (the ethically aware element).

No other manmade device since the shields and lances of the ancient knights fulfils a man's ego like an automobile.

ROOTES English car manufacturer.

Quoted in 'Who Said That?', BBC TV, 14 Jan 1958

Section through a fertilized egg

egg Section through a fertilized bird egg. Inside a bird's egg is a complex structure of liquids and membranes designed to meet the needs of the growing embryo. The yolk, which is rich in fat, is gradually absorbed by the embryo. The white of the egg provides protein and water. The chalaza is a twisted band of protein which holds the yolk in place and acts as a shock absorber. The airspace allows gases to be exchanged through the shell. The allantois contains many blood vessels which carry gases between the embryo and the outside.

egret any of several ζ herons with long tufts of feathers on the head or neck. They belong to the order Ciconiiformes.

eider large marine ζ duck of the genus *Somateria*, family Anatidae, order Anseriformes. They are found on the northern coasts of the Atlantic and Pacific Oceans. The common eider *S. mollissima* is highly valued for its soft down, which is used in quilts and cushions for warmth. The adult male has a black cap and belly and a green nape. The rest of the plumage is white with a pink breast and throat, while the female is a mottled brown. The bill is large and flattened and both bill and feet are olive green.

Other species are the king eider-duck *S. spectabilis*, Steller's eider *Polysticta stelleri*, and the spectacled eider *S. fischeri*.

eidophor television projection system that produces pictures up to 10 m/33 ft square, at sports events or rock concerts, for example. The system uses three coloured beams of light, one of each primary colour (red, blue, and green), which scan the screen. The intensity of each beam is controlled by the strength of the corresponding colour in the television picture.

Imagination is more important than knowledge.

ALBERT EINSTEIN German-born US physicist.
On Science

EINSTEIN'S LEGACY

<http://www.ncsa.uiuc.edu/Cyberia/NumRel/EinsteinLegacy.html>

Illustrated introduction to the man and his greatest legacy – relativity and the concept of space-time. There is a film and audio clip version of the page courtesy of a US scientist and details about how current research is linked to Einstein's revolutionary ideas.

Einstein, Albert (1879–1955)

German-born US physicist whose theories of relativity revolutionized our understanding of matter, space, and time. Einstein established that light may have a particle nature and deduced the photoelectric law, for which he was awarded the Nobel Prize for Physics in 1921. He also investigated Brownian motion, confirming the existence of atoms. His last conception of the basic laws governing the universe was outlined in his unified field theory, made public in 1953.

Brownian motion Einstein's first major achievement concerned Brownian movement, the random movement of fine particles that can be seen through a microscope, which was first observed in 1827 by Robert Brown when studying a suspension of pollen grains in water. The motion of the pollen grains increased when the temperature increased but decreased if larger particles were used. Einstein explained this phenomenon as being the effect of large numbers of molecules (in this case, water molecules) bombarding the particles. He was able to make predictions of the movement and sizes of the particles, which were later verified experimentally by the French physicist Jean Perrin (1870–1942).

Einstein's explanation of Brownian motion and its subsequent experimental confirmation was one of the most important pieces of evidence for the hypothesis that matter is composed of atoms. Experiments based on this work were used to obtain an accurate value of Avogadro's number (the number of atoms in one mole of a substance) and the first accurate values of atomic size.

the photoelectric effect and the Nobel Prize Einstein's work on photoelectricity began with an explanation of the radiation law proposed in 1901 by Max Planck: $E=h\nu$, where E is the energy of radiation, h is Planck's constant, and ν is the frequency of radiation. Einstein suggested that packets of light energy are capable of behaving as particles called 'light quanta' (later called photons). Einstein used this hypothesis to explain the photoelectric effect, proposing that light particles striking the surface of certain metals cause electrons to be emitted.

It had been found experimentally that electrons are not emitted by light of less than a certain frequency ν_0 : that when electrons are emitted, their energy increases with an increase in the frequency of the light; and that an increase in light intensity produces more electrons but does not increase their energy. Einstein suggested that the kinetic energy of each electron, $\frac{1}{2}mv^2$, is equal to the difference in the incident light energy $h\nu$ and the light energy needed to overcome the threshold of emission, $h\nu_0$. This can be written mathematically as:

$$\frac{1}{2}mv^2 = h\nu - h\nu_0$$

the speed of light and the special theory of relativity The special theory of relativity started with the premises that (1) the laws of nature are the same for all observers in unaccelerated motion, and (2) the speed of light is independent of the motion of its source. Until then, there had been a steady accumulation of knowledge that suggested that light and other electromagnetic radiation do not

behave as predicted by classical physics. It proved impossible, for example, to measure the expected changes in the speed of light relative to the motion of the Earth. The Michelson–Morley experiment demonstrated that the velocity of light is constant and does not vary with the motion of either the source or the observer. Their experiment also confirmed that no 'ether' exists in the Universe as a medium to carry light waves, as was required by classical physics.

These findings did not worry Einstein, who viewed light as behaving like particles. He recognized that light, being different from waves that travel in a medium, has a measured speed that is independent of the speed of the observer. Thus, contrary to everyday experience with phenomena such as sound waves, the velocity of light is the same for an observer travelling at high speed towards a light source as it is for an observer travelling rapidly away from the light source. To Einstein it followed that, if the speed of light is the same for both these observers, the time and distance framework they use to measure the speed of light cannot be the same. Time and distance vary, depending on the velocity of each observer.

From the notions of relative motion and the constant velocity of light, Einstein derived that, in a system in motion relative to an observer, length would be observed to decrease, time would slow down, and mass would increase. The magnitude of these effects is negligible at ordinary velocities and Newton's laws still hold good. But at velocities approaching that of light, they become substantial. If a system were to move at the velocity of light, to an observer carried with it, its length would be zero, time would be at a stop, and its mass would be infinite. Einstein therefore concluded that no system can move at a velocity equal to or greater than the velocity of light.

Einstein's conclusions regarding time dilation and mass increase were later verified with observations of fast-moving atomic clocks and cosmic rays. Einstein went on to show in 1907 that mass is related to energy by the famous equation $E=mc^2$, which indicates the enormous amount of energy that is stored as mass, some of which is released in radioactivity and nuclear reactions, for example in the Sun.

gravity and the general theory of relativity In the general theory of relativity, the properties of space–time were to be conceived as modified locally by the presence of a body with mass; and light rays should bend when they pass by a massive object. A planet's orbit around the Sun arises from its natural trajectory in modified space–time – there is no need to invoke, as Isaac Newton did, a force of gravity. General relativity theory was inspired by the simple idea that it is impossible in a small region to distinguish between acceleration and gravitation effects (as in a lift one feels heavier when it accelerates upwards).

Einstein used the general theory to account for an anomaly in the orbit of the planet Mercury that could not be explained by Newtonian mechanics. Furthermore, the general theory made two predictions concerning light and gravitation. The first was that a red shift is produced if light passes through an intense gravitational field, and this was subsequently detected in astronomical observations in 1925. The second was a prediction that the apparent positions of stars would shift when they are seen near the Sun because the Sun's intense gravity would bend the light rays from the stars as they pass the Sun. Einstein was triumphantly vindicated when observations of a solar eclipse in 1919 showed apparent shifts of exactly the amount he had predicted.

Mary Evans Picture Library

einsteinium synthesized, radioactive, metallic element of the actinide series, symbol Es, atomic number 99, relative atomic mass 254.09.

It was produced by the first thermonuclear explosion, in 1952,

and discovered in fallout debris in the form of the isotope Es-253 (half-life 20 days). Its longest-lived isotope, Es-254, with a half-life of 276 days, allowed the element to be studied at length. It is now synthesized by bombarding lower-numbered transuranic

elements in particle accelerators. It was first identified by A Giorso and his team who named it in 1955 after Albert Einstein, in honour of his theoretical studies of mass and energy.

EIS (abbreviation for *executive information systems*) software applications that extract information from an organization's computer applications and data files and present the data in a form required by management.

EISA (abbreviation for *extended industry standard architecture*) in computing, one of several types of δ data bus created to improve on the original ISA (industry standard architecture) design introduced with the IBM PC AT microcomputer in 1984. The EISA bus adds speed and capacity because it is a 32-bit bus (ISA is a 16-bit bus), although it can still accept ISA-compatible expansion cards.

The EISA bus was developed by a consortium of PC manufacturers to counter IBM's proprietary MCA (micro channel architecture) bus in 1987, but it has since been superseded by the δ PCI (peripheral component interconnect) bus designed by Intel. See also δ local bus.

ejecta in astronomy, any material thrown out of a δ crater due to volcanic eruption or the impact of a δ meteorite or other object. Ejecta from impact craters on the δ Moon often form long bright streaks known as rays, which in some cases can be traced for thousands of kilometres across the lunar surface.

ejector seat device for propelling an aircraft pilot out of the plane to parachute to safety in an emergency, invented by the British engineer James Martin (1893-1981). The first seats of 1945 were powered by a compressed spring; later seats used an explosive charge. By the early 1980s, 35,000 seats had been fitted worldwide, and the lives of 5,000 pilots saved by their use.

Seats that can be ejected on takeoff and landing or at low altitude were a major breakthrough of the 1980s. They are as effective as those originally designed for parachuting from high altitudes.

Ekman spiral effect in oceanography, theoretical description of a consequence of the δ Coriolis effect on ocean currents, whereby currents flow at an angle to the winds that drive them. It derives its name from the Swedish oceanographer Vagn Ekman (1874-1954).

In the northern hemisphere, surface currents are deflected to the right of the wind direction. The surface current then drives the subsurface layer at an angle to its original deflection. Consequent subsurface layers are similarly affected, so that the effect decreases with increasing depth. The result is that most water is transported at about right-angles to the wind direction. Directions are reversed in the southern hemisphere.

eland largest species of δ antelope, *Taurotragus oryx*. Pale fawn in colour, it is about 2 m/6 ft high, and both sexes have spiral horns about 45 cm/18 in long. It is found in central and southern Africa.

Elasmobranchii subclass of class Chondrichthyes (cartilaginous fish), which includes the δ sharks and δ rays. They are characterized by having five to seven pairs of gill clefts that open separately to the exterior and are not covered by a protective fold of skin.

elastic collision in physics, a collision between two or more bodies in which the total δ kinetic energy of the bodies is conserved (remains constant); none is converted into any other form of energy. The molecules of a gas may be considered to collide elastically, but large objects may not because some of their kinetic energy will be converted on collision to heat and sound, or used to deform the object.

elasticity in physics, the ability of a solid to recover its shape once deforming forces (stresses modifying its dimensions or shape) are removed. An elastic material obeys Hooke's law, which states that its deformation is proportional to the applied stress up to a certain point, called the **elastic limit**, beyond which additional stress will deform it permanently. Elastic materials include metals and rubber; however, all materials have some degree of elasticity.

elastomer any material with rubbery properties that stretches easily and then quickly returns to its original length when released.

Natural and synthetic rubbers and such materials as polychloroprene and butadiene copolymers are elastomers. The convoluted molecular chains making up these materials are uncoiled by a stretching force, but return to their original position when released because there are relatively few crosslinks between the chains.

elater beetle another name for δ click beetle.

E layer (formerly called the Kennelly-Heaviside layer) the lower regions (90-120 km/56-75 mi) of the δ ionosphere, which reflect radio waves, allowing their reception around the surface of the Earth. The E layer approaches the Earth by day and recedes from it at night.

elder in botany, any of a group of small trees or shrubs belonging to the honeysuckle family, native to North America, Europe, Asia, and North Africa. Some are grown as ornamentals for their showy yellow or white flower clusters and their colourful black or scarlet berries. (Genus *Sambucus*, family Caprifoliaceae.)

The American elder (*Sambucus canadensis*) reaches tree size and has blue berries. The common elder (*S. nigra*) of Europe, North Africa, and western Asia has pinnate leaves (leaflets growing either side of a stem) and heavy heads of small, sweet-scented, white flowers in early summer. These are followed by clusters of small, black, shiny berries. The scarlet-berried *S. racemosa* is found in parts of Europe, Asia, and North America.

electrical energy form of energy carried by an electric current. It may be converted into other forms of energy such as heat, light, and motion.

Through which a current I amperes passes and across which there is a potential difference of V volts is given by the formula:

$$W = IV$$

electrical relay an electromagnetic switch; see δ relay.

electrical safety measures taken to protect human beings from electric shock or from fires caused by electrical faults. They are of paramount importance in the design of electrical equipment. Safety measures include the fitting of earth wires, and fuses or circuit breakers; the insulation of wires; the double insulation of portable equipment; and the use of residual-current devices (RCDs), which will break a circuit and cut off all currents if there is any imbalance between the currents in the live and neutral wires connected to an appliance (caused, for example, if some current is being conducted through a person).

The effects of electric shock vary from a tingling sensation to temporary paralysis and even death, and depend upon the amount of current passing through the body, and upon whether it passes through the central nervous system thereby affecting brain and heart function. Fires are usually caused by overheated cables or loose connections.

electric arc a continuous electric discharge of high current between two electrodes, giving out a brilliant light and heat. The phenomenon is exploited in the carbon-arc lamp, once widely used in film projectors. In the electric-arc furnace an arc struck between very large carbon electrodes and the metal charge provides the heating. In arc welding an electric arc provides the heat to fuse the metal. The discharges in low-pressure gases, as in neon and sodium lights, can also be broadly considered as electric arcs.

electric bell a bell that makes use of electromagnetism. At its heart is a wire-wound coil on an iron core (an electromagnet) which, when a direct current (from a battery) flows through it, attracts an iron δ armature. The armature acts as a switch, whose movement causes contact with an adjustable contact point to be broken, so breaking the circuit. A spring rapidly returns the armature to the contact point, once again closing the circuit, and so bringing about the oscillation. The armature oscillates back and forth, and the clapper or hammer fixed to the armature strikes the bell.

electric charge property of some bodies that causes them to exert forces on each other. Two bodies both with positive or both with

negative charges repel, each other, whereas bodies with opposite or 'unlike' charges attract each other, since each is in the electric field of the other. In atoms, electrons possess a negative charge, and protons an equal positive charge. The SI unit of electric charge is the coulomb (symbol C).

A body can be charged by friction, induction, or chemical change and shows itself as an accumulation of electrons (negative charge) or loss of electrons (positive charge) on an atom or body. Atoms have no charge but can sometimes gain electrons to become negative ions or lose them to become positive ions. So-called static electricity, seen in such phenomena as the charging of nylon shirts when they are pulled on or off, or in brushing hair, is in fact the gain or loss of electrons from the surface atoms. A flow of charge (such as electrons through a copper wire) constitutes an electric current; the flow of current is measured in amperes (symbol A).

electric current the flow of electrically charged particles through a conducting circuit due to the presence of a potential difference. The current at any point in a circuit is the amount of charge flowing per second; its SI unit is the ampere (coulomb per second).

Current carries electrical energy from a power supply, such as a battery of electrical cells, to the components of the circuit, where it is converted into other forms of energy, such as heat, light, or motion. It may be either direct current or alternating current.

heating effect When current flows in a component possessing resistance, electrical energy is converted into heat energy. If the resistance of the component is R ohms and the current through it is I amperes, then the heat energy W (in joules) generated in a time t seconds is given by the formula:

$$W = I^2 R t$$

magnetic effect A magnetic field is created around all conductors that carry a current. When a current-bearing conductor is made into a coil it forms an electromagnet with a magnetic field that is similar to that of a bar magnet, but which disappears as soon as the current is switched off. The strength of the magnetic field is directly proportional to the current in the conductor – a property that allows a small electromagnet to be used to produce a pattern of magnetism on recording tape or disc that accurately represents the sound or data to be stored. The direction of the field created around a conducting wire may be predicted by using Maxwell's screw rule.

motor effect A conductor carrying current in a magnetic field experiences a force, and is impelled to move in a direction perpendicular to both the direction of the current and the direction of the magnetic field. The direction of motion may be predicted by Fleming's left-hand rule (see Fleming's rules). The magnitude of the force experienced depends on the length of the conductor and on the strengths of the current and the magnetic field, and is greatest when the conductor is at right angles to the field. A conductor wound into a coil that can rotate between the poles of a magnet forms the basis of an electric motor.

electric eel South American freshwater bony fish. It grows to almost 3 m/10 ft and the electric shock produced, normally for immobilizing prey, is enough to stun an adult human. Electric eels are not true eels.

classification *Electrophorus electricus* is in the order Cypriniformes, class Osteichthyes.

electric field in physics, a region in which a particle possessing electric charge experiences a force owing to the presence of another electric charge. The strength of an electric field, E , is measured in volts per metre ($V\ m^{-1}$). It is a type of electromagnetic field.

electric fish any of several unrelated fishes that have electricity-producing powers, including the South American 'electric eel'. These include *Electrophorus electricus*, which is not a true eel, and in which the lateral tail muscles are modified to form electric organs capable of generating 650 volts; the current passing from tail to head is strong enough to stun another animal. Not all electric fishes produce such strong discharges; most use weak electric fields to navigate and to detect nearby objects.

electricity all phenomena caused by electric charge, whether static or in motion. Electric charge is caused by an excess or deficit

SEE

Bees exposed to the electrical fields of high-voltage power cables produce their honey in an erratic manner. As a consequence, bee-keepers have learned not to place their hives under power cables.

of electrons in the charged substance, and an electric current is the movement of charge through a material. Substances may be electrical conductors, such as metals, that allow the passage of electricity through them readily, or insulators, such as rubber, that are extremely poor conductors. Substances with relatively poor conductivities that can be improved by the addition of heat or light are known as semiconductors.

electrical properties of solids The first artificial electrical phenomenon to be observed was that some naturally occurring materials such as amber, when rubbed with a piece of cloth, would then attract small objects such as dust and pieces of paper. Rubbing the object caused it to become electrically charged so that it had an excess or deficit of electrons. When the amber is rubbed with a piece of cloth electrons are transferred from the cloth to the amber so that the amber has an excess of electrons and is negatively charged, and the cloth has a deficit of electrons and is positively charged. This accumulation of charge is called static electricity.

This charge on the object exerts an electric field in the space around itself that can attract or repel other objects. It was discovered that there are only two types of charge, positive and negative, and that they neutralize one another. Objects with a like charge always repel one another while objects with an unlike charge attract each other. Neutral objects (such as pieces of paper) can be attracted to charged bodies by electrical induction. For example, the charge on a negatively charged body causes a separation of charge across the neutral body. The positive charges tend to move towards the side near the negatively charged body and the negative charges tend to move towards the opposite side so that the neutral body is weakly attracted to the charged body by induction.

The electroscope is a device used to demonstrate the presence of electric charges and to measure its size and whether it is positive or negative. The electroscope was invented by Michael Faraday.

current, charge, and energy An electric current in a material is the passage of charge through it. In metals and other conducting materials, the charge is carried by free electrons that are not bound tightly to the atoms and are thus able to move through the material. For charge to flow in a circuit there must be a potential difference (pd) applied across the circuit. This is often supplied in the form of a battery that has a positive terminal and a negative terminal. Under the influence of the potential difference, the electrons are repelled from the negative terminal side of the circuit and attracted to the positive terminal of the battery. A steady flow of electrons around the circuit is produced.

Current flowing through a circuit can be measured using an ammeter and is measured in amperes (or amps). A coulomb (C) is the unit of charge, defined as the charge passing a point in a wire each second when the current is exactly 1 amp. The unit of charge is named after Charles Augustin de Coulomb. Direct current (DC) flows continuously in one direction; alternating current (AC) flows alternately in each direction.

In a circuit the battery provides energy to make charge flow through the circuit. The amount of energy supplied to each unit of charge is called the electromotive force (emf). The unit of emf is the volt (V). A battery has an emf of 1 volt when it supplies 1 joule of energy to each coulomb of charge flowing through it. The energy carried by flowing charges can be used to do work, for example to light a bulb, to cause current to flow through a resistor, to emit radiation, or to produce heat. When the energy carried by a current is made to do work in this way, a potential difference can be measured across the circuit component concerned by a voltmeter or a cathode-ray oscilloscope. The potential difference is also measured in volts. Power, measured in watts, is the product of current and voltage.

Although potential difference and current measure different things, they are related to one another. This relationship was

discovered by Georg Ohm, and is expressed by Ohm's law: the current through a wire is proportional to the potential difference across its ends. The potential difference divided by the current is a constant for a given piece of wire. This constant for a given material is called the resistance.

conduction in liquids and gases In liquids, current can flow by the movement of charged ions through a solution or molten salt (the electrolyte), resulting in the migration of ions to the electrodes: positive ions (cations) to the negative electrode (cathode) and negative ions (anions) to the positive electrode (anode). This process is called electrolysis and represents bi-directional flow of charge as opposite charges move to oppositely charged electrodes. In metals, charges are only carried by free electrons and therefore move in only one direction.

electromagnetism Magnetic fields are produced either by current-carrying conductors or by permanent magnets. In current-carrying wires, the magnetic field lines are concentric circles around the wire. Their direction depends on the direction of the current and their strength on the size of the current.

If a conducting wire is moved within a magnetic field, the magnetic field acts on the free electrons within the conductor, displacing them and causing a current to flow. The force acting on the electrons and causing them to move is greatest when the wire is perpendicular to the magnetic field lines. The direction of the current is given by the left-hand rule. The generation of a current by the relative movement of a conductor in a magnetic field is called electromagnetic induction. This is the basis of how a dynamo works.

generation of electricity Electricity is the most useful and most convenient form of energy, readily convertible into heat and light and used to power machines. Electricity can be generated in one place and distributed anywhere because it readily flows through wires. It is generated at power stations where a suitable energy source is harnessed to drive (turbines that spin electricity generators. Current energy sources are coal, oil, water power (hydroelectricity), natural gas, and nuclear energy. Research is under way to increase the contribution of wind, tidal, solar, and geothermal power. Nuclear fuel has proved a more expensive source of electricity than initially anticipated and worldwide concern over radioactivity may limit its future development.

Electricity is generated at power stations at a voltage of about 25,000 volts, which is not a suitable voltage for long-distance transmission. For minimal power loss, transmission must take place at very high voltage (400,000 volts or more). The generated voltage is therefore increased ('stepped up') by a transformer. The resulting high-voltage electricity is then fed into the main arteries of the grid system, an interconnected network of power stations and distribution centres covering a large area. After transmission to a local substation, the line voltage is reduced by a step-down transformer and distributed to consumers.

Among specialized power units that convert energy directly to electrical energy without the intervention of any moving mechanisms, the most promising are thermionic converters. These use conventional fuels such as propane gas, as in portable military power packs, or, if refuelling is to be avoided, radioactive fuels, as in uncrewed navigational aids and spacecraft.

UK electricity generation was split into four companies in 1990 in preparation for privatization. The nuclear power stations remain in the hands of the state through Nuclear Electric (accounting for 20% of electricity generated); National Power (50%) and PowerGen (30%) generate electricity from fossil-fuel and renewable sources. Transmission lines and substations are owned by the National Grid, which was privatized in 1996.

Electricity generated on a commercial scale was available from the early 1880s and used for electric motors driving all kinds of machinery, and for lighting, first by carbon arc, but later by incandescent filaments (first of carbon and then of tungsten), enclosed in glass bulbs partially filled with inert gas under vacuum. Light is also produced by passing electricity through a gas or metal vapour or a fluorescent lamp. Other practical applications include telephone, radio, television, X-ray machines, and many other applications in electronics.

An important consideration in the design of electrical equipment is electrical safety. This includes measures to minimize the risk of

electric shock or fire caused by electrical faults. Safety measures include the fitting of earth wires, and fuses or circuit breakers, and the insulation of wires.

history The fact that amber has the power, after being rubbed, of attracting light objects, such as bits of straw and feathers, is said to have been known to Thales of Miletus and to the Roman naturalist Pliny. William Gilbert, Queen Elizabeth I's physician, found that many substances possessed this power, and he called it 'electric' after the Greek word meaning 'amber'.

In the early 1700s, it was recognized that there are two types of electricity and that unlike kinds attract each other and like kinds repel. The charge on glass rubbed with silk came to be known as positive electricity, and the charge on amber rubbed with wool as negative electricity. These two charges were found to cancel each other when brought together.

In 1800 Alessandro Volta found that a series of cells containing brine, in which were dipped plates of zinc and copper, gave an electric current, which later in the same year was shown to evolve hydrogen and oxygen when passed through water (see electrolysis). Humphry Davy, in 1807, decomposed soda and potash (both thought to be elements) and isolated the metals sodium and potassium, a discovery that led the way to electroplating. Other properties of electric currents discovered were the heating effect, now used in lighting and central heating, and the deflection of a magnetic needle, described by Hans Oersted in 1820 and elaborated by André Ampère in 1825. This work made possible the electric telegraph.

For Michael Faraday, the fact that an electric current passing through a wire caused a magnet to move suggested that moving a wire or coil of wire rapidly between the poles of a magnet would induce an electric current. He demonstrated this in 1831, producing the first dynamo, which became the basis of electrical engineering. The characteristics of currents were crystallized about 1827 by Georg Ohm, who showed that the current passing along a wire was equal to the electromotive force across the wire multiplied by a constant, which was the conductivity of the wire. The unit of resistance (ohm) is named after Ohm, the unit of emf (volt) is named after Volta, and the unit of current (amp) after Ampère.

The work of the late 1800s indicated the wide interconnections of electricity (with magnetism, heat, and light), and about 1855 James Clerk Maxwell formulated a single electromagnetic theory. The universal importance of electricity was decisively proved by the discovery that the atom, until then thought to be the ultimate particle of matter, is composed of a positively charged central core, the nucleus, about which negatively charged electrons rotate in various orbits.

electric motor a machine that converts electrical energy into mechanical energy. There are various types, including direct-current and induction motors, most of which produce rotary motion. A linear induction motor produces linear (in a straight line) rather than rotary motion.

electric motor In an electric motor, magnetic fields generated by electric currents push against each other, causing a shaft (the armature) to rotate.

A simple **direct-current motor** consists of a horseshoe-shaped permanent magnet with a wire-wound coil (armature) mounted so that it can rotate between the poles of the magnet. A commutator reverses the current (from a battery) fed to the coil on each half-turn, which rotates because of the mechanical force exerted on a conductor carrying a current in a magnetic field.

An induction motor employs alternating current. It comprises a stationary current-carrying coil (stator) surrounding another coil (rotor), which rotates because of the current induced in it by the magnetic field created by the stator; it thus requires no commutator.

electric organs specialized organs that discharge electricity and occur only in fish; see *electric fish*.

electric power the rate at which an electrical machine uses electrical energy or converts it into other forms of energy – for example, light, heat, mechanical energy. Usually measured in watts (equivalent to joules per second), it is equal to the product of the voltage and the current flowing.

An electric lamp that passes a current of 0.4 amperes at 250 volts uses 100 watts of electrical power and converts it into light and heat – in ordinary terms it is a 100-watt lamp. An electric motor that requires 6 amperes at the same voltage consumes 1,500 watts (1.5 kilowatts), equivalent to delivering about 2 horsepower of mechanical power.

electric ray another name for the *torpedo*.

electrocardiogram (ECG) graphic recording of the electrical activity of the heart, as detected by electrodes placed on the skin. Electrocardiography is used in the diagnosis of heart disease.

electrochemical series or **electromotive series** list of chemical elements arranged in descending order of the ease with which they can lose electrons to form cations (positive ions). An element can be displaced (displacement reaction) from a compound by any element above it in the series.

electrochemistry the branch of science that studies chemical reactions involving electricity. The use of electricity to produce chemical effects, *electrolysis*, is employed in many industrial processes, such as the manufacture of chlorine and the extraction of aluminium. The use of chemical reactions to produce electricity is the basis of electrical cells, such as the dry cell and the Leclanché cell.

Since all chemical reactions involve changes to the electronic structure of atoms, all reactions are now recognized as electrochemical in nature. Oxidation, for example, was once defined as a process in which oxygen was combined with a substance, or hydrogen was removed from a compound; it is now defined as a process in which electrons are lost.

Electrochemistry is also the basis of new methods of destroying toxic organic pollutants. For example, the development of electrochemical cells that operate with supercritical water (see *fluid, supercritical*) to combust organic waste materials.

electroconvulsive therapy (ECT) or **electroshock therapy** treatment mainly for severe depression, given under anaesthesia and with a muscle relaxant. An electric current is passed through one or both sides of the brain to induce alterations in its electrical activity. The treatment can cause distress and loss of concentration and memory, and so there is much controversy about its use and effectiveness.

ECT was first used in 1938 but its success in treating depression led to its excessive use for a wide range of mental illnesses against which it was ineffective. Its side effects included broken bones and severe memory loss.

The procedure in use today is much improved, using the minimum shock necessary to produce a seizure, administered under general anaesthetic with muscle relaxants to prevent spasms and fractures. It is the seizure rather than the shock itself that produces improvement. The smaller the shock administered the less damage there is to memory.

electrode any terminal by which an electric current passes in or out of a conducting substance; for example, the anode or cathode

in a battery or the carbons in an arc lamp. The terminals that emit and collect the flow of electrons in thermionic valves (electron tubes) are also called electrodes; for example, cathodes, plates, and grids.

electrodynamics the branch of physics dealing with electric charges, electric currents and associated forces. Quantum electrodynamics (QED) studies the interaction between charged particles and their emission and absorption of electromagnetic radiation. This field combines quantum theory and relativity theory, making accurate predictions about subatomic processes involving charged particles such as electrons and protons.

electroencephalogram (EEG) graphic record of the electrical discharges of the brain, as detected by electrodes placed on the scalp. The pattern of electrical activity revealed by electroencephalography is helpful in the diagnosis of some brain disorders, in particular epilepsy.

electrolysis in chemistry, the production of chemical changes by passing an electric current through a solution or molten salt (the electrolyte), resulting in the migration of ions to the electrodes: positive ions (cations) to the negative electrode (cathode) and negative ions (anions) to the positive electrode (anode).

During electrolysis, the ions react with the electrode, either receiving or giving up electrons. The resultant atoms may be liberated as a gas, or deposited as a solid on the electrode, in amounts that are proportional to the amount of current passed, as discovered by English chemist Michael Faraday. For instance, when acidified water is electrolysed, hydrogen ions (H^+) at the cathode receive electrons to form hydrogen gas; hydroxide ions (OH^-) at the anode give up electrons to form oxygen gas and water.

One application of electrolysis is **electroplating**, in which a solution of a salt, such as silver nitrate ($AgNO_3$), is used and the object to be plated acts as the negative electrode, thus attracting silver ions (Ag^+). Electrolysis is used in many industrial processes, such as coating metals for vehicles and ships, and refining bauxite into aluminium; it also forms the basis of a number of electrochemical analytical techniques, such as polarography.

electrolysis Passing an electric current through acidified water (such as diluted sulphuric acid) breaks down the water into its constituent elements – hydrogen and oxygen.

electrolyte solution or molten substance in which an electric current is made to flow by the movement and discharge of ions in accordance with Faraday's laws of electrolysis.

The term 'electrolyte' is frequently used to denote a substance that, when dissolved in a specified solvent, usually water,

dissociates into ions to produce an electrically conducting medium.

In medicine the term is often used for the ion itself (sodium or potassium, for example). Electrolyte balance may be severely disrupted in illness or injury.

electromagnet coil of wire wound around a soft iron core that acts as a magnet when an electric current flows through the wire. Electromagnets have many uses: in switches, electric bells, solenoids, and metal-lifting cranes.

electromagnetic field in physics, the region in which a particle with an electric charge experiences a force. If it does so only when

moving, it is in a pure magnetic field; if it does so when stationary, it is in an electric field. Both can be present simultaneously.

electromagnetic force one of the four fundamental forces of nature, the other three being gravity, the strong nuclear force, and the weak nuclear force. The elementary particle that is the carrier for the electromagnetic force is the photon.

electromagnetic induction in electronics, the production of an electromotive force (emf) in a circuit by a change of magnetic flux through the circuit or by relative motion of the circuit and the magnetic flux. In a closed circuit an induced current will be produced. All dynamos and generators make use of this effect. When magnetic tape is driven past the playback head (a small coil) of a tape-recorder, the moving magnetic field induces an emf in the head, which is then amplified to reproduce the recorded sounds.

If the change of magnetic flux is due to a variation in the current flowing in the same circuit, the phenomenon is known as self-induction; if it is due to a change of current flowing in another circuit it is known as mutual induction.

electromagnetic spectrum the complete range, over all wavelengths, of electromagnetic waves.

To remember the different categories of radiation, in order of increasing wavelength:

CARY GRANT EXPECTS UNANIMOUS VOTES IN MOVIE REVIEWS TONIGHT

COSMIC, GAMMA, X-RAYS,
ULTRAVIOLET, VISIBLE, INFRARED,
MICROWAVE, RADIO, TELEVISION

electromagnetic system of units former system of absolute electromagnetic units (emu) based on the c.g.s. system and having, as its primary electrical unit, the unit magnetic pole. It was replaced by SI units.

electromagnetic waves oscillating electric and magnetic fields travelling together through space at a speed of nearly 300,000 km/186,000 mi per second. The (dimless) range of possible wavelengths or frequencies of electromagnetic waves, which can be thought of as making up the electromagnetic spectrum, includes radio waves, infrared radiation, visible light, ultraviolet radiation, X-rays, and gamma rays.

electromotive force (emf) loosely, the voltage produced by an electric battery or generator in an electrical circuit or, more precisely, the energy supplied by a source of electric power in driving a unit charge around the circuit. The unit is the volt.

electron stable, negatively charged elementary particle; it is a constituent of all atoms, and a member of the class

electromagnetic waves Radio waves have the lowest frequency. Infrared radiation, visible light, ultraviolet radiation, X-rays, and gamma rays have progressively higher frequencies.

of particles known as leptons. The electrons in each atom surround the nucleus in groupings called shells; in a neutral atom the number of electrons is equal to the number of protons in the nucleus. This electron structure is responsible for the chemical properties of the atom (see atomic structure).

Electrons carry a charge of 1.602192×10^{-19} coulomb and have a mass of 9.109×10^{-31} kg, which is $1/1836$ times the mass of a proton. A beam of electrons will undergo diffraction (scattering) and produce interference patterns in the same way as electromagnetic waves such as light; hence they may be regarded as waves as well as particles.

The electron is not as simple as it looks.

