subdivisions *p_x*, *p_y*, and *p_z* in the p subshell, for example, of the same energy level). No two electrons in an atom can have the same set of quantum numbers (the *q*Pauli exclusion principle).

quantum simulation the use of *q*omputer simulation to study the quantum behaviour of matter. Simulations based on just 50 or 60 atoms are able to mimic the properties of real matter. If a small group of atoms is surrounded by other identical groups every atom behaves as if it were part of a larger material. This makes it possible, for example, to simulate the behaviour of solids and liquids at high temperatures, and to study chemical reactions at surfaces to aid in the design of better catalysts.

QUANTUM AGE BEGINS

http://www-history.mcs.st-and.ac.uk/~history/HistTopics/The_Quantum_age_begins.html

St Andrews University-run Web site chronicling the discovery of quantum theory. Biographical details of the mathematicians and physicists involved is also provided. The site also includes links to many other history of mathematics related Web resources.

quantum theory or **quantum mechanics** in physics, the theory that *q*uenergy does not have a continuous range of values, but is, instead, absorbed or radiated discontinuously, in multiples of definite, indivisible units called quanta. Just as earlier theory showed how light, generally seen as a wave motion, could also in some ways be seen as composed of discrete particles (*q*hphotons), quantum theory shows how atomic particles such as electrons may also be seen as having wavelike properties. Quantum theory is the basis of particle physics, modern theoretical chemistry, and the solid-state physics that describes the behaviour of the silicon chips used in computers.

The theory began with the work of Max Planck in 1900 on radiated energy, and was extended by Albert Einstein to electromagnetic radiation generally, including light. Danish physicist Niels Bohr used it to explain the *q*pectrum of light emitted by excited hydrogen atoms. Later work by Erwin Schrödinger, Werner Heisenberg, Paul Dirac, and others elaborated the theory to what is called quantum mechanics (or wave mechanics).

Our task is not to penetrate into the essence of things, the meaning of which we don't know anyway, but rather to develop concepts which allow us to talk in a productive way about phenomena in nature.

NIELS BOHR Danish physicist.
Letter to H P E Hansen 20 July 1935

quarantine from French *quarantaine* '40 days' any period for which people, animals, plants, or vessels may be detained in isolation to prevent the spread of contagious diseases.

quark in physics, the elementary particle that is the fundamental constituent of all hadrons (subatomic particle that experiences the strong nuclear force and divided into baryons, such as neutrons and protons, and mesons). Quarks have electric charges that are fractions of the electronic charge ($+\frac{2}{3}$ or $-\frac{1}{3}$ of the electronic charge). There are six types, or 'flavours': up, down, top, bottom, strange, and charmed, each of which has three varieties, or 'colours': red, green, and blue (visual colour is not meant, although the analogy is useful in many ways). To each quark there is an antiparticle, called an antiquark. See *q*uantum chromodynamics.

The Top Quark

BY PETER RODGERS

The standard model

All forms of matter are made from two types of particles called quarks and leptons. These particles interact with each other through four forces: gravity, electromagnetism, and the strong and weak nuclear forces. All these forces are thought to be carried by other particles known as gauge bosons. This model of fundamental particles and their interactions is known as the *standard model of particle physics*.

Particle families

Quarks and leptons come in families. The lightest family contains the up quark, the down quark, the electron and the electron neutrino. The up quark has an electric charge of $+\frac{2}{3}$, the down quark has a charge of $-\frac{1}{3}$ and the electron has a charge of -1 . The neutrino has no mass (i.e. it does not weigh anything) and no charge. Everyday matter is made up of up and down quarks and electrons. Single quarks have never been observed in experiments – they always combine in twos and threes to form other particles known as mesons and baryons. Each particle in the standard model also has an antiparticle with the same mass but opposite electric charge. One of the biggest mysteries in particle physics is why the universe is made of matter rather than antimatter.

Heavy particles

By the middle of 1980 physicists knew that there were only three families of particles. The second family comprised the charm and strange quarks, the muon, and the muon neutrino. These particles had the same pattern of behaviour as the particles in the first

family but were heavier: the muon, for example, was 212 times heavier than the electron. The particles were also short-lived and decayed into lighter particles. The particles in the third family were heavier still and even more short-lived. The third family included the bottom quark and the tau lepton, both discovered in the mid 1970s. A sixth quark was needed to complete the picture but the top quark remained elusive until it was discovered at FermiLab in the US in 1995.

How to make new particles

The top quark was the last quark to be discovered because it was the heaviest. Physicists discover new particles by colliding high-energy beams of other particles together: the more energetic the collisions, the heavier the particles that can be discovered. The top quark turned out to have a mass of 175 gigaelectronvolts – as heavy as an atom of gold.

What next?

The top quark is not the end of the story. Physicists now hope to find the particle (or particles) which could explain why all the fundamental particles have very different masses. This particle is named after the British theoretical physicist Peter Higgs. Physicists hope to discover the Higgs particle at the large hadron collider (LHC), which is due to start in 2005 at the CERN laboratory near Geneva. The LHC will collide beams of high-energy protons in a circular particle accelerator with a circumference of 27 km/17 mi. LHC physicists also hope to discover supersymmetric particles. Supersymmetry is a theory which predicts that the two types of fundamental particles – quarks and leptons – are in fact related.

quart imperial liquid or dry measure, equal to two pints or 1.136 litres. In the USA, a liquid quart is equal to 0.946 litre, while a dry quart is equal to 1.101 litres.

quartile in statistics, any one of the three values of a variable that divide its distribution into four parts of equal frequency. They comprise the lower quartile (or 25th percentile), below which lies the lowest 25% frequency distribution of a variable; the median (or 50th percentile), which forms the dividing line between the upper, middle 25% and the lower, middle 25%; and the upper quartile (or 75th percentile), above which lies the top 25%. The difference of value between the upper and lower quartiles is known as the interquartile range, which is a useful measure of the dispersion of a statistical distribution because it is not affected by freak extreme values (see *range*).

quartz crystalline form of silica SiO_2 , one of the most abundant minerals of the Earth's crust (12% by volume). Quartz occurs in many different kinds of rock, including sandstone and granite. It ranks 7 on the Mohs' scale of hardness and is resistant to chemical or mechanical breakdown. Quarzes vary according to the size and purity of their crystals. Crystals of pure quartz are coarse, colourless, transparent, show no cleavage, and fracture unevenly; this form is usually called rock crystal. Impure coloured varieties, often used as gemstones, include *agate*, *citrine quartz*, and *amethyst*. Quartz is also used as a general name for the cryptocrystalline and noncrystalline varieties of silica, such as *chalcedony*, *chert*, and *opal*.

Three quarks for Muster Mark!

JAMES JOYCE Irish novelist.

Supposedly the source of the name 'quark': *Finnegan's Wake* 1939

Quartz is used in ornamental work and industry, where its reaction to electricity makes it valuable in electronic instruments (see *piezoelectric effect*). Quartz can also be made synthetically.

Crystals that would take millions of years to form naturally can now be 'grown' in pressure vessels to a standard that allows them to be used in optical and scientific instruments and in electronics, such as quartz wristwatches.

quartzite metamorphic rock consisting of pure quartz sandstone that has recrystallized under increasing heat and pressure.

quasar (*from quasi-stellar object or QSO*) one of the most distant extragalactic objects known, discovered in 1963. Quasars appear starlike, but each emits more energy than 100 giant galaxies. They are thought to be at the centre of galaxies, their brilliance emanating from the stars and gas falling towards an immense black hole at their nucleus.

Quasar light shows a large red shift, indicating that they are very distant. Some quasars emit radio waves (see *radio astronomy*), which is how they were first identified, but most are radio-quiet. The furthest are over 10 billion light years away.

quasi-atom particle assemblage resembling an atom, in which particles not normally found in atoms become bound together for a brief period.

Quasi-atoms are generally unstable structures, either because they are subject to matter-antimatter annihilation (positronium), or because one or more of their constituents is unstable (muonium).

quassia any of a group of tropical American trees with bitter bark and wood. The heartwood of *Q. amara* is a source of quassin, an infusion of which was formerly used as a tonic; it is now used in insecticides. (Genus *Quassia*, family Simaroubaceae.)

The quassia family includes the Asian *Ailanthus* (*Ailanthus altissima*), also called the tree of heaven.

Quaternary period of geological time that began 1.64 million years ago and is still in process. It is divided into the ζ Pleistocene and ζ Holocene epochs.

quebracho any of several South American trees belonging to the cashew family, with very hard, tannin-rich wood; chiefly the red quebracho (*S. lorentzii*), used in the tanning of leather. (Genus *Schinopsis*, family Anacardiaceae.)

quenching ζ heat treatment used to harden metals. The metals are heated to a certain temperature and then quickly plunged into cold water or oil.

? wild card character standing for any single character in most operating systems. It allows a user to specify a group of files whose names differ by only one character for mass handling. Typing 'dir part?.doc' in a DOS directory would display a list of files such as part1.doc, party.doc, and so on. The letter 'x' is often used to mean the same thing.

questionnaire a question list submitted to a certain number of people whose answers are then used to compile quantitative or qualitative statistical information. Questionnaires are a means of obtaining ζ primary data and are useful in market research, for example.

quetzal long-tailed Central American bird *Pharomachus mocinno* of the ζ trogon family, order Trogoniformes. The male is brightly coloured, with green, red, blue, and white feathers. It has a train of blue-green plumes (tail coverts) that hang far beyond the true tail feathers. There is a crest on the head and decorative drooping feathers on the wings. It is about 1.3 m/4.3 ft long including tail. The female is smaller and lacks the tail and plumage.

The quetzal eats fruit, insects, and small frogs and lizards. It is the national emblem of Guatemala, and was considered sacred by the Mayans and the Aztecs. The quetzal's forest habitat is rapidly being destroyed, and hunting of birds for trophies or souvenirs also threatens its survival.

queue in computing, backup of ζ packets of data awaiting processing, or of ζ e-mail waiting to be read.

QuickDraw object-based graphics display system used by the Apple ζ Macintosh range of microcomputers. The use of QuickDraw gives most Macintosh applications the same ζ look-and-feel.

quicksilver another name for the element ζ mercury.

QuickTime multimedia utility developed by Apple, initially for the ζ Macintosh, but now also available for ζ Windows. Allows multimedia, such as sound and video, to be embedded in other documents, including Web pages.

quince small tree native to western Asia but widely cultivated elsewhere. The bitter, yellow, pear-shaped fruit is used in preserves. Flowering quinces are cultivated mainly for their attractive flowers. (*Cydonia oblonga*; flowering quince genus *Chaenomeles*; family Rosaceae.)

quinine antimalarial drug extracted from the bark of the cinchona tree. Peruvian Indians taught French missionaries how to use the bark in 1630, but quinine was not isolated until 1820. It is a bitter alkaloid, with the formula $C_{20}H_{24}N_2O_2$.

Other antimalarial drugs have since been developed with fewer side effects, but quinine derivatives are still valuable in the treatment of unusually resistant strains.

quoting in computing, common practice in electronic communications. When replying to an e-mail, or adding to a ζ newsgroup thread, users quote all or part of the original message in their response. The usual method of doing this is by preceding each quoted line with the symbol >.

QWERTY standard arrangement of keys on a UK or US typewriter or computer keyboard. Q, W, E, R, T, and Y are the first six keys on the top alphabetic line. The arrangement was made in the days of mechanical keyboards in order that the keys would not jam together. Other European countries use different arrangements, such as AZERTY and QWERTZ, which are more appropriate to the language of the country.

R

rabbit any of several genera of hopping mammals of the order Lagomorpha, which together with hares constitute the family Leporidae. Rabbits differ from hares in bearing naked, helpless young and in occupying burrows.

The Old World rabbit (*Oryctolagus cuniculus*), originally from S Europe and N Africa, has now been introduced worldwide. It is bred for meat and for its fur, which is usually treated to resemble more expensive furs. It lives in interconnected burrows called 'warrens', unlike cottontails (genus *Sylvilagus*), of which 13 species are native to North and South America.

PAULSON'S RABBIT WORLD

<http://pages.prodigy.com/NTMX83A/>

Comprehensive guide to keeping these active and gregarious animals as pets. If you are contemplating getting a bunny this is the site to visit. There is advice on providing accommodation (while giving the rabbit the run of the house), protecting rabbits from household dangers, toilet training, diet, and common rabbit ailments. There are useful links to the House Rabbit Society and other rabbit sites.

RABBIT

Rabbits eat some of their droppings. This behaviour, called refection, is similar to chewing the cud in cows, and ensures that food is fully digested.

rabies or **hydrophobia** Greek 'fear of water' viral disease of the central nervous system that can afflict all warm-blooded creatures. It is caused by a lyssavirus. It is almost invariably fatal once symptoms have developed. Its transmission to humans is generally by a bite from an infected animal. Rabies continues to kill hundreds of thousands of people every year; almost all these deaths occur in Asia, Africa, and South America.

After an incubation period, which may vary from ten days to more than a year, symptoms of fever, muscle spasm, and delirium develop. As the disease progresses, the mere sight of water is enough to provoke convulsions and paralysis. Death is usual within four or five days from the onset of symptoms. Injections of rabies vaccine and antiserum may save those bitten by a rabid animal from developing the disease. Louis Pasteur was the first to produce a preventive vaccine, and the Pasteur Institute was founded to treat the disease.

As a control measure for foxes and other wild animals, vaccination (by bait) is recommended. In France, Germany, and the border areas of Austria and the Czech Republic, foxes are now vaccinated against rabies with capsules distributed by helicopter; as a result, rabies has been virtually eradicated in Western Europe, and no-one has died of the disease in the European Union since 1973. In spring 1994, around 6 million vaccination baits were scattered across the border areas of Poland, Slovenia, Slovakia, and Hungary to extend the vaccination area within Europe.

RACCOONS

<http://www.loomcom.com/raccoons>

Compiled with obvious enthusiasm and providing facts brought to life with images, sounds, and animations. It also includes a section on raccoons in the media, links to other sites of interest, and an interactive bulletin board for raccoon-related discussion.

raccoon any of several New World species of carnivorous mammals of the genus *Procyon*, in the family Procyonidae. The common raccoon *P. lotor* is about 60 cm/2 ft long, with a grey-brown body, a black-and-white ringed tail, and a black 'mask' around its eyes. The crab-eating raccoon *P. cancrivorus* of South America is slightly smaller and has shorter fur.

raceme in botany, a type of cymiflorescence.

rack railway railway, used in mountainous regions, that uses a toothed pinion running in a toothed rack to provide traction. The rack usually runs between the rails. Ordinary wheels lose their grip even on quite shallow gradients, but rack railways, like that on Mount Pilatus in Switzerland, can climb slopes as steep as 50% (1 in 2).

rad unit of absorbed radiation dose, now replaced in the SI system by the Gy (one rad equals 0.01 Gy), but still commonly used. It is defined as the dose when one kilogram of matter absorbs 0.01 joule of radiation energy (formerly, as the dose when one gram absorbs 100 ergs).

radar (acronym for **radio direction and ranging**) device for locating objects in space, direction finding, and navigation by means of transmitted and reflected high-frequency radio waves.

The direction of an object is ascertained by transmitting a beam of short-wavelength (1–100 cm/0.5–40 in), short-pulse radio waves, and picking up the reflected beam. Distance is determined by timing the journey of the radio waves (travelling at the speed of light) to the object and back again. Radar is also used to detect objects underground, for example service pipes, and in archaeology. Contours of remains of ancient buildings can be detected down to 20 m/66 ft below ground. Radar is essential to navigation in darkness, cloud, and fog, and is widely used in warfare to detect enemy aircraft and missiles. To avoid detection, various devices, such as modified shapes (to reduce their radar cross-section), radar-absorbent paints and electronic jamming are used. To pinpoint small targets laser 'radar', instead of microwaves, has been developed.

Developed independently in Britain, France, Germany, and the USA in the 1930s, it was first put to practical use for aircraft detection by the British, who had a complete coastal chain of radar sets installed by September 1938. It proved invaluable in the Battle of Britain 1940, when the ability to spot incoming German aircraft did away with the need to fly standing patrols. Chains of ground radar stations are used to warn of enemy attack – for example, North Warning System 1985, consisting of 52 stations across the Canadian Arctic and N Alaska. Radar is also used in meteorology and astronomy.