WILLIAM HENRY BRAGG British physicist.
 Recounted by Sir George Paget Thompson
 at electron diffraction conference 1967

electronegativity the ease with which an atom can attract electrons to itself. Electronegative elements attract electrons, so forming negative ions.

Linus Pauling devised an electronegativity scale to indicate the relative power of attraction of elements for electrons. Fluorine, the most nonmetallic element, has a value of 4.0 on this scale; oxygen, the next most nonmetallic, has a value of 3.5.

In a covalent bond between two atoms of different electronegativities, the bonding electrons will be located close to the more electronegative atom, creating a dipole.

electron gun a part in many electronic devices consisting of a series of electrodes, including a cathode for producing an electron beam. It plays an essential role in cathode-ray tubes (television tubes) and electron microscopes.

electronic banking in computing, system whereby a user can execute banking transactions via a modem, either directly or through an online service or the Internet.

electronic book in computing, software with or without specialized hardware that provides the equivalent of a book's worth of information. The term is used generally to apply even to simple text files created by scanning printed books or manuals such as those created and archived by Project Gutenberg.

'Electronic Book' refers to a specific product released by Sony, a special player for small-sized CD-ROMs containing educational and reference material.

electronic cash in computing, see e-cash.

electronic commerce in computing, business-to-business use of networks such as the Internet to handle legally binding transactions. Traditionally, electronic commerce has required expensive membership of an electronic data interchange (EDI) service. In the mid-1990s, electronic commerce began to shift to the Internet to take advantage of its global reach and inexpensive connections. By 1996 many legal issues remained to be resolved.

Electronic Communications Privacy Act in computing, US law passed in 1986 that protects the privacy of e-mail and other electronic communications.

electronic conferencing in computing, public discussions conducted on an online service or via USENET; any participant may log in at any time and read the collected messages and add new ones.

Because of its time-independent, many-to-many nature, electronic conferencing can be used to provide some of the same functions as real-life meetings, classrooms, and unstructured socializing without requiring the participants to meet face-to-face. While electronic conferencing is no substitute for live interaction, it does allow people who are widely geographically separated or who might otherwise never meet to exchange ideas.

electronic data interchange (EDI) in computing, system for managing business-to-business transactions such as invoicing and

ordering to eliminate the wastefulness of paper-based transaction systems.

Traditionally, most EDI systems relied on proprietary protocols and private data networks, with the disadvantages that individual systems were incompatible. The growth of the Internet is now opening the way for the rapid adoption of global electronic commerce.

electronic flash discharge tube that produces a high-intensity flash of light, used for photography in dim conditions. The tube contains an inert gas such as krypton. The flash lasts only a few thousandths of a second.

Electronic Frontier Foundation (EFF) US organization that lobbies for the extension of civil liberties and constitutional rights into cyberspace. It was founded by former Grateful Dead lyricist John Perry Barlow and Lotus founder Mitch Kapor in 1991 after a series of US raids on suspected computer hackers. Its offices are in San Francisco.

electronic mail or E-mail messages sent electronically from computer to computer via network connections such as Ethernet or the Internet, or via telephone lines to a host system. Messages once sent are stored on the network or by the host system until the recipient picks them up.

Subscribers to an electronic mail system type messages in ordinary letter form on a word processor, or microcomputer, and 'drop' the letters into a central computer's memory bank by means of a computer/telephone connector (a modem). The recipient 'collects' the letter by calling up the central computer and feeding a unique password into the system.

electronic point of sale (EPOS) system used in retailing in which a bar code on a product is scanned at the cash till and the information relayed to the store computer. The computer will then relay back the price of the item to the cash till. The customer can then be given an itemized receipt while the computer removes the item from stock figures.

EPOS enables efficient computer stock control and reordering as well as giving a wealth of information about turnover, profitability on different lines, stock ratios, and other important financial indicators.

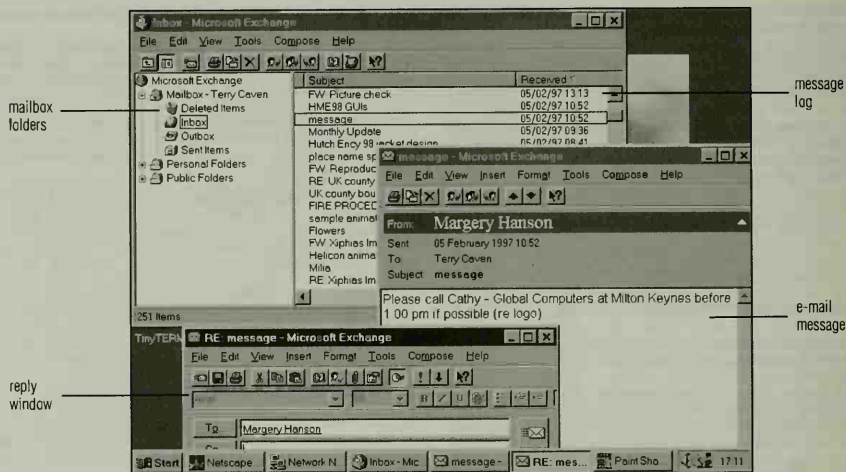

electronic publishing the distribution of information using computer-based media such as multimedia and hypertext in the creation of electronic 'books'. Critical technologies in the development of electronic publishing were CD-ROM, with its massive yet compact storage capabilities, and the advent of computer networking with its ability to deliver information instantaneously anywhere in the world.

electronics branch of science that deals with the emission of electrons from conductors and semiconductors, with the subsequent manipulation of these electrons, and with the construction of electronic devices. The first electronic device was the thermionic valve, or vacuum tube, in which electrons moved in a vacuum, and led to such inventions as radio, television, radar, and the digital computer. Replacement of valves with the comparatively tiny and reliable transistor from 1948 revolutionized electronic development. Modern electronic devices are based on minute integrated circuits (silicon chips), wafer-thin crystal slices holding tens of thousands of electronic components.

By using solid-state devices such as integrated circuits, extremely complex electronic circuits can be constructed, leading to the development of digital watches, pocket calculators, powerful microcomputers, and word processors.

electronic shopping in computing, using an online service or Internet service such as the World Wide Web to select and buy merchandise.

electron microscope instrument that produces a magnified image by using a beam of electrons instead of light rays, as in an optical microscope. An electron lens is an arrangement of electromagnetic coils that control and focus the beam. Electrons are not visible to the eye, so instead of an eyepiece there is a fluorescent screen or a photographic plate on which the electrons form an

electronic mail A typical E-mail user interface. Because messages can be created 'off-line' and are sent at high speed, line connection time, and therefore costs, can be kept to a minimum.

image. The wavelength of the electron beam is much shorter than that of light, so much greater magnification and resolution (ability to distinguish detail) can be achieved. The development of the electron microscope has made possible the observation of very minute organisms, viruses, and even large molecules.

electron microscope The scanning electron microscope. Electrons from the electron gun are focused to a fine point on the specimen surface by the lens systems. The beam is moved across the specimen by the scan coils. Secondary electrons are emitted by the specimen surface and pass through the detector, which produces an electrical signal. The signal is passed to an electronic console, and produces an image on a screen.

A transmission electron microscope passes the electron beam through a very thin slice of a specimen. A scanning electron microscope looks at the exterior of a specimen. A scanning transmission electron microscope (STEM) can produce a magnification of 90 million times. See also atomic force microscope.

electron probe microanalyser modified electron microscope in which the target emits X-rays when bombarded by electrons. Varying X-ray intensities indicate the presence of different chemical elements. The composition of a specimen can be mapped without the specimen being destroyed.

electrons, delocalized electrons that are not associated with individual atoms or identifiable chemical bonds, but are shared collectively by all the constituent atoms or ions of some chemical substances (such as metals, graphite, and aromatic compounds).

A metallic solid consists of a three-dimensional arrangement of metal ions through which the delocalized electrons are free to travel. Aromatic compounds are characterized by the sharing of delocalized electrons by several atoms within the molecule.

electrons, localized a pair of electrons in a covalent bond that are located in the vicinity of the nuclei of the two contributing atoms. Such electrons cannot move beyond this area.

electron volt unit (symbol eV) for measuring the energy of a charged particle (ion or electron) in terms of the energy of motion an electron would gain from a potential difference of one volt. Because it is so small, more usual units are mega-(million) and giga-(billion) electron volts (MeV and GeV).

electrophoresis the diffusion of charged particles through a fluid under the influence of an electric field. It can be used in the biological sciences to separate molecules of different sizes, which diffuse at different rates. In industry, electrophoresis is used in painting operations to ensure that paint reaches awkward corners.

electroplating deposition of metals upon metallic surfaces by electrolysis for decorative and/or protective purposes. It is used in the preparation of printers' blocks, 'master' audio discs, and in many other processes.

A current is passed through a bath containing a solution of a salt of the plating metal, the object to be plated being the cathode (negative terminal); the anode (positive terminal) is either an inert substance or the plating metal. Among the metals most commonly used for plating are zinc, nickel, chromium, cadmium, copper, silver, and gold.

In electropolishing, the object to be polished is made the anode in an electrolytic solution and by carefully controlling conditions the high spots on the surface are dissolved away, leaving a high-quality stain-free surface. This technique is useful in polishing irregular stainless-steel articles.

electroporation in biotechnology, technique of introducing foreign DNA into pollen with a strong burst of electricity, used in creating genetically engineered plants.

electropositivity in chemistry, a measure of the ability of elements (mainly metals) to donate electrons to form positive ions. The greater the metallic character, the more electropositive the element.

electrorheological fluid another name for ψ smart fluid, a liquid suspension that gels when an electric field is applied across it.

electroscope apparatus for detecting electric charge. The simple gold-leaf electroscope consists of a vertical conducting (metal) rod ending in a pair of rectangular pieces of gold foil, mounted inside and insulated from an earthed metal case or glass jar. An electric charge applied to the end of the metal rod makes the gold leaves diverge, because they each receive a similar charge (positive or negative) and so repel each other.

The polarity of the charge can be found by bringing up another charge of known polarity and applying it to the metal rod. A like charge has no effect on the gold leaves, whereas an opposite charge neutralizes the charge on the leaves and causes them to collapse.

electrostatic precipitator device that removes dust or other particles from air and other gases by electrostatic means. An electric discharge is passed through the gas, giving the impurities a negative electric charge. Positively charged plates are then used to attract the charged particles and remove them from the gas flow. Such devices are attached to the chimneys of coal-burning power stations to remove ash particles.

electrostatics the study of stationary electric charges and their fields (not currents). See static electricity.

electrovalent bond another name for an ionic bond, a chemical bond in which the combining atoms lose or gain electrons to form ions.

electrum naturally occurring alloy of gold and silver used by early civilizations to make the first coins, about the 6th century BC.

element substance that cannot be split chemically into simpler substances. The atoms of a particular element all have the same number of protons in their nuclei (their atomic number). Elements are classified in the periodic table of the elements. Of the known elements, 92 are known to occur in nature (those with atomic numbers 1–92). Those elements with atomic numbers above 92 do not occur in nature and are synthesized only, produced in particle accelerators. Of the elements, 81 are stable; all the others, which include atomic numbers 43, 61, and from 84 up, are radioactive.

Elements are classified as metals, nonmetals, or metalloids (weakly metallic elements) depending on a combination of their physical and chemical properties; about 75% are metallic. Some elements occur abundantly (oxygen, aluminium); others occur moderately or rarely (chromium, neon); some, in particular the radioactive ones, are found in minute (neptunium, plutonium) or very minute (technetium) amounts.

Symbols (devised by Swedish chemist Jöns J. Berzelius) are used to denote the elements; the symbol is usually the first letter or letters of the English or Latin name (for example, C for carbon, Ca for calcium, Fe for iron, from the Latin *ferrum*). The symbol represents one atom of the element.

According to current theories, hydrogen and helium were produced in the Big Bang at the beginning of the universe. Of the other elements, those up to atomic number 26 (iron) are made by nuclear fusion within the stars. The more massive elements, such as lead and uranium, are produced when an old star explodes; as its centre collapses, the gravitational energy squashes nuclei together to make new elements.

Two or more elements bonded together form a compound so that they cannot be separated by physical means. Compounds are held together by ionic or covalent bonds. The number of atoms of an element that combine together to form a molecule is its **atomicity**. A molecule of oxygen (O_2) has atomicity 2; sulphur (S_8) has atomicity 8.

element in mathematics, a member of a ψ set.

elementary particle in physics, a subatomic particle that is not made up of smaller particles, and so can be considered one of the fundamental units of matter. There are three groups of elementary particles: quarks, leptons, and gauge bosons.

Quarks, of which there are 12 types (up, down, charm, strange, top, and bottom, plus the antiparticles of each), combine in groups of three to produce heavy particles called baryons, and in groups of two to produce intermediate-mass particles called mesons. They and their composite particles are influenced by the strong nuclear force.

Leptons are light particles. Again, there are 12 types: the electron, muon, tau; their neutrinos, the electron neutrino, muon neutrino, and tau neutrino; and the antiparticles of each. These particles are influenced by the weak nuclear force.

Gauge bosons carry forces between other particles. There are four types: gluon, photon, weakon, and graviton. The gluon carries the strong nuclear force, the photon the electromagnetic force, the weakon the weak nuclear force, and the graviton the force of gravity (see forces, fundamental).

elements, the four earth, air, fire, and water. The Greek philosopher Empedocles believed that these four elements made up the fundamental components of all matter and that they were destroyed and renewed through the action of love and discord.

This belief was shared by Aristotle who also claimed that the elements were mutable and contained specific qualities: cold and dry for earth, hot and wet for air, hot and dry for fire, and cold and wet for water. The transformation of the elements formed the basis of medieval alchemy, and the belief that base metals could be turned into gold. The theory of the elements prevailed until the 17th century when Robert Boyle redefined an element as a substance 'simple or unmixed, not made of other bodies' and proposed the existence of a greater number than four.

elephant large grazing mammal with thick, grey wrinkled skin, large ears, a long flexible trunk, and huge curving tusks. There are fingerlike projections at the end of trunk used for grasping food and carrying it to its mouth. The trunk is also used for carrying water to the mouth. The elephant is herbivorous and, because of its huge size, much of its time must be spent feeding on leaves, shoots, bamboo, reeds, grasses and fruits and, where possible, cultivated crops such as maize and bananas. They are the largest living land animal.

Elephants usually live in herds containing between 20–40 females (cows), led by a mature, experienced cow. Most bull elephants live alone or in small groups; young males remain with the herd until they reach sexual maturity. Elephants have the longest gestation period of any animal (18–23 months between conception and birth) and usually produce one calf, which takes between 10–15 years to reach maturity. Elephants can live up to 60 years in

TO DISTINGUISH BETWEEN INDIAN AND AFRICAN ELEPHANTS:

INDIAN ELEPHANTS HAVE LITTLE EARS, AFRICAN ELEPHANTS HAVE LARGE EARS

ELEPHANT

http://www.fws.gov/~r9extaff/biologues/bio_elep.html

Presentation on the Asian and African elephant with details about their physical appearance, food, social life, status of protection, and more. It is a useful, quick reference tool for all those concerned about wildlife and its protection.

the wild, but those in captivity have been known to reach over 65. There are two species of elephant, the African and the Indian or Asian elephant.

Elephants have one of the lowest metabolic rates among placental mammals. Their tusks, which are initially tipped with enamel but later consist entirely of ivory, continue growing throughout life. They are preceded by milk tusks, which are shed at an early age. **species differences** The African elephant is much the larger of the two species, growing to heights of 4 m/13 ft and weighing up to 8 tonnes compared with the 2.7 m/9 ft and 4 tonnes of the Indian elephant. The African elephant has larger ears and longer tusks than its Asian relative (many Asian elephants, particularly the females are tuskless). The African elephant has a sloping forehead and a hollow back, whereas the Asian elephant has two domes on its forehead just above its ears, and an arched back. The trunk of the African elephant is ridged with two fingerlike projections; the Asian species only has a smooth trunk with one finger. The African species has four nails on its front foot and three on its hind (back) foot, whereas the Asian elephant has five on its front foot and four on its hind. African elephants live only in Africa, south of the Sahara desert. The Indian or Asian elephant can be found in parts of India and Southeast Asia.

Young Asian elephants are hairy, and in this respect somewhat resemble the extinct mammoth genus; the adults have smooth, nearly naked skin. The African species is of fiercer disposition and can move rapidly over rough ground.

endangered species Elephants are slaughtered for ivory, and this, coupled with the fact that they reproduce slowly and do not breed readily in captivity, is leading to their extinction. In Africa, over-hunting caused numbers to collapse during the 1980s and the elephant population of E Africa is threatened with extinction. There were 1.3 million African elephants in 1981; fewer than 700,000 in 1988; 600,000 in 1990; and fewer than 580,000 in 1997. They were placed on the CITES list of most endangered species in 1989, and a world ban on trade in ivory was imposed in 1990, resulting in an apparent drop in poaching. In 1997, at the 10th CITES convention, the elephant was downlisted to CITES Appendix II (vulnerable) and the ban on ivory exportation was lifted.

The Asian elephant was also listed on the CITES endangered list; its wild population in 1996 was only 35,000–54,000. There are about 10,000 working elephants in Asia, most of which are caught from the wild and 'tamed' by starvation and brutality.

It was estimated in 1997 that in Sri Lanka alone elephants might be extinct within ten years. The country's government maintained that there were 4,000 animals left, whereas the Wildlife and Nature Protection Society of Sri Lanka claimed there were only 2,500.

classification Elephants belong to the phylum Chordata, class Mammalia (mammals), order Proboscidea, family Elephantidae. There are two species, the African elephant (*Loxodonta africana*), and the Indian or Asian elephant (*Elephas maximus*).

elephant bird another name for extinct members of the genus *Aepyornis*.

elephantiasis in the human body, a condition of local enlargement and deformity, most often of a leg, though the scrotum, vulva, or breast may also be affected.

The commonest form of elephantiasis is the tropical variety (filariasis) caused by infestation by parasitic roundworms (filaria); the enlargement is due to damage of the lymphatic system which impairs immunity. This leaves sufferers susceptible to infection

from bacteria and fungi, entering through skin splits. The swelling reduces dramatically if the affected area is kept rigorously clean and treated with antibiotic cream, combined with rest, after drug treatment has killed all filarial worms.

elephant's tusk shell burrowing marine mollusc with a tusk-shaped shell open at both ends, from the larger of which the long foot appears and is used in creeping movements. The elephant's tusk shell has tentacles around its mouth, lacks eyes and heart, and lives in muddy sand sometimes at great depths of the sea.

classification Elephant's tusk shells are in genus *Dentalium*, class Scaphopoda, phylum Mollusca.

elephant-trunk fish African freshwater fish *Gnathonemus petersii* in the order Mormyridae. They grow to about 23 cm/9 in in length, have small eyes and fins and are mainly nocturnal. They generate an electric field which they use to detect obstacles. Elephant-trunk fish live in lakes in West and Central Africa.

Their brains are very large in proportion to their bodies: 3.1% of body mass compared with less than 1% for most fish and 2.3% for humans.

elevation a drawing to scale of one side of an object or building.

elevation of boiling point raising of the boiling point of a liquid above that of the pure solvent, caused by a substance being dissolved in it. The phenomenon is observed when salt is added to boiling water; the water ceases to boil because its boiling point has been elevated.

How much the boiling point is raised depends on the number of molecules of substance dissolved. For a single solvent, such as pure water, all substances in the same molecular concentration produce the same elevation of boiling point. The elevation e produced by the presence of a solute of molar concentration C is given by the equation $e = KC$, where K is a constant (called the ebullioscopic constant) for the solvent concerned.

elevator any mechanical device for raising or lowering goods or materials. Such a device used for lifting people in buildings is known as an elevator in the USA and as a lift in Britain.

elk large deer *Alces alces* inhabiting northern Europe, Asia, Scandinavia, and North America, where it is known as the moose. It is brown in colour, stands about 2 m/6 ft at the shoulders, has very large palmate antlers, a fleshy muzzle, short neck, and long legs. It feeds on leaves and shoots. In North America, the *čwapiti* is called an elk.

elkhound Norwegian dog resembling the *čhusky* but much smaller. Its coat is thick, with a full undercoat and the tail is bushy. Elkhounds are grey, with a darker shade on the back, and are about 50 cm/20 in high, weighing approximately 22 kg/48 lb.

elk, Irish extinct Pleistocene species of deer *Cervus megaceros*, the bones of which are found in Irish bogs and also in certain parts of Great Britain and mainland Europe. It stood about 2 m/6 ft in height, and is characterized by the enormous size of its antlers, which sometimes had a spread of almost 3.3 m/11 ft.

classification The Irish Elk is in family Cervidae, order Artiodactyla.

It is closely allied to the present day fallow deer and became extinct after the coming of humans to Europe.

ellipse curve joining all points (foci) around two fixed points (foci) such that the sum of the distances from those points is always constant. The diameter passing through the foci is the major axis, and the diameter bisecting this at right angles is the minor axis. An ellipse is one of a series of curves known as conic sections. A slice across a cone that is not made parallel to, and does not pass through, the base will produce an ellipse.

elliptical galaxy in astronomy, one of the main classes of galaxy in the Hubble classification and characterized by a featureless elliptical profile. Unlike spiral galaxies, elliptical galaxies have very little gas or dust and no stars have recently formed within them. They range greatly in size from giant ellipticals, which are often found at the centres of clusters of galaxies and may be strong radio

ellipse Technical terms used to describe the ellipse; for all points on the ellipse, the sum of the distances from the two foci, F_1 and F_2 , is the same.

sources, to tiny dwarf ellipticals, containing about a million stars, which are the most common galaxies of any type. More than 60% of known galaxies are elliptical.

elm any of a group of trees found in temperate regions of the northern hemisphere and in mountainous parts of the tropics. All have doubly-toothed leaf margins and clusters of small flowers. (Genus *Ulmus*, family Ulmaceae.)

Species include the wych elm (*Ulmus glabra*), native to Britain; the North American white elm (*U. americana*); and the red or slippery elm (*U. fulva*). Most elms (apart from the wych elm) reproduce not by seed but by suckering (new shoots arising from the root system). This nonsexual reproduction results in an enormous variety of forms.

The fungus disease *Ceratocystis ulmi*, known as Dutch elm disease because of a severe outbreak in the Netherlands in 1924, has reduced the numbers of elm trees in Europe and North America. It is carried from tree to tree by beetles. Elms were widespread throughout Europe to about 4000 BC, when they suddenly disappeared and were not common again until the 12th century. This may have been due to an earlier epidemic of Dutch elm disease. In 1997 the US National Arboretum developed a Valley Forge elm that is resistant to the disease. It is expected to be available to the public in 2000.

Elm in computing, mail reader commonly used on online systems. It is typically found on older, text-based systems running under UNIX.

El Niño Spanish 'the child' warm ocean surge of the ϕ Peru Current, so called because it tends to occur at Christmas, recurring about every 5–8 years in the eastern Pacific off South America. It involves a change in the direction of ocean currents, which prevents the upwelling of cold, nutrient-rich waters along the coast of Ecuador and Peru, killing fishes and plants. It is an important factor in global weather.

El Niño is believed to be caused by the failure of trade winds and, consequently, of the ocean currents normally driven by these winds. Warm surface waters then flow in from the east. The phenomenon can disrupt the climate of the area disastrously, and has played a part in causing famine in Indonesia, drought and bush fires in the Galápagos Islands, rainstorms in California and South America, and the destruction of Peru's anchovy harvest and

wildlife in 1982–83. El Niño contributed to algal blooms in Australia's drought-stricken rivers and an unprecedented number of typhoons in Japan in 1991. It is also thought to have caused the 1997 drought in Australia and contributed to certain ecological disasters such as bush fires in Indonesia.

El Niño usually lasts for about 18 months, but the 1990 occurrence lasted until June 1995; US climatologists estimated this duration to be the longest in 2,000 years. The last prolonged El Niño of 1939–41 caused extensive drought and famine in Bengal. It is understood that there might be a link between El Niño and ϕ global warming.

elongation in astronomy, the angular distance between the Sun and a planet or other solar-system object. This angle is 0° at ϕ conjunction, 90° at ϕ quadrature, and 180° at ϕ opposition.

elution in chemistry, washing of an adsorbed substance from the adsorbing material; it is used, for example, in the separation processes of chromatography and electrophoresis.

elytra horny wing cases characteristic of beetles. The elytra are adapted from the beetles' forewings (only the hindwings are used for flight). They fold over the back, generally meeting in the middle in a straight line, and serve to protect the hindwings and the soft posterior parts of the body.

Elytra are also to be found in ϕ earwigs.

In Hemiptera (true bugs) the forewings are hardened over half their length and are known as hemelytra. In Orthoptera (crickets, grasshoppers, and locusts) the forewings are greatly thickened and are known as tegmina.

EMACS or, more properly, GNU EMACS in computing, a heavyweight ϕ text editor used mainly by UNIX hackers. The name is derived from Editing Macros, but is humorously, and recursively, said to stand for EMACS Makes A Computer Slow. EMACS was written by Richard Stallman at the MIT AI Lab and is published as ϕ public-domain software. Emacs was created by the US Free Software Foundation.

e-mail (abbreviation for *electronic mail*) in computing, a system that enables the users of a computer network to send messages to other users. The messages (which may contain enclosed text files, artwork, or multimedia clips) are usually placed in a reserved area ('mailbox') on a central computer until they are retrieved by the receiving user. Passwords are frequently used to prevent unauthorized access to stored messages (see ϕ data security). The high speed of transmission for e-mail messages means that they cost less than comparable phone calls or faxes.

embolism blockage of a blood vessel by an obstruction called an embolus (usually a blood clot, fat particle, or bubble of air).

EL NIÑO THEME PAGE

<http://www.pmel.noaa.gov/toga-tao/el-nino/home.html>

Wealth of scientific information about El Niño (a 'disruption of the ocean-atmosphere system in the tropical Pacific') with animated views of the monthly sea changes brought about by it, El Niño-related climate predictions, and forecasts from meteorological centres around the world. It also offers an illuminating FAQ section with basic and more advanced questions as well as an interesting historical overview of the phenomenon starting from 1550.

embryo early developmental stage of an animal or a plant following fertilization of an ovum (egg cell), or activation of an ovum by ϕ parthenogenesis. In humans, the term embryo describes the fertilized egg during its first seven weeks of existence; from the eighth week onwards it is referred to as a fetus.

In animals the embryo exists either within an egg (where it is nourished by food contained in the yolk), or in mammals, in the ϕ uterus of the mother. In mammals (except marsupials) the embryo is fed through the ϕ lacenta. The plant embryo is found within the seed in higher plants. It sometimes consists of only a few cells, but usually includes a root, a shoot (or primary bud), and one or two ϕ cotyledons, which nourish the growing seedling.

embryology study of the changes undergone by an organism from its conception as a fertilized ovum (egg) to its emergence into the world at hatching or birth. It is mainly concerned with the

El Niño – The Christmas Child

by NIGEL DUDLEY

In 1997, more tropical forest burned than at any other time in recorded history. Vast fires in Indonesia and the Amazon appeared on television screens all over the world, but fires also blazed throughout Africa, Papua New Guinea, and Australia. Unlike some temperate and boreal forests, most tropical moist forests do not readily burn under natural conditions. Reasons for the increase are complex, and include changes to the forest through over-logging and uncontrolled use of fire as a land management tool. However, the 1997 fires were given a fresh impetus by a catastrophic drought that affected vast areas of Africa, Asia, and South America. This drought was, in turn, associated with a hitherto fairly obscure climatic event known as El Niño (literally 'The Child') that principally affects large parts of the Pacific coast of South America.

Theory

El Niño is a current of warm water in the southeastern Pacific, which usually reaches the Pacific coast of South America around Christmas – hence the name. Although normally benign, it can periodically become extremely damaging when it is associated with another climatic phenomenon known as the Southern Oscillation, a complex series of events including changes in wind temperature, ocean currents, and sea levels. The combination, often known as an El Niño/Southern Oscillation or ENSO event, creates an invasion of warm water into usually cool areas, causing wet and stormy weather in the west Pacific and sometimes as far as North America, and drought conditions in Africa, Brazil, Australia, and parts of Asia and the Pacific.

Immediate impact

The immediate impact on the Latin American coastline can be catastrophic. Warmer water kills plankton, squid, and smaller fish such as anchovy and sardine. Lack of food in turn kills larger fish such as herring and hake. This also sometimes causes extreme short-term declines in the seabird colonies found along the coast and on offshore islands – which may also have their nests inundated by rising waters. Coral reefs sometimes suffer bleaching, perhaps as a result of warmer water. In human terms, fisheries face extreme hardship and agricultural crops are likely to collapse. Along the coasts of Chile and off the southern USA, sardine populations can virtually disappear for a period. Particularly spectacular ENSO events occurred in 1940–41, 1957–58, and 1982–83. Loss of sardines caused a collapse in the industry in California during the 1940s, as recorded in John Steinbeck's *Cannery Row*.

Wider implications

The wider climatic conditions have other impacts. Increased forest fires have been mentioned above, but it is only in recent years that their full significance has been recognized. For example, over several months in the summer of 1997, an area of Southeast Asia from the Philippines to Australia was enveloped in smog caused by forest fires on the Indonesian islands of Java, Borneo, Sulawesi, Irian Jaya, and Sumatra. Over 2 million hectares of forests and other land were destroyed. More than 40,000 Indonesians became ill as a result and over a million suffered eye infections; smog also resulted in plane crashes and shipping accidents. Primary forest and at least 19 protected areas were damaged in Indonesia, and

endangered species such as the orang-utan were threatened further. Rains after the fire caused soil erosion and consequent damage to offshore fisheries as coral was smothered with debris. Business, including tourism, suffered badly and initial estimates put costs at a massive US\$20 billion. Although most fires were set deliberately – often illegally – by commercial interests such as plantation owners, impacts were exacerbated by the El Niño climatic effect. ENSO events are also associated with particularly bad burning seasons in Australia and the Amazon.

Drought also causes direct human hardship as a result of crop failures. At the end of 1997, hundreds of thousands of people in the Indonesian-controlled area of Irian Jaya and in neighbouring Papua New Guinea faced starvation after the worst drought for 50 years. Associated fires in Papua New Guinea created such a dense pall of smoke that pilots bringing in emergency food supplies were sometimes unable to land.

The future

Currently, El Niño and the associated ENSO events appear to be growing both more frequent and more severe. An increasing number of scientists are linking this to changes caused by pollution-related climatic change, although others think that it may be largely the result of natural fluctuations that will reverse later. Whatever the cause, the impacts are becoming more intense, and off the coast of western South America and the southern USA marine life seems to be undergoing longer-term changes. Since the 1950s, there has been an 80 percent decline in zooplankton along California's coast between San Diego and San Francisco, accompanied by a 1.2–1.6°C temperature rise. This decline is affecting seabird populations, particularly the sooty shearwater, which has declined by 90%.

Timing of ENSO events is also becoming more erratic. In the past, severe El Niño events tended to last around 18 months, and would be separated by long breaks so that marine and bird life could become re-established. However, the 1990 ENSO event appears to be continuing, with a series of unpredictable peaks and troughs. It apparently reached maturity in early 1992 and started to decline in the expected manner, but unexpectedly increased in strength again the following November. It stayed through 1994 and it appears as if the 1997 events may be simply another continuation. A link between climate change and changes in ENSO events is suspected but is as yet unproven.

Climate change specialists are also interested in El Niño because the main oceanic effects – a rise in sea level, higher water temperatures, and reduced offshore flow – are those most often associated with predictions relating to climate change. Scientists and fisheries experts have studied El Niño to find out what might happen under conditions of global warming.

Given their importance there is a strong incentive to predict ENSO events. For example, scientists are currently using the occurrence of a temperature-sensitive algae, *Emiliana huxleyi*, in layers of sediment to create an accurate profile of changing sea temperatures in the eastern Pacific between 1915 and 1988. However, many aspects of this extremely important phenomenon remain as elusive as when early settlers named the warming after the birth of the Christ child, which they were celebrating when it arrived.

changes in cell organization in the embryo and the way in which these lead to the structures and organs of the adult (the process of differentiation).

Applications of embryology include embryo transplants, both commercial (for example, in building up a prize dairy-cow herd quickly at low cost) and in obstetric medicine (as a method for helping couples with fertility problems to have children).

embryo sac large cell within the ovule of flowering plants that represents the female gametophyte when fully developed. It typically contains eight nuclei. Fertilization occurs when one of these nuclei, the egg nucleus, fuses with a male gamete.

emerald a clear, green gemstone variety of the mineral beryl. It occurs naturally in Colombia, the Ural Mountains in Russia,

embryo The development of a bird and a human embryo. In the human, division of the fertilized egg, or ovum, begins within hours of conception. Within a week, a hollow, fluid-containing ball – a blastocyst – with a mass of cells at one end has developed. After the third week, the embryo has changed from a mass of cells into a recognizable shape. At four weeks, the embryo is 3 mm/0.1 in long, with a large bulge for the heart and small pits for the ears. At six weeks, the embryo is 1.5 cm/0.6 in long with a pulsating heart and ear flaps. By the eighth week, the embryo (now technically a fetus) is 2.5 cm/1 in long and recognizably human, with eyelids and small fingers and toes.

Zimbabwe, and Australia. The green colour is caused by the presence of the element chromium in the beryl.

emergent properties features of a system that are due to the way in which its components are structured in relation to each other, rather than to the individual properties of those components.

Thus the distinctive characteristics of chemical compounds are emergent properties of the way in which the constituent elements are organized, and cannot be explained by the particular properties of those elements taken in isolation. In biology, ecosystem stability is an emergent property of the interaction between the constituent species, and not a property of the species themselves.

emery black to greyish form of impure corundum that also contains the minerals magnetite and hematite. It is used as an abrasive.

emetic any substance administered to induce vomiting. Emetics are used to empty the stomach in many cases of deliberate or accidental drug overdose. The most frequently used is ipecacuanha.

emf in physics, abbreviation for electromotive force.

emission line in astronomy, bright line in the spectrum of a luminous object caused by atoms emitting light at sharply defined wavelengths.

emission spectroscopy in analytical chemistry, a technique for determining the identity or amount present of a chemical substance by measuring the amount of electromagnetic radiation it emits at specific wavelengths; see spectroscopy.

emoticon (contraction of *emotion* and *icon*) in computing, symbol composed of punctuation marks designed to express some form of emotion in the form of a human face. Emoticons were invented by e-mail users to overcome the fact that communication using text only cannot convey nonverbal information (body language or vocal intonation) used in ordinary speech.

The following examples should be viewed sideways:--) smiling :-O shouting :-(glum 8-) wearing glasses and smiling.

emotion in psychology, a powerful feeling; a complex state of body and mind involving, in its bodily aspect, changes in the viscera (main internal organs) and in facial expression and posture, and in its mental aspect, heightened perception, excitement and, sometimes, disturbance of thought and judgement. The urge to action is felt and impulsive behaviour may result.

emphysema incurable lung condition characterized by disabling breathlessness. Progressive loss of the thin walls dividing the air spaces (alveoli) in the lungs reduces the area available for the exchange of oxygen and carbon dioxide, causing the lung tissue to expand. The term 'emphysema' can also refer to the presence of air in other body tissues.

Emphysema is most often seen at an advanced stage of chronic bronchitis, although it may develop in other long-standing diseases of the lungs. It destroys lung tissue, leaving behind scar tissue in the form of air blisters called bullae. As the disease progresses, the bullae occupy more and more space in the chest cavity, inflating the lungs and causing severe breathing difficulties. The bullae may be removed surgically, and since early 1994 US trials have achieved measured success using lasers to eliminate them in a procedure called lung-reduction pneumoplasty (LRP). Lasers are particularly useful where the emphysema is diffuse and bullae are interspersed within healthy tissue. As LRP is a less invasive process, survival rates are improved (90% compared with 75% for conventional surgery) and patients recover quicker.

EMS in computing, abbreviation for expanded memory specification.

emu flightless bird *Dromaius novaehollandiae*, family Dromaiidae, order Casuariidae, native to Australia. It stands about 1.8 m/6 ft high and has coarse brown plumage, small rudimentary

EMU

While a male emu is incubating his eggs, he cannot move from the nest to eat or drink. He must survive on his existing fat reserves for eight weeks. When the chicks are hatched they remain in their father's care for at least seven months.

wings, short feathers on the head and neck, and powerful legs, which are well adapted for running and kicking.

The female has a curious bag or pouch in the windpipe that enables her to emit a characteristic loud booming note. Emus are monogamous, and the male wholly or partially incubates the eggs.

In Western Australia emus are farmed for their meat, skins, feathers, and oil.

emulator in computing, an item of software or firmware that allows one device to imitate the functioning of another. Emulator software is commonly used to allow one make of computer to run programs written for a different make of computer. This allows a user to select from a wider range of applications programs, and perhaps to save money by running programs designed for an expensive computer on a cheaper model.

Many printers contain emulator firmware that enables them to imitate Hewlett Packard and Epson printers, because so much software is written to work with these widely used machines.

emulsifier food additive used to keep oils dispersed and in suspension, in products such as mayonnaise and peanut butter. Egg yolk is a naturally occurring emulsifier, but most of the emulsifiers in commercial use today are synthetic chemicals.

emulsion a stable dispersion of a liquid in another liquid – for example, oil and water in some cosmetic lotions.

encapsulate in computing, term used to describe the technique that uses one protocol as an envelope for another for transmission across a network.

encapsulated PostScript (EPS) computer graphics file format used by the PostScript page-description language. It is essentially a PostScript file with a special structure designed for use by other applications.

encephalin a naturally occurring chemical produced by nerve cells in the brain that has the same effect as morphine or other derivatives of opium, acting as a natural painkiller. Unlike morphine, enkephalins are quickly degraded by the body, so there is no build-up of tolerance to them, and hence no addiction. Enkephalins are a variety of peptides, as are endorphins, which have similar effects.

encephalitis inflammation of the brain, nearly always due to viral infection but it may also occur in bacterial and other infections. It varies widely in severity, from shortlived, relatively slight effects of headache, drowsiness, and fever to paralysis, coma, and death.

Encke's comet comet with the shortest known orbital period, 3.3 years. It is named after German mathematician and astronomer Johann Franz Encke (1791–1865), who calculated its orbit in 1819 from earlier sightings.

It was first seen in 1786 by the French astronomer Pierre Méchain (1744–1804). It is the parent body of the Taurid meteor shower and a fragment of it may have hit the Earth in the Tunguska Event in 1908.

In 1913, it became the first comet to be observed throughout its entire orbit when it was photographed near Aphelion (the point in its orbit furthest from the Sun) by astronomers at Mount Wilson Observatory in California, USA.

endangered species plant or animal species whose numbers are so few that it is at risk of becoming extinct. Officially designated endangered species are listed by the International Union for the Conservation of Nature (IUCN).

Endangered species are not a new phenomenon; extinction is an integral part of evolution. The replacement of one species by another usually involves the eradication of the less successful form, and ensures the continuance and diversification of life in all forms. However, extinctions induced by humans are thought to be destructive, causing evolutionary dead-ends that do not allow for succession by a more fit species. The great majority of recent extinctions have been directly or indirectly induced by humans; most often by the loss, modification, or pollution of the organism's habitat, but also by hunting for 'sport' or for commercial purposes.

According to a 1995 report to Congress by the US Fish and

Wildlife Service, although seven of the 893 species listed as endangered under the US Endangered Species Act 1968–93 have become extinct, 40% are no longer declining in number. In February 1996, a private conservation group, Nature Conservancy, reported around 20,000 native US plant and animal species to be rare or imperilled.

According to the Red Data List of endangered species, published in 1996 by the IUCN, 25% of all mammal species (including 46% of primates, 36% of insectivores, and 33% of pigs and antelopes), and 11% of all bird species are threatened with extinction.

endive cultivated annual plant, the leaves of which are used in salads and cooking. One variety has narrow, curled leaves; another has wide, smooth leaves. It is related to chicory. (*Cichorium endivia*, family Compositae.)

endocrine gland gland that secretes hormones into the bloodstream to regulate body processes. Endocrine glands are most highly developed in vertebrates, but are also found in other animals, notably insects. In humans the main endocrine glands are the pituitary, thyroid, parathyroid, adrenal, pancreas, ovary, and testis.

endocrine gland The main human endocrine glands. These glands produce hormones – chemical messengers – which travel in the bloodstream to stimulate certain cells.

endolymph fluid found in the inner ear, filling the central passage of the cochlea as well as the semicircular canals.

Sound waves travelling into the ear pass eventually through the three small bones of the middle ear and set up vibrations in the endolymph. These vibrations are detected by receptors in the cochlea, which send nerve impulses to the hearing centres of the brain.

endometriosis common gynaecological complaint in which patches of endometrium (the lining of the womb) are found outside the uterus.

This ectopic (abnormally positioned) tissue is present most often in the ovaries, although it may invade any pelvic or abdominal site, as well as the vagina and rectum. Endometriosis may be treated with analgesics, hormone preparations, or surgery. Between 30 and 40% of women treated for infertility are suffering from the condition.

endoparasite *☐* parasite that lives inside the body of its host.

endoplasm inner, liquid part of a cell's cytoplasm.

endoplasmic reticulum (ER) a membranous system of tubes, channels, and flattened sacs that form compartments within eukaryotic cells. It stores and transports proteins within cells and also carries various enzymes needed for the synthesis of fats. The cisternomes, or the organelles that carry out protein synthesis, are attached to parts of the ER.

Under the electron microscope, ER looks like a series of channels and vesicles, but it is in fact a large, sealed, baglike structure crumpled and folded into a convoluted mass. The interior of the 'bag', the ER lumen, stores various proteins needed elsewhere in the cell, then organizes them into transport vesicles formed by a small piece of ER membrane budding from the main membrane.

endorphin natural substance (a polypeptide) that modifies the action of nerve cells. Endorphins are produced by the pituitary gland and hypothalamus of vertebrates. They lower the perception of pain by reducing the transmission of signals between nerve cells.

Endorphins not only regulate pain and hunger, but are also involved in the release of sex hormones from the pituitary gland. Opiates act in a similar way to endorphins, but are not rapidly degraded by the body, as natural endorphins are, and thus have a long-lasting effect on pain perception and mood. Endorphin release is stimulated by exercise.

endoscopy examination of internal organs or tissues by an instrument allowing direct vision. An endoscope is equipped with an eyepiece, lenses, and its own light source to illuminate the field of vision. The endoscope used to examine the digestive tract is a flexible fiberoptic instrument swallowed by the patient.

There are various types of endoscope in use – some rigid, some flexible – with names prefixed by their site of application (for example, bronchoscope and laryngoscope). The value of endoscopy is in permitting diagnosis without the need for exploratory surgery. Biopsies (tissue samples) and photographs may be taken by way of the endoscope as an aid to diagnosis, or to monitor the effects of treatment. Some surgical procedures can be performed using fine instruments introduced through the endoscope. Keyhole surgery is increasingly popular as a cheaper, safer option for some conditions than conventional surgery.

endoskeleton the internal supporting structure of vertebrates, made up of cartilage or bone. It provides support, and acts as a system of levers to which muscles are attached to provide movement. Certain parts of the skeleton (the skull and ribs) give protection to vital body organs.

Sponges are supported by a network of rigid, or semirigid, spiky structures called spicules; a bath sponge is the proteinaceous skeleton of a sponge.

endosperm nutritive tissue in the seeds of most flowering plants. It surrounds the embryo and is produced by an unusual process that parallels the fertilization of the ovum by a male gamete. A second male gamete from the pollen grain fuses with two female nuclei within the embryo sac. Thus endosperm cells are triploid (having three sets of chromosomes); they contain food reserves such as starch, fat, and protein that are utilized by the developing seedling.

In 'non-endospermic' seeds, absorption of these food molecules by the embryo is completed early, so that the endosperm has disappeared by the time of germination.

endotherm 'warm-blooded', or *homeothermic*, animal. Endotherms have internal mechanisms for regulating their body temperatures to levels different from the environmental temperature. See *homeothermy*.

endothermic reaction chemical reaction that requires an input of energy in the form of heat for it to proceed; the energy is absorbed from the surroundings by the reactants.

The dissolving of sodium chloride in water and the process of photosynthesis are both endothermic changes. See *energy of reaction*.

endotoxin in biology, heat stable complex of protein and lipopolysaccharide that is produced following the death of certain bacteria. Endotoxins are typically produced by the Gram negative bacteria and can cause fever. They can also cause shock by rendering the walls of the blood vessels permeable so that fluid leaks into the tissues and blood pressure falls sharply.

end user the user of a computer program; in particular, someone who uses a program to perform a task (such as accounting or playing a computer game), rather than someone who writes programs (a programmer).

Energiya most powerful Soviet space rocket, first launched 15 May 1987.

Used to launch the Soviet space shuttle, the Energiya booster is capable, with the use of strap-on boosters, of launching payloads of up to 190 tonnes into Earth orbit.

energy capacity for doing work. Energy can exist in many different forms. For example, potential energy (PE) is energy deriving from position; thus a stretched spring has elastic PE, and an object raised to a height above the Earth's surface, or the water in an elevated reservoir, has gravitational PE. Moving bodies possess kinetic energy (KE). Energy can be converted from one form to another, but the total quantity in a system stays the same (in accordance with the conservation of energy principle). Energy cannot be created or destroyed. For example, as an apple falls it loses gravitational PE but gains KE.

Although energy is never lost, after a number of conversions it tends to finish up as the kinetic energy of random motion of molecules (of the air, for example) at relatively low temperatures. This is 'degraded' energy that is difficult to convert back to other forms. **energy is the capacity to do work** A body with no energy can do no work. For example, a flat battery in a torch will not light the torch. If the battery is fully charged, it should contain enough chemical energy to do the work involved in illuminating the torch bulb. When one body A does work on another body B, A transfers energy to B. The energy transferred is equal to the work done by A on B. Energy is therefore measured in joules. The rate of doing work or consuming energy is called power and is measured in watts (joules per second).

energy types and transfer Energy can be converted from any form into another. A ball resting on a slope possesses potential energy that is gradually changed into kinetic energy of rotation and translation as the ball rolls down. As a pendulum swings, energy is constantly being changed from a potential form at the highest points of the swing to kinetic energy at the lowest point. At positions in between these two extremes, the system possesses both kinetic and potential energy in varying proportions.

A weightlifter changes chemical energy from his muscles into potential energy of the weight when the weight is lifted. If the weightlifter releases the weight, the potential energy is converted to kinetic energy as it falls, and this in turn is converted to heat energy and sound energy as it hits the floor. A lump of coal and a tank of petrol, together with the oxygen needed for their combustion, have chemical energy. Other sorts of energy include electrical and nuclear energy, and light and sound.

resources So-called energy resources are stores of convertible energy. Nonrenewable resources include the fossil fuels (coal, oil, and gas) and nuclear-fission 'fuels' – for example, uranium 235. The term 'fuel' is used for any material from which energy can be obtained. We use up fuel reserves such as coal and oil, and convert the energy they contain into other, useful forms. The chemical energy released by burning fuels can be used to do work.

Renewable resources, such as wind, tidal, and geothermal power, have so far been less exploited. Hydroelectric projects are well established, and wind turbines and tidal systems are being developed.

energy conservation and efficiency All forms of energy are interconvertible by appropriate processes. Energy is transferred from one form to another, but the sum total of the energy after the conversion is always the same as the initial energy. This is the principle of conservation of energy. This principle can be illustrated by the use of energy flow diagrams, called Sankey diagrams, which show the energy transformations that take place.

Energy Resources

BY PETER LAFFERTY

Humans are using up the world's energy resources in a way no other animal has ever done. We use them to provide light and heating in our homes, to plough the land, to cook our food, to travel, to run our factories, and in countless other ways. Whether we are rural workers in a developing country or urban workers in a wealthy industrial country, we all need energy, although the sources of the energy and the amounts used vary greatly from one society to another.

Sources of energy

There are different forms or types of energy. Fuels such as coal, oil (petroleum), and wood contain chemical energy. When these fuels are burnt, the chemical energy changes to heat and light energy. Electricity is the most important form of energy in the industrialized world, because it can be transported over long distances via cables and transmission lines. It is also a very convenient form of energy, since it can power a wide variety of household appliances and industrial machinery. It is produced by converting the chemical energy from coal, oil, or natural gas in power stations.

Energy resources fall into two broad groups: renewable and nonrenewable. Renewable resources are those which replenish themselves naturally and will either always be available – hydroelectric power, solar energy, wind and wave power, tidal energy, and geothermal energy – or will continue to be available provided supplies are given sufficient time to replenish themselves – peat and firewood. Nonrenewable resources are those of which there are limited supplies and which once used are gone forever. These include coal, oil, natural gas, and uranium.

Fossil fuels

Coal, oil, and natural gas are called fossil fuels because they are the fossilized remains of plants and animals that lived hundreds of millions of years ago. Burning fossil fuels releases chemicals that cause acid rain, and is gradually increasing the carbon dioxide in the atmosphere, causing global warming.

Fossil fuel resources are not evenly distributed around the world. Over half the world's known oil reserves are in the Middle East; about 40% of the reserves of natural gas are in the Commonwealth of Independent States (CIS), and 25% in the Middle East. About two-thirds of the world's coal is shared between North America, the CIS, and China.

Uranium

Uranium is a radioactive metallic element and a very concentrated source of energy; large reserves are found in Australia, North America, and South Africa. Used to produce electricity in a nuclear power station, a single ton of uranium can produce as much energy as 15,000 tons of coal, or 10,000 tons of oil. Used in the type of nuclear power station now in operation, the world's known uranium supplies have about the same energy content as the known oil reserves. However, these power stations, known as thermal stations or reactors, use only a small part of the energy available in uranium. The next generation of reactors, known as fast or breeder reactors, release virtually all its energy. These reactors would increase the world's uranium energy reserves by sixty times. However, although nuclear power stations do not produce carbon dioxide or cause acid rain, they do produce radioactive waste that is dangerous and difficult to process or store safely.

Solar energy

Many renewable resources take advantage of the energy in sunlight. The Sun's energy can be tapped directly by photovoltaic cells that convert light into electricity. Other solar energy plants

use mirrors to direct sunlight onto pipes containing a liquid. The liquid boils and is used to drive an electricity generator. The Sun's energy also drives the wind and waves, so energy produced by wind farms and wave-driven generators is also derived from the Sun.

Gravitational energy

Hydroelectricity and tidal power stations make use of gravitational forces. The Earth's gravity pulls water downward through the turbines in a hydroelectric power station. In a tidal power station, the Moon's gravity lifts water as the tides rise, giving the water potential energy (energy due to position) which is released as the water flows through a turbine. Geothermal energy (the heat energy of hot rocks deep beneath the Earth's surface) is due to gravity compressing and heating the rocks when the Earth formed.

The worldwide energy pie

Globally, the largest contributions to current energy resources come from oil (31%), coal (26%), and natural gas (19%). Renewable energy currently supplies about 20% of the world's energy needs, with hydroelectricity supplying 6% of the world's needs and traditional biofuels (firewood, crop wastes, peat, and dung) supplying 12%. A small contribution is made by new renewables, such as the conversion of crops such as sugar into alcohol fuel and the burning of waste material.

The contribution solar, wave, tidal, and geothermal power can make to the world's energy resources is currently limited. This is because renewable energy depends on the development of means of capturing and concentrating it. In addition, renewable energy is not always available when needed – rivers can dry up, the wind does not always blow.

Future demands

It is clear that, in the future, demand for energy will be higher than at present, due to population growth and increased industrialization. Furthermore, the energy available must be at a reasonable cost or economic growth will be held back. This is especially important for developing countries, where the inability to meet high-energy costs hinders development.

Future solutions

In principle, known resources of nonrenewable energy should be sufficient for several hundred years or more. At the present rate of consumption, oil reserves will last about 40 years; gas reserves will last about 60 years; coal reserves will last about 250 years; and uranium reserves, if used in fast reactors, would last for more than 1,000 years. It is also likely that further fossil-fuel reserves will be discovered as currently known supplies run out. However, in practice, the outlook is uncertain. Increasing concern about pollution might make dirty coal-fired power stations unacceptable in the future.

One alternative is to make greater use of nuclear power, moving to fast reactors and then developing nuclear fusion plants that would mimic the power production process found in the Sun. However, anxiety about safety and waste disposal is already limiting the use of nuclear energy, so it is unlikely to provide an answer in the future.

There is considerable room for development in the use of renewable resources, but with most of the world's energy production based around nonrenewable fuel supplies, the widespread introduction of efficient renewable energy will require a complete restructuring of the ways we produce and use energy.

When a petrol engine is used to power a car, about 75% of the energy from the fuel is wasted. The total energy input equals the total energy output, but a lot of energy is wasted as heat so that the engine is only about 25% efficient. The combustion of the petrol-air mixture produces heat energy as well as kinetic energy. All forms of energy tend to be transformed into heat and can not then readily be converted into other, useful forms of energy.

heat transfer A difference in temperature between two objects in thermal contact leads to the transfer of energy as heat. Heat is energy transferred due to a temperature difference. Heat is transferred by the movement of particles (that possess kinetic energy) by conduction, convection, and radiation. Conduction involves the movement of heat through a solid material by the movement of free electrons. For example, thermal energy is lost from a house by conduction through the walls and windows. Convection involves the transfer of energy by the movement of fluid particles. All objects radiate heat in the form of radiation of electromagnetic waves. Hotter objects emit more energy than cooler objects.

Methods of reducing energy transfer as heat through the use of insulation are important because the world's fuel reserves are limited and heating homes costs a lot of money in fuel bills. Heat transfer from the home can be reduced by a variety of methods, such as loft insulation, cavity wall insulation, and double glazing. The efficiency of insulating materials in the building industry are compared by measuring their heat-conducting properties, represented by a \dot{U} -value. A low \dot{U} -value indicates a good insulating material.

$E = mc^2$ It is now recognised that mass can be converted into energy under certain conditions, according to Einstein's theory of relativity. This conversion of mass into energy is the basis of atomic power. Einstein's special theory of relativity 1905 correlates any gain, E , in energy with a gain, m , in mass, by the equation $E = mc^2$, in which c is the speed of light. The conversion of mass into energy in accordance with this equation applies universally, although it is only for nuclear reactions that the percentage change in mass is large enough to detect.

energy, alternative energy from sources that are renewable and ecologically safe, as opposed to sources that are nonrenewable with toxic by-products, such as coal, oil, or gas (fossil fuels), and uranium (for nuclear power). The most important alternative energy source is flowing water, harnessed as hydroelectric power. Other sources include the oceans' tides and waves (tidal power station and wave power), wind power (harnessed by windmills and wind turbines), the Sun (solar energy), and the heat trapped in the Earth's crust (geothermal energy) (see also cold fusion).

energy conservation methods of reducing energy use through insulation, increasing energy efficiency, and changes in patterns of use. Profligate energy use by industrialized countries contributes greatly to air pollution and the greenhouse effect when it draws on nonrenewable energy sources.

It has been calculated that increasing energy efficiency alone could reduce carbon dioxide emissions in several high-income countries by 1-2% a year. The average annual decrease in energy consumption in relation to gross national product 1973-87 was 1.2% in France, 2% in the UK, 2.1% in the USA, and 2.8% in Japan.

energy level the permitted energy that an electron can have in any particular atom. Energy levels can be calculated using quantum theory. The permitted energy levels depend mainly on the distance of the electron from the nucleus. See orbital, atomic.

energy of reaction energy released or absorbed during a chemical reaction, also called enthalpy of reaction or heat of reaction. In a chemical reaction, the energy stored in the reacting molecules is rarely the same as that stored in the product molecules. Depending on which is the greater, energy is either released (an exothermic reaction) or absorbed (an endothermic reaction) from the surroundings (see conservation of energy). The amount of energy released or absorbed by the quantities of substances represented by the chemical equation is the energy of reaction.

Energy Star in computing, US programme requiring all computer equipment to conserve electrical power. Key features of Energy Star-compliant hardware include a built-in function to put the computer and monitor into suspended animation after a specified period

of disuse and limits on the amount of power computers and printers can draw.

engine device for converting stored energy into useful work or movement. Most engines use a fuel as their energy store. The fuel is burnt to produce heat energy - hence the name 'heat engine' - which is then converted into movement. Heat engines can be classified according to the fuel they use (petrol engine or diesel engine), or according to whether the fuel is burnt inside (internal combustion engine) or outside (steam engine) the engine, or according to whether they produce a reciprocating or rotary motion (turbine or Wankel engine).

engine in computing, core piece of software around which other features and functions are built. A database search engine, for example, accepts user input and handles the processing necessary to find matches between the user input and the database records.

In a computer game, the term 'engine' is also used to refer to the core software that allows users to move around the game's levels and pick up weapons and treasure.

The scientist describes what is; the engineer creates what never was.

THEODORE VON KÁRMÁN Hungarian-born US aerodynamicist.
Biogr. Mem. FRS 1980 26 110

engineering the application of science to the design, construction, and maintenance of works, machinery, roads, railways, bridges, harbour installations, engines, ships, aircraft and airports, spacecraft and space stations, and the generation, transmission, and use of electrical power. The main divisions of engineering are aerospace, chemical, civil, computer, electrical, electronic, gas, marine, materials, mechanical, mining, production, radio, and structural.

Did you know that if a beaver two feet long with a tail a foot and a half long can build a dam twelve feet high and six feet wide in two days, all you would need to build the Kariba Dam is a beaver sixty-eight feet long with a fifty-one foot tail!

NORTON JUSTER US writer.
The Phantom Tollbooth ch 14

TO REMEMBER THAT TO TIGHTEN A BOLT OR NUT YOU TURN IT CLOCKWISE (RIGHT), AND TO TAKE IT OFF YOU TURN IT ANTICLOCKWISE (LEFT):

RIGHTY TIGHTY, LEFTY LOOSE

engineering drawing technical drawing that forms the plans for the design and construction of engineering components and structures. Engineering drawings show different projections, or views of objects, with the relevant dimensions, and show how all the separate parts fit together. They are often produced by computers using computer-aided design (CAD).

English toy terrier or black-and-tan terrier breed of toy dog closely resembling the Manchester terrier but smaller and with erect ears. It weighs no more than 3.5 kg/8 lb and is 25-30 cm/10-12 in high.

enset *Ensete ventricosum* relative of the banana with edible corms and stems. It was domesticated between 5,000 and 10,000 years ago but is now grown only in southern Ethiopia. It is resistant to drought and when mashed and fermented can be kept for months, or even years, before being made into a wide variety of

foods. Its fibre can also be used to produce material.

Wild onset grows over much of western and southern Africa. In 1993 a US research team was set up to explore the possibility of cultivating onset in the drought-stricken north of Ethiopia.

enthalpy in chemistry, alternative term for Δ energy of reaction, the heat energy associated with a chemical change.

entomology study of insects.

entropy in thermodynamics, a parameter representing the state of disorder of a system at the atomic, ionic, or molecular level; the greater the disorder, the higher the entropy. Thus the fast-moving disordered molecules of water vapour have higher entropy than those of more ordered liquid water, which in turn have more entropy than the molecules in solid crystalline ice.

In a closed system undergoing change, entropy is a measure of the amount of energy unavailable for useful work. At Δ absolute zero ($-273.15^{\circ}\text{C}/-459.67^{\circ}\text{F}/0\text{ K}$), when all molecular motion ceases and order is assumed to be complete, entropy is zero.

... a living organism ... feeds upon negative entropy ... Thus the device by which an organism maintains itself stationary at a fairly high level of orderliness (fairly low level of entropy) really consists in continually sucking orderliness from its environment.

ERWIN SCHRÖDINGER Austrian physicist.
What is Life? 1944

E number code number for additives that have been approved for use by the European Commission (EC). The E written before the number stands for European. E numbers do not have to be displayed on lists of ingredients, and the manufacturer may choose to list additives by their name instead. E numbers cover all categories of additives apart from flavourings.

Additives, other than flavourings, that are not approved by the European Commission, but are still used in Britain, are represented by a code number without an E.

envelope in geometry, a curve that touches all the members of a family of lines or curves. For example, a family of three equal circles all touching each other and forming a triangular pattern (like a clover leaf) has two envelopes: a small circle that fits in the space in the middle, and a large circle that encompasses all three circles.

environment in ecology, the sum of conditions affecting a particular organism, including physical surroundings, climate, and influences of other living organisms. See also Δ biosphere and Δ habitat.

In common usage, 'the environment' often means the total global environment, without reference to any particular organism. In genetics, it is the external influences that affect an organism's development, and thus its Δ phenotype.

The sun, the moon and the stars would have disappeared long ago ... had they happened to be within the reach of predatory human hands.

HAWELOCK ELLIS British psychologist.
The Dance of Life ch 7

environmental audit another name for Δ green audit, the inspection of a company to assess its environmental impact.

environmentalism theory emphasizing the primary influence of the environment on the development of groups or individuals. It stresses the importance of the physical, biological, psychological, or cultural environment as a factor influencing the structure or behaviour of animals, including humans.

In politics this has given rise in many countries to Green parties, which aim to 'preserve the planet and its people'.

Environmentally Sensitive Area (ESA) scheme introduced by the UK Ministry of Agriculture in 1984, as a result of EC legislation, to protect some of the most beautiful areas of the British countryside from the loss and damage caused by agricultural change. The first areas to be designated ESAs were in the Pennine Dales, the North Peak District, the Norfolk Broads, the Breckland, the Suffolk River Valleys, the Test Valley, the South Downs, the Somerset Levels and Moors, West Penwith, Cornwall, the Shropshire Borders, the Cambrian Mountains, and the Lleyn Peninsula.

The total area designated as ESA's was estimated 1993 at 785,600 hectares. The scheme is voluntary, with farmers being encouraged to adapt their practices so as to enhance or maintain the natural features of the landscape and conserve wildlife habitat. A farmer who joins the scheme agrees to manage the land in this way for at least five years. In return for this agreement, the Ministry of Agriculture pays the farmer a sum that reflects the financial losses incurred as a result of reconciling conservation with commercial farming.

Environmental Protection Agency (EPA) US agency set up 1970 to control water and air quality, industrial and commercial wastes, pesticides, noise, and radiation. In its own words, it aims to protect 'the country from being degraded, and its health threatened, by a multitude of human activities initiated without regard to long-ranging effects upon the life-supporting properties, the economic uses, and the recreational value of air, land, and water'.

environment-heredity controversy see Δ nature-nurture controversy.

enzyme biological Δ catalyst produced in cells, and capable of speeding up the chemical reactions necessary for life. They are large, complex Δ proteins, and are highly specific, each chemical reaction requiring its own particular enzyme. The enzyme's specificity arises from its active site, an area with a shape corresponding to part of the molecule with which it reacts (the substrate). The enzyme and the substrate slot together forming an enzyme-substrate complex that allows the reaction to take place, after which the enzyme falls away unaltered.

The activity and efficiency of enzymes are influenced by various factors, including temperature and pH conditions. Temperatures above $60^{\circ}\text{C}/140^{\circ}\text{F}$ damage (denature) the intricate structure of enzymes, causing reactions to cease. Each enzyme operates best within a specific pH range, and is denatured by excessive acidity or alkalinity.

Digestive enzymes include amylases (which digest starch), lipases (which digest fats), and proteases (which digest protein). Other enzymes play a part in the conversion of food energy into Δ ATP; the manufacture of all the molecular components of the body; the replication of Δ DNA when a cell divides; the production of hormones; and the control of movement of substances into and out of cells.

Enzymes have many medical and industrial uses, from washing powders to drug production, and as research tools in molecular biology. They can be extracted from bacteria and moulds, and Δ genetic engineering now makes it possible to tailor an enzyme for a specific purpose.

ENZYME

The reason that pigs never suffer from gout is because of an enzyme. In humans, this painful disease is caused by a build-up of uric acid. Pigs have an enzyme that breaks uric acid into soluble components. Humans do not have this enzyme, so they suffer from gout and pigs do not.

Eocene second epoch of the Tertiary period of geological time, 56.5–35.5 million years ago. Originally considered the earliest division of the Tertiary, the name means 'early recent', referring to the early forms of mammals evolving at the time, following the extinction of the dinosaurs.

eotvos unit unit (symbol E) for measuring small changes in the intensity of the Earth's ϕ gravity with horizontal distance.

ephemeral plant plant with a very short life cycle, sometimes as little as six to eight weeks. It may complete several generations in one growing season.

epicentre the point on the Earth's surface immediately above the seismic focus of an ϕ earthquake. Most damage usually takes place at an earthquake's epicentre. The term sometimes refers to a point directly above or below a nuclear explosion ('at ground zero').

epicyclic gear or **sun-and-planet gear** gear system that consists of one or more gear wheels moving around another. Epicyclic gears are found in bicycle hub gears and in automatic gearboxes.

epicycloid in geometry, a curve resembling a series of arches traced out by a point on the circumference of a circle that rolls around another circle of a different diameter. If the two circles have the same diameter, the curve is a ϕ cardioid.

epicycloid A seven-cusped epicycloid, formed by a point on the circumference of a circle (of diameter d) that rolls around another circle (of diameter $7d/3$).

epidemic outbreak of infectious disease affecting large numbers of people at the same time. A widespread epidemic that sweeps across many countries (such as the ϕ Black Death in the late Middle Ages) is known as a **pandemic**.

epidermis outermost layer of ϕ cells on an organism's body. In plants and many invertebrates such as insects, it consists of a single layer of cells. In vertebrates, it consists of several layers of cells.

The epidermis of plants and invertebrates often has an outer noncellular cuticle that protects the organism from desiccation.

epididymis in male vertebrates, a long coiled tubule in the ϕ testis, in which sperm produced in the seminiferous tube are stored. In men, it is a duct about 6 m/20 ft long, convoluted into a small space.

epigeal seed germination in which the ϕ cotyledons (seed leaves) are borne above the soil.

epiglottis small flap located behind the root of the tongue in mammals. It closes off the end of the windpipe during swallowing to prevent food from passing into it and causing choking.

The action of the epiglottis is a highly complex reflex process involving two phases. During the first stage a mouthful of chewed food is lifted by the tongue towards the top and back of the mouth. This is accompanied by the cessation of breathing and by the blocking of the nasal areas from the mouth. The second phase involves

the epiglottis moving over the larynx while the food passes down into the oesophagus.

epilepsy medical disorder characterized by a tendency to develop fits, which are convulsions or abnormal feelings caused by abnormal electrical discharges in the cerebral hemispheres of the ϕ brain. Epilepsy can be controlled with a number of anticonvulsant drugs.

The term epilepsy covers a range of conditions from mild 'absences', involving momentary loss of awareness, to major convulsions. In some cases the abnormal electrical activity is focal (confined to one area of the brain); in others it is generalized throughout the cerebral cortex. Fits are classified according to their clinical type. They include: the **grand mal** seizure with convulsions and loss of consciousness; the fleeting absence of awareness **petit mal**, almost exclusively a disorder of childhood; **Jacksonian** seizures, originating in the motor cortex; and **temporal-lobe** fits, which may be associated with visual hallucinations and bizarre disturbances of the sense of smell.

Epilepsy affects 1-3% of the world's population. It may arise spontaneously or may be a consequence of brain surgery, organic brain disease, head injury, metabolic disease, alcoholism or withdrawal from some drugs. Almost a third of patients have a family history of the condition.

Most epileptics have infrequent fits that have little impact on their daily lives. Epilepsy does not imply that the sufferer has any impairment of intellect, behaviour, or personality.

UNDERSTANDING EPILEPSY

<http://www.epinet.org.au/efvunder.html>

Clear and concise guide to epilepsy provided by EpiNet courtesy of the Epilepsy Foundation of Victoria, Australia. It covers the basics of the subject under the headings of 'What is Epilepsy?', 'Diagnosis', and 'Recognizing Seizures'. It also provides a guide to the different types of seizure and suggests first aid measures for each.

epiphyte any plant that grows on another plant or object above the surface of the ground, and has no roots in the soil. An epiphyte does not parasitize the plant it grows on but merely uses it for support. Its nutrients are obtained from rainwater, organic debris such as leaf litter, or from the air.

The greatest diversity of epiphytes is found in tropical areas and includes many orchids.

epithelium in animals, tissue of closely packed cells that forms a surface or lines a cavity or tube. Epithelium may be protective (as in the skin) or secretory (as in the cells lining the wall of the gut).

epoch subdivision of a geological period in the geological time scale. Epochs are sometimes given their own names (such as the

HOLOCENE, PLEISTOCENE, PLOCIENE, MIOCENE, OLIGOCENE, EOCENE, PALAEOCENE

PALAEOCENE, EOCENE, OLIGOCENE, MIOCENE, PLOCIENE, PLEISTOCENE, HOLOCENE

Palaeocene, Eocene, Oligocene, Miocene, and Pliocene epochs comprising the Tertiary period), or they are referred to as the late, early, or middle portions of a given period (as the Late Cretaceous or the Middle Triassic epoch).