RADAR

<http://chide.museum.org.uk/radar.index.html>

Radar information ranging from biographies and reminiscences of the people involved in developing the technology, to pictures of radar exhibits at the Centre of the History of Electronic Defence. A brief history of the development of radar is also included, which gives credit to British researchers for their role in the winning of the Battle of Britain.

radar astronomy bouncing of radio waves off objects in the Solar System, with reception and analysis of the 'echoes'. Radar contact with the Moon was first made in 1945 and with Venus in 1961. The travel time for radio reflections allows the distances of objects to be determined accurately. Analysis of the reflected beam reveals the rotation period and allows the object's surface to be mapped. The rotation periods of Venus and Mercury were first determined by radar. Radar maps of Venus were obtained first by Earth-based radar and subsequently by orbiting space probes.

radial artery in biology, artery that passes down the forearm and supplies blood to the hand and the fingers. The brachial artery, a large artery supplying blood to the arm, divides at the elbow to form the radial and ulnar arteries. The pulsation of blood through the radial artery can be felt at the wrist. This is generally known as the pulse.

radial circuit circuit used in household electric wiring in which all electrical appliances are connected to cables that radiate out from the main supply point or fuse box. In more modern systems, the appliances are connected in a ring, or ring circuit, with each end of the ring connected to the fuse box.

radial nerve in biology, the nerve in the upper arm. Nervous impulses to regulate the function of the muscles which extend the arm, the wrist, and some fingers pass along these nerves. They also relay sensation to parts of the arm and hand. The radial nerve arises from the brachial plexus (network of nerves supplying the arm) in the armpit and descends the upper arm before dividing into the superficial radial and interosseous nerves.

radial velocity in astronomy, the velocity of an object, such as a star or galaxy, along the line of sight, moving towards or away from an observer. The amount of Doppler shift (apparent change in wavelength) of the light reveals the object's velocity. If the object is approaching, the Doppler effect causes a blue shift in its light. That is, the wavelengths of light coming from the object appear to be shorter, tending toward the blue end of the spectrum. If the object is receding, there is a red shift, meaning the wavelengths appear to be longer, toward the red end of the spectrum.

radian SI unit (symbol rad) of plane angles, an alternative unit to the degree. It is the angle at the centre of a circle when the centre is joined to the two ends of an arc (part of the circumference) equal in length to the radius of the circle. There are 2π (approximately 6.284) radians in a full circle (360°).

One radian is approximately 57° , and 1° is $\pi/180$ or approximately 0.0175 radians. Radians are commonly used to specify angles in polar coordinates.

radiant heat energy that is radiated by all warm or hot bodies. It belongs to the infrared part of the electromagnetic spectrum and causes heating when absorbed. Radiant heat is invisible and should not be confused with the red glow associated with very hot objects, which belongs to the visible part of the spectrum.

Infrared radiation can travel through a vacuum and it is in this form that the radiant heat of the Sun travels through space. It is the trapping of this radiation by carbon dioxide and water vapour in the atmosphere that gives rise to the greenhouse effect.

radiata pine softwood timber tree *Pinus radiata* native to California; in Australia it is the most widely cultivated softwood, covering many thousands of hectares.

radiation in physics, emission of radiant energy as particles or waves – for example, heat, light, alpha particles, and beta particles (see electromagnetic waves and radioactivity). See also atomic radiation.

Of the radiation given off by the Sun, only a tiny fraction of it, called insolation, reaches the Earth's surface; much of it is absorbed and scattered as it passes through the atmosphere. The radiation given off by the Earth itself is called ground radiation.

radiation biology study of how living things are affected by radioactive (ionizing) emissions (see radioactivity) and by electromagnetic (nonionizing) radiation (electromagnetic waves). Both are potentially harmful and can cause mutations as well as

leukaemia and other cancers; even low levels of radioactivity are very dangerous. Both however, are used therapeutically, for example to treat cancer, when the radiation dose is very carefully controlled (radiotherapy or X-ray therapy).

Radioactive emissions are more harmful. Exposure to high levels produces radiation burns and radiation sickness, plus genetic damage (resulting in birth defects) and cancers in the longer term. Exposure to low-level ionizing radiation can also cause genetic damage and cancers, particularly leukaemia.

Electromagnetic radiation is usually harmful only if exposure is to high-energy emissions, for example close to powerful radio transmitters or near radar-wave sources. Such exposure can cause organ damage, cataracts, loss of hearing, leukaemia and other cancers, or premature ageing. It may also affect the nervous system and brain, distorting their electrical nerve signals and leading to depression, disorientation, headaches, and other symptoms. Individual sensitivity varies and some people are affected by electrical equipment, such as televisions, computers, and refrigerators.

Background radiation is the natural radiation produced by cosmic rays and radioactive rocks such as granite, and this must be taken into account when calculating the effects of nuclear accidents or contamination from power stations.

radiation monitoring system network of monitors to detect any rise in background gamma radiation and to warn of a major nuclear accident within minutes of its occurrence. The accident at Chernobyl in Ukraine in 1986 prompted several W European countries to begin installation of such systems locally, and in 1994 work began on a pilot system to provide a gamma curtain, a dense net of radiation monitors, throughout E and W Europe.

radiation sickness sickness resulting from exposure to radiation, including X-rays, gamma rays, neutrons, and other nuclear radiation, as from weapons and fallout. Such radiation ionizes atoms in the body and causes nausea, vomiting, diarrhoea, and other symptoms. The body cells themselves may be damaged even by very small doses, causing leukaemia and other cancers.

Science has nothing to be ashamed of, even in the ruins of Nagasaki.

JACOB BRONOWSKI Polish-born scientist, broadcaster, and writer.

Science and Human Values 1978

radiation units units of measurement for radioactivity and radiation doses. In SI units, the activity of a radioactive source is measured in becquerels (symbol Bq), where one becquerel is equal to one nuclear disintegration per second (an older unit is the curie). The exposure is measured in coulombs per kilogram (C kg⁻¹); the amount of ionizing radiation (X-rays or gamma rays) which produces one coulomb of charge in one kilogram of dry air (replacing the roentgen). The absorbed dose of ionizing radiation is measured in grays (symbol Gy) where one gray is equal to one joule of energy being imparted to one kilogram of matter (the rad is the previously used unit). The dose equivalent, which is a measure of the effects of radiation on living organisms, is the absorbed dose multiplied by a suitable factor which depends upon the type of radiation. It is measured in sieverts (symbol Sv), where one sievert is a dose equivalent of one joule per kilogram (an older unit is the rem).

radical in chemistry, a group of atoms forming part of a molecule, which acts as a unit and takes part in chemical reactions without disintegration, yet often cannot exist alone for any length of time; for example, the methyl radical $\text{-CH}_3\cdot$, or the carboxyl radical $\text{-COOH}\cdot$.

radicle part of a plant embryo that develops into the primary root. Usually it emerges from the seed before the embryonic shoot, or plumule, its tip protected by a root cap, or calyptra, as it pushes through the soil. The radicle may form the basis of the entire root system, or it may be replaced by adventitious roots (positioned on the stem).

radio *Radio transmission and reception. The radio frequency oscillator generates rapidly varying electrical signals, which are sent to the transmitting aerial. In the aerial, the signals produce radio waves (the carrier wave), which spread out at the speed of light. The sound signal is added to the carrier wave by the modulator. When the radio waves fall on the receiving aerial, they induce an electrical current in the aerial. The electrical current is sent to the tuning circuit, which picks out the signal from the particular transmitting station desired. The demodulator separates the sound signal from the carrier wave and sends it, after amplification, to the loudspeaker.*

radio transmission and reception of radio waves. In radio transmission a microphone converts sound waves (pressure variations in the air) into electromagnetic waves that are then picked up by a receiving aerial and fed to a loudspeaker, which converts them back into sound waves.

The theory of electromagnetic waves was first developed by Scottish physicist James Clerk Maxwell 1864, given practical confirmation in the laboratory in 1888 by German physicist Heinrich Hertz, and put to practical use by Italian inventor Guglielmo Marconi, who in 1901 achieved reception of a signal in Newfoundland, Canada, transmitted from Cornwall, England.

To carry the transmitted electrical signal, an oscillator produces a carrier wave of high frequency; different stations are allocated different transmitting carrier frequencies. A modulator superimposes the audiofrequency signal on the carrier. There are two main ways of doing this: amplitude modulation (AM), used for long- and medium-wave broadcasts, in which the strength of the carrier is made to fluctuate in time with the audio signal; and frequency modulation (FM), as used for VHF broadcasts, in which the frequency of the carrier is made to fluctuate. The transmitting aerial emits the modulated electromagnetic waves, which travel outwards from it.

In radio reception a receiving aerial picks up minute voltages in response to the waves sent out by a transmitter. A tuned circuit selects a particular frequency, usually by means of a variable capacitor connected across a coil of wire. A demodulator disentangles the audio signal from the carrier, which is now discarded, having served its purpose. An amplifier boosts the audio signal for feeding to the loudspeaker. In a superheterodyne receiver, the incoming signal is mixed with an internally-generated signal of fixed frequency so that the amplifier circuits can operate near their optimum frequency.

radioactive decay process of disintegration undergone by the nuclei of radioactive elements, such as radium and various isotopes of uranium and the transuranic elements. This changes the element's atomic number, thus transmuting one element into another, and is accompanied by the emission of radiation. Alpha and beta decay are the most common forms.

In **alpha decay** (the loss of a helium nucleus – two protons and two neutrons) the atomic number decreases by two; in **beta decay** (the loss of an electron) the atomic number increases by one. Certain lighter artificially created isotopes also undergo radioactive

decay. The associated radiation consists of alpha rays, beta rays, or gamma rays (or a combination of these), and it takes place at a constant rate expressed as a specific half-life, which is the time taken for half of any mass of that particular isotope to decay completely. Less commonly occurring decay forms include heavy-ion emission, electron capture, and spontaneous fission (in each of these the atomic number decreases).

The original nuclide is known as the parent substance, and the product is a daughter nuclide (which may or may not be radioactive). The final product in all modes of decay is a stable element.

radioactive tracer any of various radioactive isotopes used in labelled compounds; see *tracer*.

radioactive waste any waste that emits radiation in excess of the background level. See *nuclear waste*.

radioactivity spontaneous alteration of the nuclei of radioactive atoms, accompanied by the emission of radiation. It is the property exhibited by the radioactive isotopes of stable elements and all isotopes of radioactive elements, and can be either natural or induced. See *radioactive decay*.

the discovery of radioactivity Radioactivity was first discovered in 1896, when Becquerel observed that some photographic plates, although securely wrapped up, became blackened when placed near certain uranium compounds. A closer investigation showed that thin metal coverings were unable to prevent the blackening of the plates. It was clear that the uranium compounds emitted radiation that was able to penetrate the metal coverings. Pierre and Marie Curie soon succeeded in isolating other radioactive elements. One of these was radium, which was found to be over 1 million times more radioactive than uranium.

radioactive radiations Further investigation of the nature of radiation by Ernest Rutherford revealed that there are three types of radiation: alpha particles, beta particles, and gamma rays. Alpha particles are positively charged, high-energy particles emitted from the nucleus of a radioactive atom. They consist of two neutrons and two protons and are thus identical to the nucleus of a helium atom. Because of their large mass, alpha particles have a short range of only a few centimetres in air, and can be stopped by a sheet of paper. Beta particles are more penetrating and can travel through a 3-mm/0.1-in sheet of aluminium or up to 1 m/3 ft of air. They consist of high-energy electrons emitted at high velocity from a radioactive atom that is undergoing spontaneous disintegration.

Digital Radio

BY BARRY FOX

Conventional radio is broadcast as an analogue signal, using either amplitude modulation (AM) or frequency modulation (FM). The sound suffers interference from other stations and 'multipath' reflections from hills and buildings. If the signal is weak and the receiver is straining to pick it up, the sound is polluted with background hiss.

If analogue sound is converted into digital code before transmission, as long as the signal is strong enough to decode, it is immune from interference and free from hiss. Less transmitter power is needed to cover the same area as an analogue signal. However, if reflections are as strong as the code, the receiver does not work at all. Also, when analogue sound is converted into digits, the raw code takes up more space on the airwaves than the analogue signal.

There is more space in the satellite bands, and some broadcasters and music delivery services have transmitted CD quality digital sound from space. But the satellite bands are now crowding. Also, the signals can only be received with a dish aerial, mounted in a fixed position.

Digital Audio Broadcasting (DAB) lets a receiver work with a simple rod aerial, even when moving. It also reduces the number of digital bits needed so that the signal takes up less space than an analogue transmission. Although DAB signals can be transmitted from satellites, they will initially come from conventional terrestrial transmitters.

Pan-European Eureka research team number 147 developed a DAB system, and this has been adopted as the standard for Europe. The only difference between countries is in the transmission frequencies to be used; high VHF in some and L band at 1,500 MHz in others.

The Eureka system combines two processes. Analogue sound is first converted into digital code and compressed by a system known as 'MUSICAM'. When there are two sounds of similar frequency, but different volume level, the 'MUSICAM' encoder

ignores the quieter sound. This can reduce the number of bits by a factor of ten, without the ear noticing.

The bitstream is then split into several hundred parallel channels, so that each carries only slow-moving bits of data. The many channels are broadcast simultaneously on closely neighbouring frequencies. The receiver recombines the channels and rebuilds the sound. Because the bits in each channel are travelling slowly, the receiver can distinguish between wanted signals which arrive direct from the transmitter, and unwanted 'multipath' reflections which arrive later.

The introduction of DAB does not take anything away from existing listeners, but a new radio is needed to listen to new digital broadcasts. These radios will often tune to all possible DAB bands, so that owners can use them anywhere in Europe.

The Eureka system is on offer to other countries, and Canada looks likely to adopt it. The situation in the USA is still fluid, because rival systems use 'in-band, on-channel' (IBOC) technology. IBOC transmits digital code at very low level, underneath a conventional analogue radio broadcast. So conventional AM and FM radio analogue receivers should continue working as normal, while a new digital radio retrieves the low-level signal and decodes it to deliver high-quality sound.

So new frequencies are not needed for IBOC, but critics say it may be susceptible to 'multipath' reflections and interference. There may be no single agreed standard for the USA, with open market competition left to create a de facto standard – like VHS versus Beta home video.

Britain's BBC started regular Eureka DAB transmissions in September 1995, and the commercial stations soon followed, along with most other countries in Europe. At first the only receivers were bulky engineering test prototypes. Compact radios are expected during 1998, with the prices falling to consumer levels by the end of the century.

Gamma rays comprise very high-frequency electromagnetic radiation. Gamma rays are stopped only by direct collision with an atom and are therefore very penetrating; they can, however, be stopped by about 4 cm/1.5 in of lead.

When alpha, beta, and gamma radiation pass through matter they tend to knock electrons out of atoms, ionizing them. They are therefore called ionizing radiation. Alpha particles are the most ionizing, being heavy, slow moving and carrying two positive charges. Gamma rays are weakly ionizing as they carry no charge. Beta particles fall between alpha and gamma radiation in ionizing potential.

detection of radioactivity Detectors of ionizing radiation make use of the ionizing properties of radiation to cause changes that can be detected and measured. A Geiger counter detects the momentary current that passes between electrodes in a suitable gas when ionizing radiation causes the ionization of that gas. The device is named after the German physicist Hans Geiger. The activity of a radioactive source describes the rate at which nuclei are disintegrating within it. One becquerel (1 Bq) is defined as a rate of one disintegration per second.

radioactive decay Radioactive decay occurs when an unstable nucleus emits alpha, beta, or gamma radiation in order to become more stable. The energy given out by disintegrating atoms is called atomic radiation. An alpha particle consists of two protons and two neutrons. When alpha decay occurs (the emission of an alpha particle from a nucleus) it results in the formation of a new nucleus. An atom of uranium isotope of mass 238, on emitting an alpha particle, becomes an atom of thorium, mass 234. β Beta decay, the loss of an electron from an atom, is accomplished by the transformation of a neutron into a proton, thus resulting in an increase in the

atomic number of one. For example, the decay of the carbon 14 isotope results in the formation of an atom of nitrogen (mass 14, atomic number 7) and the emission of an electron. Gamma emission usually occurs as part of alpha or beta emission. High-speed electromagnetic radiation is emitted from the nucleus in order to make it more stable during the loss of an alpha or beta particle.

Isotopes of an element have different atomic masses. They have the same number of protons but different numbers of neutrons in the nucleus. For example, uranium 235 and uranium 238 both have 92 protons but the latter has three more neutrons than the former. Some isotopes are naturally radioactive (see *radioisotopes*) while others are not. Radioactive decay can take place either as a one-step decay, or through a series of steps that transmute one element into another. This is called a decay series or chain, and sometimes produces an element more radioactive than its predecessor. For example, uranium 238 decays by alpha emission to thorium 234; thorium 234 is a beta emitter and decays to give protactinium 234. This emits a beta particle to form uranium 234, which in turn undergoes alpha decay to form thorium 230. A further alpha decay yields the isotope radium 226.

the rate of radioactive decay The emission of radioactivity by an atom occurs spontaneously and quite unpredictably. However, in a sample containing many radioactive atoms, the overall rate of decay appears to be governed by the number of nuclei left undecayed. The time taken for half the radioactive atoms in a sample to decay remains constant and is called the half-life. Radioactive substances decay exponentially with time, and the value of the half-life for a substance can vary from a fraction of a second to billions of years.

health hazards We are surrounded by radioactive substances. Our food contains traces of radioactive isotopes and our own bodies are

made of naturally radioactive matter. In addition, we are bombarded by streams of high-energy charged particles from outer space. Radiation present in the environment is known as background radiation and we should take this into account when considering the risk of exposure to other sources.