Geological time is broken up into geochronological units of which epoch is just one level of division. The hierarchy of geochronological divisions is eon, era, period, epoch, age, and chron. Epochs are subdivisions of periods and ages are subdivisions of epochs. Rocks representing an epoch of geological time comprise a series.

epoxy resin synthetic resin used as an adhesive and as an ingredient in paints. Household epoxy resin adhesives come in component form as two separate tubes of chemical, one (tube containing resin, the other a curing agent (hardener). The two chemicals are mixed just before application, and the mix soon sets hard.

EPROM (acronym for *erasable programmable read-only memory*) computer memory device in the form of an integrated circuit (chip) that can record data and retain it indefinitely. The data can be erased by exposure to ultraviolet light, and new data recorded. Other kinds of computer memory chips are ROM (read-only memory), PROM (programmable read-only memory), and RAM (random-access memory).

EPS in computing, abbreviation for Encapsulated PostScript.

Epsilon Aurigae eclipsing binary star in the constellation Auriga. One of the pair is an 'ordinary' star, but the other seems to be an enormous distended object whose exact nature remains unknown. The period (time between eclipses) is 27 years, the longest of its kind. The last eclipse was in 1982-84.

Epsom salts $MgSO_4 \cdot 7H_2O$ hydrated magnesium sulphate, used as a relaxant and laxative and added to baths to soothe the skin. The name is derived from a bitter saline spring at Epsom, Surrey, England, which contains the salt in solution.

equation in chemistry, representation of a chemical reaction by symbols and numbers; see chemical equation.

equation in mathematics, expression that represents the equality of two expressions involving constants and/or variables, and thus usually includes an equals (=) sign. For example, the equation $A = \pi r^2$ equates the area A of a circle of radius r to the product πr^2 .

The algebraic equation $y = mx + c$ is the general one in coordinate geometry for a straight line.

If a mathematical equation is true for all variables in a given domain, it is sometimes called an identity and denoted by \equiv .

Thus $(x + y)^2 = x^2 + 2xy + y^2$ for all $x, y \in \mathbb{R}$.

An indeterminate equation is an equation for which there is an infinite set of solutions - for example, $2x = y$. A diophantine equation is an indeterminate equation in which both the solution and the terms must be whole numbers (after Diophantus of Alexandria, c. AD 250).

equation of motion mathematical equation that gives the position and velocity of a moving object at any time. Given the mass of an object, the forces acting on it, and its initial position and velocity, an equation of motion is used to calculate its position and velocity at any later time. The equation must be based on Newton's laws of motion or, if speeds near that of light are involved, on the theory of relativity.

equations of motion or kinematic equations mathematical equations that give the position or velocity at any time of an object moving with constant acceleration. The five common equations are:

$$v = u + at \quad s = \frac{1}{2}(u + v)t \quad s = ut + \frac{1}{2}at^2 \quad v^2 = u^2 + 2as$$

as in which a is the object's constant acceleration, u is its initial velocity, v is its velocity after a time t , and s is the distance travelled by it in that time.

Equator or terrestrial equator the great circle whose plane is perpendicular to the Earth's axis (the line joining the poles). Its length is 40,092 km/24,901.8 mi, divided into 360 degrees of longitude.

The Equator encircles the broadest part of the Earth, and represents 0° latitude. It divides the Earth into two halves, called the northern and the southern hemispheres.

The celestial equator is the circle in which the plane of the Earth's Equator intersects the celestial sphere.

equatorial coordinates in astronomy, a system for measuring the position of astronomical objects on the celestial sphere with reference to the plane of the Earth's equator.

Declination (symbol δ), analogous to latitude, is measured in degrees from the equator to the north ($\delta = 90^\circ$) or south ($\delta = -90^\circ$) celestial poles. Right ascension (symbol α), analogous to longitude, is normally measured in hours of time ($\alpha = 0$ h to 24 h) eastward along the equator from a fixed point known as the first point of Aries or the vernal equinox.

equatorial mounting in astronomy, a method of mounting a telescope to simplify the tracking of celestial objects. One axis (the polar axis) is mounted parallel to the rotation axis of the Earth so that the telescope can be turned about it to follow objects across the sky. The declination axis moves the telescope in declination and is clamped before tracking begins. Another advantage over the simpler altazimuth mounting is that the orientation of the image is fixed, permitting long-exposure photography.

Equidae horse family in the order Perissodactyla, which includes the odd-toed hoofed animals. Besides the domestic horse, wild asses, wild horses, onagers, and zebras, there are numerous extinct species known from fossils.

All species in the family are inhabitants of flat, open country, except the mountain zebra from the hills of southern Africa. They have long legs, adapted to carry the animals at speed over firm ground; only one toe, terminating in a hoof, is present on each limb. They are all herbivorous and have keen senses to detect their enemies. Their jaws are strong and able to chew the tough grasses and herbs on which they feed in the wild state.

equilateral geometrical figure, having all sides of equal length.

equilibrium in physics, an unchanging condition in which an undisturbed system can remain indefinitely in a state of balance. In a static equilibrium, such as an object resting on the floor, there is no motion. In a dynamic equilibrium, in contrast, a steady state is maintained by constant, though opposing, changes. For example, in a sealed bottle half-full of water, the constancy of the water level is a result of molecules evaporating from the surface and condensing on it at the same rate.

equinox the points in spring and autumn at which the Sun's path, the ecliptic, crosses the celestial equator, so that the day and night are of approximately equal length. The vernal equinox occurs about 21 March and the autumnal equinox, 23 September.

era any of the major divisions of geological time, each including several periods, but smaller than an eon. The currently recognized eras all fall within the Phanerozoic eon - or the vast span of time, starting about 570 million years ago, when fossils are found to become abundant. The eras in ascending order are the Palaeozoic, Mesozoic, and Cenozoic. We are living in the Recent epoch of the Quaternary period of the Cenozoic era.

Geological time is broken up into geochronological units of which era is just one level of division. The hierarchy of geochronological divisions is eon, era, period, epoch, age, and chron. Eras are subdivisions of eons and periods are subdivisions of eras. Rocks representing an era of geological time comprise an erathem.

erasable optical disc in computing, another name for a floptical disc.

Erasthenes' sieve a method for finding prime numbers. It involves writing in sequence all numbers from 2. Then, starting with 2, cross out every second number (but not 2 itself), thus eliminating numbers that can be divided by 2. Next, starting with 3, cross out every third number (but not 3 itself), and continue the process for 5, 7, 11, 13, and so on. The numbers that remain are primes.

erbium soft, lustrous, greyish, metallic element of the lanthanide series, symbol Er, atomic number 68, relative atomic mass 167.26. It occurs with the element yttrium or as a minute part of various minerals. It was discovered in 1843 by Carl Mosander (1797–1858), and named after the town of Ytterby, Sweden, near which the lanthanides (rare-earth elements) were first found.

Erbium has been used since 1987 to amplify data pulses in optical fibre, enabling faster transmission. Erbium ions in the fibre-glass, charged with infrared light, emit energy by amplifying the data pulse as it moves along the fibre.

erg c.g.s. unit of work, replaced in the SI system by the joule. One erg of work is done by a force of one dyne moving through one centimetre.

ergonomics study of the relationship between people and the furniture, tools, and machinery they use at work. The object is to improve work performance by removing sources of muscular stress and general fatigue: for example, by presenting data and control panels in easy-to-view form, making office furniture comfortable, and creating a generally pleasant environment.

Good ergonomic design makes computer systems easier to use and minimizes the health hazards and physical stresses of working with computers for many hours a day: it helps data entry workers to avoid conditions like strain injury (RSI), eyestrain, and back and muscle aches.

ergot any of a group of parasitic fungi (especially of the genus *Claviceps*), whose brown or black grainlike masses replace the kernels of rye or other cereals. *C. purpurea* attacks the rye plant. Ergot poisoning is caused by eating infected bread, resulting in burning pains, gangrene, and convulsions.

The large grains of the fungus contain the poison ergotamine.

ERIC (abbreviation for *Educational Resources Information Center*) in computing, database of resources for education available on the Internet. Established 1966, ERIC is a federally funded network of educational information. Sixteen clearing houses index educational materials for the database, which is housed at the University of Saskatchewan, Canada. The database is distributed in a variety of formats including printed books, CD-ROM, and microfiche.

erica any plant of a large group that includes the heathers. There are about 500 species, distributed mainly in South Africa with some in Europe. (Genus *Erica*, family Ericaceae.)

Eridanus in astronomy, the sixth largest constellation, which meanders from the celestial equator (see celestial sphere) deep into the southern hemisphere of the sky. Eridanus is represented as a river. Its brightest star is Achernar, a corruption of the Arabic for 'the end of the river'.

ermine the stoat during winter, when its coat becomes white.

In northern latitudes the coat becomes completely white, except for a black tip on the tail, but in warmer regions the back may remain brownish. The fur is used commercially.

ERNIE acronym for *electronic random number indicator*, machine designed and produced by the UK Post Office Research Station to select a series of random 9-figure numbers to indicate prizewinners among Premium Bond holders.

Eros in astronomy, an asteroid, discovered in 1898, that can pass 22 million km/14 million mi from the Earth, as observed in 1975. Eros was the first asteroid to be discovered that has an orbit coming within that of Mars. It is elongated, measures about $36 \times 12 \text{ km} \times 27 \text{ mi}$, rotates around its shortest axis every 5.3 hours, and orbits the Sun every 1.8 years.

The Near Earth Asteroid Rendezvous (NEAR) launched February 1996 is estimated to take three years to reach Eros. It will spend a year circling the asteroid in an attempt to determine what it is made of.

erosion wearing away of the Earth's surface, caused by the breakdown and transportation of particles of rock or soil (by contrast, weathering does not involve transportation). Agents of

erosion include the sea, rivers, glaciers, and wind.

Water, consisting of sea waves and currents, rivers, and rain; ice, in the form of glaciers; and wind, hurling sand fragments against exposed rocks and moving dunes along, are the most potent forces of erosion.

People also contribute to erosion by bad farming practices and the cutting down of forests, which can lead to the formation of dust bowls.

There are several processes of erosion including hydraulic action, corrosion, attrition, and solution.

erratic in geology, a displaced rock that has been transported by a glacier or some other natural force to a site of different geological composition.

error in computing, a fault or mistake, either in the software or on the part of the user, that causes a program to stop running (crash) or produce unexpected results. Program errors, or bugs, are largely eliminated in the course of the programmer's initial testing procedure, but some will remain in most programs. All computer operating systems are designed to produce an error message (on the display screen, or in an error file or printout) whenever an error is detected, reporting that an error has taken place and, wherever possible, diagnosing its cause.

Truth comes out of error more easily than out of confusion.

FRANCIS BACON English politician, philosopher, and essayist.

Quoted in R L Weber, *A Random Walk in Science*

error detection in computing, the techniques that enable a program to detect incorrect data. A common method is to add a check digit to important codes, such as account numbers and product codes. The digit is chosen so that the code conforms to a rule that the program can verify. Another technique involves calculating the sum (called the 'hash total') of each instance of a particular item of data, and storing it at the end of the data.

error message message produced by a computer to inform the user that an error has occurred.

erythroblast in biology, a series of nucleated cells that go through various stages of development in the bone marrow until they form red blood cells (erythrocytes). This process is known as erythropoiesis. Erythroblasts can appear in the blood of people with blood cancers.

erythrocyte another name for red blood cell.

Eryx genus of egg-laying snakes, closely allied to the boa constrictor. The species of *Eryx* differ from boas in having a very short, obtuse tail and narrower ventral plates. They occur in Asia and Africa.

ESA abbreviation for European Space Agency.

escalator automatic moving staircase that carries people between floors or levels. It consists of treads linked in an endless belt arranged to form steps (steps), powered by an electric motor that moves both steps and handrails at the same speed. Towards the top and bottom the steps flatten out for ease of passage. The first escalator was exhibited in Paris in 1900.

escape sequence in computing, string of characters sent to a modem to switch it from sending data to a state in which it can accept and act upon commands.

Most modems use the escape sequence patented by Hayes, which consists of three plus signs (+++) with a brief pause on either side to distinguish the characters from data.

escape velocity in physics, minimum velocity with which an object must be projected for it to escape from the gravitational pull of a planetary body. In the case of the Earth, the escape velocity is 11.2 kps/6.9 mps; the Moon, 2.4 kps/1.5 mps; Mars, 5 kps/3.1 mps; and Jupiter, 59.6 kps/37 mps.

escarpment or *cuesta* large ridge created by the erosion of dipping sedimentary rocks. It has one steep side (scarp) and one gently sloping side (dip). Escarpments are common features of chalk landscapes, such as the Chiltern Hills and the North Downs in England. Certain features are associated with chalk escarpments, including dry valleys (formed on the dip slope), combs (steep-sided valleys on the scarp slope), and springs.

Escherichia coli rod-shaped Gram-negative bacterium (see bacteria) that lives, usually harmlessly, in the colon of most warm-blooded animals. It is the commonest cause of urinary tract infections in humans. It is sometimes found in water or meat where faecal contamination has occurred and can cause severe gastric problems.

The mapping of the genome of *E. coli*, consisting of 4,403 genes, was completed in 1997.

classification *Escherichia coli* is the only species in the bacterial family Enterobacteriaceae.

ESP abbreviation for extrasensory perception.

esparto species of grass native to southern Spain, southern Portugal, and the Balearics, but now widely grown in dry, sandy locations throughout the world. The plant is just over 1 m/3 ft high, producing greyish-green leaves, which are used for making paper, ropes, baskets, mats, and cables. (*Stipa tenacissima*.)

ESPRIT (abbreviation for *European Strategic Programme for Research and Development in Information Technology*) European Union programme that funds technology research at an early stage of development. ESPRIT's goals include encouraging the development of international standards and cooperation between European companies, universities, and research centres in order to develop the infrastructure necessary for Europe to be able to compete with Japan and the USA.

essential amino acid water-soluble organic molecule vital to a healthy diet; see amino acid.

essential fatty acid organic compound consisting of a hydrocarbon chain and important in the diet; see fatty acid.

ester organic compound formed by the reaction between an alcohol and an acid, with the elimination of water. Unlike salts, esters are covalent compounds.

ester Molecular model of the ester ethyl ethanoate (ethyl acetate)
 $\text{CH}_3\text{CH}_2\text{COOCH}_3$

estradiol alternative spelling of oestradiol, a type of oestrogen (female sex hormone).

ethanal common name *acetaldehyde* CH_3CHO one of the chief members of the group of organic compounds known as aldehydes. It is a colourless inflammable liquid boiling at $20.8^\circ\text{C}/69.6^\circ\text{F}$. Ethanal is formed by the oxidation of ethanol or ethene and is used to make many other organic chemical compounds.

ethanal trimer common name *paraaldehyde* $(\text{CH}_3\text{CHO})_3$ colourless liquid formed from ethanal. It is soluble in water.

ethane C_2H_6 colourless, odourless gas, the second member of the alkane series of hydrocarbons (paraffins).

ethane-1,2-diol technical name for glycol.

ethanoate common name *acetate* CH_3CO_2^- negative ion derived from ethanoic (acetic) acid; any salt containing this ion. In textiles,

acetate rayon is a synthetic fabric made from modified cellulose (wood pulp) treated with ethanoic acid; in photography, acetate film is a non-flammable film made of cellulose ethanoate.

ethanoic acid common name *acetic acid* $\text{CH}_3\text{CO}_2\text{H}$ one of the simplest fatty acids (a series of organic acids). In the pure state it is a colourless liquid with an unpleasant pungent odour; it solidifies to an icelike mass of crystals at $16.7^\circ\text{C}/62.4^\circ\text{F}$, and hence is often called glacial ethanoic acid. Vinegar contains 5% or more ethanoic acid, produced by fermentation.

Cellulose (derived from wood or other sources) may be treated with ethanoic acid to produce a cellulose ethanoate (acetate) solution, which can be used to make plastic items by injection moulding or extruded to form synthetic textile fibres.

ethanol common name *ethyl alcohol* $\text{C}_2\text{H}_5\text{OH}$ alcohol found in beer, wine, cider, spirits, and other alcoholic drinks. When pure, it is a colourless liquid with a pleasant odour, miscible with water or ether; it burns in air with a pale blue flame. The vapour forms an explosive mixture with air and may be used in high-compression internal combustion engines.

It is produced naturally by the fermentation of carbohydrates by yeast cells. Industrially, it can be made by absorption of ethene and subsequent reaction with water, or by the reduction of ethanal in the presence of a catalyst, and is widely used as a solvent.

Ethanol is used as a raw material in the manufacture of ether, chloral, and iodoform. It can also be added to petrol, where it improves the performance of the engine, or be used as a fuel in its own right (as in Brazil). Crops such as sugar cane may be grown to provide ethanol (by fermentation) for this purpose.

ethene common name *ethylene* C_2H_4 colourless, flammable gas, the first member of the alkene series of hydrocarbons. It is the most widely used synthetic organic chemical and is used to produce the plastics polyethene (polyethylene), polychloroethene, and polyvinyl chloride (PVC). It is obtained from natural gas or coal gas, or by the dehydration of ethanol.

Ethene is produced during plant metabolism and is classified as a plant hormone. It is important in the ripening of fruit and in abscission. Small amounts of ethene are often added to the air surrounding fruit to artificially promote ripening. Tomato and marigold plants show distorted growth in concentrations as low as 0.01 parts per million. Plants also release ethene when they are under stress. German physicists invented a device in 1997 that measures stress levels in plants by measuring surrounding ethene levels.

ether in chemistry, any of a series of organic chemical compounds having an oxygen atom linking the carbon atoms of two hydrocarbon radical groups (general formula R-O-R'); also the common name for ethoxyethane $\text{C}_2\text{H}_5\text{OC}_2\text{H}_5$ (also called diethyl ether).

This is used as an anaesthetic and as an external cleansing agent before surgical operations. It is also used as a solvent, and in the extraction of oils, fats, waxes, resins, and alkaloids.

Ethoxyethane is a colourless, volatile, inflammable liquid, slightly soluble in water, and miscible with ethanol. It is prepared by treatment of ethanol with excess concentrated sulphuric acid at $140^\circ\text{C}/284^\circ\text{F}$.

ether or *aether* in the history of science, a hypothetical medium permeating all of space. The concept originated with the Greeks, and has been revived on several occasions to explain the properties and propagation of light. It was supposed that light and other electromagnetic radiation – even in outer space – needed a medium, the ether, in which to travel. The idea was abandoned with the acceptance of relativity.

Ethernet in computing, the most popular protocol for local area networks. Ethernet was developed principally by the Xerox Corporation, but can now be used on most computers. It normally allows data transfer at rates up to 10 Mbps, but 100 Mbps Fast Ethernet – often called 100Base-T – is already in widespread use while Gigabit Ethernet is being tipped for future success.

Ethernet and Fast Ethernet are IEEE standards, and Gigabit Ethernet should become a standard in 1998.

Ethiopian wolf *Simien jackal* or *Abyssinian wolf* member of the family Canidae, *Canis simensis*, and genetically close to the grey wolf and coyote. They are found mainly in Ethiopia's Bale and Simien Mountains, but numbers are seriously in decline with only about 400 left in 1997.

ethnography study of living cultures, using anthropological techniques like participant observation (where the anthropologist lives in the society being studied) and a reliance on informants. Ethnography has provided much data of use to archaeologists as analogies.

ethnology study of contemporary peoples, concentrating on their geography and culture, as distinct from their social systems. Ethnologists make a comparative analysis of data from different cultures to understand how cultures work and why they change, with a view to deriving general principles about human society.

ethnopaediatrics in anthropology, the study of child-rearing practices in different cultures. Areas studied include the comparison of feeding regimes, sleeping arrangements, and degree of verbal stimulation.

ethology comparative study of animal behaviour in its natural setting. Ethology is concerned with the causal mechanisms (both the stimuli that elicit behaviour and the physiological mechanisms controlling it), as well as the development of behaviour, its function, and its evolutionary history.

Ethology was pioneered during the 1930s by the Austrians Konrad Lorenz and Karl von Frisch who, with the Dutch zoologist Nikolaas Tinbergen, received the Nobel prize in 1973. Ethologists believe that the significance of an animal's behaviour can be understood only in its natural context, and emphasize the importance of field studies and an evolutionary perspective. A recent development within ethology is *ψ*sociobiology, the study of the evolutionary function of *ψ*social behaviour.

ethyl alcohol common name for ethanol.

ethylene common name for ethene.

ethylene glycol alternative name for glycol.

ethyne common name *acetylene* CHCH colourless inflammable gas produced by mixing calcium carbide and water. It is the simplest member of the *alkyne* series of hydrocarbons. It is used in the manufacture of the synthetic rubber neoprene, and in oxy-acetylene welding and cutting.

Ethyne was discovered by Edmund Davy in 1836 and was used in early gas lamps, where it was produced by the reaction between water and calcium carbide. Its combustion provides more heat, relatively, than almost any other fuel known (its calorific value is five times that of hydrogen). This means that the gas gives an intensely hot flame; hence its use in oxyacetylene torches.

etiolation in botany, a form of growth seen in plants receiving insufficient light. It is characterized by long, weak stems, small leaves, and a pale yellowish colour (chlorosis) owing to a lack of chlorophyll. The rapid increase in height enables a plant that is surrounded by others to quickly reach a source of light, after which a return to normal growth usually occurs.

Etruscan art the art of the inhabitants of Etruria, central Italy, a civilization that flourished 8th–2nd centuries BC. The Etruscans produced sculpture, painting, pottery, metalwork, and jewellery. Etruscan terracotta coffins (sarcophagi), carved with reliefs and topped with portraits of the dead reclining on one elbow, were to influence the later Romans and early Christians.

painting Most examples of Etruscan painting come from excavated tombs, whose frescoes depict scenes of everyday life, mythology, and mortuary rites, typically in bright colours and a vigorous, animated style. Scenes of feasting, dancing, swimming, fishing, and playing evoke a confident people who enjoyed life to the full, and who even in death depicted themselves in a joyous and festive manner. The decline of their civilization, in the shadow of Rome's expansion, is reflected in their later art, which loses its original *joie de vivre* and becomes sombre.

influences Influences from archaic Greece and the Middle East are evident, as are those from the preceding Iron Age Villanovan culture, but the full flowering of Etruscan art represents a unique synthesis of existing traditions and artistic innovation, which was to have a profound influence on the development of Western art.

eucalyptus any tree of a group belonging to the myrtle family, native to Australia, where they are commonly known as gumtrees. About 90% of Australian timber belongs to the eucalyptus genus, which contains about 500 species. The trees have dark hardwood timber which is used for heavy construction work such as railway and bridge building. They are mostly tall, aromatic, evergreen trees with pendant leaves and white, pink, or red flowers. (Genus *Eucalyptus*, family Myrtaceae.)

Compounds isolated from eucalyptus leaves were found in 1996 to be highly effective in killing *Streptococcus mutans*, the bacteria found in the mouth that cause dental decay.

EUCALYPTUS

The tallest tree ever measured was an Australian eucalyptus (*Eucalyptus regnans*), reported in 1872. It was 132 m/435 ft tall.

Eudora in computing, popular program for handling and receiving Internet e-mail. Published by the Californian company Qualcomm, Eudora uses *POP3*, and by the mid-1990s was one of the most commonly used e-mail programs on the Net.

eugenics *Greek eugenes 'well-born'* study of ways in which the physical and mental characteristics of the human race may be improved. The eugenic principle was abused by the Nazi Party in Germany during the 1930s and early 1940s to justify the attempted extermination of entire social and ethnic groups and the establishment of selective breeding programmes. Modern eugenics is concerned mainly with the elimination of genetic disease.

The term was coined by the English scientist Francis Galton in 1883, and the concept was originally developed in the late 19th century with a view to improving human intelligence and behaviour.

In 1986 Singapore became the first democratic country to adopt an openly eugenic policy by guaranteeing pay increases to female university graduates when they give birth to a child, while offering grants towards house purchases for nongraduate married women on condition that they are sterilized after the first or second child. In China in June 1995, a law was passed making it illegal for carriers of certain genetic diseases to marry unless they agree to sterilization or long-term contraception. All couples wishing to marry must undergo genetic screening.

Knowledge is the death of research.

WALTHER NERNST German physical chemist.

On examinations, in C G Gillespie (ed)

The Dictionary of Scientific Biography 1981

Euglena genus of single-celled organisms in the *ψ*protozoan phylum Sarcomastigophora that live in fresh water. They are usually oval or cigar-shaped, less than 0.5 mm/0.2 in long, and have a nucleus, green pigment in chloroplasts, a contractile vacuole, a light-sensitive eyespot, and one or two *ψ*flagella, with which they swim. A few species are colourless or red.

classification Euglena are members of the order Euglenida in class Phytomastigophora, subphylum Mastigophora, phylum Sarcomastigophora.

This organism combines animal and plant characteristics. Its plantlike characteristics include the chloroplasts and its consequent ability to photosynthesize, and the rigid cellulose wall of

some species. Its main animal characteristic is its motility, but it can also absorb food from its environment, and many species have a flexible body covering.

eukaryote in biology, one of the two major groupings into which all organisms are divided. Included are all organisms, except bacteria and cyanobacteria (blue-green algae), which belong to the prokaryote grouping.

The cells of eukaryotes possess a clearly defined nucleus, bounded by a membrane, within which DNA is formed into distinct chromosomes. Eukaryotic cells also contain mitochondria, chloroplasts, and other structures (organelles) that, together with a defined nucleus, are lacking in the cells of prokaryotes.

Euratom acronym for European Atomic Energy Community, forming part of the *European Union organization*.

eureka in chemistry, alternative name for the copper-nickel alloy constantan, which is used in electrical equipment.

eureka Greek 'I've got it' exclamation supposedly made by Archimedes on his discovery of fluid displacement.

Eurocodes series of codes giving design rules for all types of engineering structures, except certain very specialized forms, such as nuclear reactors. The codes will be given the status of ENs (European standards) and will be administered by CEN (European Committee for Standardization). ENs will eventually replace national codes, in Britain currently maintained by the BSI (British Standards Institute), and will include parameters to reflect local requirements.

Europa in astronomy, the fourth-largest moon of the planet Jupiter, diameter 3,140 km/1,950 mi, orbiting 671,000 km/417,000 mi from the planet every 3.55 days. It is covered by ice and crisscrossed by thousands of thin cracks, each some 50,000 km/30,000 mi long.

NASA's robot probe, *Galileo*, began circling Europa in February 1997 and is expected to send back around 800 images from 50 different sites by 1999. NASA plans to send a \$250 million robot probe in 2001 or 2002 to circle 100 km/60 mi above the surface, using radar and lasers to establish whether water exists beneath the icy surface. If found, a lander would be launched by 2006 to release a robot that would melt its way through the ice and release a submarine to take pictures. This operation is also billed at \$250 million. One of the first discoveries was that what were thought to be cracks covering the surface of the moon are in fact low ridges. Further investigation is needed to determine their origin.

European Atomic Energy Community (Euratom) organization established by the second Treaty of Rome 1957, which seeks the cooperation of member states of the European Union in nuclear research and the rapid and large-scale development of nonmilitary nuclear energy.

European corn borer moth whose larvae are a serious menace in countries, such as the USA, where maize is an important crop.

European Southern Observatory observatory operated jointly by Belgium, Denmark, France, Germany, Italy, the Netherlands, Sweden, and Switzerland with headquarters near Munich. Its telescopes, located at La Silla, Chile, include a 3.6-m/142-in reflector opened 1976 and the 3.58-m/141-in New Technology Telescope opened in 1990. By 1988 work began on the Very Large Telescope, consisting of four 8-m/315-in reflectors mounted independently but capable of working in combination.

European Space Agency (ESA) organization of European countries (Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Italy, the Netherlands, Norway, Spain, Sweden, Switzerland, and the UK) that engages in space research and technology. It was founded in 1975, with headquarters in Paris.

ESA has developed various scientific and communications satellites, the *Giotto* space probe, and the *Ariane rockets*. *ESA built* *Spacelab*, and plans to build its own space station, *Columbus*, for attachment to a US space station.

The ESA's earth-sensing satellite ERS-2 was launched successfully in 1995. It will work in tandem with ERS-1 launched in 1991, and should improve measurements of global ozone.

European Strategic Programme for Research and Development in Information Technology full name for *ESPRIT*.

euporium soft, greyish, metallic element of the lanthanide series, symbol Eu, atomic number 63, relative atomic mass 151.96. It is used in lasers and as the red phosphor in colour televisions; its compounds are used to make control rods for nuclear reactors. It was named in 1901 by French chemist Eugène Demarcay (1852–1940) after the continent of Europe, where it was first found.

eusociality form of social life found in insects such as honey bees and termites, in which the colony is made up of special castes (for example, workers, drones, and reproductives) whose membership is biologically determined. The worker castes do not usually reproduce. Only one mammal, the naked mole rat, has a social organization of this type. A eusocial shrimp was discovered in 1996 living in the coral reefs of Belize. *Synalpheus regalis* lives in colonies of up to 300 individuals, all the offspring of a single reproductive female. See also *social behaviour*.

Eustachian tube small air-filled canal connecting the middle ear with the back of the throat. It is found in all land vertebrates and equalizes the pressure on both sides of the eardrum.

Eutelsat acronym for *European Telecommunications Satellite Organization*.

euthanasia in medicine, mercy killing of someone with a severe and incurable condition or illness. Euthanasia is an issue that creates much controversy on medical and ethical grounds.

In Australia, a bill legalizing voluntary euthanasia for terminally ill patients was passed by the Northern Territory state legislature in May 1995.

In the Netherlands, where approximately 2,700 patients formally request it each year, euthanasia is technically illegal. However, provided guidelines issued by the Royal Dutch Medical Association are followed, doctors are not prosecuted.

In the USA, the Supreme Court ruled in June 1997 that the terminally ill do not have the fundamental right to have doctors help them to die. The Court upheld state laws in Washington and New York that forbid assisted suicides.

A patient's right to refuse life-prolonging treatment is recognized in several countries, including the UK.

Eutheria former division of class Mammalia, comprising all mammals mammals with a placenta.

eutrophication excessive enrichment of rivers, lakes, and shallow sea areas, primarily by nitrate fertilizers washed from the soil by rain, by phosphates from fertilizers, and from nutrients in municipal sewage, and by sewage itself. These encourage the growth of algae and bacteria which use up the oxygen in the water, thereby making it uninhabitable for fishes and other animal life.

evaporation process in which a liquid turns to a vapour without its temperature reaching boiling point. A liquid left to stand in a saucer eventually evaporates because, at any time, a proportion of its molecules will be fast enough (have enough kinetic energy) to escape through the attractive intermolecular forces at the liquid surface into the atmosphere. The temperature of the liquid tends to fall because the evaporating molecules remove energy from the liquid. The rate of evaporation rises with increased temperature because as the mean kinetic energy of the liquid's molecules rises, so will the number possessing enough energy to escape.

A fall in the temperature of the liquid, known as the *cooling effect*, accompanies evaporation because as the faster molecules escape through the surface the mean energy of the remaining molecules falls. The effect may be noticed when wet clothes are worn, and sweat evaporates from the skin. *Refrigeration* makes use of the cooling effect to extract heat from foodstuffs, and in the body it plays a part in temperature control.

Euthanasia

BY ROY PORTER

Euthanasia literally means a good or an easy death. Within traditional Christian culture, a good death (as prescribed by the *ars moriendi* – the art of dying well) was a Christian death, departing in a state of grace, denouncing Satan, praying to God, repenting one's sins and (for Roman Catholics) receiving the sacraments.

In the 17th century Francis Bacon argued that relief of suffering was a desideratum in terminal care and that the physician may sometimes hasten death. The idea of dying well was gradually secularized. Dying, it was said, should be like sleep, for a peaceful death betokened a serene conscience, a life well lived. In the new idea of euthanasia emerging in the 19th century, it was the duty of the doctor to ensure a peaceful death, by careful management and judicious application of opiates. At the wishes of family or patient, the family doctor was doubtless the frequent agent of informal (and strictly illegal) euthanasia.

This unofficial trend has been rendered more problematic in recent times. The Nazi 'final solution' perverted euthanasia for supremely evil purposes and created suspicion that any legalization of euthanasia would lead in time to (possibly compulsory) public euthanasia programmes for problem people and the senile. Moreover, death now increasingly occurs in public institutions, notably hospitals and hospices. This may make humane euthanasia more difficult, as physicians and nursing staff involved in such practices may fear exposure and legal prosecution from Christian pressure groups such as 'Life'.

Yet the circumstances of modern death have also increased backing for euthanasia. Thanks to life-support systems, it is now relatively easy to keep many 'dead' people artificially alive, with respirators and support systems. Repugnance is widespread for the 'cruelty' of this meaningless prolongation of life amongst those in

a 'permanent vegetative state'. Hence there is a growing desire to devise acceptable procedures for mercy killing, promoted by bodies such as 'Exit'. Euthanasia may be squared with the professional ethics of the physician and with normal morality through the argument that while it is the doctor's duty to save life, that duty does not run so far as to prolong life through artificial means in all circumstances.

Change has been most marked in The Netherlands, where since 1984 the medical colleges have accepted medical euthanasia under strictly controlled circumstances. By 1995 a survey suggested that active euthanasia (a physician humanely intervening to end a terminally ill patient's life at the request of that patient) was taking place in around 1.8% of all deaths. Public acceptance of this practice had been facilitated by the development of 'living wills'. Since 1994 Dutch physicians have been legally obliged to honour such 'living wills'. 'Living wills' have been legally binding in South Australia since the 'Natural Death Act' of 1983.

Such proposals have met with a much more divided reception elsewhere. In Britain, euthanasia remains illegal, living wills have no standing, and 'Exit' has been subject to prosecution – as has the maverick American pathologist, Dr Jack Kevorkian, who has practised doctor-assisted suicide at the patient's request. A law (1996) in Australia's Northern Territories permitting voluntary euthanasia has since been overturned by the Federal Government. In 1997 the British Medical Association came out against voluntary euthanasia.

The advance of modern medicine presents deep ethical dilemmas in the case of death. There is no easy way to balance the sanctity of human life against the right of personal autonomy. Fundamental legal and moral questions are also raised.

evening primrose any of a group of plants that typically have pale yellow flowers which open in the evening. About 50 species are native to North America, several of which now also grow in Europe. Some are cultivated for their oil, which is rich in gamma-linoleic acid (GLA). The body converts GLA into substances which resemble hormones, and evening primrose oil is beneficial in relieving the symptoms of premenstrual tension. It is also used in treating eczema and chronic fatigue syndrome. (Genus *Oenothera*, family Onagraceae.)

event-driven in computing, computer system that does not do anything until events are detected, such as mouse-clicks. Microsoft Windows is an event-driven operating environment.

evergreen in botany, a plant such as pine, spruce, or holly, that sheds its leaves all year round. Most conifers are evergreen. Plants that shed their leaves in autumn or during a dry season are described as deciduous.

everlasting flower any flower head with coloured bracts that retains its colour when cut and dried.

Nature does not make jumps.

CAROLUS LINNAEUS Swedish naturalist and physician.
Philosophia Botanica

evolution the slow, gradual process of change from one form to another, as in the evolution of the universe from its formation to its present state, or in the evolution of life on Earth. In biology, it is the process by which life has developed by stages from single-celled

EVOLUTION: THEORY AND HISTORY

<http://www.ucmp.berkeley.edu/history/evolution.html>

Dedicated to the study of the history and theories associated with evolution, this site explores topics on classification, taxonomy, and dinosaur discoveries, and then looks at the key figures in the field and reviews their contributions.

organisms into the multiplicity of animal and plant life, extinct and existing, that inhabit the Earth. The development of the concept of evolution is usually associated with the English naturalist Charles Darwin who attributed the main role in evolutionary change to natural selection acting on randomly occurring variations. However, these variations in species are now known to be adaptations produced by spontaneous changes or mutations in the genetic material of organisms.

evolution and creationism Organic evolution traces the development of simple unicellular forms to more complex forms, ultimately to the flowering plants and vertebrate animals, including humans. The Earth contains an immense diversity of living organisms: about a million different species of animals and half a million species of plants have so far been described. Some religions deny the theory of evolution considering it conflicts with their belief that God created all things (see *creationism*). But most people accept that there is overwhelming evidence the diversity of life arose by a gradual process of evolutionary divergence and not by individual acts of divine creation. There are several lines of evidence: the fossil record, the existence of similarities or homologies between different groups of organisms, embryology, and geographical distribution.

We must, however, acknowledge, as it seems to me, that man with all his noble qualities, still bears in his bodily frame the indelible stamp of his lowly origin.

CHARLES DARWIN British naturalist.
Last words of *Descent of Man* 1871

evolutionary stable strategy (ESS) in ϕ sociobiology, an assemblage of behavioural or physical characters (collectively termed a 'strategy') of a population that is resistant to replacement by any forms bearing new traits, because the new traits will not be capable of successful reproduction.

ESS analysis is based on ϕ game theory and can be applied both to genetically determined physical characters (such as horn length), and to learned behavioural responses (for example, whether to fight or retreat from an opponent). An ESS may be conditional on the context, as in the rule 'fight if the opponent is smaller, but retreat if the opponent is larger'.

evolutionary toxicology study of the effects of pollution on evolution. A polluted habitat may cause organisms to select for certain traits, as in industrial melanism for example, where some insects, such as the peppered moth, are darker in polluted areas, and therefore better camouflaged against predation.

Pollutants may also trigger mutations, for example, voles living around the Chernobyl exploded nuclear reactor have a very high mutation rate despite appearing healthy and reproducing successfully. Fish in polluted rivers also exhibit mutations.

excavation or dig in archaeology, the systematic recovery of data through the exposure of buried sites and artefacts. Excavation is destructive, and is therefore accompanied by a comprehensive recording of all material found and its three-dimensional locations (its context). As much material and information as possible must be recovered from any dig. A full record of all the techniques employed in the excavation itself must also be made, so that future archaeologists will be able to evaluate the results of the work accurately.

Besides being destructive, excavation is also costly. For both these reasons, it should be used only as a last resort. It can be partial, with only a sample of the site investigated, or total. Samples are chosen either intuitively, in which case excavators investigate those areas they feel will be most productive, or statistically, in which case the sample is drawn using various statistical techniques, so as to ensure that it is representative.

An important goal of excavation is a full understanding of a site's stratigraphy; that is, the vertical layering of a site.

These layers or levels can be defined naturally (for example, soil changes), culturally (for example, different occupation levels), or arbitrarily (for example, 10 cm/4 in levels). Excavation can also be done horizontally, to uncover larger areas of a particular layer and reveal the spatial relationships between artefacts and features in that layer. This is known as open-area excavation and is used especially where single-period deposits lie close to the surface, and the time dimension is represented by lateral movement rather than by the placing of one building on top of the preceding one.

Most excavators employ a flexible combination of vertical and horizontal digging adapting to the nature of their site and the questions they are seeking to answer.

excavator machine designed for digging in the ground, or for earth-moving in general. Diggers with hydraulically powered digging arms are widely used on building sites. They may run on wheels or on ϕ caterpillar tracks. The largest excavators are the draglines used in mining to strip away earth covering the coal or mineral deposit.

Excel ϕ spreadsheet program produced by ϕ Microsoft in 1985. Versions are available for PC-compatibles running ϕ Windows and for the Apple Macintosh. Excel pioneered many advanced features in the ease of use of spreadsheets, and has displaced ϕ Lotus 1-2-3 as the standard spreadsheet program.

exclusion principle in physics, a principle of atomic structure originated by Austrian-US physicist Wolfgang ϕ Pauli. It states that no two electrons in a single atom may have the same set of quantum numbers.

Hence, it is impossible to pack together certain elementary particles, such as electrons, beyond a certain critical density, otherwise they would share the same location and quantum number. A white dwarf star, which consists of electrons and other elementary particles, is thus prevented from contracting further by the exclusion principle and never collapses.

excretion in biology, the removal of waste products from the cells of living organisms. In plants and simple animals, waste products are removed by diffusion, but in higher animals they are removed by specialized organs. In mammals the kidneys are the principal organs of excretion. Water and metabolic wastes are also excreted in the faeces and, in humans, through the sweat glands; carbon dioxide and water are removed via the lungs.

TO REMEMBER THE EXCRETORY ORGANS OF THE BODY:

SKIN / KIDNEYS / INTESTINES / LIVER / LUNGS

executable file in computing, a file – always a program of some kind – that can be run by the computer directly. The file will have been generated from a ϕ source program by an ϕ assembler or ϕ compiler. It will therefore not be coded in ϕ ASCII and will not be readable as text. On ϕ MS-DOS systems executable files have an .EXE or .COM extension.

exfoliation in biology, the separation of pieces of dead bone or skin in layers.

exobiology study of life forms that may possibly exist elsewhere in the universe, and of the effects of extraterrestrial environments on Earth organisms. Techniques include space probe experiments designed to detect organic molecules, and the monitoring of radio waves from other star systems.

exocrine gland gland that discharges secretions, usually through a tube or a duct, on to a surface. Examples include sweat glands which release sweat on to the skin, and digestive glands which release digestive juices on to the walls of the intestine. Some animals also have ϕ endocrine glands (ductless glands) that release hormones directly into the bloodstream.

exon in genetics, a sequence of bases in ϕ DNA that codes for a protein. Exons make up only 2% of the body's total DNA. The remainder is made up of ϕ introns. During RNA processing the introns are cut out of the molecule and the exons spliced together.

exoskeleton the hardened external skeleton of insects, spiders, crabs, and other arthropods. It provides attachment for muscles and protection for the internal organs, as well as support. To permit growth it is periodically shed in a process called ϕ ecdysis.

exosphere the uppermost layer of the ϕ atmosphere. It is an ill-defined zone above the thermosphere, beginning at about 700 km/435 mi and fading off into the vacuum of space. The gases are extremely thin, with hydrogen as the main constituent.

exothermic reaction a chemical reaction during which heat is given out (see ϕ energy of reaction).

expanded memory in computing, additional memory in an ϕ MS-DOS-based computer, usually installed on an expanded-memory board. Expanded memory requires an expanded-memory manager, which gives access to a limited amount of memory at any one time, and is slower to use than ϕ extended memory. Software is available under both MS-DOS and ϕ Windows to simulate expanded memory for those applications that require it.

expansion in physics, the increase in size of a constant mass of substance caused by, for example, increasing its temperature

expansion board An expansion board may be fitted into any free expansion slot in a computer to provide additional facilities or functionality.

(of thermal expansion) or its internal pressure. The **expansivity**, or coefficient of thermal expansion, of a material is its expansion (per unit volume, area, or length) per degree rise in temperature.

expansion board or **expansion card** printed circuit board that can be inserted into a computer in order to enhance its capabilities (for example, to increase its memory) or to add facilities (such as graphics).

expectorant any substance, often added to cough mixture, to encourage secretion of mucus in the airways to make it easier to cough up. It is debatable whether expectorants have an effect on lung secretions.

experiment in science, a practical test designed with the intention that its results will be relevant to a particular theory or set of theories. Although some experiments may be used merely for gathering more information about a topic that is already well understood, others may be of crucial importance in confirming a new theory or in undermining long-held beliefs.

The manner in which experiments are performed, and the relation between the design of an experiment and its value, are therefore of central importance. In general, an experiment is of most value when the factors that might affect the results (variables) are carefully controlled; for this reason most experiments take place in a well-managed environment such as a laboratory or clinic.

experimental psychology the application of scientific methods to the study of mental processes and behaviour.

EXPERIMENTAL PSYCHOLOGY LAB

<http://www.uni-tuebingen.de/uni/sii/Ulf/Lab/WebExpPsyLab.html>

Take part in online psychology experiments carried out by the University of Tübingen's Psychology Institute. There are a variety of experiments here, some requiring Java and ActiveX, and some only in German.

This covers a wide range of fields of study, including: **human and animal learning**, in which learning theories describe how new behaviours are acquired and modified; **cognition**, the study of a number of functions, such as perception, attention, memory, and language; and **physiological psychology**, which relates the study of cognition to different regions of the brain. **Artificial intelligence** refers to the computer simulation of cognitive processes, such as language and problem-solving.

expert system computer program for giving advice (such as diagnosing an illness or interpreting the law) that incorporates knowledge derived from human expertise. It is a kind of knowledge-based system containing rules that can be applied to find the solution to a problem. It is a form of artificial intelligence.

expire in computing, function for removing old USENET articles from an off-line reader program. Sometimes also called 'prune' or 'purge', this function is necessary to make room for new articles.

explanation in science, an attempt to make clear the cause of any natural event by reference to physical laws and to observations.

The extent to which any explanation can be said to be true is one of the chief concerns of philosophy, partly because observations may be wrongly interpreted, partly because explanations should help us predict how nature will behave. Although it may be reasonable to expect that a physical law will hold in the future, that expectation is problematic in that it relies on induction, a much criticized feature of human thought; in fact no explanation, however 'scientific', can be held to be true for all time, and thus the difference between a scientific and a common-sense explanation remains the subject of intense philosophical debate.

Explorer series of US scientific satellites. *Explorer 1*, launched January 1958, was the first US satellite in orbit and discovered the Van Allen radiation belts around the Earth.

explosive any material capable of a sudden release of energy and the rapid formation of a large volume of gas, leading, when compressed, to the development of a high-pressure wave (blast).

types of explosive Combustion and explosion differ essentially only in rate of reaction, and many explosives (called low explosives) are capable of undergoing relatively slow combustion under suitable conditions. High explosives produce uncontrollable blasts. The first low explosive was gunpowder; the first high explosive was nitroglycerine.

exponent or **index** in mathematics, a number that indicates the number of times a term is multiplied by itself; for example $x^2 = x \times x$, $4^3 = 4 \times 4 \times 4$.

Exponents obey certain rules. Terms that contain them are multiplied together by adding the exponents; for example, $x^2 \times x^5 = x^7$. Division of such terms is done by subtracting the exponents; for example, $y^5 \div y^3 = y^2$. Any number with the exponent 0 is equal to 1; for example, $x^0 = 1$ and $99^0 = 1$.

exponential in mathematics, descriptive of a function in which the variable quantity is an exponent (a number indicating the power to which another number or expression is raised).

Exponential functions and series involve the constant $e = 2.71828...$. Scottish mathematician John Napier devised natural logarithms in 1614 with e as the base.

Exponential functions are basic mathematical functions, written as ex or $\exp x$. The expression ex has five definitions, two of which are: (i) ex is the solution of the differential equation $dx/dt = x$ ($x =$

1 if $t = 0$; (ii) ex is the limiting sum of the infinite series $1 + x + (x^2/2!) + (x^3/3!) + \dots + (x^n/n!)$.

export file in computing, a file stored by the computer in a standard format so that it can be accessed by other programs, possibly running on different makes of computer.

For example, a word-processing program running on an Apple $\text{\textcircled{C}}$ Macintosh computer may have a facility to save a file on a floppy disc in a format that can be read by a word-processing program running on an IBM PC-compatible computer. When the file is being read by the second program or computer, it is often referred to as an import file.

exposure meter instrument used in photography for indicating the correct exposure – the length of time the camera shutter should be open under given light conditions. Meters use substances such as cadmium sulphide and selenium as light sensors. These materials change electrically when light strikes them, the change being proportional to the intensity of the incident light. Many cameras have a built-in exposure meter that sets the camera controls automatically as the light conditions change.

extended memory in computing, memory in an $\text{\textcircled{C}}$ MS-DOS-based system that exceeds the 1 Mbyte that DOS supports. Extended memory is not accessible to the operating system and requires an extended memory manager.

extensor a muscle that straightens a limb.

exterior angle one of the four external angles formed when a straight line or transversal cuts through a pair of (usually parallel) lines. Also, an angle formed by extending a side of a polygon.

external modem in computing, a (modem that is a self-contained unit sitting outside a personal computer (PC) and connected to it by a cable. There are two main types of external modem: mains-powered desktop modems and credit-card sized modems that fit the PCMCIA slots in notebook and handheld computers.

External modems have the advantage over internal ones in that they are easy to move from computer to computer as needed. However, high-speed modems outstrip the capabilities of the serial ports on older and cheaper PCs by taking in data too fast for the computer to be able to read it.

extinction in biology, the complete disappearance of a species or higher taxon. Extinctions occur when an animal becomes unfit for survival in its natural habitat usually to be replaced by another, better-suited animal. An organism becomes ill-suited for survival because its environment is changed or because its relationship to other organisms is altered. For example, a predator's fitness for survival depends upon the availability of its prey.

past extinctions Mass extinctions are episodes during which large numbers of species have become extinct virtually simultaneously, the best known being that of the dinosaurs, other large reptiles, and various marine invertebrates about 65 million years ago between the end of the $\text{\textcircled{C}}$ retaceous period and the beginning of the Tertiary period. The latter, known as the K-T extinction, has been attributed to catastrophic environmental changes following a meteor impact or unusually prolonged and voluminous volcanic eruptions.

Another mass extinction occurred about 10,000 years ago when many giant species of mammal died out. This is known as the 'Pleistocene overkill' because their disappearance was probably hastened by the hunting activities of prehistoric humans. The greatest mass extinction occurred about 250 million years ago, marking the Permian-Triassic boundary (see $\text{\textcircled{C}}$ geological time), when up to 96% of all living species became extinct. Mass extinctions apparently occur at periodic intervals of approximately 26 million years.

current extinctions Humans have the capacity to profoundly influence many habitats and today a large number of extinctions are attributable to human activity. Some species, such as the $\text{\textcircled{C}}$ dodo of Mauritius, the $\text{\textcircled{C}}$ moas of New Zealand, and the passenger pigeon of North America, were exterminated by hunting. Others became extinct when their habitat was destroyed. $\text{\textcircled{C}}$ Endangered species are close to extinction. The rate of extinction is difficult to estimate, but

appears to have been accelerated by humans. Conservative estimates put the rate of loss due to deforestation alone at 4,000 to 6,000 species a year. Overall, the rate could be as high as one species an hour, with the loss of one species putting those dependent on it at risk. Australia has the worst record for extinction: 18 mammals have disappeared since Europeans settled there, and 40 more are threatened.

If we are still here to witness the destruction of our planet [by the Sun] some five billion years or more hence, then we will have achieved something so unprecedented in the history of life that we should be willing to sing our swan song with joy.

STEPHEN JAY GOULD US palaeontologist and writer.
The Panda's Thumb 1980

extracellular matrix strong material naturally occurring in animals and plants, made up of protein and long-chain sugars (polysaccharides) in which cells are embedded. It is often called a 'biological glue', and forms part of connective tissues such as bone and skin.

The cell walls of plants and bacteria, and the $\text{\textcircled{C}}$ exoskeletons of insects and other arthropods, are also formed by types of extracellular matrix.

extrasensory perception (ESP) any form of perception beyond and distinct from the known sensory processes. The main forms of ESP are clairvoyance (intuitive perception or vision of events and situations without using the senses); precognition (the ability to foresee events); and telepathy or thought transference (communication between people without using any known visible, tangible, or audible medium). Verification by scientific study has yet to be achieved.

extroversion or **extraversion** personality dimension described by the psychologists Carl Jung and, later, Hans Eysenck. The typical extrovert is sociable, impulsive, and carefree. The opposite of extroversion is $\text{\textcircled{C}}$ introversion.

extruded shape in computer graphics, a three-dimensional shape created by extending a two-dimensional shape along a third dimension.

extrusion common method of shaping metals, plastics, and other materials. The materials, usually hot, are forced through the hole in a metal die and take its cross-sectional shape. Rods, tubes, and sheets may be made in this way.

extrusive rock or **volcanic rock** $\text{\textcircled{C}}$ igneous rock formed on the surface of the Earth by volcanic activity. The term includes fine-grained crystalline or glassy rocks formed from hot lava quenched at or near Earth's surface and rocks composed of solid debris, called pyroclastics, deposited by explosive eruptions.

Large amounts of extrusive rock called $\text{\textcircled{C}}$ basalt form at the Earth's $\text{\textcircled{C}}$ ocean ridges from lava that fills the void formed when two tectonic plates spread apart. Explosive volcanoes that deposit pyroclastics generally occur where one tectonic plate descends beneath another. $\text{\textcircled{C}}$ Andesite is often formed by explosive volcanoes. Magmas that give rise to pyroclastic extrusive rocks are explosive because they are viscous. The island of Montserrat, West Indies, is an example of an explosive volcano that spews pyroclastics of andesite composition. Magmas that produce crystalline or glassy volcanic rocks upon cooling are less viscous. The low viscosity allows the extruding lava to flow easily. Fluid-like lavas that flow from the volcanoes of the Hawaiian Islands have low viscosity and cool to form basalt.

eye the organ of vision. In the human eye, the light is focused by the combined action of the curved cornea, the internal fluids, and the lens. The insect eye is compound – made up of many separate facets – known as ommatidia, each of which collects light and directs it separately to a receptor to build up an image. Invertebrates have much simpler eyes, with no lenses. Among molluscs, cephalopods have complex eyes similar to those of vertebrates.

eye The human eye. The retina of the eye contains about 137 million light-sensitive cells in an area of about 650 sq mm/1 sq in. There are 130 million rod cells for black and white vision and 7 million cone cells for colour vision. The optic nerve contains about 1 million nerve fibres. The focusing muscles of the eye adjust about 100,000 times a day. To exercise the leg muscles to the same extent would need an 80 km/50 mi walk.

The mantis shrimp's eyes contain ten colour pigments with which to perceive colour; some flies and fishes have five, while the human eye has only three.

human eye This is a roughly spherical structure contained in a bony socket. Light enters it through the cornea, and passes through the circular opening (pupil) in the iris (the coloured part of the eye).

The ciliary muscles act on the lens (the rounded transparent structure behind the iris) to change its shape, so that images of objects at different distances can be focused on the retina. This is at the back of the eye, and is packed with light-sensitive cells (rods and cones), connected to the brain by the optic nerve.

Don't believe what your eyes are telling you, all they show is limitation. Look with your understanding, find out what you already know, and you'll see the way to fly.

RICHARD BACH US writer.
Jonathan Livingstone Seagull

eyebright any of a group of annual plants belonging to the figwort family. They are 2–30 cm/1–12 in high and have whitish flowers streaked with purple. The name indicates their traditional use as an eye-medicine. (Genus *Euphrasia*, family Scrophulariaceae.)

eye, defects of the abnormalities of the eye that impair vision. Glass or plastic lenses, in the form of spectacles or contact lenses, are the usual means of correction. Common optical defects are (short-sightedness or myopia; farsightedness or hypermetropia; lack of accommodation or presbyopia; and astigmatism. Other eye defects include colour blindness.

e-zine (contraction of *electronic magazine*) in computing, periodical sent by e-mail. E-zines can be produced very cheaply, as there are no production costs for design and layout, and minimal costs for distribution. Like printed magazines, e-zines typically have multiple contributors and an editor responsible for selecting content.

One of the best-known e-zines is the *Computer Underground Digest*, which tracks battles over freedom of speech online and issues concerning hacking and computer crime.

F

°F symbol for degrees Fahrenheit.

F1 on personal computers (PCs), the key to access online help.

face in geometry, a plane surface of a solid enclosed by edges. A cube has six square faces, a cuboid has six rectangular faces, and a tetrahedron has four triangular faces.

facies in geology, body of rock strata possessing unifying characteristics indicative of the environment in which the rocks were formed. The term is also used to describe the environment of formation itself or unifying features of the rocks that comprise the facies.

Features that define a facies can include collections of fossils, sequences of rock layers, or the occurrence of specific minerals. Sedimentary rocks deposited at the same time, but representing different facies belong to a single **chronostratigraphic unit** (see stratigraphy). But these same rocks may belong to different **lithostratigraphic units**. For example, beach sand is deposited at the same time that mud is deposited further offshore. The beach sand eventually turns to sandstone while the mud turns to shale. The resulting sandstone and shale strata comprise two different facies, one representing the beach environment and the other the offshore environment, formed at the same time; the sandstone and shale belong to the same chronostratigraphic unit but distinct lithostratigraphic units.

facsimile transmission full name for fax or telefax.

factor a number that divides into another number exactly. For example, the factors of 64 are 1, 2, 4, 8, 16, 32, and 64. In algebra, certain kinds of polynomials (expressions consisting of several or many terms) can be factorized. For example, the factors of $x^2 + 3x + 2$ are $x + 1$ and $x + 2$, since $x^2 + 3x + 2 = (x + 1)(x + 2)$. This is called factorization. See also number.

factorial of a positive number, the product of all the whole numbers (integers) inclusive between 1 and the number itself. A factorial is indicated by the symbol '!'. Thus $6! = 1 \times 2 \times 3 \times 4 \times 5 \times 6 = 720$. Factorial zero, $0!$, is defined as 1.

factory farming intensive rearing of poultry or other animals for food, usually on high-protein foodstuffs in confined quarters. Chickens for eggs and meat, and calves for veal are commonly factory farmed. Some countries restrict the use of antibiotics and growth hormones as aids to factory farming because they can persist in the flesh of the animals after they are slaughtered. The emphasis is on productive yield rather than animal welfare so that conditions for the animals are often very poor. For this reason, many people object to factory farming on moral as well as health grounds.

Egg-laying hens are housed in 'batteries' of cages arranged in long rows. If caged singly, they lay fewer eggs, so there are often four to a cage with a floor area of only 2,400 sq cm/372 sq in. In the course of a year, battery hens average 261 eggs each, whereas for free-range chickens the figure is 199.

faeces remains of food and other waste material eliminated from the digestive tract of animals by way of the anus. Faeces consist of quantities of fibrous material, bacteria and other microorganisms, rubbed-off lining of the digestive tract, bile fluids, undigested food, minerals, and water.

Many things about our bodies would not seem so filthy and obscene if we did not have the idea of nobility in our heads.

G C LICHTENBERG German physicist and philosopher.
Aphorisms, 'Notebook D' 6

Fahrenheit, Gabriel Daniel (1686-1736) Polish-born Dutch physicist who invented the first accurate thermometer in 1724 and devised the Fahrenheit temperature scale. Using his thermometer, Fahrenheit was able to determine the boiling points of liquids and found that they vary with atmospheric pressure.

Fahrenheit scale temperature scale invented in 1714 by Gabriel Fahrenheit which was commonly used in English-speaking countries until the 1970s, after which the Celsius scale was generally adopted, in line with the rest of the world. In the Fahrenheit scale, intervals are measured in degrees (°F); $F = (C \times 9/5) + 32$.

Fahrenheit took as the zero point the lowest temperature he could achieve anywhere in the laboratory, and, as the other fixed point, body temperature, which he set at 96°F. On this scale, water freezes at 32°F and boils at 212°F.

fainting sudden, temporary loss of consciousness caused by reduced blood supply to the brain. It may be due to emotional shock or physical factors, such as pooling of blood in the legs from standing still for long periods.

falcon any bird of prey of the genus *Falco*, family Falconidae, order Falconiformes. Falcons are the smallest of the hawks (15-60 cm/6-24 in). They have short curved beaks with one tooth in the upper mandible; the wings are long and pointed, and the toes elongated. They nest in high places and kill their prey on the wing by 'stooping' (swooping down at high speed). They include the peregrine and kestrel.

The peregrine *F. peregrinus*, up to about 50 cm/1.8 ft long, has become re-established in North America and Britain after near extinction (by pesticides, gamekeepers, and egg collectors). When stooping on its intended prey, it is the fastest creature in the world, timed at 240 kph/150 mph. The US government announced preliminary measures to remove the American peregrine falcon from the endangered species list in 1995 following a successful breeding programme.

Fallopian tube or **oviduct** in mammals, one of two tubes that carry eggs from the ovary to the uterus. An egg is fertilized by sperm in the Fallopian tubes, which are lined with cells whose cilia move the egg towards the uterus.

fallout harmful radioactive material released into the atmosphere in the debris of a nuclear explosion and descending to the surface of the Earth. Such material can enter the food chain, cause radiation sickness, and last for hundreds of thousands of years (see half-life).

fallow land ploughed and tilled, but left unsown for a season to allow it to recuperate. In Europe, it is associated with the medieval three-field system. It is used in some modern crop rotations and in countries that do not have access to fertilizers to maintain soil fertility.

fallow deer one of two species of deer. Fallow deer are characterized by the expansion of the upper part of their antlers in palmate form. Usually they stand about 1 m/3.3 ft high, and have small heads, large ears, and rather long tails. In colour they are fawn, with a number of large white spots, or they may be yellowish-brown or, more rarely, dark brown.

The commonest species *Dama dama* is a native of North Africa and the countries bordering the Mediterranean, and was introduced into Britain at an early period. *D. mesopotamica* is a native of the mountains of Iran.

classification The fallow deer is in genus *Dama* in the Cervidae family of the mammalian order Artiodactyla.

false of a statement, untrue. Falseness is used in proving propositions by considering the negative of the proposition to be true, then

making deductions until a contradiction is reached which proves the negative to be false and the proposition to be true.

false-colour imagery graphic technique that displays images in false (not true-to-life) colours so as to enhance certain features. It is widely used in displaying electronic images taken by spacecraft; for example, Earth-survey satellites such as *Landsat*. Any colours can be selected by a computer processing the received data.

falsificationism in philosophy of science, the belief that a scientific theory must be under constant scrutiny and that its merit lies only in how well it stands up to rigorous testing. It was first expounded by philosopher Karl Popper in his *Logic of Scientific Discovery* 1934.

Such thinking also implies that a theory can be held to be scientific only if it makes predictions that are clearly testable. Critics of this belief acknowledge the strict logic of this process, but doubt whether the whole of scientific method can be subsumed into so narrow a programme. Philosophers and historians such as Thomas Kuhn and Paul Feyerabend have attempted to use the history of science to show that scientific progress has resulted from a more complicated methodology than Popper suggests.

family in biological classification, a group of related genera (see *genus*). Family names are not printed in italic (unlike genus and species names), and by convention they all have the ending *-idae* (animals) or *-aceae* (plants and fungi). For example, the genera of hummingbirds are grouped in the hummingbird family, *Trochilidae*. Related families are grouped together in an *order*.

family planning spacing or preventing the birth of children. Access to family-planning services (see *contraception*) is a significant factor in women's health as well as in limiting population growth. If all those women who wished to avoid further childbirth were able to do so, the number of births would be reduced by 27% in Africa, 33% in Asia, and 35% in Latin America; and the number of women who die during pregnancy or childbirth would be reduced by about 50%.

The average number of pregnancies per woman is two in the industrialized countries, where 71% use family planning, as compared to six or seven pregnancies per woman in the Third World. According to a World Bank estimate, doubling the annual \$2 billion spent on family planning would avert the deaths of 5.6 million infants and 250,000 mothers each year.

fanjet another name for *turbobfan*, the jet engine used by most airliners.

fantail variety of domestic *pigeon*, often white, with a large, widely fanning tail.

FAQ (abbreviation for *frequently asked questions*) in computing, file of answers to commonly asked questions on any topic. First used on USENET, where regular posters to *newsgroups* got tired of answering the same questions over and over and wrote these information files to end the repetition. 'Newbies' are recommended to read the FAQ for any newsgroup they join before posting. Most FAQs are available via FTP from rftm.mit.edu or via the World-Wide Web from <http://www.cis.ohio-state.edu/htbin/search-usenet-faq>. By 1996 FAQ was a common term for any information file, on line or off line.

farad SI unit (symbol F) of electrical capacitance (how much electric charge a capacitor can store for a given voltage). One farad is a capacitance of one coulomb per volt. For practical purposes the microfarad (one millionth of a farad, symbol μF) is more commonly used.

faraday unit of electric charge equal to the charge on one mole of electrons. Its value is 9.648×10^4 coulombs.

Faraday's constant constant (symbol *F*) representing the electric charge carried on one mole of electrons. It is found by multiplying Avogadro's constant by the charge carried on a single electron, and is equal to 9.648×10^4 coulombs per mole.

One faraday is this constant used as a unit. The constant is used to calculate the electric charge needed to discharge a particular quantity of ions during *electrolysis*.

Faraday's laws three laws of electromagnetic induction, and two laws of electrolysis, all proposed originally by English scientist Michael Faraday:

induction (1) a changing magnetic field induces an electromagnetic force in a conductor; (2) the electromagnetic force is proportional to the rate of change of the field; (3) the direction of the induced electromagnetic force depends on the orientation of the field.

electrolysis (1) the amount of chemical change during electrolysis is proportional to the charge passing through the liquid; (2) the amount of chemical change produced in a substance by a given amount of electricity is proportional to the electrochemical equivalent of that substance.

far point the farthest point that a person can see clearly. The eye is unable to focus a sharp image on the retina of an object beyond this point. The far point for a normal eye should be at infinity; any eye that has a far point nearer than this is short-sighted (see *short-sightedness*).

fast breeder or breeder reactor alternative names for *fast reactor*, a type of nuclear reactor.

fasting the practice of voluntarily going without food. It can be undertaken as a religious observance, a sign of mourning, a political protest (hunger strike), or for slimming purposes.

Fasting or abstinence from certain types of food or beverages occurs in most religious traditions. It is seen as an act of self-discipline that increases spiritual awareness by lessening dependence on the material world. In the Roman Catholic church, fasting is seen as a penitential rite, a means to express repentance for sin. The most commonly observed Christian fasting is in Lent, from Ash Wednesday to Easter Sunday, and recalls the 40 days Jesus spent in the wilderness. Roman Catholics and Orthodox Christians usually fast before taking communion and monastic communities observe regular weekly fasts. Devout Muslims go without food or water between sunrise and sunset during the month of Ramadan. Jews fast for *Yom Kippur* and before several other festivals. Many devout Hindus observe a weekly day of partial or total fast.

Total abstinence from food for a limited period is prescribed by some *naturopaths* to eliminate body toxins or make available for recuperative purposes the energy normally used by the digestive system. Prolonged fasting can be dangerous. The liver breaks up its fat stores, releasing harmful by-products called ketones, which results in a condition called ketosis, which develops within three days. An early symptom is a smell of pear drops on the breath. Other symptoms include nausea, vomiting, fatigue, dizziness, severe depression, and irritability. Eventually the muscles and other body tissues become wasted, and death results.

fast reactor or fast breeder reactor *nuclear reactor* that makes use of fast neutrons to bring about fission. Unlike other reactors used by the nuclear-power industry, it has little or no *moderator*, to slow down neutrons. The reactor core is surrounded by a 'blanket' of uranium carbide. During operation, some of this uranium is converted into plutonium, which can be extracted and later used as fuel.

Fast breeder reactors can extract about 60 times the amount of energy from uranium than thermal reactors do. In the 1950s, when uranium stocks were thought to be dwindling, the fast breeder was considered to be the reactor of the future. Now, however, when new uranium reserves have been found and because of various technical difficulties in their construction, development of the fast breeder has slowed in most parts of the world.

fat in the broadest sense, a mixture of *lipids* – chiefly triglycerides (lipids containing three fatty acid molecules linked to a molecule of glycerol). More specifically, the term refers to a lipid mixture that is solid at room temperature (20°C); lipid mixtures that are liquid at room temperature are called oils. The higher the proportion of saturated fatty acids in a mixture, the harder the fat.