Alpha, beta, and gamma radiation are dangerous to body tissues because of their ionizing properties, especially if a radioactive substance is ingested or inhaled. Illness resulting from exposure to radioactive substances can take various forms, which are collectively known as radiation sickness.

radioactivity in use Radioactivity has a number of uses in modern science, but its use should always be carefully controlled and monitored to minimize the risk of harm to living things. In science, a small quantity of a radioactive tracer can be used to follow the path of a chemical reaction or a physical or biological process. Radiocarbon dating is a technique for measuring the age of organic materials. Another application is in determining the age of rocks. This is based on the fact that in many uranium and thorium ores, all of which have been decaying since the formation of the rock, the alpha particles released during decay have been trapped as helium atoms in the rock. The age of the rock can be assessed by calculating the relative amounts of helium, uranium, and thorium in it. This calculation can help to estimate the age of the Earth at around 4.6 billion years.

In medicine, radioactive emissions and electromagnetic radiation can be used therapeutically; for example, to treat cancer, when the radiation dose is very carefully controlled (see radiotherapy).

nuclear fission and fusion Fission of a nucleus occurs when the nucleus splits into two approximately equal fragments. The fission of the nucleus results in the release of neutrons and a large amount of energy. In a nuclear reactor, the fission of uranium 235 is caused by bombarding it with neutrons. A nuclear chain reaction is caused as neutrons released by the splitting of atomic nuclei themselves go on to split other nuclei, releasing even more neutrons. In a nuclear reactor this process is carefully controlled to release nuclear energy.

In nuclear fusion, two light nuclei combine to form a bigger nucleus. As fusion is accompanied by the release of large amounts of energy, the process might one day be harnessed to form the basis of commercial energy production. So far, no successful fusion reactor has been built.

RADIOACTIVITY IN NATURE

<http://www.sph.umich.edu/group/eih/UMSCHPS/natural.htm>

Detailed explanation of the different types of radiation found naturally on Earth and in its atmosphere, as well as those produced by humans. It includes tables of the breakdown of nuclides commonly found in soil, the oceans, the air, and even the human body.

radio astronomy study of radio waves emitted naturally by objects in space, by means of a radio telescope. Radio emission comes from hot gases (thermal radiation); electrons spiralling in magnetic fields (synchrotron radiation); and specific wavelengths (lines) emitted by atoms and molecules in space, such as the 21-cm/8-in line emitted by hydrogen gas.

Radio astronomy began in 1932 when US astronomer Karl Jansky detected radio waves from the centre of our Galaxy, but the subject did not develop until after World War II. Radio astronomy has greatly improved our understanding of the evolution of stars, the structure of galaxies, and the origin of the universe. Astronomers have mapped the spiral structure of the Milky Way from the radio waves given out by interstellar gas, and they have detected many individual radio sources within our Galaxy and beyond.

Among radio sources in our Galaxy are the remains of supernova explosions, such as the Crab nebula and pulsars. Short-wavelength radio waves have been detected from complex

molecules in dense clouds of gas where stars are forming. Searches have been undertaken for signals from other civilizations in the Galaxy, so far without success.

Strong sources of radio waves beyond our Galaxy include galaxies and quasars. Their existence far off in the universe demonstrates how the universe has evolved with time. Radio astronomers have also detected weak background radiation thought to be from the Big Bang explosion that marked the birth of the universe.

radio beacon radio transmitter in a fixed location, used in marine and aerial navigation. Ships and aircraft pinpoint their positions by reference to continuous signals given out by two or more beacons.

radio button in computing, in a dialog box, a round button denoting an option. Users are offered a choice of radio buttons, and can choose only one.

radiocarbon dating or carbon dating method of dating organic materials (for example, bone or wood), used in archaeology. Plants take up carbon dioxide gas from the atmosphere and incorporate it into their tissues, and some of that carbon dioxide contains the radioactive isotope of carbon, ^{14}C or carbon-14. As this decays at a known rate (half of it decays every 5,730 years), the time elapsed since the plant died can be measured in a laboratory. Animals take carbon-14 into their bodies from eating plant tissues and their remains can be similarly dated. After 120,000 years so little carbon-14 is left that no measure is possible (see half-life).

Radiocarbon dating was first developed 1949 by the US chemist Willard Libby. The method yields reliable ages back to about 50,000 years, but its results require correction since Libby's assumption that the concentration of carbon-14 in the atmosphere was constant through time has subsequently been proved wrong. Discrepancies were noted between carbon-14 dates for Egyptian tomb artefacts and construction dates recorded in early local texts. Radiocarbon dates from tree rings (see dendrochronology) showed that material before 1000 BC had been exposed to greater concentrations of carbon-14. Now radiocarbon dates are calibrated against calendar dates obtained from tree rings, or, for earlier periods, against uranium/thorium dates obtained from coral. The carbon-14 content is determined by counting beta particles with either a proportional gas or a liquid scintillation counter for a period of time. A new advance, accelerator mass spectrometry, requires only tiny samples and counts the atoms of carbon-14 directly, disregarding their decay.

radio, cellular portable telephone system; see cellular phone.

radiochemistry chemical study of radioactive isotopes and their compounds (whether produced from naturally radioactive or irradiated materials) and their use in the study of other chemical processes.

When such isotopes are used in labelled compounds, they enable the biochemical and physiological functioning of parts of the living body to be observed. They can help in the testing of new drugs, showing where the drug goes in the body and how long it stays there. They are also useful in diagnosis – for example cancer, fetal abnormalities, and heart disease.

radio frequencies and wavelengths classification of, see electromagnetic waves.

radio galaxy galaxy that is a strong source of electromagnetic waves of radio wavelengths. All galaxies, including our own, emit some radio waves, but radio galaxies are up to a million times more powerful.

In many cases the strongest radio emission comes not from the visible galaxy but from two clouds, invisible through an optical telescope, that can extend for millions of light years either side of the galaxy. This double structure at radio wavelengths is also shown by some quasars, suggesting a close relationship between the two types of object. In both cases, the source of energy is thought to be a massive black hole at the centre. Some radio galaxies are thought to result from two galaxies in collision or recently merged.

radiography branch of science concerned with the use of radiation (particularly X-rays) to produce images on photographic film or fluorescent screens. X-rays penetrate matter according to its nature, density, and thickness. In doing so they can cast shadows on photographic film, producing a radiograph. Radiography is widely used in medicine for examining bones and tissues and in industry for examining solid materials; for example, to check welded seams in pipelines

radioisotope (contraction of *radioactive isotope*) in physics, a naturally occurring or synthetic radioactive form of an element. Most radioisotopes are made by bombarding a stable element with neutrons in the core of a nuclear reactor. The radiations given off by radioisotopes are easy to detect (hence their use as tracers), can in some instances penetrate substantial thicknesses of materials, and have profound effects (such as genetic mutation) on living matter. Although dangerous, radioisotopes are used in the fields of medicine, industry, agriculture, and research.

radioisotope scanning use of radioactive materials (radioisotopes or radionuclides) to pinpoint disease. It reveals the size and shape of the target organ and whether any part of it is failing to take up radioactive material, usually an indication of disease.

The speciality known as nuclear medicine makes use of the affinity of different chemical elements for certain parts of the body. Iodine, for instance, always makes its way to the thyroid gland. After being made radioactive, these materials can be given by mouth or injected, and then traced on scanners working on the Geiger-counter principle. The diagnostic record gained from radioisotope scanning is known as a *scintigram*.

radiology medical speciality concerned with the use of radiation, including X-rays, and radioactive materials in the diagnosis and treatment of injury and disease.

radiometric dating method of dating rock by assessing the amount of radioactive decay of naturally occurring isotopes. The dating of rocks may be based on the gradual decay of uranium into lead. The ratio of the amounts of 'parent' to 'daughter' isotopes in a sample gives a measure of the time it has been decaying, that is, of its age. Different elements and isotopes are used depending on the isotopes present and the age of the rocks to be dated. Once-living matter can often be dated by radiocarbon dating, employing the half-life of the isotope carbon-14, which is naturally present in organic tissue.

Radiometric methods have been applied to the decay of long-lived isotopes, such as potassium-40, rubidium-87, thorium-232, and uranium-238, which are found in rocks. These isotopes decay very slowly and this has enabled rocks as old as 3,800 million years to be dated accurately. Carbon dating can be used for material between 1,000 and 100,000 years old. Potassium dating is used for material more than 100,000 years old, rubidium for rocks more than 10 million years old, and uranium and thorium dating is suitable for rocks older than 20 million years.

radiosonde balloon carrying a compact package of meteorological instruments and a radio transmitter, used to 'sound', or measure, conditions in the atmosphere. The instruments measure temperature, pressure, and humidity, and the information gathered is transmitted back to observers on the ground. A radar target is often attached, allowing the balloon to be tracked.

radio telescope instrument for detecting radio waves from the universe in radio astronomy. Radio telescopes usually consist of a metal bowl that collects and focuses radio waves the way a concave mirror collects and focuses light waves. Radio telescopes are much larger than optical telescopes, because the wavelengths they are detecting are much longer than the wavelength of light. The largest single dish is 305 m/1,000 ft across, at Arecibo, Puerto Rico.

A large dish such as that at Jodrell Bank, England, can see the sky sky less clearly than a small optical telescope sees the visible sky. Interferometry is a technique in which the output from two dishes is combined to give better resolution of detail than with a single dish. Very long baseline interferometry (VBLI) uses radio telescopes spread across the world to resolve minute details of radio sources.

In aperture synthesis, several dishes are linked together to simulate the performance of a very large single dish. This technique was pioneered by Martin Ryle at Cambridge, England, site of a radio telescope consisting of eight dishes in a line 5 km/3 mi long. The Very Large Array in New Mexico, USA, consists of 27 dishes arranged in a Y-shape, which simulates the performance of a single dish 27 km/17 mi in diameter. Other radio telescopes are shaped like long troughs, and some consist of simple rod-shaped aerials.

radiotherapy treatment of disease by radiation from X-ray machines or radioactive sources. Radiation, which reduces the activity of dividing cells, is of special value for its effect on malignant tissues, certain nonmalignant tumours, and some diseases of the skin.

Generally speaking, the rays of the diagnostic X-ray machine are not penetrating enough to be efficient in treatment, so for this purpose more powerful machines are required, operating from 10,000 to over 30 million volts. The lower-voltage machines are similar to conventional X-ray machines; the higher-voltage ones may be of special design; for example, linear accelerators and betatrons. Modern radiotherapy is associated with fewer side effects than formerly, but radiotherapy to the head can cause temporary hair loss, and if the treatment involves the gut, diarrhoea and vomiting may occur. Much radiation now given uses synthesized radioisotopes. Radioactive cobalt is the most useful, since it produces gamma rays, which are highly penetrating, and it is used instead of very high-energy X-rays.

radio wave electromagnetic wave possessing a long wavelength (ranging from about 10^{-3} to 10^4 m) and a low frequency (from about 10^5 to 10^{11} Hz). Included in the radio-wave part of the spectrum are microwaves, used for both communications and for cooking; ultra-high- and very-high-frequency waves, used for television and FM (frequency modulation) radio communications; and short, medium, and long waves, used for AM (amplitude modulation) radio communications. Radio waves that are used for communications have all been modulated (see modulation) to carry information. Certain astronomical objects emit radio waves, which may be detected and studied using radio telescopes.

radish annual herb native to Europe and Asia, and cultivated for its fleshy, pungent, edible root, which is usually reddish but sometimes white or black; it is eaten raw in salads. (*Raphanus sativus*, family Cruciferae.)

radium Latin *radius* 'ray' white, radioactive, metallic element, symbol Ra, atomic number 88, relative atomic mass 226.02. It is one of the alkaline-earth metals, found in nature in pitchblende and other uranium ores. Of the 16 isotopes, the commonest, Ra-226, has a half-life of 1,620 years. The element was discovered and named in 1898 by Pierre and Marie Curie, who were investigating the residues of pitchblende.

Radium decays in successive steps to produce radon (a gas), polonium, and finally a stable isotope of lead. The isotope Ra-223 decays through the uncommon mode of heavy-ion emission, giving off carbon-14 and transmuting directly to lead. Because radium luminesces, it was formerly used in paints that glowed in the dark; when the hazards of radioactivity became known its use was abandoned, but factory and dump sites remain contaminated and many former workers and neighbours contracted fatal cancers.

It would be impossible, it would go against the scientific spirit ... Physicists should always publish their researches completely. If our discovery has a commercial future that is a circumstance from which we should not profit. If radium is to be used in the treatment of disease, it is impossible for us to take advantage of that.

MARIE CURIE Polish-born French scientist. On the patenting of radium. Discussion with her husband, Pierre, quoted in Eve Curie *The discovery of radium* in Marie Curie transl V Sheean 1938

radius in biology, one of the two bones in the lower forelimb of tetrapod (four-limbed) vertebrates.

radius in mathematics, a straight line from the centre of a circle to its circumference, or from the centre to the surface of a sphere.

radon colourless, odourless, gaseous, radioactive, nonmetallic element, symbol Rn, atomic number 86, relative atomic mass 222. It is grouped with the inert gases and was formerly considered nonreactive, but is now known to form some compounds with fluorine. Of the 20 known isotopes, only three occur in nature; the longest half-life is 3.82 days (Rn-222).

discovery Radon is the densest gas known and occurs in small amounts in spring water, streams, and the air, being formed from the natural radioactive decay of radium. Ernest Rutherford discovered the isotope Rn-220 in 1899, and Friedrich Dorn (1848–1916) in 1900; after several other chemists discovered additional isotopes, William Ramsay and R W Whytlaw-Gray isolated the element, which they named niton in 1908. The name radon was adopted in the 1920s.

rafflesia or **stinking corpse lily** any of a group of parasitic plants without stems, native to Malaysia, Indonesia, and Thailand. There are 14 species, several of which are endangered by the destruction of the forests where they grow. The fruit is used locally for medicine. The largest flowers in the world are produced by *R. arnoldiana*. About 1 m³ ft across, they exude a smell of rotting flesh, which attracts flies to pollinate them. (Genus *Rafflesia*, family Rafflesiaceae.)

RAFFLESIA

The world's largest flower smells of rotting flesh.

The flower of the parasitic *Rafflesia* has a diameter of up to 1 m/3.3 ft and attracts pollinating insects by mimicking the smell of decomposing corpses. It flowers only once every ten years.

ragworm marine bristle-worm (polychaete), characterized by its prominent parapodia (lateral, paired 'paddles' found on each of its segments). Ragworms are usually well adapted to an active existence, with large muscle blocks and stout parapodia for swimming as well as crawling and burrowing, and a large head complete with complex sense organs. Some, such as *Nereis virens*, reach several metres in length, but most are 2–10 cm/1–4 in long.

Ragworms can be found on the seashore at low tide sheltering from dehydration and high temperatures under rocks, in crevices, or shallow burrows and are often brightly coloured. They are often scavengers feeding on general animal debris or are active predators possessing a large proboscis and stout jaws for feeding on other soft-bodied invertebrates; some feed on algae.

classification The ragworm is in genus *Nereis*, a member of class Polychaeta in phylum Annelida.

ragwort any of several European perennial plants, usually with yellow flower heads; some are poisonous. (Genus *Senecio*, family Compositae.)

Raid (acronym for **redundant array of independent (or inexpensive) discs**) in computing, arrays of discs, each connected to a bus, that can be configured in different ways, depending on the application. Raid 1 is, for example, disc mirroring, while Raid 5 spreads every character between discs. Raid is intended to improve performance and data security.

rail any wading bird of the family Rallidae, including the rails proper (genus *Rallus*), coots, moorhens, and gallinules. Rails have dark plumage, a short neck and wings, and long legs. They are 10–45 cm/4–18 in long.