Boiling fats in strong alkali forms soaps (*saponification*). Fats are essential constituents of food for many animals, with a caloric value twice that of carbohydrates; however, eating too much fat, especially fat of animal origin, has been linked with heart disease

Faraday, Michael (1791–1867)

English chemist and physicist. In 1821, he began experimenting with electromagnetism, and discovered the induction of electric currents and made the first dynamo, the first electric motor, and the first transformer. Faraday isolated benzene from gas oils and produced the basic laws of electrolysis in 1834. He also pointed out that the energy of a magnet is in the field around it and not in the magnet itself, extending this basic conception of field theory to electrical and gravitational systems.

chemistry and the discovery of benzene Faraday was mainly interested in chemistry during his early years at the Royal Institution. He investigated the effects of including precious metals in steel in 1818, producing high-quality alloys that later stimulated the production of special high-grade steels. In 1823, Faraday produced liquid chlorine by heating crystals of chlorine hydrate in an inverted U-tube, one limb of which was heated and the other placed in a freezing mixture. After the production of liquid carbon dioxide in 1835, he used this coolant to liquefy other gases. In the same year, Faraday isolated benzene from gas oils and demonstrated the use of platinum as a catalyst. He also demonstrated the importance in chemical reactions of surfaces and inhibitors, foreshadowing a huge area of the modern chemical industry.

laws of electrolysis Faraday's laws of electrolysis established the link between electricity and chemical affinity, one of the most fundamental concepts in science. Electrolysis is the production of chemical changes by passing an electric current through a solution. It was Faraday who coined the terms anode, cathode, cation, anion, electrode, and electrolyte. He postulated that, during the electrolysis of an aqueous electrolyte, positively-charged cations move towards the negatively-charged cathode and negatively-charged anions migrate to the positively-charged anode. Faraday demonstrated that the ions are discharged at each electrode according to the following rules:

(a) the quantity of a substance produced is proportional to the amount of electricity passed;

(b) the relative quantities of different substances produced by the same amount of electricity are proportional to their equivalent weights (that is, the relative atomic mass divided by the oxidation state or valency).

electromagnetism and the electric motor In 1821, only one year after Hans Oersted had discovered with a compass needle that a current of electricity flowing through a wire produces a magnetic field, Faraday was asked to investigate the phenomenon of electromagnetism by the editor of the *Philosophical Magazine*. Faraday conceived that circular lines of magnetic force are produced around the wire to explain the orientation of Oersted's compass needle.

Faraday's conviction that an electric current gives rise to lines of magnetic force arose from his idea that electricity was a form of vibration and not a moving fluid. He believed that electricity was a

state of varying strain in the molecules of the wire conductor, and that this gave rise to a similar strain in the medium surrounding the conductor. It was reasonable to consider therefore that the transmitted strain might set up a similar strain in the molecules of another near-by conductor.

Faraday set about devising an apparatus that would demonstrate the conversion of electrical energy into motive force. His device consisted of two vessels of mer-

cury connected to a battery. Above the vessels and connected to each other were suspended a magnet and a wire, which were free to move and dipped just below the surface of the mercury. In the mercury were fixed a wire and a magnet respectively. When the current was switched on, it flowed through both the fixed and free wires, generating a magnetic field in them. This caused the free magnet to revolve around the fixed wire, and the free wire to revolve around the fixed magnet.

The experiment demonstrated the basic principles governing the electric motor. Although the practical motors that subsequently developed had a very different form to Faraday's apparatus, he is usually credited with the invention of the electric motor.

electromagnetic induction and the transformer Faraday hunted for the effect of electromagnetic induction from 1824 onwards, expecting to find that a magnetic field would induce a steady electric current in a conductor. Faraday eventually succeeded in producing induction in 1831. He wound two coils around an iron bar and connected one to a battery and the other to a galvanometer (an instrument for detecting small electric currents by their magnetic effect). Nothing happened when the current flowed through the first coil, but Faraday noticed that the galvanometer responded whenever the current was switched on or off. Faraday found an immediate explanation with his lines of force. If the lines of force were cut – that is, if the magnetic field changed – then an electric current would be induced in a conductor placed within the magnetic field. The iron bar helped to concentrate the magnetic field, as Faraday later came to understand, and a current was induced in the second coil by the magnetic field momentarily set up as current entered or left the first coil. With this device, Faraday had discovered the transformer, a modern transformer being no different in essence even though the alternating current required had not then been discovered.

Faraday is thus also credited with the simultaneous discovery of electromagnetic induction, although the same discovery had been made in the same way by Joseph Henry in 1830. However, busy teaching, Henry had not been able to publish his findings before Faraday did, although both men are now credited with the independent discovery of induction.

Arago's wheel and the electric generator In 1824, Francois Arago found that a rotating non-magnetic disc, specifically of copper, caused the deflection of a magnetic needle placed above it. This was in fact a demonstration of electromagnetic induction, but nobody at that time could explain 'Arago's wheel'. Faraday realized that the motion of the copper wheel relative to the magnet in Arago's experiment caused an electric current to flow in the disc, which in turn set up a magnetic field and deflected the magnet. He set about constructing a similar device in which the current produced could be led off, and built the first electric generator in 1831. It consisted of a copper disc that was rotated between the poles of a magnet; Faraday touched wires to the edge and centre of the disc and connected them to a galvanometer, which registered a steady current.

electrostatic charge In 1832 Faraday showed that an electrostatic charge gives rise to the same effects as current electricity. He demonstrated in 1837 that electrostatic force consists of a field of curved lines of force, and that different substances have specific inductive capacities – that is, they take up different amounts of electric charge when subjected to an electric field.

In 1838, he proposed a theory of electricity elaborating his idea of varying strain in molecules. In a good conductor, a rapid build-up and breakdown of strain took place, transferring energy quickly from one molecule to the next. This also accounted for the decomposition of compounds in electrolysis. At the same time, Faraday wrongly rejected the notion that electricity involved the movement of any kind of electrical fluid (the motion of electrons is involved). However, in that this motion causes a rapid transfer of electrical

private collection

energy through a conductor, Faraday's ideas were valid.

polarization of light Finally, Faraday considered the nature of light and in 1846 arrived at a form of the electromagnetic theory of light that was later developed by Scottish physicist James Clerk Maxwell. In 1845, Lord Kelvin suggested that Faraday investigate the action of electricity on polarized light. Faraday had in fact already carried out such experiments with no success, but this could have been because electrical forces were not strong. Faraday now used an electromagnet to give a strong magnetic field instead and found that it causes the plane of polarization to rotate, the angle of rotation being proportional to the strength of the magnetic field.

paramagnetism and diamagnetism Several further discoveries

resulted from this experiment. Faraday realized that the glass block used to transmit the beam of light must also transmit the magnetic field, and he noticed that the glass tended to set itself at right-angles to the poles of the magnet rather than lining up with it as an iron bar would. He showed that the differing responses of substances to a magnetic field depended on the distribution of the lines of force through them. He called materials that are attracted to a magnetic field paramagnetic, and those that are repelled diamagnetic. Faraday then went on to point out that the energy of a magnet is in the field around it and not in the magnet itself, and he extended this basic conception of field theory to electrical and gravitational systems.

in humans. In many animals and plants, excess carbohydrates and proteins are converted into fats for storage. Mammals and other vertebrates store fats in specialized connective tissues (adipose tissues), which not only act as energy reserves but also insulate the body and cushion its organs.

As a nutrient, fat serves five purposes: it is a source of energy (9 kcal/g); makes the diet palatable; provides basic building blocks for cell structure; provides essential fatty acids (linoleic and linolenic); and acts as a carrier for fat-soluble vitamins (A, D, E, and K). Foods rich in fat are butter, lard, margarine, and cooking oils. Products high in monounsaturated or polyunsaturated fats are thought to be less likely to contribute to cardiovascular disease.

fat The molecular structure of typical fat. The molecule consists of three fatty acid molecules linked to a molecule of glycerol.

FAT in computing, abbreviation for file allocation table.

fat hen plant belonging to the goosefoot family, widespread in temperate regions. It grows up to 1 m/3 ft tall and has lance- or diamond-shaped leaves and compact heads of small inconspicuous flowers. Now considered a weed, fat hen was once valued for its fatty seeds and edible leaves, (*Chenopodium album*, family Chenopodiaceae.)

fathom Anglo-Saxon *faethm* 'to embrace' in mining, seafaring, and handling timber, a unit of depth measurement (1.83 m/6 ft) used prior to metrication; it approximates to the distance between an adult man's hands when the arms are outstretched.

fatigue in muscle, reduced response brought about by the accumulation of lactic acid in muscle tissue due to excessive cellular activity.

fatty acid or **carboxylic acid** organic compound consisting of a hydrocarbon chain, up to 24 carbon atoms long, with a carboxyl group (-COOH) at one end. The covalent bonds between the carbon atoms may be single or double; where a double bond occurs the carbon atoms concerned carry one instead of two hydrogen atoms. Chains with only single bonds have all the hydrogen they can carry,

so they are said to be **saturated** with hydrogen. Chains with one or more double bonds are said to be **unsaturated** (see **polyunsaturated**). Fatty acids are produced in the small intestine when fat is digested.

Saturated fatty acids include palmitic and stearic acids; unsaturated fatty acids include oleic (one double bond), linoleic (two double bonds), and linolenic (three double bonds). Linoleic acid accounts for more than one third of some margarines. Supermarket brands that say they are high in polyunsaturates may contain as much as 39%. Fatty acids are generally found combined with glycerol in lipids such as triglycerides.

fault in geology, a fracture in the Earth either side of which rocks have moved past one another. Faults involve displacements, or offsets, ranging from the microscopic scale to hundreds of kilometres. Large offsets along a fault are the result of the accumulation of smaller movements (metres or less) over long periods of time. Large motions cause detectable earthquakes.

Faults are planar features. Fault orientation is described by the inclination of the fault plane with respect to horizontal and its direction in the horizontal plane (see **strike**). Faults at high angle with respect to horizontal (in which the fault plane is steep) are classified as either **normal** faults, where one block has apparently moved downhill along the inclined fault plane, or **reverse** faults, where one block appears to have moved uphill along the fault

fault Faults are caused by the movement of rock layers, producing such features as block mountains and rift valleys. A normal fault is caused by a tension or stretching force acting in the rock layers. A reverse fault is caused by compression forces. Faults can continue to move for thousands or millions of years.

plane. Normal faults occur where rocks on either side have moved apart. Reverse faults occur where rocks on either side have been forced together. A reverse fault that forms a low angle with the horizontal plane is called a thrust fault.

A lateral fault, or tear fault, occurs where the relative movement along the fault plane is sideways. A particular kind of fault found only in ocean ridges is the transform fault (a term coined by Canadian geophysicist John Tuzo Wilson in 1965). On a map, an ocean ridge has a stepped appearance. The ridge crest is broken into sections, each section offset from the next. Between each section of the ridge crest the newly generated plates are moving past one another, forming a transform fault.

Faults produce lines of weakness on the Earth's surface (along their strike) that are often exploited by processes of weathering and erosion. Coastal caves and geos (narrow inlets) often form along faults and, on a larger scale, rivers may follow the line of a fault.

favourites menu option on Microsoft's Internet Explorer Web browser that allows users to go quickly to sites that have been bookmarked, as with the bookmarks feature in Netscape Navigator. The access software for the AOL and CompuServe online services uses Favourite Places to provide the same feature.

fax (common name for *facsimile transmission* or *telefax*) the transmission of images over a telecommunications link, usually the telephone network. When placed on a fax machine, the original image is scanned by a transmitting device and converted into coded signals, which travel via the telephone lines to the receiving fax machine, where an image is created that is a copy of the original. Photographs as well as printed text and drawings can be sent. The

standard transmission takes place at 4,800 or 9,600 bits of information per second.

The world's first fax machine, the *pantélégraphe*, was invented by Italian physicist Giovanni Caselli in 1866, over a century before the first electronic model came on the market. Standing over 2 m/6.5 ft high, it transmitted by telegraph nearly 5,000 handwritten documents and drawings between Paris and Lyon in its first year.

fax modem (modem capable of transmitting and receiving data in the form of a fax).

A normal fax machine sends data in binary form down a telephone line, in a similar way to a modem. A modem can therefore act as a fax machine, given suitable software. This means a document does not need to be printed before faxing and an incoming fax can be viewed before printing out on a plain-paper printer. However, the computer must be permanently turned on in order to receive faxes.

FDDI (abbreviation for *fibre-optic digital device interface*) in computing, a series of network protocols, developed by the American National Standards Institute, concerned with high-speed networks using fibre optic cable.

FDDI supports data transmission rates of up to 100 Mb per second and is being introduced in many sites as a replacement for Ethernet. FDDI not only makes possible transmission of large amounts of data, for example colour pictures, but also allows the transmission of voice and video data. See also optical fibres.

feather rigid outgrowth of the outer layer of the skin of birds, made of the protein keratin. Feathers provide insulation and facilitate flight. There are several types, including long quill feathers on

feather Types of feather. A bird's wing is made up of two types of feather: contour feathers and flight feathers. The primary and secondary feathers are flight feathers. The coverts are contour feathers, used to streamline the bird. Semi-plume and down feathers insulate the bird's body and provide colour.

the wings and tail, fluffy down feathers for retaining body heat, and contour feathers covering the body. The colouring of feathers is often important in camouflage or in courtship and other displays. Feathers are normally replaced at least once a year.

There is an enormous variation between species in the number of feathers, for example a whistling swan has over 25,000 contour feathers, whereas a ruby-throated hummingbird has less than 950.

Feathers generally consist of two main parts, axis and barbs, the former of which is divided into the quill, which is bare and hollow, and the shaft, which bears the barbs. The quill is embedded in the skin, and has at its base a small hole through which the nourishment passes during the growth of the feather. The barbs which constitute the vane are lath-shaped and taper to a point, and each one supports a series of outgrowths known as barbules, so that each barb is like a tiny feather. Adjacent barbs are linked to each other by hooks on the barbules.

feather star any of an unattached, free-swimming group of sea lilies, order Comatulida. The arms are branched into numerous projections (hence 'feather' star), and grow from a small cup-shaped body. Below the body are appendages that can hold on to a surface, but the feather star is not permanently attached.

fecundity the rate at which an organism reproduces, as distinct from its ability to reproduce (fertility). In vertebrates, it is usually measured as the number of offspring produced by a female each year.

Federal Aviation Administration (FAA) agency of the US Department of Transportation that controls air traffic. Its responsibilities include regulating air transportation, aviation safety, developing and operating a system of air-traffic control, requiring airports and airlines to provide antijacking security, and conducting aviation research. The agency is also responsible for investigating aeroplane accidents. It was established in 1958 as the Federal Aviation Agency and was renamed upon its assignment to Transportation in 1967. It is directed by an administrator (assistant secretary) appointed directly by the president.

feedback in biology, another term for biofeedback.

feedback general principle whereby the results produced in an ongoing reaction become factors in modifying or changing the reaction; it is the principle used in self-regulating control systems, from a simple thermostat and steam-engine governor to automatic computer-controlled machine tools. A fully computerized control system, in which there is no operator intervention, is called a closed-loop feedback system. A system that also responds to control signals from an operator is called an open-loop feedback system.

In self-regulating systems, information about what is happening in a system (such as level of temperature, engine speed, or size of workpiece) is fed back to a controlling device, which compares it with what *should* be happening. If the two are different, the device takes suitable action (such as switching on a heater, allowing more steam to the engine, or resetting the tools). The idea that the Earth is a self-regulating system, with feedback operating to keep nature in balance, is a central feature of the Gaia hypothesis.

Fehling's test chemical test to determine whether an organic substance is a reducing agent (substance that donates electrons to other substances in a chemical reaction). It is usually used to detect reducing sugars (monosaccharides, such as glucose, and the disaccharides maltose and lactose) and aldehydes.

If the test substance is heated with a freshly prepared solution containing copper(II) sulphate, sodium hydroxide and sodium potassium tartrate, the production of a brick-red precipitate indicates the presence of a reducing agent.

feldspar a group of silicate minerals. Feldspars are the most abundant mineral type in the Earth's crust. They are the chief constituents of igneous rock and are present in most metamorphic and sedimentary rocks. All feldspars contain silicon, aluminium, and oxygen, linked together to form a framework. Spaces within this framework structure are occupied by sodium, potassium, calcium, or occasionally barium, in various proportions. Feldspars

form white, grey, or pink crystals and rank 6 on the Mohs' scale of hardness.

The four extreme compositions of feldspar are represented by the minerals orthoclase, KAlSi_3O_8 , albite, $\text{NaAlSi}_3\text{O}_8$, anorthite, $\text{CaAl}_2\text{Si}_2\text{O}_8$, and celadon, $\text{BaAl}_2\text{Si}_2\text{O}_8$. Plagioclase feldspars contain variable amounts of sodium (as in albite) and calcium (as in anorthite) with a negligible potassium content. Alkali feldspars (including orthoclase) have a high potassium content, less sodium, and little calcium.

The type known as moonstone has a pearl-like effect and is used in jewellery. Approximately 4,000 tonnes of feldspar are used in the ceramics industry annually.

feldspathoid any of a group of silicate minerals resembling feldspars but containing less silica. Examples are nepheline ($\text{Na}_4\text{Al}_3\text{Si}_3\text{O}_{14}$ with a little potassium) and leucite (KAlSi_2O_6). Feldspathoids occur in igneous rocks that have relatively high proportions of sodium and potassium. Such rocks may also contain alkali feldspar, but they do not generally contain quartz because any free silica would have combined with the feldspathoid to produce more feldspar instead.

felsic rock a plutonic rock composed chiefly of light-coloured minerals, such as quartz, feldspar and mica. It is derived from feldspar, lenard (meaning feldspathoid), and silica. The term felsic also applies to light-coloured minerals as a group, especially quartz, feldspar, and feldspathoids.

femtosecond SI unit of time. It is 10^{-15} seconds (one millionth of a billionth).

femur the *thigh-bone*; also the upper bone in the hind limb of a four-limbed vertebrate.

fence lizard or *swift* name given to several species of lizard found in North and Central America. They are viviparous (the young develop in the mother before birth).

Fermat, Pierre de (1601–1665)

French mathematician who, with Blaise Pascal, founded the theory of probability and the modern theory of numbers. Fermat also made contributions to analytical geometry. In 1657, Fermat published a series of problems as challenges to other mathematicians, in the form of theorems to be proved.

Fermat's last theorem states that equations of the form $x^n + y^n = z^n$ where x, y, z , and n are all integers have no solutions if $n > 2$. Fermat scribbled the theorem in the margin of a mathematics textbook and noted that he could have shown it to be true had he enough space in which to write the proof. The theorem remained unproven for 300 years (and therefore, strictly speaking, constituted a conjecture rather than a theorem). In 1993, Andrew Wiles, the English mathematician of Princeton University, USA, announced a proof; this turned out to be premature, but he put forward a revised proof in 1994.

Fermat's last theorem was finally laid to rest in June 1997 when Wiles collected the Wolfskehl prize (the legacy bequeathed in the 19th century for the problem's solution).

Mary Evans Picture Library

classification Fence lizards are all in genus *Sceloporus*, family Iguanidae, suborder Sauria, order Squamata, class Reptilia.

fennec small nocturnal desert fox *Fennecus zeda* found in North Africa and Arabia. It has a head and body only 40 cm/1.3 ft long, and its enormous ears act as radiators to lose excess heat. It eats insects and small animals.

fennel any of several varieties of a perennial plant with feathery green leaves, belonging to the carrot family. Fennels have an aniseed (liquorice) flavour, and the leaves and seeds are used in seasoning. The thickened leafstalks of sweet fennel (*F. vulgare dulce*) are eaten as a vegetable. (*Foeniculum vulgare*, family Umbelliferae.)

Fermat's principle in physics, the principle that a ray of light, or other radiation, moves between two points along the path that takes the minimum time.

The principle is named after French mathematician Pierre de Fermat, who used it to deduce the laws of reflection and refraction.

FERMAT'S LAST THEOREM

http://www-groups.dcs.st-and.ac.uk/~history/HistTopics/Fermat's_last_theorem.html

Account of Fermat's last theorem and of the many attempts made to prove it. It is extensively hyperlinked to related mathematical and also includes a list of 17 references for further reading.

fermentation the breakdown of sugars by bacteria and yeasts using a method of respiration without oxygen (anaerobic). Fermentation processes have long been utilized in baking bread, making beer and wine, and producing cheese, yoghurt, soy sauce, and many other foodstuffs.

In baking and brewing, yeasts ferment sugars to produce ethanol and carbon dioxide; the latter makes bread rise and puts bubbles into beers and champagne. Many antibiotics are produced by fermentation; it is one of the processes that can cause food spoilage.

Wine is the most healthful and most hygienic of beverages.

LOUIS PASTEUR French chemist and microbiologist.
Etudes sur la Vin Pt 1 Ch 2

fermi unit of length equal to 10^{-15} m, used in atomic and nuclear physics. The unit is named after Enrico Fermi.

Fermilab (shortened form of *Fermi National Accelerator Laboratory*)

US centre for particle physics at Batavia, Illinois, near Chicago. It is named after Italian-US physicist Enrico Fermi. Fermilab was opened in 1972, and is the home of the Tevatron, the world's most powerful particle accelerator. It is capable of boosting protons and antiprotons to speeds near that of light (to energies of 20 TeV).

fermion in physics, a subatomic particle whose spin can only take values that are half-integers, such as $\frac{1}{2}$ or $\frac{3}{2}$. Fermions may be classified as leptons, such as the electron, and baryons, such as the proton and neutron. All elementary particles are either fermions or bosons.

The exclusion principle, formulated by Austrian-US physicist Wolfgang Pauli in 1925, asserts that no two fermions in the same system (such as an atom) can possess the same position, energy state, spin, or other quantized property.

fermium synthesized, radioactive, metallic element of the actinide series, symbol Fm, atomic number 100, relative atomic

Fermi, Enrico (1901–1954)

Italian-born US physicist who proved the existence of new radioactive elements produced by bombardment with neutrons, and discovered nuclear reactions produced by low-energy neutrons. This research won him the Nobel Prize for Physics in 1938 and was the basis for studies leading to the atomic bomb and nuclear energy. Fermi built the first nuclear reactor in 1942 at Chicago University and later took part in the Manhattan Project to construct an atom bomb. His theoretical work included the study of the weak nuclear force, one of the fundamental forces of nature, and beta decay.

neutron bombardment and the Nobel Prize Following the work of the Joliot-Curies, who discovered artificial radioactivity in 1934 using alpha particle bombardment, Fermi began producing new radioactive isotopes by neutron bombardment. Unlike the alpha particle, which is positively charged, the neutron is charge neutral. Fermi realized that less energy would be wasted when a bombarding neutron encounters a positively charged target nucleus.

He also found that a block of paraffin wax or a jacket of water around the neutron source produced slow, or 'thermal', neutrons. Slow-neutrons are more effective at producing artificial radioactive elements because they remain longer near the target nucleus and have a greater chance of being absorbed.

He did, however, misinterpret the results of experiments involving neutron bombardment of uranium, failing to recognize that nuclear fission had occurred. Instead, he maintained that the bombardment produced two new transuranic elements. It was left to Lise Meitner and Otto Frisch to explain nuclear fission in 1938.

nuclear reactors and the atomic bomb In the USA, Fermi continued the work on the fission of uranium (initiated by neutrons) by building the first nuclear reactor, then called an atomic pile, because it had a moderator consisting of a pile of purified graphite blocks (to slow the neutrons) with holes drilled in them to take rods of enriched uranium. Other neutron-absorbing rods of cadmium, called control rods, could be lowered into or withdrawn from the pile to limit the number of slow-neutrons available to initiate the fission of uranium. The reactor was built on the squash court of Chicago University. On the afternoon of 2 December 1942, the control rods were withdrawn for the first time and the reactor began to work, using a self-sustaining nuclear chain reaction. Two years later, the USA, through a team led by Arthur Compton and Fermi, had constructed an atomic bomb, which used the same reaction but without control, resulting in a nuclear explosion.

beta decay and the neutrino Fermi's experimental work on beta decay in radioactive materials provided further evidence for the existence of the neutrino, predicted by Austrian physicist Wolfgang Pauli. The decay, which takes place spontaneously in the unstable nuclei of radioactive elements, results from the conversion of a neutron into a proton, an electron (beta particle) and an antineutrino:
$$n \rightarrow p + e^- + \bar{\nu}$$

Mary Evans Picture Library

mass 257.10. Ten isotopes are known, the longest-lived of which, Fm-257, has a half-life of 80 days. Fermium has been produced only in minute quantities in particle accelerators.

fern The life cycle of a fern. Ferns have two distinct forms that alternate during their life cycle. For the main part of its life, a fern consists of a short stem (or rhizome) from which roots and leaves grow. The other part of its life is spent as a small heart-shaped plant called a prothallus.

It was discovered in 1952 in the debris of the first thermonuclear explosion. The element was named in 1955 in honour of US physicist Enrico Fermi.

fern any of a group of plants related to horsetails and clubmosses. Ferns are spore-bearing, not flowering, plants and most are perennial, spreading by slow-growing roots. The leaves, known as fronds, vary widely in size and shape. Some taller types, such as tree ferns, grow in the tropics. There are over 7,000 species. (Order Filicales.)

ferret domesticated variety of the Old World polecat.

About 35 cm/1.2 ft long, it usually has yellowish-white fur and pink eyes, but may be the dark brown colour of a wild polecat.

Ferrets may breed with wild polecats. They have been used since ancient times to hunt rabbits and rats.

ferric ion traditional name for the trivalent condition of iron, Fe^{3+} ; the modern name is iron(III). Ferric salts are usually reddish or yellow in colour and form reddish-yellow solutions. $\text{Fe}_2(\text{SO}_4)_3$ is iron(III) sulphate (ferric sulphate).

ferrimagnetism form of magnetism in which adjacent molecular magnets are aligned anti-parallel, but have unequal strength, producing a strong overall magnetization. Ferrimagnetism is found in certain inorganic substances, such as ferrites.

ferrite ceramic ferrimagnetic material. Ferrites are iron oxides to which small quantities of transition metal oxides (such as cobalt

and nickel oxides) have been added. They are used in transformer cores, radio antennae, and, formerly, in computer memories.

ferro-alloy alloy of iron with a high proportion of elements such as manganese, silicon, chromium, and molybdenum. Ferro-alloys are used in the manufacture of alloy steels. Each alloy is generally named after the added metal - for example, ferrochromium.

ferroelectric material ceramic dielectric material that, like ferromagnetic materials, has a domain structure that makes it exhibit magnetism and usually the piezoelectric effect. An example is Rochelle salt (potassium sodium tartrate tetrahydrate, $\text{KNaC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$).

ferromagnetism form of magnetism in which magnetism can be acquired in an external magnetic field and usually retained in its absence, so that ferromagnetic materials are used to make permanent magnets. A ferromagnetic material may therefore be said to have a high magnetic permeability and susceptibility (which depends upon temperature). Examples are iron, cobalt, nickel, and their alloys.

Ultimately, ferromagnetism is caused by spinning electrons in the atoms of the material, which act as tiny weak magnets. They align parallel to each other within small regions of the material to form domains, or areas of stronger magnetism. In an unmagnetized material, the domains are aligned at random so there is no overall magnetic effect. If a magnetic field is applied to that material, the domains align to point in the same direction, producing a strong overall magnetic effect. Permanent magnetism arises if the domains remain aligned after the external field is removed. Ferromagnetic materials exhibit hysteresis.

ferrous ion traditional name for the divalent condition of iron, Fe^{2+} ; the modern name is iron(II). Ferrous salts are usually green, and form yellow-green solutions. FeSO_4 is iron(II) sulphate (ferrous sulphate).

fertility an organism's ability to reproduce, as distinct from the rate at which it reproduces (fecundity). Individuals become infertile (unable to reproduce) when they cannot generate gametes (eggs or sperm) or when their gametes cannot yield a viable embryo after fertilization.

fertility drug any of a range of drugs taken to increase a female's fertility, developed in Sweden in the mid-1950s. They increase the chances of a multiple birth.

The most familiar is gonadotrophin, which is made from hormone extracts taken from the human pituitary gland; follicle-stimulating hormone and luteinizing hormone. It stimulates ovulation in women. As a result of a fertility drug, in 1974 the first sextuplets to survive were born to Susan Rosenkowitz of South Africa.

fertilization in sexual reproduction, the union of two gametes (sex cells, often called egg and sperm) to produce a zygote, which combines the genetic material contributed by each parent. In self-fertilization the male and female gametes come from the same plant; in cross-fertilization they come from different plants. Self-fertilization rarely occurs in animals; usually even hermaphrodite animals cross-fertilize each other.

In terrestrial insects, mammals, reptiles, and birds, fertilization occurs within the female's body. In humans it usually takes place in the Fallopian tube. In the majority of fishes and amphibians, and most aquatic invertebrates, fertilization occurs externally, when both sexes release their gametes into the water. In most fungi, gametes are not released, but the hyphae of the two parents grow towards each other and fuse to achieve fertilization. In higher plants, pollination precedes fertilization.

fertilizer substance containing some or all of a range of about 20 chemical elements necessary for healthy plant growth, used to compensate for the deficiencies of poor or depleted soil. Fertilizers may be organic, for example farmyard manure, composts, bone-meal, blood, and fishmeal; or inorganic, in the form of compounds, mainly of nitrogen, phosphate, and potash, which have been used on a very much increased scale since 1945.

Because externally applied fertilizers tend to be in excess of

fertilization In a flowering plant pollen grains land on the surface of the stigma, and if conditions are acceptable the pollen grain germinates, forming a pollen tube, through which the male gametes pass, entering the ovule via the micropyle in order to reach the female egg.

plant requirements and drain away to affect lakes and rivers (see eutrophication), attention has turned to the modification of crop plants themselves. Plants of the legume family, including the bean, clover, and lupin, live in symbiosis with bacteria located in root nodules, which fix nitrogen from the atmosphere. Research is now directed to producing a similar relationship between such bacteria and crops such as wheat.

fescue any grass of a widely distributed group. Many are used in temperate regions for lawns and pasture. Many upland species are viviparous, producing young plantlets instead of flowers. (Genus *Festuca*, family Gramineae.)

fetal therapy diagnosis and treatment of conditions arising in the unborn child. While some anomalies can be diagnosed antenatally, fetal treatments are only appropriate in a few cases - mostly where the development of an organ is affected.

Fetal therapy was first used 1963 with exchange transfusion for haemolytic disease of the newborn, once a serious problem (see also rhesus factor). Today the use of fetal therapy remains limited. Most treatments involve 'needling': introducing fine instruments through the mother's abdominal and uterine walls under ultrasound guidance. Open-womb surgery (hysterotomy) remains controversial because of the risks involved. It is available only in some centres in the United States.

fetch-execute cycle or **processing cycle** in computing, the two-phase cycle used by the computer's central processing unit to process the instructions in a program. During the **fetch phase**, the next program instruction is transferred from the computer's immediate-access memory to the instruction register (memory location used to hold the instruction while it is being executed). During the **execute phase**, the instruction is decoded and obeyed. The process is repeated in a continuous loop.

fetishism in psychology, the transfer of erotic interest to an object, such as an item of clothing, whose real or fantasized presence is necessary for sexual gratification. The fetish may also be a part of the body not normally considered erogenous, such as the feet.

fetus or **foetus** stage in mammalian embryo development. The human embryo is usually termed a fetus after the eighth week of development, when the limbs and external features of the head are recognizable.

fever condition of raised body temperature, usually due to infection.

fibre, dietary or **roughage** plant material that cannot be digested by human digestive enzymes; it consists largely of cellulose, a

Feynman, Richard P(hillips) (1918-1988)

US physicist whose work laid the foundations of quantum electrodynamics. For his work on the theory of radiation he shared the Nobel Prize for Physics 1965 with Julian Schwinger and Sin-iti Tomonaga (1906-1979). He also contributed to many aspects of particle physics, including quark theory and the nature of the weak nuclear force.

For his work on quantum electrodynamics, he developed a simple and elegant system of Feynman diagrams to represent interactions between particles and how they moved from one space-time point to another. He had rules for calculating the

probability associated with each diagram.

His other major discoveries are the theory of superfluidity (frictionless flow) in liquid helium, developed in the early 1950s; his work on the weak interaction (with US physicist Murray Gell-Mann) and the strong force; and his prediction that the proton and neutron are not elementary particles. Both particles are now known to be composed of quarks.

Californian Institute of Technology

carbohydrate found in plant cell walls. Fibre adds bulk to the gut contents, assisting the muscular contractions that force food along the intestine. A diet low in fibre causes constipation and is believed to increase the risk of developing diverticulitis, diabetes, gall-bladder disease, and cancer of the large bowel - conditions that are rare in nonindustrialized countries, where the diet contains a high proportion of unrefined cereals.

Soluble fibre consists of indigestible plant carbohydrates (such as pectins, hemicelluloses, and gums) that dissolve in water. A high proportion of the fibre in such foods as oat bran, pulses, and

vegetables is of this sort. Its presence in the diet has been found to reduce the amount of cholesterol in blood over the short term, although the mechanism for its effect is disputed.

fibreglass glass that has been formed into fine fibres, either as long continuous filaments or as a fluffy, short-fibred glass wool. Fibreglass is heat- and fire-resistant and a good electrical insulator. It has applications in the field of fibre optics and as a strengthening for plastics in GFRP (glass-reinforced plastics).

The long filament form is made by forcing molten glass through the holes of a spinneret, and is woven into textiles. Glass wool is made by blowing streams of molten glass in a jet of high-pressure steam, and is used for electrical, sound, and thermal insulation, especially for the roof space in houses.

fibre optics branch of physics dealing with the transmission of light and images through glass or plastic fibres known as optical fibres.

fibrin insoluble protein involved in blood clotting. When an injury occurs fibrin is deposited around the wound in the form of a mesh, which dries and hardens, so that bleeding stops. Fibrin is developed in the blood from a soluble protein, fibrinogen.

The conversion of fibrinogen to fibrin is the final stage in blood clotting. Platelets, a type of cell found in blood, release the enzyme thrombin when they come into contact with damaged tissue, and the formation of fibrin then occurs. Calcium, vitamin K, and a variety of enzymes called factors are also necessary for efficient blood clotting.

fibula the rear lower bone in the hind leg of a vertebrate. It is paired and often fused with a smaller front bone, the tibia.

Fidonet in computing, early network of bulletin board systems (BBSs) which sends mail and news around the world via an arrangement whereby the individual systems call each other to exchange data every night. Such systems are called 'store-and-forward'.

field in computing, a specific item of data. A field is usually part of a record, which in turn is part of a file.

field in physics, a region of space in which an object exerts a force on another separate object because of certain properties they both possess. For example, there is a force of attraction between any two objects that have mass when one is in the gravitational field of the other.

Other fields of force include electric fields (caused by electric charges) and magnetic fields (caused by circulating electric currents), either of which can involve attractive or repulsive forces.

field enclosed area of land used for farming. Traditionally fields were measured in acres; the current unit of measurement is the hectare (2.47 acres).

In Britain, regular field systems were functioning before the Romans' arrival. The open-field system was in use at the time of the Norman Conquest. Enclosure began in the 14th century and continued into the 19th century.

In the Middle Ages, the farmland of an English rural community was often divided into three large fields (the open-field system). These were worked on a simple rotation basis of one year wheat, one year barley, and one year fallow. The fields were divided into individually owned strips of the width that one plough team with oxen could plough (about 20 m/66 ft). At the end of each strip would be a turning space, either a road or a headland. Through repeated ploughing a ridge-and-furrow pattern became evident. A farmer worked a number of strips, not necessarily adjacent to each other, in one field.