Many oceanic islands have their own species of rail, often flightless, such as the Guam rail *R. oustoni* and Auckland Island rail

R. muelleri. Several of these species have declined sharply, usually because of introduced predators such as rats and cats.

railway method of transport in which trains convey passengers and goods along a twin rail track. Following the work of English steam pioneers such as Scottish engineer James Watt, English engineer George Stephenson built the first public steam railway, from Stockton to Darlington, England, in 1825. This heralded extensive railway building in Britain, continental Europe, and North America, providing a fast and economical means of transport and communication. After World War II, steam engines were replaced by electric and diesel engines. At the same time, the growth of road building, air services, and car ownership destroyed the supremacy of the railways.

growth years Four years after building the first steam railway, Stephenson opened the first steam passenger line, inaugurating it with his locomotive *Rocket*, which achieved speeds of 50 kph/30 mph. The railway construction that followed resulted in 250 separate companies in Britain, which resolved into four systems 1921 and became the nationalized British Railways in 1948, known as British Rail from 1965. In North America the growth of railways during the 19th century made shipping from the central and western territories economical and helped the North to win the American Civil War; US rail travel reached its peak in 1929. Railways were extended into Asia, the Middle East, Africa, and Latin America in the late 19th century and were used for troop and supply transport in both world wars. **gauge** Railway tracks were at first made of wood but later of iron or steel, with ties wedging them apart and keeping them parallel. The distance between the wheels is known as the gauge. Since much of the early development of the railway took place in Tyneside, England, the gauge of local coal wagons, 1.24 m/4 ft 8.5 in, was adopted 1824 for the Stockton–Darlington railway, and most other early railways followed suit. The main exception was the Great Western Railway (GWR) of Isambard Kingdom Brunel, opened in 1841, with a gauge of 2.13 m/7 ft. The narrow gauge won legal backing in the UK 1846, but parts of GWR carried on with Brunel's broad gauge until 1892. British engineers building railways overseas tended to use the narrow gauge, and it became the standard in the USA from 1885. Other countries, such as Ireland and Finland, favoured the broad gauge. Although expensive, it offers a more comfortable journey. **decline of railways** With the increasing use of private cars and government-encouraged road haulage after World War II, and the demise of steam, rising costs on the railways meant higher fares, fewer passengers, and declining freight traffic. In the UK many rural rail services closed down on the recommendations of the Beeching Report 1963, reducing the size of the network by more than 20% between 1965 and 1970, from a peak of 24,102 km/14,977 mi. In the 1970s, national railway companies began investing in faster intercity services: in the UK, the diesel high-speed train (HST) was introduced. Elsewhere such trains run on specially built tracks; for example, the Shinkansen (Japan) and TGV (France) networks.

rain form of precipitation in which separate drops of water fall to the Earth's surface from clouds. The drops are formed by the accumulation of fine droplets that condense from water vapour in the air. The condensation is usually brought about by rising and subsequent cooling of air.

Rain can form in three main ways – frontal (or cyclonic) rainfall, orographic (or relief) rainfall, and convective rainfall. **Frontal rainfall** takes place at the boundary, or front, between a mass of warm air from the tropics and a mass of cold air from the poles. The water vapour in the warm air is chilled and condenses to form clouds and rain.

Orographic rainfall occurs when an airstream is forced to rise over a mountain range. The air becomes cooled and precipitation takes place. In the UK, the Pennine hills, which extend southwards from Northumbria to Derbyshire in N England, interrupt the path of the prevailing southwesterly winds, causing orographic rainfall. Their presence is partly responsible for the west of the UK being wetter than the east. **Convective rainfall**, associated with hot climates, is brought about by rising and abrupt cooling of air that has been warmed by the extreme heat of the ground surface. The

Railways: chronology

| | | | |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1500s | Tramways – wooden tracks along which trolleys ran – were in use in mines. | 1901 | The world's longest-established monorail, the Wuppertal Schwebebahn, went into service in Germany. |
| 1789 | Flanged wheels running on cast-iron rails were first introduced; cars were still horse-drawn. | 1912 | The first diesel locomotive took to the rails in Germany. |
| 1804 | Richard Trevithick built the first steam locomotive, and ran it on the track at the Pen-y-darren ironworks in South Wales. | 1938 | The British steam locomotive <i>Mallard</i> set a steam-rail speed record of 203 kph/126 mph. |
| 1825 | George Stephenson in England built the first public railway to carry steam trains – the Stockton and Darlington line – using his engine locomotion. | 1941 | Swiss Federal Railways introduced a gas-turbine locomotive. |
| 1829 | Stephenson designed his locomotive <i>Rocket</i> . | 1964 | Japan National Railways inaugurated the 515 km/320 mi New Tokaido line between Osaka and Tokyo, on which the 210 kph/130 mph 'bullet' trains run. |
| 1830 | Stephenson completed the Liverpool and Manchester Railway, the first steam passenger line. The first US-built locomotive, <i>Best Friend of Charleston</i> , went into service on the South Carolina Railroad. | 1973 | British Rail's High Speed Train (HST) set a diesel-rail speed record of 229 kph/142 mph. |
| 1835 | Germany pioneered steam railways in Europe, using <i>Der Adler</i> , a locomotive built by Stephenson. | 1979 | Japan National Railways' maglev test vehicle ML-500 attained a speed of 517 kph/321 mph. |
| 1863 | Robert Fairlie, a Scot, patented a locomotive with pivoting driving bogies, allowing tight curves in the track (this was later applied in the Garrett locomotives). London opened the world's first underground railway, powered by steam. | 1981 | France's Train à Grande Vitesse (TGV) superfast trains began operation between Paris and Lyons, regularly attaining a peak speed of 270 kph/168 mph. |
| 1869 | The first US transcontinental railway was completed at Promontory, Utah, when the Union Pacific and the Central Pacific Railroads met. George Westinghouse of the USA invented the compressed-air brake. | 1987 | British Rail set a new diesel-traction speed record of 238 kph/148.5 mph, on a test run between Darlington and York; France and the UK began work on the Channel Tunnel, a railway link connecting the two countries, running beneath the English Channel. |
| 1879 | Werner von Siemens demonstrated an electric train in Germany. Volk's Electric Railway along the Brighton seafront in England was the world's first public electric railway. | 1988 | The West German Intercity Experimental train reached 405 kph/252 mph on a test run between Würzburg and Fulda. |
| 1883 | Charles Lartigue built the first monorail, in Ireland. | 1990 | A new rail-speed record of 515 kph/320 mph was established by a French TGV train, on a stretch of line between Tours and Paris. |
| 1885 | The trans-Canada continental railway was completed, from Montréal in the east to Port Moody, British Columbia, in the west. | 1991 | The British and French twin tunnels met 23 km/14 mi out to sea to form the Channel Tunnel. |
| 1890 | The first electric underground railway opened in London. | 1993 | British Rail privatization plans announced; government investment further reduced. |
| | | 1994 | Rail services start through the Channel Tunnel. |

water vapour carried by the air condenses and so rain falls heavily. Convective rainfall is usually accompanied by a thunderstorm, and it can be intensified over urban areas due to higher temperatures.

rainbow arch in the sky displaying the colours of the spectrum formed by the refraction and reflection of the Sun's rays through rain or mist. Its cause was discovered by Theodorich of Freiberg in the 14th century.

ABOUT RAINBOWS

<http://www.unidata.ucar.edu/staff/blynds/rnbw.html>

Wealth of information on rainbows with fact sheets and lucid diagrams, answers to a series of standard questions, an experiment section, and extensive bibliographies.

rainforest dense forest usually found on or near the Equator where the climate is hot and wet. Heavy rainfall results as the moist air brought by the converging tradewinds rises because of the heat. Over half the tropical rainforests are in Central and South America, the rest in SE Asia and Africa. They provide the bulk of the oxygen needed for plant and animal respiration. Tropical rainforest once covered 14% of the Earth's land surface, but are now being destroyed at an increasing rate as their valuable timber is harvested and the land cleared for agriculture, causing problems of deforestation. Although by 1991 over 50% of the world's rainforest had been removed, they still comprise about 50% of all growing wood on the planet, and harbour at least 40% of the Earth's species (plants and animals).

Tropical rainforests are characterized by a great diversity of species, usually of tall broad-leaved evergreen trees, with many climbing vines and ferns, some of which are a main source of raw materials for medicines. A tropical forest, if properly preserved, can yield medicinal plants, oils (from cedar, juniper, cinnamon, sandalwood), spices, gums, resins (used in inks, lacquers, linoleum), tanning and dyeing materials, forage for animals, beverages, poisons, green manure, rubber, and animal products (feathers, hides, honey). Other rainforests include montane, upper montane or cloud, mangrove, and subtropical.

Rainforests comprise some of the most complex and diverse ecosystems on the planet and help to regulate global weather patterns. When deforestation occurs, the microclimate of the mature forest disappears; soil erosion and flooding become major problems since rainforests protect the shallow tropical soils. Once an area is cleared it is very difficult for shrubs and bushes to re-establish because soils are poor in nutrients. This causes problems for plans to convert rainforests into agricultural land – after two or three years the crops fail and the land is left bare. Clearing of the rainforests may lead to a global warming of the atmosphere, and contribute to the greenhouse effect.

raisin dried grape, for eating as a fruit and also used in baking and confectionery. The chief kinds are the seedless raisin, the sultana, and the currant. The main producers are the Mediterranean area, California, Mexico, and Australia.

Grapes may be dried in the sun or artificially, using hot air. The dark colour of the dried fruit comes from the caramelization of natural sugars during the drying process. Drying reduces grapes to 25% of their original weight, while retaining almost all the nutritional value of the fresh fruit.

RAM (acronym for *random-access memory*) in computing, a memory device in the form of a collection of integrated circuits (chips), frequently used in microcomputers. Unlike ROM (read-only memory) chips, RAM chips can be both read from and written

to by the computer, but their contents are lost when the power is switched off.

Many modern commercial programs require a great deal of RAM to work efficiently. While Windows 95 will run in 8 megabytes (MB) of RAM and is usable with 16 MB, 32 MB is better and many people now fit more.

RAMdisc $\hat{\text{C}}$ RAM that has been configured to appear to the operating system as a disc. It is much faster to access than an actual hard disc and therefore can be used for applications that need frequent read-and-write operations. However, as the data is stored in RAM, it will be lost when the computer is turned off.

ramjet simple jet engine (see under $\hat{\text{C}}$ jet propulsion) used in some guided missiles. It only comes into operation at high speeds. Air is then 'rammed' into the combustion chamber, into which fuel is sprayed and ignited.

Ramón y Cajal, Santiago (1852–1934)

Spanish cell biologist and anatomist whose research revealed that the nervous system is based on units of nerve cells (neurons). He shared the 1906 Nobel Prize for Physiology or Medicine.

ramp another name for an inclined plane, a slope used as a simple machine.

random access in computing, an alternative term for $\hat{\text{C}}$ direct access.

random event in statistics, an event that is not affected by either previous or future events. For example, if a new book is opened at random, all page numbers are equally likely.

random number one of a series of numbers having no detectable pattern. Random numbers are used in $\hat{\text{C}}$ computer simulation and $\hat{\text{C}}$ computer games. It is impossible for an ordinary computer to generate true random numbers, but various techniques are available for obtaining pseudo-random numbers – close enough to true randomness for most purposes.

range in statistics, a measure of dispersion in a frequency distribution, equalling the difference between the largest and smallest values of the variable. The range is sensitive to extreme values in the sense that it will give a distorted picture of the dispersion if one measurement is unusually large or small. The $\hat{\text{C}}$ interquartile range is often preferred.

range check in computing, a $\hat{\text{C}}$ validation check applied to a numerical data item to ensure that its value falls in a sensible range.

range finder instrument for determining the range or distance of an object from the observer; used to focus a camera or to sight a gun accurately. A range finder camera has a rotating mirror or prism that alters the image seen through the viewfinder, and a secondary window. When the two images are brought together into one, the lens is sharply focused.

rape in botany, either of two plant species of the mustard family grown for their seeds, which yield a pungent edible oil. The common turnip is a variety of *B. rapa* and the swede turnip is a variety of *B. napus*. (*Brassica rapa* and *B. napus*, family Cruciferae.)

Oilseed rape, or canola, is the world's third most important oilseed crop. Plant breeders developed it from the 'weed' rapeseed (*B. napus oleifera*). The first variety was marketed 1974, and the bright yellow fields of oilseed rape in flower are now a familiar sight in the countryside.

Rape methyl ester provides a renewable replacement for diesel fuel that gives off fewer sooty particles and none of the sulphur dioxide that causes acid rain.

RARE (abbreviation for *Réseaux Associés pour la Recherche Européenne*) association of national and international European computer networks and their users.

rare-earth element alternative name for $\hat{\text{C}}$ lanthanide.

rare gas alternative name for $\hat{\text{C}}$ inert gas.

rash in medicine, eruption on the surface of the skin. It is usually raised and red or it may contain vesicles filled with fluid. It may also be scaly or crusty. Characteristic rashes are produced by infectious diseases, such as chickenpox, measles, German measles, and scarlet fever. The severity of the rash usually reflects the severity of the disease. Rashes are also produced as an allergic response to stings from insects and plants. These are often alleviated by antihistamines and they usually resolve within a few days.

Chronic rashes are present in patients with some skin diseases, such as $\hat{\text{C}}$ eczema and $\hat{\text{C}}$ psoriasis.

raspberry any of a group of prickly cane plants native to Europe, Asia, and North America, and widely cultivated. They have white flowers followed by hollow red composite fruits, which are eaten fresh as a delicacy and used for making jam and wine. (Genus *Rubus*, family Rosaceae.)

raster graphics computer graphics that are stored in the computer memory by using a map to record data (such as colour and intensity) for every $\hat{\text{C}}$ pixel that makes up the image. When transformed (enlarged, rotated, stretched, and so on), raster graphics become ragged and suffer loss of picture resolution, unlike $\hat{\text{C}}$ vector graphics. Raster graphics are typically used for painting applications, which allow the user to create artwork on a computer screen much as if they were painting on paper or canvas.

raster image processor full name for printer program $\hat{\text{C}}$ RIP.

rat any of numerous long-tailed $\hat{\text{C}}$ rodents (especially of the families Muridae and Cricetidae) larger than mice and usually with scaly, naked tails. The genus *Rattus* in the family Muridae includes the rats found in human housing.

The brown rat *R. norvegicus* is about 20 cm/8 in long with a tail of almost equal length. It is believed to have originated in central Asia, and is now found worldwide after being transported from Europe by ships. Female brown rats become sexually receptive at the age of 8–12 weeks. If food is plentiful, litters of up to 12 are born every few months. The black rat *R. rattus*, responsible for the $\hat{\text{C}}$ plague, is smaller than the brown rat, but has larger ears and a longer, more pointed snout. It does not interbreed with brown rats. The pack rat or wood rat, genus *Neotoma*, is common throughout North America and there are seven different species. Their dens, made of partly eaten plants, dung, and miscellaneous objects, are known as middens and can be up to 2 m/6.5 ft across and 20–30 cm/8–12 in high. The rats' crystallized urine preserves the midden, in some cases for up to 40,000 years.

ratemeter instrument used to measure the count rate of a radioactive source. It gives a reading of the number of particles emitted from the source and captured by a detector in a unit of time (usually a second).

rate of reaction the speed at which a chemical reaction proceeds. It is usually expressed in terms of the concentration (usually in $\hat{\text{C}}$ moles per litre) of a reactant consumed, or product formed, in unit time; so the units would be moles per litre per second ($\text{mol l}^{-1} \text{s}^{-1}$). The rate of a reaction may be affected by the concentration of the reactants, the temperature of the reactants, and the presence of a catalyst. If the reaction is entirely in the gas state, the rate is affected by pressure, and, for solids, it is affected by the particle size.

During a reaction at constant temperature the concentration of the reactants decreases and so the rate of reaction decreases.

These changes can be represented by drawing graphs.

The rate of reaction is at its greatest at the beginning of the reaction and it gradually slows down. For an $\hat{\text{C}}$ endothermic reaction (one

rate of reaction The rate of reaction decreases with time whilst the concentration of product increases.

that absorbs heat) increasing the temperature may produce large increases in the rate of reaction. A 10°C rise can double the rate while a 40°C rise can produce a 50–100-fold increase in the rate.

Collision theory is used to explain these effects. Increasing the concentration or the pressure of a gas means there are more particles per unit volume, therefore there are more collisions and more fruitful collisions. Increasing the temperature makes the particles move much faster, resulting in more collisions per unit time and more fruitful collisions; consequently the rate increases.

ratio measure of the relative size of two quantities or of two measurements (in similar units), expressed as a proportion. For example, the ratio of vowels to consonants in the alphabet is 5:21; the ratio of 500 m to 2 km is 500:2,000, or 1:4.

rationalized units units for which the defining equations conform to the geometry of the system. Equations involving circular symmetry contain the factor 2π , those involving spherical symmetry 4π . SI units are rationalized, e.g. s. units are not.

rational number in mathematics, any number that can be expressed as an exact fraction (with a denominator not equal to 0), that is, as a/b where a and b are integers. For example, $\frac{2}{1}, \frac{1}{4}, \frac{15}{4}$, $-\frac{3}{2}$ are all rational numbers, whereas π (which represents the constant 3.141592...) is not. Numbers such as π are called irrational numbers.

ratite flightless bird that has a breastbone without the keel to which flight muscles are attached. Examples are ostrich, rhea, emu, cassowary, and kiwi.

rat-tail or grenadier any fish of the family Macrouridae of deep-sea bony fishes. They have stout heads and bodies, and long tapering tails. They are common in deep waters on the continental slopes. Some species have a light-emitting organ in front of the anus.

Also known as rat-tails are some of the chimaeras.

rattlesnake any of various New World pit vipers of the genera *Crotalus* and *Sistrurus* (the massasaugas and pygmy rattlers), distinguished by horny flat segments of the tail, which rattle when vibrated as a warning to attackers. They can grow to 2.5 m/8 ft long. The venom injected by some rattlesnakes can be fatal.

There are 31 species distributed from S Canada to central South America. The eastern diamondback *C. adamanteus* 0.9–2.5 m/2.8–8 ft long, is found in the flat pinelands of the southern USA.

Raunkiaer system method of classification devised by the Danish ecologist Christen Raunkiaer (1860–1938) whereby plants are divided into groups according to the position of their perennating (overwintering) buds in relation to the soil surface. For example, plants in cold areas, such as the tundra, generally have their buds protected below ground, whereas in hot, tropical areas they are above ground and freely exposed. This scheme is useful for comparing vegetation types in different parts of the world.

The main divisions are **phanerophytes** with buds situated well above the ground; **chamaephytes** with buds borne within 25 cm/10 in of the soil surface; **hemicytrophites** with buds at or imme-

diately below the soil surface; and **cryptophytes** with their buds either beneath the soil (**geophyte**) or below water (**hydrophyte**).

raven any of several large crows, genus *Corvus*, of the Corvidae family, order Passeriformes. The common raven *C. corax* is about 60 cm/2 ft long with a wingspan of nearly 1 m/3 ft, and has black, lustrous plumage; the beak and mouth, tongue, legs, and feet are also black. It is a scavenger, and is found only in the northern hemisphere.

The nest is built in cliffs or in the fork of a tall tree, and is a bulky structure. In it are laid four or five pale-green eggs spotted with brown. Incubation by the female lasts about 21 days.

Ravens are traditionally associated with death, probably from their practice of gathering in large numbers around a carcass, despite being by habit a solitary species.

ray any of several orders (especially Ragiformes) of cartilaginous fishes with a flattened body, winglike pectoral fins, and a whiplike tail.

Species include the stingray, for example the Southern stingray *Dasyatis americana*, which has a serrated, poisonous spine on the tail, and the torpedo fish.

ray, electric another name for the torpedo.

rayon any of various shiny textile fibres and fabrics made from cellulose. It is produced by pressing whatever cellulose solution is used through very small holes and solidifying the resulting filaments. A common type is viscose, which consists of regenerated filaments of pure cellulose. Acetate and triacetate are kinds of rayon consisting of filaments of cellulose acetate and triacetate.

rays original name for radiation of all types, such as X-rays and gamma rays.

ray-tracing in computer graphics, method of rendering sharp, detailed images. Designers specify the size, shape, colour, and texture of objects and the type and location of light sources, and use a program to devise a mathematical model tracing how light rays would bounce off the surfaces. The results, complete with shading, shadows, and reflections, depict 'virtual worlds' with near-photographic clarity.

razorbill North Atlantic sea bird *Alca torda* of the auk family, order Charadriiformes, which breeds on cliffs and migrates south in winter. It is about 40 cm/16 in long, has a large curved beak, and is black above and white below. It uses its wings as paddles when diving. Razorbills make no nest; the female lays a single egg, which is white with brown markings. They are common off Newfoundland.

razor-shell or razor-fish: US name **razor clam** any bivalve mollusc in two genera *Ensis* and *Solen* with narrow, elongated shells, resembling an old-fashioned razor handle and delicately coloured. They can burrow rapidly into sand and are good swimmers.

reactance property of an alternating current circuit that together with any resistance makes up the impedance (the total opposition of the circuit to the passage of a current).

The reactance of an inductance L is ωL and that of the capacitance is $1/\omega C$. Reactance is measured in ohms.

reaction in chemistry, the coming together of two or more atoms, ions, or molecules with the result that a chemical change takes place. The nature of the reaction is portrayed by a chemical equation.

reaction force in physics, the equal and opposite force described by Newton's third law of motion that arises whenever one object applies a force (action force) to another. For example, if a magnet attracts a piece of iron, then that piece of iron will also attract the magnet with a force that is equal in magnitude but opposite in direction. When any object rests on the ground the downwards contact force applied to the ground always produces an equal, upwards reaction force.

reaction principle principle stated by Newton as his third law of motion: to every action, there is an equal and opposite reaction.

In other words, a force acting in one direction is always accompanied by an equal force acting in the opposite direction. This explains how rocket and jet propulsion works and why a gun recoils after firing.

reactivity series chemical series produced by arranging the metals in order of their ease of reaction with reagents such as oxygen, water, and acids. This arrangement aids the understanding of the properties of metals, helps to explain differences between them, and enables predictions to be made about a metal's behaviour, based on a knowledge of its position or properties.

read-only storage in computing, a permanent means of storing data so that it can be read any number of times but cannot be modified. CD-ROM is a read-only storage medium; CD-ROMs come with the data already encoded on them.

RealAudio in computing, software system for broadcasting sound over the Internet in real time. Broadcasters use an encoder and a special server to provide content, and members of the 'audience' can listen to live radio or create a customized news broadcast which they can download whenever they wish. RealAudio software is supplied by RealNetworks Inc (formerly called Progressive Networks). Its RealPlayer software plays RealAudio and RealVideo.

real number in mathematics, any of the (rational numbers (which include the integers) or irrational numbers. Real numbers exclude imaginary numbers, found in complex numbers of the general form $a + bi$ where $i = \sqrt{-1}$, although these do include a real component a .

real-time system in computing, a program that responds to events in the world as they happen. For example, an automatic-pilot program in an aircraft must respond instantly in order to correct deviations from its course. Process control, robotics, games, and many military applications are examples of real-time systems.

receiver, radio component of a radio communication system that receives and processes radio waves. It detects and selects modulated radio waves (see modulation) by means of an aerial and tuned circuit, and then separates the transmitted information from the carrier wave by a process that involves rectification. The receiver device will usually also include the amplifiers that produce the audio signals (signals that are heard).

receptacle the enlarged end of a flower stalk to which the floral parts are attached. Normally the receptacle is rounded, but in some plants it is flattened or cup-shaped. The term is also used for the region on that part of some seaweeds which becomes swollen at certain times of the year and bears the reproductive organs.

receptor in biology, receptors are discrete areas of cell membranes or areas within cells with which neurotransmitters, hormones, and drugs interact. Such interactions control the activities of the body. For example, adrenaline transmits nervous impulses to receptors in the sympathetic nervous system which initiates the characteristic response to excitement and fear in an individual.

Other types of receptors, such as the proprioceptors, are located in muscles, tendons, and joints. They relay information on the position of the body and the state of muscle contraction to the brain.

recessive gene in genetics, an allele (alternative form of a gene) that will show in the phenotype (observed characteristics of an organism) only if its partner allele on the paired chromosome is similarly recessive. Such an allele will not show if its partner is dominant, that is if the organism is heterozygous for a particular characteristic. Alleles for blue eyes in humans, and for shortness in pea plants are recessive. Most mutant alleles are recessive and therefore are only rarely expressed (see haemophilia and sickle-cell disease).

Natural selection has no vision, no foresight, no sight at all. If it can be said to play the role of watchmaker in nature, it is the blind watchmaker.

RICHARD DAWKINS English zoologist.
The Blind Watchmaker 1986

reciprocal in mathematics, the result of dividing a given quantity into 1. Thus the reciprocal of 2 is $\frac{1}{2}$; of $\frac{2}{3}$ is $\frac{3}{2}$; of x^2 is $\frac{1}{x^2}$ or x^{-2} . Reciprocals are used to replace division by multiplication, since multiplying by the reciprocal of a number is the same as dividing by that number.

recombinant DNA in genetic engineering, DNA formed by splicing together genes from different sources into new combinations.

recombination in genetics, any process that recombines, or 'shuffles', the genetic material, thus increasing genetic variation in the offspring. The two main processes of recombination both occur during meiosis (reduction division of cells). One is crossing over, in which chromosome pairs exchange segments; the other is the random reassignment of chromosomes that occurs when each gamete (sperm or egg) receives only one of each chromosome pair.

record in computing, a collection of related data items or fields. A record usually forms part of a file.

recording any of a variety of techniques used to capture, store, and reproduce music, speech, and other information carried by sound waves. A microphone first converts the sound waves into an electrical signal which varies in proportion to the loudness of the sound. The signal can be stored in digital or analogue form, or on magnetic tape.

analogue recording In analogue recording, the pattern of the signal is copied into another form. In a vinyl gramophone record, for example, a continuous spiral groove is cut into a plastic disc by vibrating needle. The recording is replayed by a stylus which follows the undulations in the groove, so reproducing the vibrations which are amplified and turned back into sound. In a magnetic tape recording, the signal is recorded as a pattern of magnetization on a plastic tape coated with a magnetic powder. When the tape is played back, the magnetic patterns create an electrical signal which, as with the gramophone record, is used to recreate the original sound. All analogue recording techniques suffer from background noise and the quality of reproduction is gradually degraded as the disc or tape wears.

digital recording In digital recording, the signals picked up by the microphone are converted into a stream of numbers which can then be stored in several ways. The most well-known of these is the compact disc, in which numbers are coded as a string of tiny pits pressed into a 12-cm plastic disc. When the recording is played back, using a laser, the exact values are retrieved and converted into a varying electrical signal and then back into sound. Digital recording is relatively immune to noise and interference and gives a very high quality of reproduction. It is also suitable for storing information to be processed by computers.

record player device for reproducing recorded sound stored as a spiral groove on a vinyl disc. A motor-driven turntable rotates the record at a constant speed, and a stylus or needle on the head of a

pick-up is made to vibrate by the undulations in the record groove. These vibrations are then converted to electrical signals by a transducer in the head (often a piezoelectric crystal). After amplification, the signals pass to one or more loudspeakers, which convert them into sound. Alternative formats are compact disc and magnetic tape recording.

The pioneers of the record player were Thomas Edison, with his phonograph, and Emile Berliner (1851–1929), who invented the predecessor of the vinyl record 1896. More recent developments are stereophonic sound and digital recording on compact disc.

rectangle quadrilateral (four-sided plane figure) with opposite sides equal and parallel and with each interior angle a right angle (90°). Its area A is the product of the length l and height h ; that is, $A = l \times h$. A rectangle with all four sides equal is a square.

A rectangle is a special case of a parallelogram. The diagonals of a rectangle are equal and bisect each other.

rectangular axis another name for Cartesian coordinates.

rectangular hyperbola the graph of the function $y = 1/x$. The x and y axes are asymptotes to this curve.

rectangular prism another name for a cuboid.

rectifier in electrical engineering, a device used for obtaining one-directional current (DC) from an alternating source of supply (AC). (The process is necessary because almost all electrical power is generated, transmitted, and supplied as alternating current, but many devices, from television sets to electric motors, require direct current.) Types include plate rectifiers, thermionic diodes, and semiconductor diodes.

rectum lowest part of the large intestine of animals, which stores faeces prior to elimination (defecation).

recurring decimal any fraction that cannot be represented in the decimal system by a finite decimal. All fractions will result in recurring decimals unless the denominator of the fraction is either a power of 2 or 5, or a multiple of these. For example, $\frac{1}{4}$ is 0.25 but $\frac{1}{6}$ ($= \frac{1}{2} \times \frac{1}{3}$) is 0.1666...

recursion in computing and mathematics, a technique whereby a function or procedure calls itself into use in order to enable a complex problem to be broken down into simpler steps. For example, a function that finds the factorial of a number n (calculates the product of all the whole numbers between 1 and n) would obtain its result by multiplying n by the factorial of $n - 1$.

recycling processing of industrial and household waste (such as paper, glass, and some metals and plastics) so that the materials can be reused. This saves expenditure on scarce raw materials, slows down the depletion of nonrenewable resources, and helps to reduce pollution.

The USA recycles only around 13% of its waste, compared to around 33% in Japan. However, all US states encourage or require local recycling programmes to be set up. It was estimated 1992 that 4,000 cities collected waste from 71 million people for recycling. Most of these programmes were set up 1989–92. Around 33% of newspapers, 22% of office paper, 64% of aluminium cans, 3% of plastic containers, and 20% of all glass bottles and jars were recycled.

Aluminium is frequently recycled because of its value and special properties that allow it to be melted down and re-pressed without loss of quality, unlike paper and glass, which deteriorate when recycled.

RECYCLE CITY

<http://www.epa.gov/recyclecity/>

Child-friendly site of the US Environmental Protection Agency designed to help people to live more ecologically. The site includes a host of fun games and activities to encourage children to think about waste disposal issues.

red admiral butterfly butterfly with black wings crossed by scarlet bands and marked with white and blue spots. The spiny black caterpillar feeds on nettles.

classification The red admiral butterfly *Vanessa atalanta* is in order Lepidoptera, class Insecta, phylum Arthropoda.

red blood cell or **erythrocyte** the most common type of blood cell, responsible for transporting oxygen around the body. It contains haemoglobin, which combines with oxygen from the lungs to form oxyhaemoglobin. When transported to the tissues, these cells are able to release the oxygen because the oxyhaemoglobin splits into its original constituents.

Mammalian erythrocytes are disc-shaped with a depression in the centre and no nucleus; they are manufactured in the bone marrow and, in humans, last for only four months before being destroyed in the liver and spleen. Those of other vertebrates are oval and nucleated.

red cedar tree *Toona australis* native to New Guinea and E Australia. It is a deciduous rainforest tree and is valued for its beautiful red timber. Much early Australian colonial furniture came from this species.

redcurrent in botany, type of currant.

Red Data List report published by the World Conservation Union (IUCN) and regularly updated that lists animal species by their conservation status. Categories of risk include extinct in the wild, critically endangered, endangered, vulnerable, and lower risk (divided into three subcategories). The list was updated 1996.

red deer large deer widely distributed throughout Europe, Asia and North Africa. A full-grown male (stag or hart) stands 1.2 m/4 ft at the withers, and typical antlers measure about 80 cm/31 in in length with a spread of about the same. During the breeding season the colour is a rich brown, turning grey at the approach of winter. The young are spotted with white.

The antlers are shed in April or May, and a few days afterwards the new growth shows. While the new antlers are developing they are covered with a thick velvet, and while in this condition are very sensitive. They are full-grown in about 12 weeks, and the 'velvet' is then rubbed off. Hornless stags sometimes occur.

classification The red deer *Cervus elaphus* is in family Cervidae, order Artiodactyla.

red dwarf any star that is cool, faint, and small (about one-tenth the mass and diameter of the Sun). Red dwarfs burn slowly, and have estimated lifetimes of 100 billion years. They may be the most abundant type of star, but are difficult to see because they are so faint. Two of the closest stars to the Sun, Proxima Centauri and Barnard's Star, are red dwarfs.

The whole history of particle physics, or of physics, is one of getting down the number of concepts to as few as possible.

ABDUS SALAM Pakistani physicist.

L Wolpert and A Richards *A Passion for Science* 1988

red giant any large bright star with a cool surface. It is thought to represent a late stage in the evolution of a star like the Sun, as it runs out of hydrogen fuel at its centre. Red giants have diameters between 10 and 100 times that of the Sun. They are very bright because they are so large, although their surface temperature is lower than that of the Sun, about 2,000–3,000 K (1,700–2,700°C/3,000–5,000°F). See also Red supergiants.

red-hot poker any of a group of perennial plants native to Africa, in particular *K. uvaria*, with a flame-coloured spike of flowers. (Genus *Kniphofia*, family Liliaceae.)

redox reaction chemical change where one reactant is reduced and the other reactant oxidized. The reaction can only occur if both reactants are present and each changes simultaneously. For example, hydrogen reduces copper(II) oxide to copper while it is itself

oxidized to water. The corrosion of iron and the reactions taking place in electric and electrolytic cells are just a few instances of redox reactions.

red pepper red fruit of various *capsicums*.

red setter breed of dog. See *setter*.

redshank wading bird *Tringa totanus* of N Europe and Asia, a type of sandpiper. It nests in swampy areas, rarely in Europe, since most redshanks winter in the south. It is greyish and speckled black, and has long red legs.

red shift in astronomy, the lengthening of the wavelengths of light from an object as a result of the object's motion away from us. It is an example of the *Doppler effect*. The red shift in light from galaxies is evidence that the universe is expanding.

Lengthening of wavelengths causes the light to move or shift towards the red end of the *spectrum*, hence the name. The amount of red shift can be measured by the displacement of lines in an object's spectrum. By measuring the amount of red shift in light from stars and galaxies, astronomers can tell how quickly these objects are moving away from us. A strong gravitational field can also produce a red shift in light; this is termed **gravitational red shift**.

redstart any bird of the genus *Phoenicurus*, a member of the thrush family Muscicapidae, order Passeriformes. It winters in Africa and spends the summer in Eurasia. The American redstart *Setophaga ruticilla* belongs to the family Parulidae.