The open-field communities were subsequently reorganized, the land enclosed, and the farmers' holdings redistributed into individual blocks which were then divided into separate fields. This enclosure process reached its peak during the 18th century. 20th-century developments in agricultural science and technology have encouraged farmers to amalgamate and enlarge their fields, often to as much as 40 hectares/100 acres.

The open field system was also found in France, Germany, Greece, and Slavonic lands.

fieldfare gregarious thrush *Turdus pilaris* of the family Muscicapidae, order Passeriformes; it has chestnut underparts with a pale-grey lower back and neck, and a dark tail. The bird's underparts are a rich ochre colour, spotted with black. Its nest is of long fine grass with an intervening layer of mud; it may be built in birch or fir trees at a height of 5 m/16 ft or less. It feeds on berries, insects, and other invertebrates.

field-length check (validation check in which the characters in an input field are counted to ensure that the correct number of characters have been entered. For example, a six-figure date field may be checked to ensure that it does contain exactly six digits).

field of view angle over which an image may be seen in a mirror or an optical instrument such as a telescope. A wide field of view allows a greater area to be surveyed without moving the instrument, but has the disadvantage that each of the objects seen is smaller. A convex mirror gives a larger field of view than a plane or flat mirror. The field of view of an eye is called its field of vision or visual field.

A telephoto lens has a small field of view, around 14°, and produces a highly magnified image. A 'fish-eye' lens has a very wide angle of view, around 180°. Our eyes have a field of vision of around 45°.

field studies study of ecology, geography, geology, history, archaeology, and allied subjects, in the natural environment as opposed to the laboratory.

The most exciting phrase to hear in science, the one that heralds new discoveries, is not 'Eureka!' (I've found it!) but 'That's funny...'

ISAAC ASIMOV Russian-born US writer.

fifth-generation computer anticipated new type of computer based on emerging microelectronic technologies with high computing speeds and parallel processing. The development of very large-scale integration (VLSI) technology, which can put many more circuits on to an integrated circuit (chip) than is currently possible, and developments in computer hardware and software design may produce computers far more powerful than those in current use.

It has been predicted that such a computer will be able to communicate in natural spoken language with its user; store vast knowledge databases; search rapidly through these databases, making intelligent inferences and drawing logical conclusions; and process images and 'see' objects in the way that humans do.

In 1981 Japan's Ministry of International Trade and Industry launched a ten-year project to build the first fifth-generation computer, the 'parallel inference machine', consisting of over a thousand microprocessors operating in parallel with each other. By 1992, however, the project was behind schedule and had only produced 256-processor modules. It has since been suggested that research into other technologies, such as neural networks, may present more promising approaches to artificial intelligence. Compare earlier computer generations.

fig any of a group of trees belonging to the mulberry family, including the many cultivated varieties of *F. carica*, originally from W Asia. They produce two or three crops of fruit a year. Eaten fresh or dried, figs have a high sugar content and laxative properties. (Genus *Ficus*, family Moraceae.)

In the wild, *F. carica* is dependent on the fig wasp for pollination, and the wasp in turn is parasitic on the flowers. The tropical banyan (*F. benghalensis*) has less attractive edible fruit, and roots that grow down from its branches. The bo tree under which Buddha became enlightened is the Indian peepul or wild fig (*F. religiosa*).

fighting fish any of a southeast Asian genus *Betta* of fishes of the gourami family, especially *B. splendens*, about 6 cm/2 in long and a popular aquarium fish. It can breathe air, using an accessory

breathing organ above the gill, and can live in poorly oxygenated water. The male has large fins and various colours, including shining greens, reds, and blues. The female is yellowish brown with short fins.

The male builds a nest of bubbles at the water's surface and displays to a female to induce her to lay. Rival males are attacked, and in a confined space, fights may occur. In Thailand, public contests are held.

figwort any of a group of Old World plants belonging to the figwort family, which also includes foxgloves and snapdragons. Members of the genus have square stems, opposite leaves, and open two-lipped flowers in a cluster at the top of the stem. (Genus *Scrophularia*, family Scrophulariaceae.)

filament in astronomy, a dark, winding feature occasionally seen on images of the Sun in hydrogen light. Filaments are clouds of relatively cool gas suspended above the Sun by magnetic fields and seen in silhouette against the hotter photosphere below. During total eclipses they can be seen as bright features against the sky at the edge of the Sun where they are known as prominences.

file in computing, a collection of data or a program stored in a computer's external memory (for example, on disc). It might include anything from information on a company's employees to a program for an adventure game. Serial files hold information as a sequence of characters, so that, to read any particular item of data, the program must read all those that precede it. Random-access files allow the required data to be reached directly. Files are usually located via a directory.

file access in computing, the way in which the records in a file are stored, retrieved, or updated by computer. There are four main types of file organization, each of which allows a different form of access to the records.

Records in a **serial file** are not stored in any particular order, so a specific record can be accessed only by reading through all the previous records.

Records in a **sequential file** are sorted by reference to a key field (see *sorting*) and the computer can use a searching technique, such as a binary search, to access a specific record.

An indexed **sequential file** possesses an index, which records the position of each block of records and is created and updated with that file. By consulting the index, the computer can obtain the address of the block containing the required record, and search just that block rather than the whole file.

A **direct-access or random-access file** contains records that can be accessed directly by the computer.

file allocation table (FAT) in computing, a table used by the operating system to record the physical arrangement of files on disc. As a result of fragmentation, files can be split into many parts sited at different places on the disc.

file extension in computing, the last three letters of a file name in DOS or Windows, which indicate the type of data the file contains. Extensions in common use include .TXT for 'text', .GIF for 'graphics interchange format', and .EXE for 'executable'.

In Windows, the operating system may be configured to associate specific file extensions with specific programs, so that double-clicking on a file name starts the right program and opens the file for editing.

file format in computing, specific way data is stored in a file. Most computer programs use proprietary file formats which cannot be read by other programs. As this is inconvenient for users, in recent years software publishers have developed filters which convert older file formats into the ones the program in use can read.

Often file extensions are used to indicate which program was used to create a particular file. Some formats, such as GIF (graphics interchange format), have become so popular and widely used that they are supported by many programs.

Before transmitting data over a public network to another user, it is important to check that the receiving user can read the format the data is in. For this purpose, the most commonly readable format is plain ASCII for text and either GIF or JPEG (Joint Photographic Experts Group) for graphics.

file generation in computing, a specific version of a file. When file updating takes place, a new generation of the file is created, containing accurate, up-to-date information. The old generation of the file will often be stored to provide data security in the event that the new generation of the file is lost or damaged.

file librarian or **media librarian** job classification for computer personnel. A file librarian stores and issues the data files used by the computer department.

file merging in computing, combining two or more sequentially ordered files into a single sequentially ordered file.

file searching (searching a computer memory (usually backing storage) for a file.

file server computer on a network that handles (and usually stores) the data used by other computers on the network. See also *client-server architecture*.

file sorting arranging files in sequence; see *sorting*.

file transfer in computing, the transmission of a file (data stored on disc, for example) from one machine to another. Both machines must be physically linked (for example, by a telephone line via a modem or acoustic coupler) and both must be running appropriate communications software.

file updating in computing, reviewing and altering the records in a file to ensure that the information they contain is accurate and up-to-date. Three basic processes are involved: adding new records, deleting existing records, and amending existing records.

The updating of a **direct-access file** is a continuous process because records can be accessed individually and changed at any time. This type of updating is typical of large interactive database systems, such as airline ticket-booking systems. Each time a ticket is booked, files are immediately updated so that double booking is impossible.

In large commercial applications, however, millions of customer records may be held in a large sequentially ordered file, called the **master file**. Each time the records in the master file are to be updated (for example, when quarterly bills are being drawn up), a **transaction file** must be prepared. This will contain all the additions, deletions, and amendments required to update the master file. The transaction file is sorted into the same order as the master file, and then the computer reads both files and produces a new updated generation of the master file, which will be stored until the next file updating takes place.

film, photographic strip of transparent material (usually cellulose acetate) coated with a light-sensitive emulsion, used in cameras to take pictures. The emulsion contains a mixture of light-sensitive silver halide salts (for example, bromide or iodide) in gelatin. When the emulsion is exposed to light, the silver salts are inevitably altered, giving a latent image, which is then made visible by the process of *developing*. Films differ in their sensitivities to light, this being indicated by their speeds. Colour film consists of several layers of emulsion, each of which records a different colour in the light falling on it.

In **colour film** the front emulsion records blue light, then comes a yellow filter, followed by layers that record green and red light respectively. In the developing process the various images in the layers are dyed yellow, magenta (red), and cyan (blue), respectively.

When they are viewed, either as a transparency or as a colour print, the colours merge to produce the true colour of the original scene photographed.

filter in chemistry, a porous substance, such as blotting paper, through which a mixture can be passed to separate out its solid constituents.

filter in computing, a program that transforms data. Filters are often used when data output from one application program is input into a different program, which requires a different data format. For example files transferred between two different word-processing programs are run through either an output filter supplied with the first program or an input filter supplied with the second program.

Filters are also used to expand coding structures, which have been simplified for keyboard input, into the often more verbose form required by such standards as SGML (Standard Generalized Markup Language).

filter in electronics, a circuit that transmits a signal of some frequencies better than others. A low-pass filter transmits signals of low frequency and direct current; a high-pass filter transmits high-frequency signals; a band-pass filter transmits signals in a band of frequencies.

filter in optics, a device that absorbs some parts of the visible spectrum and transmits others. For example, a green filter will absorb or block all colours of the spectrum except green, which it allows to pass through. A yellow filter absorbs only light at the blue and violet end of the spectrum, transmitting red, orange, green, and yellow light.

filtrate liquid or solution that has passed through a filter.

filtration technique by which suspended solid particles in a fluid are removed by passing the mixture through a filter, usually porous paper, plastic, or cloth. The particles are retained by the filter to form a residue and the fluid passes through to make up the filtrate. For example, soot may be filtered from air, and suspended solids from water.

fin in aquatic animals, flattened extension from the body that aids balance and propulsion through the water.

In fish they may be paired, such as the pectoral and ventral fins, or singular, such as the caudal and dorsal fins, all being supported by a series of cartilaginous or bony rays.

The fins in cetaceans (whales and dolphins) are simple extensions of the soft tissue and have no bony rays. The flippers of seals are modified five-fingered limbs and contain the same bones as the limbs of other vertebrates.

finch any of various songbirds of the family Fringillidae, in the order Passeriformes (perching birds). They are seed-eaters with stout conical beaks. The name may also be applied to members of the Emberizidae (buntings), and Estrildidae (weaver-finches).

FINCHWORLD

<http://www.finchworld.com/>

Huge source of information on finches. Contents include practical advice for those buying a finch for the first time, tips on diet, housing, recreation activities, and avian illnesses. There are links to finch sites around the world and news of ornithological research on these songbirds.

finite having a countable number of elements, the opposite of infinite.

finsen unit unit (symbol FU) for measuring the intensity of ultra-violet (UV) light; for instance, UV light of 2 FUs causes sunburn in 15 minutes.

fiord alternative spelling of fjord.

fir any of a group of conifer trees belonging to the pine family. The true firs include the balsam fir (*A. balsamea*) of northern North America and the silver fir (*A. alba*) of Europe and Asia. Douglas firs of the genus *Pseudotsuga* are native to western North America and the Far East. (True fir genus *Abies*, family Pinaceae.)

fireball in astronomy, a very bright meteorite, often bright enough to be seen in daylight and occasionally leading to the fall of a meteorite. Some fireballs are caused by satellites or other space debris burning up in the Earth's atmosphere.

firebrat any insect of the order Thysanura (bristletail).

fire clay a clay with refractory characteristics (resistant to high temperatures), and hence suitable for lining furnaces (firebrick). Its chemical composition consists of a high percentage of silicon and aluminum oxides, and a low percentage of the oxides of sodium, potassium, iron, and calcium.

fire damp gas that occurs in coal mines and is explosive when mixed with air in certain proportions. It consists chiefly of methane (CH₄, natural gas or marsh gas) but always contains small quantities of other gases, such as nitrogen, carbon dioxide, and hydrogen, and sometimes ethane and carbon monoxide.

fire-danger rating unit index used by the UK Forestry Commission to indicate the probability of a forest fire. 0 means a fire is improbable, 100 shows a serious fire hazard.

fire extinguisher device for putting out a fire. Fire extinguishers work by removing one of the three conditions necessary for fire to continue (heat, oxygen, and fuel), either by cooling the fire or by excluding oxygen.

The simplest fire extinguishers contain water, which when propelled onto the fire cools it down. Water extinguishers cannot be used on electrical fires, as there is a danger of electrocution, or on burning oil, as the oil will float on the water and spread the blaze.

Many domestic extinguishers contain liquid carbon dioxide under pressure. When the handle is pressed, carbon dioxide is released as a gas that blankets the burning material and prevents oxygen from reaching it. Dry extinguishers spray powder, which then releases carbon dioxide gas. Wet extinguishers are often of the soda-acid type; when activated, sulphuric acid mixes with sodium bicarbonate, producing carbon dioxide. The gas pressure forces the solution out of a nozzle, and a foaming agent may be added.

Some extinguishers contain halons (hydrocarbons with one or more hydrogens substituted by a halogen such as chlorine, bromine, or fluorine). These are very effective at smothering fires, but cause damage to the ozone layer, and their use is now restricted.

firefly any winged nocturnal beetle of the family Lampyridae. They all emit light through the process of bioluminescence.

fire protection methods available for fighting fires. Industrial and commercial buildings are often protected by an automatic sprinkler system: heat or smoke opens the sprinkler heads on a network of water pipes which spray the source of the fire. In circumstances where water is ineffective and may be dangerous, for example, for oil and petrol storage-tank fires, foam systems are used; for industrial plants containing flammable vapours, carbon dioxide is used; where electricity is involved, vaporizing liquids create a nonflammable barrier; for some chemicals only various dry powders can be used.

firewall in computing, security system built to block access to a particular computer or network while still allowing some types of data to flow in and out onto the Internet.

A firewall allows a company's employees to access sites on the World Wide Web or exchange e-mail while at the same time preventing hackers from gaining access to the company's data.

firewheel Australian tree *Stenocarpus sinuatus* native to rainforests of New South Wales and Queensland, which bears wheel-like whorls of bright red flowers.

FireWire in computing, Apple's implementation of the IEEE 1394 serial connection system.

firewood the principal fuel for some 2 billion people, mainly in the Third World. In principle a renewable energy source, firewood is being cut far faster than the trees can regenerate in many areas of Africa and Asia, leading to deforestation.

In Mali, for example, wood provides 97% of total energy consumption, and deforestation is running at an estimated 9,000 hectares a year. The heat efficiency of firewood can be increased by use of well-designed stoves, but for many people they are either unaffordable or unavailable. With wood for fuel becoming scarcer the UN Food and Agricultural Organization has estimated that by

the year 2000 3 billion people worldwide will face chronic problems in getting food cooked.

firmware computer program held permanently in a computer's ROM (read-only memory) chips, as opposed to a program that is read in from external memory as it is needed.

First Amendment amendment to the US Constitution that guarantees freedom of religion, of speech, of assembly, and of the press. Adopted in 1791, the First Amendment is often quoted on the Internet, even by non-US citizens, in arguments over international attempts at censorship.

First Virtual Bank joint project with the bank FirstUSA which allows shoppers on the World Wide Web to open a central account using credit cards. Shoppers use their account numbers to make purchases at any of a number of participating merchants.

FISH FAQ

<http://www.wh.who.edu/homepage/faq.html>

Answers to hundreds of questions about fish and shellfish.

Unfortunately the questions are not grouped, or searchable, in any way, but they do include answers to such things as 'Do fish sleep?' and 'Are Hawaiian monk seals coming back?'.

fish aquatic vertebrate that uses gills to obtain oxygen from fresh or sea water. There are three main groups: the bony fishes or Osteichthyes (goldfish, cod, tuna); the cartilaginous fishes or Chondrichthyes (sharks, rays); and the jawless fishes or Agnatha (hagfishes, lampreys).

Fishes of some form are found in virtually every body of water in the world except for the very salty water of the Dead Sea and some of the hot larval springs. Of the 30,000 fish species, approximately 2,500 are freshwater.

bony fishes These constitute the majority of living fishes (about 20,000 species). The skeleton is bone, movement is controlled by mobile fins, and the body is usually covered with scales. The gills are covered by a single flap. Many have a swim bladder with

fish The anatomy of a fish. All fishes move through water using their fins for propulsion. The bony fishes, like the specimen shown here, constitute the largest group of fishes with about 20,000 species.

FISH

Spurdog, alewife, twaite shad, jollytail, tadpole mactom, burmalow, walleye pollock, wrestling halfbeak, mummichog, jolthead porgy, sweetlip emperor, and slippery dick are all common names for species of fish.

which the fish adjusts its buoyancy. Most lay eggs, sometimes in vast numbers; some cod can produce as many as 28 million. These are laid in the open sea, and probably no more than 28 of them will survive to become adults. Those species that produce small numbers of eggs very often protect them in nests, or brood them in their mouths. Some fishes are internally fertilized and retain eggs until hatched inside the body, then giving birth to live young. Most bony fishes are ray-finned fishes, but a few, including lungfishes and coelacanths, are fleshy-finned.

cartilaginous fishes These are efficient hunters. There are fewer than 600 known species of sharks and rays. The skeleton is cartilage, the mouth is generally beneath the head, the nose is large and sensitive, and there is a series of open gill slits along the neck region. They have no swimbladder and, in order to remain buoyant, must keep swimming. They may lay eggs ('mermaid's purses') or bear live young. Some types of cartilaginous fishes, such as sharks, retain the shape they had millions of years ago.

jawless fishes Jawless fish have a body plan like that of some of the earliest vertebrates that existed before true fishes with jaws evolved. There is no true backbone but a notochord. The lamprey attaches itself to the fishes on which it feeds by a suckerlike rasping mouth. Hagfishes are entirely marine, very slimy, and feed on carrion and injured fishes.

The world's largest fish is the whale shark *Rhineodon typus*, more than 20 m/66 ft long; the smallest is the dwarf pygmy goby *Pandaka pygmaea*, 7.5–9.9 mm long. The study of fishes is called ichthyology.

fish as food The nutrient composition of fish is similar to that of meat, except that there are no obvious deposits of fat. Examples of fish comparatively high in fat are salmon, mackerel, and herring. White fish such as cod, haddock, and whiting contain only 0.4–4% fat. Fish are good sources of B vitamins and iodine, and the fatty fish livers are good sources of A and D vitamins. Calcium can be obtained from fish with soft skeletons, such as sardines. Roe and caviar have a high protein content (20–25%).

fisher or **pekan** North American Marten *Martes pennanti*, dark brown with greyish foreparts and blackish rump and tail. It is less arboreal than the smaller American marten *M. americana*.

fish farming or **aquaculture** raising fish (including molluscs and crustaceans) under controlled conditions in tanks and ponds, sometimes in offshore pens. It has been practised for centuries in the Far East, where Japan today produces some 100,000 tonnes of fish a year; the US, Norway, and Canada are also big producers. In the 1980s 10% of the world's consumption of fish was farmed, notably carp, catfish, trout, Atlantic salmon, turbot, eel, mussels, clams, oysters, and shrimp.

A total 600,000 tonnes of salmon was produced by world fish in 1995, accounting for 37% of salmon consumed. Fish farms are environmentally controversial because of the risk

of escapees that could spread disease and alter the genetic balance of wild populations. In 1995 1,500,000 fish escaped from Norwegian fish farms.

By 1998 shrimp farms worldwide were producing 3 million tonnes of shrimps per year.

fishing and fisheries fisheries can be classified by (1) type of water: freshwater (lake, river, pond); marine (inshore, midwater, deep sea); (2) catch: for example, salmon fishing; (3) fishing method: diving, stunning or poisoning, harpooning, trawling, drifting. The world's total fish catch is about 100 million tonnes a year (1995).

marine fishing Most of the world's catch comes from the oceans, and marine fishing accounts for around 20% of the world's animal-based protein. A wide range of species is included in the landings of the world's marine fishing nations, but the majority belong to the herring and cod groups. The majority of the crustaceans landed are shrimps, and squid and bivalves, such as oysters, are dominant among the molluscs.

Almost all marine fishing takes place on or above the continental shelf, in the photic zone, the relatively thin surface layer (50 m/165 ft) of water that can be penetrated by light, allowing photosynthesis by plant (plankton) to take place. Pelagic fishing exploits not only large fish such as tuna, which live near the surface in the open sea and are caught in purse-seine nets, with an annual catch of over 30 million tonnes, but also small, shoaling and plankton-feeding fish that live in the main body of the water.

Examples are herring, sardines, anchovies, and mackerel, which are caught with drift nets, purse seines, and pelagic trawls. The fish are often used for fish meal rather than for direct human consumption. Demersal fishes, such as haddock, halibut, plaice, and cod, live primarily on or near the ocean floor, and feed on various invertebrate marine animals. Over 20 million tonnes of them are caught each year by trawling.

freshwater fishing Such species as salmon and eels, which migrate to and from fresh and salt water for spawning, may be fished in either system. About a third of the total freshwater catch comes from fish farming methods, which are better developed in freshwater than in marine systems. There is large demand for a trout, carp, eel, bass, pike, perch, and catfish. These are caught in ponds, lakes, rivers, or swamps. In Africa, although marine fishing is generally more important, certain areas have significant freshwater fisheries; Lake Victoria annually yields a catch of 100,000 tonnes, which is four times the total catch from the whole eastern African seaboard. In western Europe there is very little food production from fresh water; instead the fish are usually exploited for recreational purposes or sport.

methods The gear and methods used to catch fish are very varied and show much geographical and historical variation. The method chosen for a particular situation will depend on the species being hunted and the nature of the habitat (for example, the speed of the current, the depth of water, and the roughness of the sea bed). It is often useful to divide gear types into active (for example trawls, seines, harpoons, dredges) and passive (drift nets, traps, hooks and lines). Passive gear relies on the fish's own movements to bring them into contact with it, and may involve some method of artificial attraction such as baits or lights. Most fishing gear is operated from boats, ranging from one-person canoes to trawlers about 100 m/330 ft long.

trawling Much of the world's fish catch is caught by trawls. These may be used on the sea bed (demersal) or in midwater (pelagic), but in all cases the equipment consists essentially of a tapered bag of netting which is towed through the water. The mouth of the net is kept open in the vertical plane by having floats on the headline and weights on the footrope. On bottom trawls these weights are usually hollow iron spheres that roll over the sea bed. In addition there may be tickler chains which help to dislodge or disturb fish from the sea bed in advance of the trawl so that they are more likely to be caught. There are three methods of keeping the net open in the horizontal plane: (1) pair trawling, in which the two trawl warps are towed by separate vessels; (2) beam trawling, in which the net is supported on a rigid frame consisting of a horizontal wooden or metal beam with a shoe at either end; and (3) otter trawling, in which an otter board (a weighted board with lines and

baited hooks attached) is incorporated into each warp and acts as a hydroplane to push the warp out sideways. Most modern trawlers are otter trawlers, and many haul the net up over the stern rather than the side. The main problem with pelagic trawls is to control the depth of fishing and to relate this to the concentrations of fish. The most effective means of tracking fish for this purpose is by using an *écho* sounder.

seine nets Seine nets operate by trapping fish within encircling gear. The Danish seine resembles a light trawl with very long side pieces, or wings, but is operated differently. The method consists of dropping a large buoy and then paying out up to 4 km/2.5 mi of warp in dogleg shape, then the net, followed by a further length of rope warp in reverse dogleg, bringing the boat back to the buoy, which is then picked up before hauling in the rope warps. As the ropes straighten on the sea bed, they channel the fish into a narrow path between them. The fish are then swept up by the net as it is hauled towards the boat. This method requires smooth sandy ground. Beach seines are similar to Danish seines but may consist simply of a wall of netting. They are set in a line or semicircle parallel to a beach and can then be hauled onto the beach, trapping the fish between the net and the shore. Salmon are often caught this way in estuaries. Purse seines, nets that close like a purse, are used to catch pelagic fish such as herring, mackerel, and tuna, which form dense shoals near the surface. Once a shoal has been located, usually by *écho* sounder, the net is shot around it by one vessel and later hauled in towards another. The nets are large, often as long as 30 nautical miles, and are not usually hauled aboard like trawls. Instead the fish are scooped or pumped out of the net into the ship's hold. They have caused a crisis in the South Pacific where Japan, Taiwan, and South Korea fish illegally in other countries' fishing zones.

gill nets Gill nets passively depend on the fish entangling themselves in the meshes of the net, usually being held fast by their gill covers. An example is the drift net used for pelagic fish, but in many areas it is now superseded by purse seines and pelagic trawls. Drift nets are walls of netting suspended from floats on the surface. Those used in the East Anglian herring fishery were only 70 m/230 ft long but were set in fleets up to 4 km/2.5 mi long. Herring were caught in them as they came up to the surface at night to feed. Other types of gill net can be used near the sea bed, and one, the trammel, is still used quite commonly in inshore fisheries along the south coast of England. This typically consists of a curtain of large- and small-mesh netting into which the fish swim, forcing the small-mesh net into the large and becoming trapped in a net bag.

traps Netting panels can be arranged to form traps into which fish are guided or attracted; those used on the northeast coast of England to catch salmon are good examples. Many crustaceans, such as lobsters and crabs, are normally taken in baited baskets set in strings of several hundred laid over suitable ground. Earthenware jars are used as octopus traps in the Mediterranean.

lines and hooks Although a distinct method of catching fish, lines and hooks can be regarded as a special type of trap. Natural or artificial baits are used and the gear may be fished anywhere from the sea bed to the surface. Hooks and lines fished off the sea bed may be towed from moving boats, which is called trolling. The largest lines, called long lines, are those used by the Japanese to catch tuna in ocean areas. These are up to 80 km/50 mi long and the baited hooks hang well below the surface from the buoyed lines.

dredges Dredges act like small trawls to collect molluscs and other sluggish or sessile organisms; some are hydraulic and use jets of water to dislodge the molluscs from the bottom and wash them into the dredge bag or directly onto the boat via a conveyor belt.

other methods Molluscs may also be gathered by hand, either on foot at low water or by divers below the shoreline. Rakes may be used to dig out cockles from within the sand. Other methods include dip, lift and cast nets, harpoons, and spears.

fission in physics, the splitting of a heavy atomic nucleus into two or more major fragments. It is accompanied by the emission of two or three neutrons and the release of large amounts of nuclear energy.

Fission occurs spontaneously in nuclei of uranium-235, the main fuel used in nuclear reactors. However, the process can also be

induced by bombarding nuclei with neutrons because a nucleus that has absorbed a neutron becomes unstable and soon splits. The neutrons released spontaneously by the fission of uranium nuclei may therefore be used in turn to induce further fissions, setting up a chain reaction that must be controlled if it is not to result in a nuclear explosion.

Anyone who expects a source of power from the transformation of these atoms is talking moonshine.

ERNEST RUTHERFORD New Zealand physicist.

Physics Today Oct 1970

fistula in medicine, an abnormal pathway developing between adjoining organs or tissues, or leading to the exterior of the body. A fistula developing between the bowel and the bladder, for instance, may give rise to urinary-tract infection by intestinal organisms.

fit in medicine, popular term for ϕ convulsion.

fitness in genetic theory, a measure of the success with which a genetically determined character can spread in future generations. By convention, the normal character is assigned a fitness of one, and variants (determined by other alleles) are then assigned fitness values relative to this. Those with fitness greater than one will spread more rapidly and will ultimately replace the normal allele; those with fitness less than one will gradually die out.

fixed font in computing, a ϕ font that uses fixed, rather than proportional, spacing. It is a necessary option in off-line reader software and e-mail programs, since some ASCII art and tables do not display correctly without it.

fixed point temperature that can be accurately reproduced and used as the basis of a temperature scale. In the Celsius scale, the fixed points are the temperature of melting ice, defined to be 0°C (32°F), and the temperature of boiling water (at standard atmospheric pressure), defined to be 100°C (212°F).

fixed-point notation system in which numbers are represented using a set of digits with the decimal point always in its correct position. For very large and very small numbers this requires a lot of digits. In computing, the size of the numbers that can be handled in this way is limited by the capacity of the computer, and so the slower floating-point notation is often preferred.

fjord or *fjord* narrow sea inlet enclosed by high cliffs. Fjords are found in Norway, New Zealand, and western parts of Scotland. They are formed when an overdeepened U-shaped glacial valley is drowned by a rise in sea-level. At the mouth of the fjord there is a characteristic lip causing a shallowing of the water. This is due to reduced glacial erosion and the deposition of moraine at this point.

Fiordland is the deeply indented southwest coast of South Island, New Zealand; one of the most beautiful inlets is Milford Sound.

flaccidity in botany, the loss of rigidity (turgor) in plant cells, caused by loss of water from the central vacuole so that the cytoplasm no longer pushes against the cellulose cell wall. If this condition occurs throughout the plant then wilting is seen.

Flaccidity can be induced in the laboratory by immersing the plant cell in a strong saline solution. Water leaves the cell by osmosis causing the vacuole to shrink. In extreme cases the actual cytoplasm pulls away from the cell wall, a phenomenon known as plasmolysis.

flag in botany, another name for ϕ ris, especially yellow flag (*Iris pseudacorus*), which grows wild in damp places throughout Europe; it is a true water plant but adapts to garden borders. It has a thick rhizome (underground stem), stiff blade-like leaves, and stems up to 150 cm/5 ft high. The flowers are large and yellow.

flag in computing, an indicator that can be set or unset in order to signal whether a particular condition is true – for example,

whether the end of a file has been reached, or whether an overflow error has occurred. The indicator usually takes the form of a single binary digit, or bit (either 0 or 1).

flagellum small hairlike organ on the surface of certain cells. Flagella are the motile organs of certain protozoa and single-celled algae, and of the sperm cells of higher animals. Unlike ϕ cilia, flagella usually occur singly or in pairs; they are also longer and have a more complex whiplike action.

Each flagellum consists of contractile filaments producing snakelike movements that propel cells through fluids, or fluids past cells. Water movement inside sponges is also produced by flagella.

flame angry public or private ϕ electronic mail message. Users of the ϕ Internet use flames to express disapproval of breaches of ϕ netiquette or the voicing of an unpopular opinion. An offensive message posted to, for example, a USENET ϕ newsgroup, will cause those offended to flame the culprit. Such flames maintain a level of discipline among the Internet's users.

flame test in chemistry, the use of a flame to identify metal cations present in a solid.

A nichrome or platinum wire is moistened with acid, dipped in a compound of the element, either powdered or in solution, and then held in a hot flame. The colour produced in the flame is characteristic of metals present; for example, sodium burns with an orange-yellow flame, and potassium with a lilac one.

Flame test

| element | colour of flame |
|----------------------------------------|-------------------|
| sodium | orange-yellow |
| potassium | lilac |
| calcium | red or yellow-red |
| strontium, lithium | crimson |
| barium, manganese (manganese chloride) | pale green |
| copper, thallium, boron (boric acid) | bright green |
| lead, arsenic, antimony | livid blue |
| copper (copper (II) chloride) | bright blue |

flame tree any of various trees with brilliant red flowers, including the smooth-stemmed semi-deciduous *Brachychiton acerifolium* with scarlet bell-shaped flowers, native to Australia, but spread throughout the tropics.

flame war in computing, heated electronic argument where few good points are made and most of the participants ϕ flame each other repeatedly.

Several flame wars have passed into USENET legend, including the deliberate 1994 invasion of the rec.pets.cats newsgroup by the alt.tasteless newsgroup.

flamingo long-legged and long-necked wading bird, family Phoenicopteridae, of the stork order Ciconiiformes. Largest of the family is the greater or roseate flamingo *Phoenicopterus ruber*, found in Africa, the Caribbean, and South America, with delicate pink plumage and 1.25 m/4 ft tall. They sift the mud for food with their downy bills, and build colonies of high, conelike mud nests, with a little hollow for the eggs at the top.

flannel flower Australian flower *Actinotus helianthi* found in New South Wales and Queensland, having white flannel-like bracts below the flower.

flare, solar brilliant eruption on the Sun above a ϕ sunspot, thought to be caused by release of magnetic energy. Flares reach maximum brightness within a few minutes, then fade away over about an hour. They eject a burst of atomic particles into space at up to 1,000 kps/600 mps. When these particles reach Earth they can cause radio blackouts, disruptions of the Earth's magnetic field, and aurora.

flash flood flood of water in a normally arid area brought on by a sudden downpour of rain. Flash floods are rare and usually occur

in mountainous areas. They may travel many kilometres from the site of the rainfall.

Because of the suddenness of flash floods, little warning can be given of their occurrence. In 1972 a flash flood at Rapid City, South Dakota, USA, killed 238 people along Rapid Creek.

flash memory type of ϕ EEPROM memory that can be erased and reprogrammed without removal from the computer.

flashover small fire that erupts suddenly into a much larger one. They can occur if there is sufficient build up of heat from a small fire to ignite the mixture of gas and smoke produced. This increases temperatures further igniting surroundings. Flashovers can occur extremely rapidly with temperatures of 1,100°C being reached in seconds.

FlashPix in computing, a ϕ ile format for digital imaging intended as a universal standard for both individual multimedia applications and external communications over online services. It was developed collaboratively by Kodak, Hewlett-Packard, Live Picture, and Microsoft in 1996.

flash point in physics, the lowest temperature at which a liquid or volatile solid heated under standard conditions gives off sufficient vapour to ignite on the application of a small flame.

The **fire point** of a material is the temperature at which full combustion occurs. For safe storage of materials such as fuel or oil, conditions must be well below the flash and fire points to reduce fire risks to a minimum.

flash upgrade in computing, technique for upgrading firmware by updating the software embedded in it. It is used particularly for modems and ϕ EPROMs.

flatfish bony fishes of the order Pleuronectiformes, having a characteristically flat, asymmetrical body with both eyes (in adults) on the upper side. Species include flounders, turbot, halibut, plaice, and the European sole.

flat screen type of display suitable for portable computers such as LCD (liquid crystal display) or gas plasma screens (see ϕ plasma display). Flat-screen, or flat-panel, displays are compact and lightweight compared to traditional cathode-ray tube monitors and TV sets.