Redstone rocket short-range US military missile, modified for use as a space launcher. Redstone rockets launched the first two flights of the *Mercury project*. A modified Redstone, *Juno 1*, launched the first US satellite, *Explorer 1*, in 1958.

TO REMEMBER THE PRINCIPLES OF OXIDATION AND REDUCTION:

REMEMBER THAT LEO THE LION GOES 'GER'

LOSE ELECTRONS - OXIDATION, GAIN ELECTRONS - REDUCTION

reduction in chemistry, the gain of electrons, loss of oxygen, or gain of hydrogen by an atom, ion, or molecule during a chemical reaction.

Reduction may be brought about by reaction with another compound, which is simultaneously oxidized (reducing agent), or electrically at the cathode (negative electrode) of an electric cell.

redundancy in computing, duplication of information. Redundancy is often used as a check, when an additional check digit or bit is included. See also *validation*.

redwing type of thrush *Turdus iliacus*, family Muscicapidae, order Passeriformes. It is smaller than the song thrush, with reddish wing and body markings, and there is a distinct white line over the eye. It breeds in the north of Europe and Asia, flying south in winter.

redwood giant coniferous tree, one of the two types of *sequoia*.

reed any of various perennial tall, slender grasses found growing in wet or marshy environments; also the hollow, jointed stalks of any of these plants. The common reed (*P. australis*) reaches a height of 3 m/10 ft, having stiff, upright leaves and straight stems with a plume of purplish flowers at the top. (Especially species of the genera *Phragmites* and *Arundo*, family Gramineae.)

reed switch switch containing two or three thin iron strips, or reeds, inside a sealed glass tube. When a magnet is brought near the switch, it induces magnetism in the reeds, which then attract or repel each other according to the positions of their induced magnetic poles. Electric current is switched on or off as the reeds make or break contact.

A simple burglar alarm can be constructed by inserting a magnet into the closing edge of a door, and a reed switch into the part of the doorframe facing the magnet: when the door is closed the magnet remains close to the switch, keeping a circuit open; when the door is opened the magnet moves away, closing the switch and setting off an alarm.

re-entrant polygon a *polygon* that is not completely convex. It has at least one interior angle greater than 180°.

reflecting telescope in astronomy, a *telescope* in which light is collected and brought to a focus by a concave mirror. *Cassegrain telescope* and *Newtonian telescope* are examples.

referee in science, one who reads and comments on a scientific paper before its publication, normally a scientist of at least equal standing to the author(s).

refining any process that purifies or converts something into a more useful form. Metals usually need refining after they have been extracted from their ores by such processes as *smelting*. Petroleum, or crude oil, needs refining before it can be used; the process involves fractional *distillation*, the separation of the substance into separate components or 'fractions'.

red shift The red shift causes lines in the spectra of galaxies to be shifted towards the red end of the spectrum. More distant galaxies have greater red shifts than closer galaxies. The red shift indicates that distant galaxies are moving apart rapidly, as the universe expands.

Electrolytic metal-refining methods use the principle of electrolysis to obtain pure metals. When refining petroleum, or crude oil, further refinery processes after fractionation convert the heavier fractions into more useful lighter products. The most important of these processes is cracking; others include copolymerization, hydrogenation, and reforming.

reflection in geometry, a transformation that maps a shape across a line so that the line forms an axis of reflectional symmetry. Reflections in two perpendicular axes produce a rotation of 180° (a half turn). Reflections can be used to deduce many properties of shapes.

reflection in physics, the throwing back or deflection of waves, such as light or sound waves, when they hit a surface. The law of reflection states that the angle of incidence (the angle between the ray and a perpendicular line drawn to the surface) is equal to the angle of reflection (the angle between the reflected ray and a perpendicular to the surface).

reflex in animals, a very rapid involuntary response to a particular stimulus. It is controlled by the nervous system. A reflex involves only a few nerve cells, unlike the slower but more complex responses produced by the many processing nerve cells of the brain.

A simple reflex is entirely automatic and involves no learning. Examples of such reflexes include the sudden withdrawal of a hand in response to a painful stimulus, or the jerking of a leg when the kneecap is tapped. Sensory cells (receptors) in the knee send signals to the spinal cord along a sensory nerve cell. Within the spine a reflex arc switches the signals straight back to the muscles of the leg (effectors) via an intermediate nerve cell and then a motor nerve cell; contraction of the leg occurs, and the leg kicks upwards. Only three nerve cells are involved, and the brain is only aware of the response after it has taken place. Such reflex arcs are particularly common in lower animals, and have a high survival value, enabling organisms to take rapid action to avoid potential danger. In higher animals (those with a well-developed central nervous system) the simple reflex can be modified by the involvement of the brain—for instance, humans can override the automatic reflex to withdraw a hand from a source of pain.

A conditioned reflex involves the modification of a reflex action in response to experience (learning). A stimulus that produces a simple reflex response becomes linked with another, possibly unrelated, stimulus. For example, a dog may salivate (a reflex action) when it sees its owner remove a tin-opener from a drawer because it has learned to associate that stimulus with the stimulus of being fed.

Experiment alone crowns the efforts of medicine, experiment limited only by the natural range of the powers of the human mind. Observation discloses in the animal organism numerous phenomena existing side by side, and interconnected now profoundly, now indirectly, or accidentally. Confronted with a multitude of different assumptions the mind must guess the real nature of this connection.

IVAN PAVLOV Russian physiologist,
Experimental Psychology and Other Essays, Pt X

reflex angle an angle greater than 180° but less than 360° .

reflex camera camera that uses a mirror and prisms to reflect light passing through the lens into the viewfinder, showing the photographer the exact scene that is being shot. When the shutter button is released the mirror springs out of the way, allowing light to reach the film. The most common type is the single-lens reflex (SLR) camera. The twin-lens reflex (TLR) camera has two lenses: one has a mirror for viewing, the other is used for exposing the film.

reflexology in alternative medicine, manipulation and massage of the feet to ascertain and treat disease or dysfunction elsewhere in the body.

reflection The law of reflection: the angle of incidence of a light beam equals the angle of reflection of the beam.

Correspondence between reflex points on the feet and remote organic and physical functions were discovered early in the 20th century by US physician William Fitzgerald, who also found that pressure and massage applied to these reflex points beneficially affect the related organ or function.

refraction the bending of a wave when it passes from one medium to another. Refraction occurs because waves travel at different velocities in different media.

refraction Refraction is the bending of a light beam when it passes from one transparent medium to another. This is why a spoon appears bent when standing in a glass of water and pools of water appear shallower than they really are. The quantity $\frac{\sin i}{\sin r}$ has a constant value, for each material, called the refractive index.

refractive index measure of the refraction of a ray of light as it passes from one transparent medium to another. If the angle of incidence is i and the angle of refraction is r , the ratio of the two refractive indices is given by $\frac{n_1}{n_2} = \frac{\sin i}{\sin r}$. It is also equal to the speed of light in the first medium divided by the speed of light in the second, and it varies with the wavelength of the light.

refractor in astronomy, telescope in which light is collected and brought to a focus by a convex lens (the object lens or objective).

refractory (of a material) able to resist high temperature, for example ceramics made from clay, minerals, or other earthy materials. Furnaces are lined with refractory materials such as silica and dolomite.

Alumina (aluminium oxide) is an excellent refractory, often used for the bodies of spark plugs. Titanium and tungsten are often called refractory metals because they are temperature resistant. Ceramics are refractory materials made up of ceramics and metals.

refresh in computing, to redraw the image on a video. All such images are a series of frames created by a device – in the case of a cathode ray tube, an electron beam – which ‘paints’ the image on the screen, pixel by pixel. This process is too rapid for the human eye to detect, although a high refresh rate (number of times a screen is redrawn per second) is said to reduce eye strain.

refrigeration use of technology to transfer heat from cold to warm, against the normal temperature gradient, so that a body can remain substantially colder than its surroundings. Refrigeration equipment is used for the chilling and deep-freezing of food in food technology, and in air conditioners and industrial processes.

Refrigeration is commonly achieved by a vapour-compression cycle, in which a suitable chemical (the refrigerant) travels through a long circuit of tubing, during which it changes from a vapour to a liquid and back again. A compression chamber makes it condense, and thus give out heat. In another part of the circuit, called the evaporator coils, the pressure is much lower, so the refrigerant evaporates, absorbing heat as it does so. The evaporation process takes place near the central part of the refrigerator, which therefore becomes colder, while the compression process takes place near a ventilation grille, transferring the heat to the air outside. The most commonly used refrigerants in modern systems were chlorofluorocarbons, but these are now being replaced by coolants that do not damage the ozone layer.

REFRIGERATION

The philosopher Francis Bacon was probably the first person whose death was caused by frozen food. Experimenting with the idea of preserving meat by freezing, he stuffed a chicken with snow. Unfortunately the experiment resulted in his catching a chill, then bronchitis, which led to his death.

regelation phenomenon in which water refreezes to ice after it has been melted by pressure at a temperature below the freezing point of water. Pressure makes an ice skate, for example, form a film of water that freezes once again after the skater has passed.

regeneration in biology, regrowth of a new organ or tissue after the loss or removal of the original. It is common in plants, where a new individual can often be produced from a ‘cutting’ of the original. In animals, regeneration of major structures is limited to lower organisms; certain lizards can regrow their tails if these are lost, and new flatworms can grow from a tiny fragment of an old one. In mammals, regeneration is limited to the repair of tissue in wound healing and the regrowth of peripheral nerves following damage.

The human body is an energy system ... which is never a complete structure; never static; is in perpetual inner self-construction and self-destruction; we destroy in order to make it new.

NORMAN O BROWN US philosopher.
Love's Body ch 8

register in computing, a memory location that can be accessed rapidly; it is often built into the computer's central processing unit.

Some registers are reserved for special tasks – for example, an instruction register is used to hold the machine-code command that the computer is currently executing, while a sequence-control register keeps track of the next command to be executed. Other registers are used for holding frequently used data and for storing intermediate results.

registration in computing, informing a manufacturer that you have bought their product. For computer hardware, registration brings the consumer benefits such as on-site service and access to a free telephone helpline. Software houses also give registered customers telephone support and may supply them with upgrades and new product information.

For shareware, registration is virtually synonymous with payment. Programs are supplied save-disabled, incomplete, or with frequent, annoying built-in reminders to register. Only by sending the small fee requested can the user obtain a code to release the program's full potential, as well as the legal right to continue using it.

regolith the surface layer of loose material that covers most bedrock. It consists of eroded rocky material, volcanic ash, river alluvium, vegetable matter, or a mixture of these known as soil.

regular of geometric figures, having all angles and sides equal. Also, of solids, having bases comprised of regular polygons.

Regulus or *Alpha Leonis* the brightest star in the constellation Leo, and the 21st brightest star in the sky. First-magnitude Regulus has a true luminosity 100 times that of the Sun, and is 69 light years from Earth.

Regulus was one of the four royal stars of ancient Persia marking the approximate positions of the Sun at the equinoxes and solstices. The other three were Aldebaran, Antares, and Fomalhaut.

reindeer or *caribou* deer *Rangifer tarandus* of Arctic and sub-arctic regions, common to North America and Eurasia. About 1.2 m/4 ft at the shoulder, it has a thick, brownish coat and broad hooves well adapted to travel over snow. It is the only deer in which both sexes have antlers; these can grow to 1.5 m/5 ft long, and are shed in winter.

The Old World reindeer have been domesticated by the Lapps of Scandinavia for centuries. There are two types of North American caribou: the large woodland caribou of the more southerly regions, and the barren-ground caribou of the far north. Reindeer migrate south in winter, moving in large herds. They eat grass, small plants, and lichens.

relational database database in which data are viewed as a collection of linked tables. It is the most popular of the three basic database models, the others being network and hierarchical.

relative in computing (of a value), variable and calculated from a base value. For example, a relative address is a memory location that is found by adding a variable to a base (fixed) address, and a relative cell reference locates a cell in a spreadsheet by its position relative to a base cell – perhaps directly to the left of the base cell or three columns to the right of the base cell. The opposite of relative is absolute.

relative atomic mass the mass of an atom relative to one-twelfth the mass of an atom of carbon-12. It depends primarily on the number of protons and neutrons in the atom, the electrons having

negligible mass. If more than one isotope of the element is present, the relative atomic mass is calculated by taking an average that takes account of the relative proportions of each isotope, resulting in values that are not whole numbers. The term **atomic weight**, although commonly used, is strictly speaking incorrect.

relative biological effectiveness (RBE) the relative damage caused to living tissue by different types of radiation. Some radiations do much more damage than others; alpha particles, for example, cause 20 times as much destruction as electrons (beta particles).

The RBE is defined as the ratio of the absorbed dose of a standard amount of radiation to the absorbed dose of 200 kV X-rays that produces the same amount of biological damage.

relative density the density (at 20°C/68°F) of a solid or liquid relative to (divided by) the maximum density of water (at 4°C/39.2°F). The relative density of a gas is its density divided by the density of hydrogen (or sometimes dry air) at the same temperature and pressure.

relative humidity the concentration of water vapour in the air. It is expressed as the ratio of the partial pressure of the water vapour to its saturated vapour pressure at the same temperature. The higher the temperature, the higher the saturated vapour pressure.

relative molecular mass the mass of a molecule, calculated relative to one-twelfth the mass of an atom of carbon-12. It is found by adding the relative atomic masses of the atoms that make up the molecule.

The term **molecular weight** is often used, but strictly this is incorrect.

relativity in physics, the theory of the relative rather than absolute character of motion and mass, and the interdependence of matter, time, and space, as developed by German-born US physicist Albert Einstein in two phases:

special theory of relativity (1905) Starting with the premises that (1) the laws of nature are the same for all observers in unaccelerated motion, and (2) the speed of light is independent of the motion of its source, Einstein arrived at some rather unexpected consequences. Intuitively familiar concepts, like mass, length, and time, had to be modified. For example, an object moving rapidly past the observer will appear to be both shorter and heavier than when it is at rest (that is, at rest relative to the observer), and a clock moving rapidly past the observer will appear to be running slower than when it is at rest. These predictions of relativity theory seem to be foreign to everyday experience merely because the changes are quite negligible at speeds less than about 1,500 km s⁻¹, and they only become appreciable at speeds approaching the speed of light.

general theory of relativity (1915) The geometrical properties of space-time were to be conceived as modified locally by the presence of a body with mass. A planet's orbit around the Sun (as observed in three-dimensional space) arises from its natural trajectory in modified space-time; there is no need to invoke, as Isaac Newton did, a force of gravity coming from the Sun and acting on the planet. Einstein's general theory accounts for a peculiarity in the behaviour of the motion of the perihelion of the orbit of the planet Mercury that cannot be explained in Newton's theory. The new theory also said that light rays should bend when they pass by a massive object. The predicted bending of starlight was observed during the eclipse of the Sun 1919. A third corroboration is found in the shift towards the red in the spectra of the Sun and, in particular, of stars of great density – white dwarfs such as the companion of Sirius.

Einstein showed that, for consistency with the above premises (1) and (2), the principles of dynamics as established by Newton needed modification; the most celebrated new result was the equation $E = mc^2$, which expresses an equivalence between mass (m) and energy (E), c being the speed of light in a vacuum. In 'relativistic mechanics', conservation of mass is replaced by the new concept of conservation of 'mass-energy'.

General relativity is central to modern astrophysics and cosmology; it predicts, for example, the possibility of black holes.

General relativity theory was inspired by the simple idea that it is impossible in a small region to distinguish between acceleration and gravitation effects (as in a lift one feels heavier when the lift accelerates upwards), but the mathematical development of the idea is formidable. Such is not the case for the special theory, which a nonexpert can follow up to $E = mc^2$ and beyond.

relay in electrical engineering, an electromagnetic switch. A small current passing through a coil of wire wound around an iron core attracts an armature whose movement closes a pair of sprung contacts to complete a secondary circuit, which may carry a large current or activate other devices. The solid-state equivalent is a thyristor switching device.

relay neuron nerve cell in the spinal cord, connecting motor neurons to sensory neurons. Relay neurons allow information to pass straight through the spinal cord, bypassing the brain. In humans such reflex actions, which are extremely rapid, cause the sudden removal of a limb from a painful stimulus.

reload in computing, command which asks a browser to reopen a currently-displayed URL. Reloading may 'uninstall' a partially-loaded page or bring a faster download from a busy server.

rem (acronym of **roentgen equivalent man**) unit of radiation dose equivalent.

remission in medicine, temporary disappearance of symptoms during the course of a disease.

remora any of a family of warm-water fishes that have an adhesive disc on the head, by which they attach themselves to whales, sharks, and turtles. These provide the remora with shelter and transport, as well as food in the form of parasites on the host's skin.

remote imaging photographing the Earth's surface with orbiting satellites. With a simple aerial, receiver and software it is possible to download images straight on to a personal computer – helping amateur meteorologists, for example, to make weather forecasts.

remote sensing gathering and recording information from a distance. Space probes have sent back photographs and data about planets as distant as Neptune. In archaeology, surface survey techniques provide information without disturbing subsurface deposits.

Satellites such as **Landsat** have surveyed all the Earth's surface from orbit. Computer processing of data obtained by their scanning instruments, and the application of so-called false colours (generated by the computer), have made it possible to reveal surface features invisible in ordinary light. This has proved valuable in agriculture, forestry, and urban planning, and has led to the discovery of new deposits of minerals.

REMOTE SENSING IN HISTORY

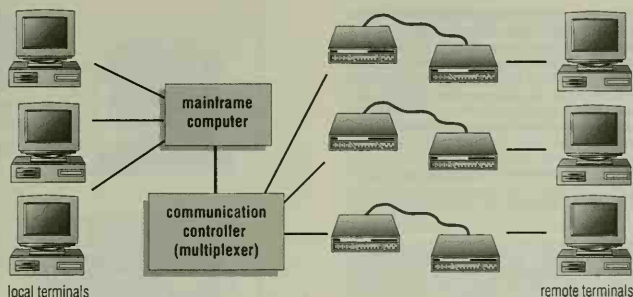

http://observe.iovv.nasa.gov/nasa/exhibits/history/history_0.html

Brief timeline with some often not appreciated landmarks in the history of remote sensing and an engaging investigation into the long-held desire of people to look further and further away from them.

remote terminal in computing, a terminal that communicates with a computer via a modem (or acoustic coupler) and a telephone line.

REM sleep (acronym for **rapid-eye-movement sleep**) phase of sleep that recurs several times nightly in humans and is associated with dreaming. The eyes flicker quickly beneath closed lids.

Renault France's largest motor-vehicle manufacturer, founded 1898. In Nov 1994 the French government began to implement

remote terminal Remote computer terminals communicate with the central mainframe via modems and telephone lines. The controller allocates computer time to the terminals according to predetermined priority rules. The multiplexor allows more than one terminal to use the same communications link at the same time (multiplexing).

plans to privatize the company, which had been nationalized from 1944.

Louis Renault (1877–1944) formed the company with his brothers Fernand and Marcel. In 1899 they began motor racing, which boosted the sales of their cars, and by 1908 they were producing 5,000 cars a year. The company produced tanks for the French army in both world wars.

rendering using a computer to draw an image on a computer screen. In graphics, this often means using ray-tracing, Phong shading, or a similar program to turn an outline sketch into a detailed image of a solid object.

renewable energy power from any source that replenishes itself. Most renewable systems rely on solar energy directly or through the weather cycle as wave power, hydroelectric power, or wind power via wind turbines, or solar energy collected by plants (alcohol fuels, for example). In addition, the gravitational force of the Moon can be harnessed through tidal power stations, and the heat trapped in the centre of the Earth is used via geothermal energy systems.

renewable resource natural resource that is replaced by natural processes in a reasonable amount of time. Soil, water, forests, plants, and animals are all renewable resources as long as they are properly conserved. Solar, wind, wave, and geothermal energies are based on renewable resources.

rennet extract, traditionally obtained from a calf's stomach, that contains the enzyme rennin, used to coagulate milk in the cheese-making process. The enzyme can now be chemically produced.

rennin or **chymase** enzyme found in the gastric juice of young mammals, used in the digestion of milk.

repellent anything whose smell, taste, or other properties discourages nearby creatures. Insect repellent is usually a chemical substance that keeps, for example, mosquitoes at bay; natural substances include citronella, lavender oil, and eucalyptus oils. A device that emits ultrasound waves is also claimed to repel insects and small mammals.

repetitive strain injury (RSI) inflammation of tendon sheaths, mainly in the hands and wrists, which may be disabling. It is found predominantly in factory workers involved in constant repetitive movements, and in those who work with computer keyboards. The symptoms include aching muscles, weak wrists, tingling fingers and in severe cases, pain and paralysis. Some victims have successfully sued their employers for damages.

REPETITIVE STRAIN INJURY

<http://engr-www.unl.edu/ee/eeshop/rsi.html>

Unofficial, but very informative and extensively-linked, site produced by a sufferer of RSI. It includes a section on the symptoms, as well as diagrams and photos of how to type without straining your back or hands. The site is largely focused upon prevention rather than cure.

replication in biology, production of copies of the genetic material DNA; it occurs during cell division (mitosis and meiosis). Most mutations are caused by mistakes during replication.

During replication the paired strands of DNA separate, exposing the bases. Nucleotides floating in the cell matrix pair with the exposed bases, adenine pairing with thymine, and cytosine with guanine.

repression in psychology, a mental process that ejects and excludes from consciousness ideas, impulses, or memories that would otherwise threaten emotional stability.

In the Austrian psychiatrist Sigmund Freud's early writing, repression is controlled by the censor, a hypothetical mechanism or agency that allows ideas, memories, and so on from the unconscious to emerge into consciousness only if distorted or disguised, as for example in dreams.

reproduction in biology, process by which a living organism produces other organisms similar to itself. There are two kinds: asexual reproduction and sexual reproduction. The ability to reproduce is considered one of the fundamental attributes of living things.

reproduction rate or fecundity in ecology, the rate at which a population or species reproduces itself.

reptile any member of a class (Reptilia) of vertebrates. Unlike amphibians, reptiles have hard-shelled, yolk-filled eggs that are laid on land and from which fully formed young are born. Some snakes and lizards retain their eggs and give birth to live young. Reptiles are cold-blooded, and their skin is usually covered with scales. The metabolism is slow, and in some cases (certain large snakes) intervals between meals may be months. Reptiles date back over 300 million years.

Many extinct forms are known, including the orders Pterosauria, Plesiosauria, Ichthyosauria, and Dinosauria. The chief living orders are the Chelonina (tortoises and turtles), Crocodilia (alligators and crocodiles), and Squamata, divided into three suborders: Lacertilia (lizards), Ophidia or Serpentes (snakes), and Amphisbaenia (worm lizards). The order Rhynchocephalia has one surviving species, the lizardlike tuatara of New Zealand.

A four-year study of rainforest in E Madagascar revealed 26 new reptile species 1995.

Reptilia class of vertebrates that comprises the reptiles.

request for comments in computing, the expansion of the abbreviation RFC.

research the primary activity in science, a combination of theory and experimentation directed towards finding scientific explanations of phenomena. It is commonly classified into two types: **pure research**, involving theories with little apparent relevance to human concerns; and **applied research**, concerned with finding solutions to problems of social or commercial importance – for instance in medicine and engineering. The two types are linked in that theories developed from pure research may eventually be found to be of great value to society.

financing research Scientific research is most often funded by government and industry, and so a nation's wealth and priorities are likely to have a strong influence on the kind of work undertaken.

In 1989 the European Community (now the European Union) Council adopted a revised programme on research and technological development for the period 1990–94, requiring a total EC finance of 5,700 million ECUs, to be apportioned as follows: information and communications technology 2,221 million; industrial and materials technologies 888 million; life sciences and technologies 741 million; energy 814 million; human capacity and mobility 518 million; environment 518 million.

reserved word word that has a meaning special to a programming language. For example, 'if' and 'for' are reserved words in most high-level languages.

residual current device or **earth leakage circuit breaker** device that protects users of electrical equipment from electric shock by interrupting the electricity supply if a short circuit or current leakage occurs.

It contains coils carrying current to and from the electrical equipment. If a fault occurs, the currents become unbalanced and the residual current trips a switch. Residual current devices are used to protect household gardening tools as well as electrical equipment in industry.

residue in chemistry, a substance or mixture of substances remaining in the original container after the removal of one or more components by a separation process.

The nonvolatile substance left in a container after evaporation of liquid, the solid left behind after removal of liquid by filtration, and the substances left in a distillation flask after removal of components by distillation, are all residues.

resin substance exuded from pines, firs, and other trees in gummy drops that harden in air. Varnishes are common products of the hard resins, and ointments come from the soft resins.

Rosin is the solid residue of distilled turpentine, a soft resin. The name 'resin' is also given to many synthetic products manufactured by polymerization; they are used in adhesives, plastics, and varnishes.

resistance in physics, that property of a conductor that restricts the flow of electricity through it, associated with the conversion of electrical energy to heat; also the magnitude of this property. Resistance depends on many factors, such as the nature of the material, its temperature, dimensions, and thermal properties; degree of impurity; the nature and state of illumination of the surface; and the frequency and magnitude of the current. The SI unit of resistance is the ohm.

resistivity in physics, a measure of the ability of a material to

resolution An example of typical resolutions of screens and printers. The resolution of a screen image when printed can only be as high as the resolution supported by the printer itself.

resist the flow of an electric current. It is numerically equal to the resistance of a sample of unit length and unit cross-sectional area, and its unit is the ohm metre (symbol Ωm). A good conductor has a low resistivity ($1.7 \times 10^{-8} \Omega\text{m}$ for copper); an insulator has a very high resistivity ($10^{15} \Omega\text{m}$ for polyethylene).

resistor in physics, any component in an electrical circuit used to introduce resistance to a current. Resistors are often made from wire-wound coils or pieces of carbon. Rheostats and potentiometers are variable resistors.

When resistors R_1, R_2, R_3, \dots are connected in a series circuit, the total resistance of the circuit is $R_1 + R_2 + R_3 + \dots$. When resistors R_1, R_2, R_3, \dots are connected in a parallel circuit, the total resistance of the circuit is R , given by $1/R = 1/R_1 + 1/R_2 + 1/R_3 + \dots$.

resolution in computing, the number of dots per unit length in which an image can be reproduced on a screen or printer. A typical screen resolution for colour monitors is 75 dpi (dots per inch). A laser printer will typically have a printing resolution of 300 dpi, and dot matrix printers typically have resolutions from 60 dpi to 180 dpi. Photographs in books and magazines have a resolution of 1,200 dpi or 2,400 dpi.

resolution of forces in mechanics, the division of a single force into two parts that act at right angles to each other. The two parts of a resolved force, called its components, have exactly the same effect when acting together on an object as the single force which they replace.

For example, the weight W of an object on a slope, tilted at an angle θ , can be resolved into two components: one acting at a right angle to the slope, equal to $W \cos \theta$, and one acting parallel to and down the slope, equal to $W \sin \theta$. The component acting down the slope (minus any friction force that may be acting in the opposite direction) is responsible for the acceleration of the object.

resolver in computing, see name server.

resonance rapid amplification of a vibration when the vibrating object is subject to a force varying at its natural frequency. In a trombone, for example, the length of the air column in the instrument is adjusted until it resonates with the note being sounded. Resonance effects are also produced by many electrical circuits. Tuning a radio, for example, is done by adjusting the natural frequency of the receiver circuit until it coincides with the frequency of the radio waves falling on the aerial.

single force W components of W 

resolution of forces In mechanics, the resolution of forces is the division of a single force into two parts that act at right angles to each other. In the diagram, the weight W of an object on a slope, tilted at an angle θ , can be resolved into two parts or components: one acting at a right angle to the slope, equal to $W \cos \theta$, and one acting parallel to and down the slope, equal to $W \sin \theta$.

Resonance has many physical applications. Children use it to increase the size of the movement on a swing, by giving a push at the same point during each swing. Soldiers marching across a bridge in step could cause the bridge to vibrate violently if the frequency of their steps coincided with its natural frequency.

Resonance was the cause of the collapse of the Tacoma Narrows Bridge, USA, 1940, when the frequency of the wind gusts coincided with the natural frequency of the bridge.

resources materials that can be used to satisfy human needs. Because human needs are diverse and extend from basic physical requirements, such as food and shelter, to ill-defined aesthetic needs, resources encompass a vast range of items. The intellectual resources of a society – its ideas and technologies – determine which aspects of the environment meet that society's needs, and therefore become resources. For example, in the 19th century, uranium was used only in the manufacture of coloured glass. Today, with the advent of nuclear technology, it is a military and energy resource. Resources are often categorized into **human resources**, such as labour, supplies, and skills, and **natural resources**, such as climate, fossil fuels, and water. Natural resources are divided into **nonrenewable resources** and **renewable resources**.

Nonrenewable resources include minerals such as coal, copper ores, and diamonds, which exist in strictly limited quantities. Once consumed they will not be replenished within the time span of human history. In contrast, water supplies, timber, food crops, and similar resources can, if managed properly, provide a steady yield virtually forever; they are therefore replenishable or renewable resources. Inappropriate use of renewable resources can lead to their destruction, as for example the cutting down of rainforests, with secondary effects, such as the decrease in oxygen and the increase in carbon dioxide and the ensuing greenhouse effect. Some renewable resources, such as wind or solar energy, are continuous; supply is largely independent of people's actions.

Demands for resources made by rich nations are causing concern that the present and future demands of industrial societies

cannot be sustained for more than a century or two, and that this will be at the expense of the Third World and the global environment. Other authorities believe that new technologies will emerge, enabling resources that are now of little importance to replace those being exhausted.

respiration biochemical process whereby food molecules are progressively broken down (oxidized) to release energy in the form of ATP. In most organisms this requires oxygen, but in some bacteria the oxidant is the nitrate or sulphate ion instead. In all higher organisms, respiration occurs in the mitochondria. Respiration is also used to mean breathing, in which oxygen is exchanged for carbon dioxide in the lung alveoli, though this is more accurately described as a form of gas exchange.

respiratory surface area used by an organism for the exchange of gases, for example the lungs, gills or, in plants, the leaf interior. The gases oxygen and carbon dioxide are both usually involved in respiration and photosynthesis. Although organisms have evolved different types of respiratory surface according to need, there are certain features in common. These include thinness and moistness, so that the gas can dissolve in a membrane and then diffuse into the body of the organism. In many animals the gas is then transported away from the surface and towards interior cells by the blood system.

response any change in an organism occurring as a result of a stimulus. There are many different types of response, some involving the entire organism, others only groups of cells or tissues. Examples include the muscular contractions in an animal, the movement of leaves towards the light, and the onset of hibernation by small mammals at the start of winter.

response time in computing, the delay between entering a command and seeing its effect.

rest mass in physics, the mass of a body when its velocity is zero. For subatomic particles, it is their mass at rest or at velocities considerably below that of light. According to the theory of relativity, at very high velocities, there is a relativistic effect that increases the mass of the particle.

restriction enzyme bacterial enzyme that breaks a chain of DNA into two pieces at a specific point; used in genetic engineering. The point along the DNA chain at which the enzyme can work is restricted to places where a specific sequence of base pairs occurs. Different restriction enzymes will break a DNA chain at different points. The overlap between the fragments is used in determining the sequence of base pairs in the DNA chain.

resultant force in mechanics, a single force acting on a particle or body whose effect is equivalent to the combined effects of two or more separate forces. The resultant of two forces acting at one point on an object can be found using the parallelogram of forces method.

resuscitation steps taken to revive anyone on the brink of death. The most successful technique for life-threatening emergencies, such as electrocution, near-drowning, or heart attack, is mouth-to-mouth resuscitation. Medical and paramedical staff are trained in cardiopulmonary resuscitation (CPR): the use of specialized equipment and techniques to attempt to restart the breathing and/or heartbeat and stabilize the patient long enough for more definitive treatment. CPR has a success rate of less than 30%.

retina light-sensitive area at the back of the eye connected to the brain by the optic nerve. It has several layers and in humans contains over a million rods and cones, sensory cells capable of converting light into nervous messages that pass down the optic nerve to the brain.

The rod cells, about 120 million in each eye, are distributed throughout the retina. They are sensitive to low levels of light, but do not provide detailed or sharp images, nor can they detect colour. The cone cells, about 6 million in number, are mostly concentrated in a central region of the retina called the fovea, and provide both detailed and colour vision. The cones of the human eye

contain three visual pigments, each of which responds to a different primary colour (red, green, or blue). The brain can interpret the varying signal levels from the three types of cone as any of the different colours of the visible spectrum.

The image actually falling on the retina is highly distorted; research into the eye and the optic centres within the brain has shown that this poor quality image is processed to improve its quality. The retina can become separated from the wall of the eyeball as a result of a trauma, such as a boxing injury. It can be reattached by being 'welded' into place by a laser.

retinol or vitamin A fat-soluble chemical derived from β -carotene and found in milk, butter, cheese, egg yolk, and liver. Lack of retinol in the diet leads to the eye disease *xerophthalmia*.

retriever any of several breeds of hunting dogs, often used as guide dogs for the blind. The commonest breeds are the Labrador retriever, large, smooth-coated, and usually black or yellow; and the golden retriever, with either flat or wavy coat. They can grow to 60 cm/2 ft high and weigh 40 kg/90 lb.

Retrievers were originally developed for retrieving birds and other small game. Their gentle, even-tempered nature makes them popular companion dogs, and Labradors are also used in police work.

retrograde in astronomy, the orbit or rotation of a planet or satellite if the sense of rotation is opposite to the general sense of rotation of the Solar System. On the celestial sphere, it refers to motion from east to west against the background of stars.

retrovirus any of a family of viruses (Retroviridae) containing the genetic material RNA rather than the more usual DNA.

For the virus to express itself and multiply within an infected cell, its RNA must be converted to DNA. It does this by using a built-in enzyme known as reverse transcriptase (since the transfer of genetic information from DNA to RNA is known as transcription, and retroviruses do the reverse of this). Retroviruses include those causing AIDS and some forms of leukaemia. See *immunity*.

Retroviruses are used as vectors in genetic engineering, but they cannot be used to target specific sites on the chromosome. Instead they incorporate their genes at random sites.

return-to-base warranty in computing, a warranty on a piece of hardware that requires the owner to return it to the retailer or the factory for service. Compare *on-site warranty*.

reuse multiple use of a product (often a form of packaging), by returning it to the manufacturer or processor each time. Many such returnable items are sold with a deposit which is reimbursed if the item is returned. Reuse is usually more energy- and resource-efficient than recycling unless there are large transport or cleaning costs.

reverberation in acoustics, the multiple reflections, or echoes, of sounds inside a building that merge and persist a short time (up to a few seconds) before fading away. At each reflection some of the sound energy is absorbed, causing the amplitude of the sound wave and the intensity of the sound to reduce a little.

Too much reverberation causes sounds to become confused and indistinct, and this is particularly noticeable in empty rooms and halls, and such buildings as churches and cathedrals where the hard, unfurnished surfaces do not absorb sound energy well. Where walls and surfaces absorb sound energy very efficiently, too little reverberation may cause a room or hall to sound dull or 'dead'. Reverberation is a key factor in the design of theatres and concert halls, and can be controlled by lining ceilings and walls with materials possessing specific sound-absorbing properties.

reverse engineering in computing, analysing an existing piece of computer hardware or software by finding out what it does and then working out how it does it. Companies perform this process on their own products in order to iron out faults, and on their competitors' products in order to find out how they work. For example, the microchips in the first IBM PCs were reverse engineered by other computer firms to make compatible machines without infringing IBM's copyright.

reverse osmosis the movement of solvent (liquid) through a semipermeable membrane from a more concentrated solution to a more dilute solution. The solvent's direction of movement is opposite to that which it would experience during osmosis, and is achieved by applying an external pressure to the solution on the more concentrated side of the membrane. The technique is used in desalination plants, when water (the solvent) passes from brine (a salt solution) into fresh water via a semipermeable filtering device.

reverse video alternative term for *inverse video*.

reversible reaction chemical reaction that proceeds in both directions at the same time, as the product decomposes back into reactants as it is being produced. Such reactions do not run to completion, provided that no substance leaves the system. Examples include the manufacture of ammonia from hydrogen and nitrogen, and the oxidation of sulphur dioxide to sulphur trioxide.

Rex cat two breeds of domestic cat with short, curly coats. The Cornish Rex was bred in 1950 in Cornwall, England. It has a wedge-shaped head, large ears, slender body with a naturally arched back, and very long legs. The Devon Rex, bred since 1966 in Devon, has a shorter wedge-shaped head than the Cornish, more pronounced cheekbones, and has less curl in its fur. The body is muscular and broad-chested. Apart from bicoloured, all coat colours and patterns are recognized.

It derives its name from the Rex curly-haired mutation in rabbits. Rex cats were recognized in Britain 1967.

Reynolds number number used in fluid mechanics to determine whether fluid flow in a particular situation (through a pipe or around an aircraft body or a fixed structure in the sea) will be turbulent or smooth. The Reynolds number is calculated using the flow velocity, density and viscosity of the fluid, and the dimensions of the flow channel. It is named after British engineer Osborne Reynolds.

RFC (abbreviation for *request for comments*) in computing, discussion document on the subject of standards for the Internet. RFCs start as technical proposals lodged with the Internet Architecture Board by computer engineers. The proposals are published on the Internet, where they are subject to general review. After any necessary amendments are made, RFCs become agreed procedures across the network.

RGB (abbreviation of *red-green-blue*) method of connecting a colour screen to a computer, involving three separate signals: red, green, and blue. All the colours displayed by the screen can be made up from these three component colours.

rhe unit of fluidity equal to the reciprocal of the poise.

rhea one of two flightless birds of the family Rheidae, order Rheiformes. The common rhea *Rhea americana* is 1.5 m/5 ft high and is distributed widely in South America. The smaller Darwin's rhea *Pterocnemia pennata* occurs only in the south of South America and has shorter, feathered legs, and mottled plumage. Rheas differ from the ostrich in their smaller size and in having a feathered neck and head, three-toed feet, and no plumelike tail feathers.

rhodium Latin *Rhenus* 'Rhine' heavy, silver-white, metallic element, symbol Re, atomic number 75, relative atomic mass 186.2. It has chemical properties similar to those of manganese and a very high melting point (3,180°C/5,756°F), which makes it valuable as an ingredient in alloys.

It was identified and named 1925 by German chemists W Noddack (1893-1960), I Tacke, and O Berg from the Latin name for the river Rhine.

Both the man of science and the man of action live always at the edge of mystery, surrounded by it.

J ROBERT OPPENHEIMER US physicist.
Address at Columbia University, New York, Dec 1954

rheostat in physics, a variable resistor, usually consisting of a high-resistance wire-wound coil with a sliding contact. It is used to vary electrical resistance without interrupting the current (for example, when dimming lights). The circular type in electronics (which can be used, for example, as the volume control of an amplifier) is also known as a potentiometer.

rhesus factor group of antigens on the surface of red blood cells of humans which characterize the rhesus blood group system. Most individuals possess the main rhesus factor (Rh+), but those without this factor (Rh-) produce antibodies if they come into contact with it. The name comes from rhesus monkeys, in whose blood rhesus factors were first found.

If an Rh- mother carries an Rh+ fetus, she may produce antibodies if fetal blood crosses the placenta. This is not normally a problem with the first infant because antibodies are only produced slowly. However, the antibodies continue to build up after birth, and a second Rh+ child may be attacked by antibodies passing from mother to fetus, causing the child to contract anaemia, heart failure, or brain damage. In such cases, the blood of the infant has to be changed for Rh- blood; a badly affected fetus may be treated in the womb (see fetal therapy). The problem can be circumvented by giving the mother anti-Rh globulin just after the first pregnancy, preventing the formation of antibodies.

rhesus monkey macaque monkey *Macaca mulatta* found in N India and SE Asia. It has a pinkish face, red buttocks, and long, straight, brown-grey hair. It can grow up to 60 cm/2 ft long, with a 20 cm/8 in. tail.

rheumatic fever or *acute rheumatism* acute or chronic illness characterized by fever and painful swelling of joints. Some victims also experience involuntary movements of the limbs and head, a form of chorea. It is now rare in the developed world.

Rheumatic fever, which strikes mainly children and young adults, is always preceded by a streptococcal infection such as scarlet fever or a severe sore throat, usually occurring a couple of weeks beforehand. It is treated with bed rest, antibiotics, and painkillers. The most important complication of rheumatic fever is damage to the heart and its valves, producing rheumatic heart disease many years later, which may lead to disability and death.

rheumatism nontechnical term for a variety of ailments associated with inflammation and stiffness of the joints and muscles.

rheumatoid arthritis inflammation of the joints; a chronic progressive disease, it begins with pain and stiffness in the small joints of the hands and feet and spreads to involve other joints, often with severe disability and disfigurement. There may also be damage to the eyes, nervous system, and other organs. The disease is treated with a range of drugs and with surgery, possibly including replacement of major joints.

Rheumatoid arthritis most often develops between the ages of 30 and 40, and is three times more common in women than men. It is an autoimmune disease and new hope has come for sufferers with the announcement in 1994 of an experimental drug which deactivates part of the immune system responsible for tissue damage. The drug, a monoclonal antibody, has performed well in preliminary trials, reducing pain and stiffness and improving mobility.

In the West it affects 2-3% of women and nearly 1% of men; an estimated 165 million people worldwide suffered from rheumatoid arthritis in 1995. In children rheumatoid arthritis is known as Still's disease.

rhin or *sand gazelle* smallish gazelle *Gazella leptoceros* that has already disappeared over most of its former range of north Africa. Populations are fragmented and often isolated. It is one of several highly threatened gazelle species in northern Africa and the Sahara.

rhinoceros large grazing mammal with one or more horns on its snout. Rhinoceroses have thick, loose skin with little hair, stumpy, powerful legs with three toes on each foot. The largest species (the one-horned Indian rhinoceros) can grow up to 2 m/6 ft high at the shoulder and weigh 2,300-4,000 kg/5,060-8,800 lb. Rhinoceroses eat grass, leafy twigs, and shrubs, and are solitary. They have poor

RHINOCEROS

The white rhino is not white, but a dirty grey. The name is a mistranslation of the Afrikaans word *weit*, which means 'wide'. The white rhino has a wider face and body than the more common black rhino.

eyesight but excellent hearing and smell. Although they look clumsy, rhinos can reach speeds of 56 kph/35 mph. In the wild they are thought to live for about 25 years, and up to 47 in captivity. There are five species: three Asian and two African, all in danger of extinction.

species The largest rhinoceros is the one-horned Indian rhinoceros *Rhinoceros unicornis*, which has a rough skin, folded into shield-like pieces; the African rhinoceroses are smooth-skinned and two-horned. The African black rhinoceros *Diceros bicornis* is 1.5 m/5 ft high, with a prehensile (grasping) upper lip for feeding on shrubs, and sometimes a smaller third horn. The broad-lipped ('white') rhinoceros *Ceratotherium simum* is actually slaty-grey, with a squarish mouth for browsing grass. The Javan rhinoceros *R. sondaicus* is near extinction, as is the two-horned Sumatran rhinoceros *Dicorhinus sumatrensis*.

in danger The Javan rhino is now one of the world's rarest mammals, and is included on the IUCN list of endangered species. In 1996, its total population numbered only 57-70, of which about 50 were in Java's Ujung Kulon National Park, and a small number, perhaps 15, in Vietnam. The total population of Indian rhinoceroses consisted of about 2,000 in 1995.

huge ancestor An extinct hornless species, the baluchither (genus *Baluchitherium*), reached 4.5 m/15 ft high.

classification Rhinoceroses belong to the phylum Chordata, subphylum Vertebrata, class Mammalia (mammal), order Perissodactyla (odd-toed ungulates), suborder Ceratomorpha, family Rhinocerotidae. Today there are four genera with five remaining species: the great Indian rhinoceros (*Rhinoceros unicornis*), the Javan or lesser one-horned rhinoceros (*R. sondaicus*), the Sumatran or Asiatic two-horned or hairy rhinoceros (*Dicorhinus sumatrensis*), the African black rhinoceros (*Diceros bicornis*) and the African white rhinoceros (*Ceratotherium simum*).

rhinoceros The Indian rhinoceros *Rhinoceros unicornis*, the largest of the Asiatic species, weighs up to two tons and has only one horn. Its skin is deeply creased at the neck, shoulders, and legs, resembling armour plating. Now restricted to areas of Nepal, Assam, and Bengal, the Indian rhinoceros, like nearly all rhinoceroses, is an endangered species. Premaphotos Wildlife

RHINOCEROS

<http://www.cm-net.com/rhino/>

Page about the ecological plight of the rhinoceros, with text and pictures describing the various species, and the differing criteria threatening them with extinction. There is also a quiz and projects to get involved in.

rhizoid hairlike outgrowth found on the gametophyte generation of ferns, mosses, and liverworts. Rhizoids anchor the plant to the substrate and can absorb water and nutrients.

They may be composed of many cells, as in mosses, where they are usually brownish, or may be unicellular, as in liverworts, where they are usually colourless. Rhizoids fulfil the same functions as the roots of higher plants but are simpler in construction.

rhizome or **rootstock** horizontal underground plant stem. It is a perennating organ in some species, where it is generally thick and fleshy, while in other species it is mainly a means of vegetative reproduction, and is therefore long and slender, with buds all along it that send up new plants. The potato is a rhizome that has two distinct parts, the tuber being the swollen end of a long, cordlike rhizome.

rhm (abbreviation of *roentgen-hour-metre*) the unit of effective strength of a radioactive source that produces gamma rays. It is used for substances for which it is difficult to establish radioactive disintegration rates.

Rhodesian ridgeback breed of large dog developed by European settlers in the late 19th and early 20th centuries in Zimbabwe (formerly Rhodesia) to pursue and hold at bay lions and other big game. Bred partly from European gundogs and mastiffs, it has the distinguishing feature of a ridge of hair that runs back up its spine towards the shoulders. It has a strong build, stands up to 69 cm/27 in tall, and has a smooth red-gold or honey-coloured coat.

rhodium *Greek rhodon 'rose'* hard, silver-white, metallic element, symbol Rh, atomic number 45, relative atomic mass 102.905. It is one of the so-called platinum group of metals and is resistant to tarnish, corrosion, and acid. It occurs as a free metal in the natural alloy osmiridium and is used in jewellery, electroplating, and thermocouples.

rhododendron any of numerous, mostly evergreen shrubs belonging to the heath family. The leaves are usually dark and leathery, and the large funnel-shaped flowers, which grow in tight clusters, occur in all colours except blue. They thrive on acid soils. *ϕ*Azaleas belong to the same genus. (Genus *Rhododendron*, family Ericaceae.)

rhombic sulphur allotropic form of sulphur. At room temperature, it is the stable allotrope, unlike monoclinic sulphur.

rhombus in geometry, an equilateral (all sides equal) parallelogram. Its diagonals bisect each other at right angles, and its area is half the product of the lengths of the two diagonals. A rhombus whose internal angles are 90° is called a square.

rhubarb perennial plant grown for its pink edible leaf stalks. The large leaves contain oxalic acid, and are poisonous. There are also

wild rhubarbs native to Europe and Asia. (*Rheum raphaniticum*, family Polygonaceae.)

Rhynchocephalia order of primitive reptiles that lived in Triassic times. The *ϕ*tuatara is the only survivor of this ancient group.

rhyolite igneous rock, the fine-grained volcanic (extrusive) equivalent of granite.

rhythm method method of natural contraception that relies on refraining from intercourse during ovulation.

The time of ovulation can be worked out by the calendar (counting days from the last period), by temperature changes, or by inspection of the cervical mucus. All these methods are unreliable because it is possible for ovulation to occur at any stage of the menstrual cycle.

rib long, usually curved bone that extends laterally from the *ϕ*spine in vertebrates. Most fishes and many reptiles have ribs along most of the spine, but in mammals they are found only in the chest area. In humans, there are 12 pairs of ribs. The ribs protect the lungs and heart, and allow the chest to expand and contract easily.

At the rear, each pair is joined to one of the vertebrae of the spine. The upper seven ('true' or vertebro-sternal ribs) are joined by *ϕ*cartilage directly to the breast bone (sternum). The next three ('false' or vertebro-costal ribs) are joined by cartilage to the end of the rib above. The last two ('floating ribs') are not attached at the front. The diaphragm and muscles between adjacent ribs are responsible for the respiratory movements which fill the lungs with air.

Every great scientific truth goes through three stages. First, people say it conflicts with the Bible. Next they say it had been discovered before. Lastly they say they always believed it.

Louis Agassiz Swiss palaeontologist.

Attributed remark

ribbonfish member of a family of marine fish. They have elongated and compressed bodies which have a ribbonlike appearance. They are pelagic (open sea) fishes.

There is no anal fin, but the dorsal fin is as long as the body, and the ventral fins have from one long ray to nine smaller ones. Ribbonfish are seldom found alive, and are usually seen floating dead on the surface of the ocean.

The *ϕ*dealfish *Trachyrhynchus arcticus*, occurs in the north Atlantic. The *ϕ*oarfish also belongs to this family.

classification Ribbonfish are in the family Trachyrhynchidae, order Lampridiformes, class Osteichthyes.

riboflavin or **vitamin B₂** *ϕ*vitamin of the B complex important in cell respiration. It is obtained from eggs, liver, and milk. A deficiency in the diet causes stunted growth.

ribonucleic acid full name of RNA.

ribosome in biology, the protein-making machinery of the cell. Ribosomes are located on the endoplasmic reticulum (ER) of eukaryotic cells, and are made of proteins and a special type of *ϕ*RNA, ribosomal RNA. They receive messenger RNA (copied from the *ϕ*DNA) and amino acids, and 'translate' the messenger RNA by using its chemically coded instructions to link amino acids in a specific order, to make a strand of a particular protein.

rice principal *ϕ*cereal of the wet regions of the tropics, derived from wild grasses probably native to India and SE Asia. Rice is unique among cereal crops in that it is grown standing in water. The yield is very large, and rice is said to be the staple food of one-third of the world's population. (*