It is predicted that eventually all TV screens will be made using this type of technology.

flatworm invertebrate of the phylum Platyhelminthes. Some are free-living, but many are parasitic (for example, tapeworms and flukes). The body is simple and bilaterally symmetrical, with one opening to the intestine. Many are hermaphrodite (with both male and female sex organs) and practise self-fertilization.

flax any of a group of plants including the cultivated *L. usitatissimum*; linen is produced from the fibre in its stems. The seeds yield linseed oil, used in paints and varnishes. The plant, of almost worldwide distribution, has a stem up to 60 cm/24 in high, small leaves, and bright blue flowers. (Genus *Linum*, family Linaceae.)

After extracting the oil, what is left of the seeds is fed to cattle. The stems are retted (soaked) in water after harvesting, and then dried, rolled, and scutched (pounded), separating the fibre from the central core of woody tissue. The long fibres are spun into linen thread, twice as strong as cotton, yet more delicate, and suitable for lace; shorter fibres are used to make string or paper.

Annual world production of flax fibre amounts to approximately 60,000 tonnes, with Russia, Ukraine, Belarus, and Latvia accounting for half of the total. Other producers are Belgium, the Netherlands, and Northern Ireland.

Colour possessed me, I didn't have to pursue it. It will possess me always ... This is the meaning of this happy hour: colour and I are one. I am a painter.

PAUL KLEE SWISS artist.
The Diaries of Paul Klee, April 1914

FLEA

As a flea jumps, its rate of acceleration is 20 times that of the space shuttle during launching. It reaches a speed of 100 m per sec within the first 500th of a second.

flea wingless insect of the order Siphonaptera, with blood-sucking mouthparts. Fleas are parasitic on warm-blooded animals. Some fleas can jump 130 times their own height.

Species include the human flea *Pulex irritans*; the rat flea *Xenopsylla cheopis*, the transmitter of plague and typhus; and (fostered by central heating) the cat and dog fleas *Ctenocephalides felis* and *C. canis*.

fleabane any of several plants of two related groups, belonging to the daisy family. Common fleabane (*P. dysenterica*) has golden-yellow flower heads and grows in wet and marshy places throughout Europe. (Genera *Pulicaria* and *Erigeron*, family Compositae.)

Fleming, Alexander (1881-1955) Scottish bacteriologist who discovered the first antibiotic drug, ϕ enicillin, in 1928. In 1922 he had discovered lysozyme, an antibacterial enzyme present in saliva, nasal secretions, and tears. While studying this, he found an unusual mould growing on a neglected culture dish, which he isolated and grew into a pure culture; this led to his discovery of penicillin. It came into use in 1941. In 1945 he won the Nobel Prize for Physiology or Medicine with Howard W Florey and Ernst B Chain, whose research had brought widespread realization of the value of penicillin.

Fleming, (John) Ambrose (1849-1945)

English electrical physicist and engineer who invented the thermionic valve in 1904 and devised Fleming's rules. Knighted 1929.

Mary Evans Picture Library

Fleming's rules memory aids used to recall the relative directions of the magnetic field, current, and motion in an electric generator or motor, using one's fingers. The three directions are represented by the thumb (for motion), forefinger (for field), and second finger (for conventional current), all held at right angles to each other. The right hand is used for generators and the left for motors.

The rules were devised by the English physicist John Fleming.

flesh fly medium-sized fly varying from golden-brown to dark grey. The larvae feed on carrion and animal waste, though the larvae of *Wohlfahrtia* often invade the skin of children and young animals and other larvae will cause myiasis (invasion of the tissues) when the skin is already broken by a cut or abrasion.

classification Flesh flies are members of the genera *Sarcophaga* and *Wohlfahrtia* in the family Sarcophagidae of the insect order Diptera, class Insecta, phylum Arthropoda.

flexor any muscle that bends a limb. Flexors usually work in opposition to other muscles, the extensors, an arrangement known as antagonistic.

Fleming's rules Fleming's rules give the direction of the magnetic field, motion, and current in electrical machines. The left hand is used for motors, and the right hand for generators and dynamos.

flight or aviation method of transport in which aircraft carry people and goods through the air. People first took to the air in balloons and began powered flight in 1852 in airships, but the history of flying, both for civilian and military use, is dominated by the aeroplane. The earliest planes were designed for gliding; the advent of the petrol engine saw the first powered flight by the Wright brothers in 1903 in the USA. This inspired the development of aircraft throughout Europe. Biplanes were succeeded by monoplanes in the 1930s. The first jet plane (see jet propulsion) was produced in 1939, and after the end of World War II the development of jetliners brought about a continuous expansion in passenger air travel. In 1969 came the supersonic aircraft Concorde. **history** In the 14th century the English philosopher Roger Bacon spoke of constructing an aircraft by means of a hollow globe and liquid fire. He was followed in the 15th century by Albert of Saxony, who also spoke of balloon flight by means of fire in a light sphere. During the 16th and 17th centuries a number of fantastic ideas were put forward; one was that swans' eggs be filled with sulphur or mercury and thereby drawn up to the Sun.

early ideas Francisco de Lana in 1670 proposed that four hollow balls made of very thin brass should be emptied of air. To them should be attached a small boat and sail, and in that way a balloon would be contrived which could carry a person. The idea was not feasible, since the globes, made of brass only 0.1 mm thick, would have collapsed by reason of their own weight. But although de Lana saw this difficulty, he argued that their shape would prevent that.

balloons It was not until the next century that the real balloon was invented. The beginning of the development of the balloon was the work of two brothers, Joseph and Etienne Montgolfier, who came to the conclusion that a paper bag filled with a 'substance of a cloud-like nature' would float in the atmosphere. They made a number of experiments which attracted attention and further efforts from others. Progress was made gradually, and the first person-carrying ascent took place in October 1783, when Pilatre de Rozier went up in a Montgolfier captive balloon. The first woman to ascend was Madame Thibie, who went up from Lyons in 1784. In 1859 a flight of over 1,600 km/994 mi was made in the USA.

adding power It had long been recognized that the difficulty with balloons was navigating through the air. Oars were tried, but were not successful. The first attempt to navigate the balloon by means of a small, light engine came in 1852, the experiment being made by Henri Giffard. From 1897 the development of the airship was

the special work of Ferdinand von Zeppelin. In 1900 he made his first flight with a dirigible balloon carrying five men. It was made of aluminium, supported by gas-bags, and driven by two motors, each of about 12 kW. His first experiment met with some success, a second, more powerful version was wrecked, and a third met with great success. This airship carried 11 passengers and attained a speed of about 55 kph/34 mph, travelling about 400 km/248 mi in 11 hours, but was wrecked by a storm in 1908, caught fire, and was completely destroyed.

powered flight In the late 19th century experiments were being made with soaring machines and hang gliders, chiefly by Otto Lilienthal, who, with an arrangement formed on the plan of birds' wings, attempted to imitate their 'soaring flight'. Following up Lilienthal's ideas, the Wright brothers produced their first powered aeroplane in 1903. Their first successful machine was simply an aeroplane that flew in a straight line, but this received many modifications; and in 1908 they went to France to carry on experiments, during which Wilbur Wright created a record by remaining in the air for over an hour while carrying a passenger. He also attained a speed of 60 kph/37 mph.

In Europe, at the beginning of the 20th century, France led in aeroplane design and Louis Blériot brought aviation much publicity by crossing the English Channel in 1909, as did the Reims air races of that year. The first powered flight in the UK was made by Samuel Franklin Cody 1908. In 1912 Sopwith and Bristol both built small biplanes. The first big twin-engine aeroplane was the Handley Page bomber 1917. The stimulus of World War I (1914-18) and rapid development of the petrol engine led to increased power, and speeds rose to 320 kph/200 mph. Streamlining the body of planes became imperative: the body, wings, and exposed parts were reshaped to reduce drag. Eventually the biplane was superseded by the internally braced monoplane structure, for example, the Hawker Hurricane and Supermarine Spitfire fighters and Avro Lancaster and Boeing Flying Fortress bombers of World War II (1939-45).

jet aircraft The German Heinkel 178, built in 1939, was the first jet plane; it was driven, not by a propeller as all planes before it, but by a jet of hot gases. The first British jet aircraft, the Gloster E.28/39, flew from Cranwell, Lincolnshire, on 15 May 1941, powered by a jet engine invented by British engineer Frank Whittle. Twin-jet Meteor fighters were in use by the end of WWII. The rapid development of the jet plane led to enormous increases in power and speed until air-compressibility effects were felt near the speed of sound, which at first seemed to be a flight speed limit (the sound barrier). The sound barrier was first broken in the USA in 1947 by a rocket-powered aircraft piloted by Chuck Yeager. To attain supersonic speed, streamlining the aircraft body became insufficient: wings were swept back, engines buried in wings and tail units, and bodies were even eliminated in all-wing delta designs. In the 1950s the first jet airliners, such as the Comet (first introduced in 1949), were introduced into service. Today jet planes dominate both military and civilian aviation, although many light planes still use piston engines and propellers. The late 1960s saw the introduction of the Concorde, and in 1976 the Anglo-French Concorde, which makes a transatlantic crossing in under three hours, came into commercial service.

other developments During the 1950s and 1960s research was done on VTOL (vertical and/or short takeoff and landing) aircraft. The British Harrier jet fighter has been the only VTOL aircraft to achieve commercial success, but STOL technology has fed into subsequent generations of aircraft. The 1960s and 1970s also saw the development of variable geometry ('swing-wing') aircraft, the wings of

HOW DO PLANES FLY?

http://observe.ivv.nasa.gov/nasa/exhibits/planes/planes_1a.html

Lucid exposition of the whys and hows connected with the flight of an aeroplane. Kids are invited to perform a number of related experiments and the answers are given with a series of fun interactive steps.

which can be swept back in flight to achieve higher speeds. In the 1980s much progress was made in 'fly-by-wire' aircraft with computer-aided controls. International partnerships have developed both civilian and military aircraft. The Airbus is a wide-bodied airliner built jointly by companies from France, Germany, the UK, the Netherlands, and Spain. The Eurofighter 2000 is a joint project between the UK, Italy, Germany, and Spain. The B-2 bomber, (a stealth bomber) developed by the US Air Force in 1989, is invisible to radar. The altitude record for a solar-powered plane was set in 1997 by Pathfinder, a 30-m/98-ft wingspan aircraft, which reached 20,528 m/67,349 ft above sea level over Hawaii.

flight simulator computer-controlled pilot-training device, consisting of an artificial cockpit mounted on hydraulic legs, that simulates the experience of flying a real aircraft. Inside the cockpit, the trainee pilot views a screen showing a computer-controlled projection of the view from a real aircraft, and makes appropriate adjustments to the controls. The computer monitors these adjustments, changes both the alignment of the cockpit on its hydraulic legs, and the projected view seen by the pilot. In this way a trainee pilot can progress to quite an advanced stage of training without leaving the ground.

flint compact, hard, brittle mineral (a variety of chert), brown, black, or grey in colour, found as nodules in limestone or shale deposits. It consists of cryptocrystalline (grains too small to be visible even under a light microscope) silica, SiO_2 , principally in the crystalline form of quartz. Implements fashioned from flint were widely used in prehistory.

The best flint, used for Neolithic tools, is floorstone, a shiny black flint that occurs deep within chalk.

Because of their hardness (7 on the Mohs' scale), flint splinters are used for abrasive purposes and, when ground into powder, added to clay during pottery manufacture. Flints have been used for making fire by striking the flint against steel, which produces a spark, and for discharging guns. Flints in cigarette lighters are made from cerium alloy.

flip-flop in computing, another name for a bistable circuit.

floating state of equilibrium in which a body rests on or is suspended in the surface of a fluid (liquid or gas). According to Archimedes' principle, a body wholly or partly immersed in a fluid will be subjected to an upward force, or upthrust, equal in magnitude to the weight of the fluid it has displaced.

If the density of the body is greater than that of the fluid, then its weight will be greater than the upthrust and it will sink. However, if the body's density is less than that of the fluid, the upthrust will be the greater and the body will be pushed upwards towards the surface. As the body rises above the surface the amount of fluid that it displaces (and therefore the magnitude of the upthrust) decreases. Eventually the upthrust acting on the submerged part of the body will equal the body's weight, equilibrium will be reached, and the body will float.

floating-point notation system in which numbers are represented by means of a decimal fraction and an exponent. For example, in floating-point notation, 123,000,000,000 would be represented as 0.123×10^{12} , where 0.123 is the fraction, or mantissa, and 12 the exponent. The exponent is the power of 10 by which the fraction must be multiplied in order to obtain the true value of the number.

In computing, floating-point notation enables programs to work with very large and very small numbers using only a few digits; however, it is slower than fixed-point notation and suffers from small rounding errors.

flocculation in soils, the artificially induced coupling together of particles to improve aeration and drainage. Clay soils, which have very tiny particles and are difficult to work, are often treated in this way. The method involves adding more lime to the soil.

floppy disc in computing, a storage device consisting of a light, flexible disc enclosed in a cardboard or plastic jacket. The disc is placed in a disc drive, where it rotates at high speed. Data are recorded magnetically on one or both surfaces.

Floppy discs were invented by IBM in 1971 as a means of loading programs into the computer. They were originally 20 cm/8 in in diameter and typically held about 240 kilobytes of data. Present-day floppy discs, widely used on microcomputers, are usually either 13.13 cm/5.25 in or 8.8 cm/3.5 in in diameter, and generally hold 0.5–2 megabytes, depending on the disc size, recording method, and whether one or both sides are used.

Floppy discs are inexpensive, and light enough to send through the post, but have slower access speeds and are more fragile than hard discs. (See also disc).

FLOPS (abbreviation for *floating point operations per second*) measure of the speed at which a computer program can be run.

floptical disc or **erasable optical disc** in computing, a type of optical disc that can be erased and loaded with new data, just like a magnetic disc. By contrast, most optical discs are read-only. A single optical disc can hold as much as 1,000 megabytes of data, about 800 times more than a typical floppy disc. Floptical discs need a special disc drive, but some such drives are also capable of accepting standard 3.5 inch floppy discs.

floral diagram diagram showing the arrangement and number of parts in a flower, drawn in cross section. An ovary is drawn in the centre, surrounded by representations of the other floral parts, indicating the position of each at its base. If any parts such as the petals or sepals are fused, this is also indicated. Floral diagrams allow the structure of different flowers to be compared, and are usually shown with the floral formula.

floral formula symbolic representation of the structure of a flower. Each kind of floral part is represented by a letter (K for calyx, C for corolla, P for perianth, A for androecium, G for gynoecium) and a number to indicate the quantity of the part present, for example, C5 for a flower with five petals. The number is in brackets if the parts are fused. If the parts are arranged in distinct whorls within the flower, this is shown by two separate figures, such as A5 + 5, indicating two whorls of five stamens each.

A flower with radial symmetry is known as *actinomorphic*; a flower with bilateral symmetry as *zygomorphic*.

floret small flower, usually making up part of a larger, composite flower head. There are often two different types present on one flower head: disc florets in the central area, and ray florets around the edge which usually have a single petal known as the ligule. In the common daisy, for example, the disc florets are yellow, while the ligules are white.

flotation, law of law stating that a floating object displaces its own weight of the fluid in which it floats. See Archimedes principle.

flotation process common method of preparing mineral ores for subsequent processing by making use of the different wetting properties of various components. The ore is finely ground and then mixed with water and a specially selected wetting agent. Air is bubbled through the mixture, forming a froth; the desired ore particles attach themselves to the bubbles and are skimmed off, while unwanted dirt or other ores remain behind.

flounder small flatfish *Platyichthys flesus* of the NE Atlantic and Mediterranean, although it sometimes lives in estuaries. It is dull in colour and grows to 50 cm/1.6 ft.

FLOUNDER

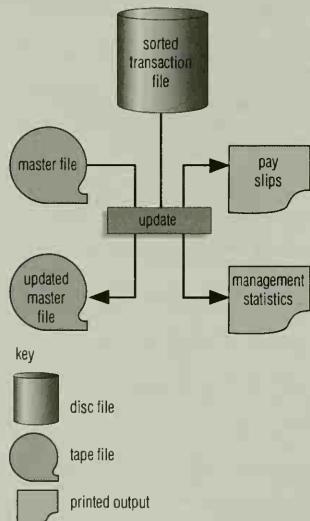

Flounders attempt to merge into any background. They will even assume an approximate chequered pattern if the floor of their tank resembles a chess-board.

flour beetle beetle that is a major pest of stored agricultural products, such as flour. They are found worldwide in granaries and stores where both the adult beetles and the larvae feed on damaged grain or flour. Neither adults nor larvae can eat intact grains.

classification Flour beetles are in the genus *Tribolium*, family Tenebrionidae, class Insecta, phylum Arthropoda.

flow chart diagram, often used in computing, to show the possible paths that data can take through a system or program.

A system flow chart, or **data flow chart**, is used to describe the flow of data through a complete data-processing system. Different graphic symbols represent the clerical operations involved and the different input, storage, and output equipment required. Although the flow chart may indicate the specific programs used, no details are given of how the programs process the data.

flow chart A system flow chart describes the flow of data through a data-processing system. This chart shows the data flow in a basic accounting system.

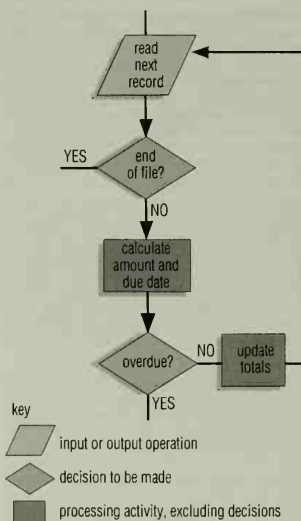

A **program flow chart** is used to describe the flow of data through a particular computer program, showing the exact sequence of operations performed by that program in order to process the data. Different graphic symbols are used to represent data input and output, decisions, branches, and (sub)routines.

flow control in data communications, hardware or software signals that control the flow of data to ensure that it is not transmitted too quickly for the receiving computer to handle.

flower the reproductive unit of an angiosperm or flowering plant, typically consisting of four whorls of modified leaves: (sepals, petals, stamens, and carpels. These are borne on a central axis or receptacle. The many variations in size, colour, number, and arrangement of parts are closely related to the method of pollination. Flowers adapted for wind pollination typically have reduced or absent petals and sepals and long, feathery stigmas that hang outside the flower to trap airborne pollen. In contrast, the petals of insect-pollinated flowers are usually conspicuous and brightly coloured.

structure The sepals and petals form the calyx and corolla respectively and together comprise the perianth with the function of protecting the reproductive organs and attracting pollinators.

The stamens lie within the corolla, each having a slender stalk, or filament, bearing the pollen-containing anther at the top. Collectively they are known as the **androecium** (male organs). The

flow chart A program flow chart shows the sequence of operations needed to achieve a task, in this case reading customer accounts and calculating the amount due for each customer. After an account has been processed, the program loops back to process the next one.

inner whorl of the flower comprises the carpels, each usually consisting of an ovary in which are borne the ovules, and a stigma borne at the top of a slender stalk, or style. Collectively the carpels are known as the **gynoecium** (female organs).

types of flower In size, flowers range from the tiny blooms of duckweeds scarcely visible to the naked eye to the gigantic flowers of the Malaysian *Rafflesia*, which can reach over 1 m/3 ft across. Flowers may either be borne singly or grouped together in inflorescences. The stalk of the whole inflorescence is termed a **peduncle**, and the stalk of an individual flower is termed a **pedicel**. A

flower Cross section of a typical flower showing its basic components: sepals, petals, stamens (anthers and filaments), and carpel (ovary and stigma). Flowers vary greatly in the size, shape, colour, and arrangement of these components.

flower is termed hermaphrodite when it contains both male and female reproductive organs. When male and female organs are carried in separate flowers, they are termed **monoecious**; when male and female flowers are on separate plants, the term **dioecious** is used.

flowering plant term generally used for angiosperms, which bear flowers with various parts, including sepals, petals, stamens, and carpels.

Sometimes the term is used more broadly, to include both angiosperms and gymnosperms, in which case the cones of conifers and cycads are referred to as 'flowers'. Usually, however, the angiosperms and gymnosperms are referred to collectively as **seed plants**, or **spermatophytes**.

In 1996 UK palaeontologists found fossils in southern England of what may be the world's oldest flowering plant, *Bevalstia pehja*, a wetland herb about 25 cm/10 in high, has been dated as early Cretaceous, about 130 million years old.

flue-gas desulphurization process of removing harmful sulphur pollution from gases emerging from a boiler. Sulphur compounds such as sulphur dioxide are commonly produced by burning fossil fuels, especially coal in power stations, and are the main cause of acid rain.

The process is environmentally beneficial but expensive, adding about 10% to the cost of electricity generation.

fluid any substance, either liquid or gas, in which the molecules are relatively mobile and can 'flow'.

fluid mechanics the study of the behaviour of fluids (liquids and gases) at rest and in motion. Fluid mechanics is important in the study of the weather, the design of aircraft and road vehicles, and in industries, such as the chemical industry, which deal with flowing liquids or gases.

fluid, supercritical fluid brought by a combination of heat and pressure to the point at which, as a near vapour, it combines the properties of a gas and a liquid. Supercritical fluids are used as solvents in chemical processes, such as the extraction of lubricating oil from refinery residues or the decaffeination of coffee, because they avoid the energy-expensive need for phase changes (from liquid to gas and back again) required in conventional distillation processes.

flake any of various parasitic flatworms of the classes Monogenea and Digenea, that as adults live in and destroy the livers of sheep, cattle, horses, dogs, and humans. Monogenic flukes can complete their life cycle in one host; digenetic flukes require two or more hosts, for example a snail and a human being, to complete their life cycle.

An estimated 40 million people worldwide are infected by food-borne flukes, mostly from undercooked or raw fish or shellfish, according to a 1994 WHO report.

fluorescence in scientific usage, very short-lived luminescence (a glow not caused by high temperature). Generally, the term is used for any luminescence regardless of the persistence. Phosphorescence lasts a little longer.

Fluorescence is used in strip and other lighting, and was developed rapidly during World War II because it was a more efficient means of illumination than the incandescent lamp. Recently, small bulb-size fluorescence lamps have reached the market. It is claimed that, if widely used, their greater efficiency could reduce demand for electricity. Other important applications are in fluorescent screens for television and cathode-ray tubes.

fluorescence microscopy technique for examining samples under a microscope without slicing them into thin sections. Instead, fluorescent dyes are introduced into the tissue and used as a light source for imaging purposes. Fluorescent dyes can also be bonded to monoclonal antibodies and used to highlight areas where particular cell proteins occur.

fluoridation addition of small amounts of fluoride salts to drinking water by certain water authorities to help prevent tooth decay. Experiments in Britain, the USA, and elsewhere have indicated that

a concentration of fluoride of 1 part per million in tap water retards the decay of children's teeth by more than 50%.

Much concern has been expressed about the risks of medicating the population at large by the addition of fluoride to the water supply, but the medical evidence demonstrates conclusively that there is no risk to the general health from additions of 1 part per million of fluoride to drinking water.

fluoride negative ion (F⁻) formed when hydrogen fluoride dissolves in water; compound formed between fluorine and another element in which the fluorine is the more electronegative element (see **electronegativity**, **halide**).

In parts of India, the natural level of fluoride in water is 10 parts per million. This causes fluorosis, or chronic fluoride poisoning, mottling teeth and deforming bones.

fluorine pale yellow, gaseous, nonmetallic element, symbol F, atomic number 9, relative atomic mass 19. It is the first member of the halogen group of elements, and is pungent, poisonous, and highly reactive, uniting directly with nearly all the elements. It occurs naturally as the minerals fluorite (CaF₂) and cryolite (Na₃AlF₆). Hydrogen fluoride is used in etching glass, and the freons, which all contain fluorine, are widely used as refrigerants.

Fluorine was discovered by the Swedish chemist Karl Scheele in 1771 and isolated by the French chemist Henri Moissan in 1886. Combined with uranium as UF₆, it is used in the separation of uranium isotopes.

The Infrared Space Observatory detected hydrogen fluoride molecules in an interstellar gas cloud in the constellation Sagittarius in 1997. It was the first time fluorine had been detected in space.

fluorite or **fluorspar** a glassy, brittle halide mineral, calcium fluoride CaF₂, forming cubes and octahedra; colourless when pure, otherwise violet, blue, yellow, brown, or green.

Fluorite is used as a flux in iron and steel making; colourless fluorite is used in the manufacture of microscope lenses. It is also used for the glaze on pottery, and as a source of fluorine in the manufacture of hydrofluoric acid.

fluorocarbon compound formed by replacing the hydrogen atoms of a hydrocarbon with fluorine. Fluorocarbons are used as inert coatings, refrigerants, synthetic resins, and as propellants in aerosols.

There is concern that the release of fluorocarbons – particularly those containing chlorine (chlorofluorocarbons, CFCs) – depletes the ozone layer, allowing more ultraviolet light from the Sun to penetrate the Earth's atmosphere, and increasing the incidence of skin cancer in humans.

FLY

Fruit flies (*Drosophila*) reach sexual maturity in less than two weeks. This means that there are 25 generations a year. Every female can lay 100 eggs or more.

fly any insect of the order Diptera. A fly has a single pair of wings, antennae, and compound eyes; the hind wings have become modified into knoblike projections (halteres) used to maintain equilibrium in flight. There are over 90,000 species.

The mouthparts project from the head as a proboscis used for sucking fluids, modified in some species, such as mosquitoes, to pierce a victim's skin and suck blood. Discs at the ends of hairs on their feet secrete a fluid enabling them to walk up walls and across ceilings. Flies undergo complete metamorphosis; their larvae (maggots) are without true legs, and the pupae are rarely enclosed in a cocoon. The sexes are similar and coloration is rarely vivid, though some are metallic green or blue. The fruitfly, genus *Drosophila*, is much used in genetic experiments as it is easy to keep, fast-breeding, and has easily visible chromosomes.

flying dragon lizard *Draco volans* of the family Agamidae. It lives in southeast Asia, and can glide on flaps of skin spread and

fly A tachinid fly *Blepharella snyderi* in Kakamega Forest, Kenya. The females of the family Tachinidae lay their eggs on or near the bodies of other arthropods (future hosts), or on food which is likely to be eaten by a host at some point. The fly's larvae eventually live as internal parasites in other insects.

supported by its ribs. This small (7.5 cm/3 in head and body) arboreal lizard can glide between trees for 6m/20 ft or more.

flying fish any marine bony fishes of the family Exocoetidae, order Beloniformes, best represented in tropical waters. They have winglike pectoral fins that can be spread to glide over the water.

flying fox another name for the fruit bat, a fruit-eating bat of the suborder Megachiroptera.

flying gurnard any of various marine fishes of the order Dactylopteriformes (especially the genus *Dactylopterus*), having winglike pectoral fins and capable of gliding for short distances.

They are not related to flying fishes.

flying lemur commonly used, but incorrect, name for ϕ colugo. It cannot fly, and it is not a lemur.

flying lizard another name for ϕ flying dragon.

flying squirrel any of 43 known species of squirrel, not closely related to the true squirrels. They are characterized by a membrane along the side of the body from forelimb to hindlimb (in some species running to neck and tail) which allows them to glide through the air. Several genera of flying squirrel are found in the Old World; the New World has the genus *Glaucomys*. Most species are eastern Asian.

The giant flying squirrel *Petaurista* grows up to 1.1 m/3.5 ft including tail.

flystrike or **blowfly strike** or **sheep strike** infestation of the flesh of living sheep by blowfly maggots, especially those of the blue blowfly. It is one of the most costly sheep diseases in Australia, affecting all the grazing areas of New South Wales. Control has mainly been by insecticide, but non-chemical means, such as docking of tails and mulesing, are increasingly being encouraged. Mulesing involves an operation to remove the wrinkles of skin which trap moisture and lay the sheep open to infestation.

flythrough in ϕ virtual reality, animation allowing users to view a model of a proposed or actual site as if they were inside it and moving through it.

For the 1996 Olympics in Atlanta, USA, flythroughs assisted site planners to identify areas in the main stadium where camera positions would be blocked by the audience, allowing solutions to be found in advance of construction.

flywheel heavy wheel in an engine that helps keep it running and smooths its motion. The crankshaft in a petrol engine has a flywheel at one end, which keeps the crankshaft turning in between the intermittent power strokes of the pistons. It also comes into contact with the ϕ clutch, serving as the connection between the engine and the car's transmission system.

FM in physics, abbreviation for ϕ frequency modulation.

C = centre of curvature
F = focus

P = pole
f = focal length

focal length The distance from the pole (P), or optical centre, of a lens or spherical mirror to its principal focus (F). The focal length of a spherical mirror is equal to half the radius of curvature ($f = r/2$). The focal length of a lens is inversely proportional to the power of that lens (the greater the power the shorter the focal length).

FM synthesizer (abbreviation for *frequency modulation synthesizer*) in computing, method for generating synthetic sounds based on techniques used to transmit FM radio signals.

FMV abbreviation for *full-motion video*.

f-number or **f-stop** measure of the relative aperture of a telescope or camera lens; it indicates the light-gathering power of the lens. In photography, each successive f-number represents a halving of exposure speed.

focal length or **focal distance** the distance from the centre of a lens or curved mirror to the focal point. For a concave mirror or convex lens, it is the distance at which rays of light parallel to the principal axis of the mirror or lens are brought to a focus (for a mirror, this is half the radius of curvature). For a convex mirror or concave lens, it is the distance from the centre to the point from which rays of light parallel to the principal axis of the mirror or lens diverge.

With lenses, the greater the power (measured in dioptres) of the lens, the shorter its focal length. The human eye has a lens of adjustable focal length to allow the light from objects of varying distance to be focused on the retina.

focus in astronomy, either of two points lying on the major axis of an elliptical orbit on either side of the centre. One focus marks the centre of mass of the system and the other is empty. In a circular orbit the two foci coincide at the centre of the circle and in a parabolic orbit the second focus lies at infinity. See *Kepler's Laws*.

focus or **focal point** in optics, the point at which light rays converge, or from which they appear to diverge. Other electromagnetic rays, such as microwaves, and sound waves may also be brought together at a focus. Rays parallel to the principal axis of a lens or mirror are converged at, or appear to diverge from, the principal focus.

focus in photography, the distance that a lens must be moved in order to focus a sharp image on the light-sensitive film at the back of the camera. The lens is moved away from the film to focus the image of closer objects. The focusing distance is often marked on a scale around the lens; however, some cameras now have an automatic focusing (autofocus) mechanism that uses an electric motor to move the lens.

fog cloud that collects at the surface of the Earth, composed of water vapour that has condensed on particles of dust in the atmos-

phere. Cloud and fog are both caused by the air temperature falling below dew point. The thickness of fog depends on the number of water particles it contains. Officially, fog refers to a condition when visibility is reduced to 1 km/0.6 mi or less, and mist or haze to that giving a visibility of 1–2 km or about 1 mi.

There are two types of fog. An advection fog is formed by the meeting of two currents of air, one cooler than the other, or by warm air flowing over a cold surface. Sea fogs commonly occur where warm and cold currents meet and the air above them mixes. A radiation fog forms on clear, calm nights when the land surface loses heat rapidly (by radiation); the air above is cooled to below its dew point and condensation takes place. A mist is produced by condensed water particles, and a haze by smoke or dust.

In drought areas, for example, Baja California, Canary Islands, Cape Verde Islands, Namib Desert, Peru, and Chile, coastal fogs enable plant and animal life to survive without rain and are a potential source of water for human use (by means of water collectors exploiting the effect of condensation).

Industrial areas uncontrolled by pollution laws have a continual haze of smoke over them, and if the temperature falls suddenly, a dense yellow smog forms. At some airports since 1975 it has been possible for certain aircraft to land and take off blind in fog, using radar navigation.

fold in geology, a bend in beds or layers of rock. If the bend is arched up in the middle it is called an anticline; if it sags downwards in the middle it is called a syncline. The line along which a bed of rock folds is called its axis. The axial plane is the plane joining the axes of successive beds.

folder in computing, name for a computer directory in Windows 95 and on the Macintosh operating system.

folic acid a vitamin of the B complex. It is found in liver and green leafy vegetables, and is also synthesized by the intestinal bacteria. It is essential for growth, and plays many other roles in the body. Lack of folic acid causes anaemia because it is necessary for the synthesis of nucleic acids and the formation of red blood cells.

follicle in botany, a dry, usually many-seeded fruit that splits along one side only to release the seeds within. It is derived from a single carpel. Examples include the fruits of the larkspurs *Delphinium* and columbine *Aquilegia*. It differs from a pod, which always splits open (dehiscence) along both sides.

follicle in zoology, a small group of cells that surround and nourish a structure such as a hair (hair follicle) or a cell such as an egg (Graafian follicle; see *menstrual cycle*).

advection fog

warm moist air cools either as it passes over a cool sea or comes into contact with cold land surface

radiation fog

during a clear night, heat is lost rapidly from the land. This cools the air which, if moist, becomes saturated – fog forms as it condenses

fog Advection fog occurs when two currents of air, one cooler than the other meet, or by warm air flowing over a cold surface. Radiation fog forms through rapid heat loss from the land, causing condensation to take place and a mist to appear.

follicle-stimulating hormone (FSH) a hormone produced by the pituitary gland. It affects the ovaries in women, stimulating the production of an egg cell.

Luteinizing hormone is needed to complete the process. In men, FSH stimulates the testes to produce sperm. It is used to treat some forms of infertility.

follow-up post in computing, publicly posted reply to a USENET message; unlike a personal e-mail reply, follow-up post can be read by anyone.

Full-featured newsgroups include a facility for setting the names of the newsgroups to which follow-ups should be posted. If, for example, an original message was posted to a number of groups, several of which were inappropriate, the person posting the follow-up might want to restrict further replies to only those groups where the message actually belongs.

Fomalhaut or Alpha Piscis Austrini the brightest star in the southern constellation Piscis Austrinus and the 18th brightest star in the night sky. It is 22 light years from Earth, with a true luminosity 13 times that of the Sun.

Fomalhaut is one of a number of stars around which IRAS (the Infra-Red Astronomy Satellite) detected excess infrared radiation, presumably from a region of solid particles around the star. This material may be a planetary system in the process of formation.

font or **fount** complete set of printed or display characters of the same typeface, size, and style (bold, italic, underlined, and so on).
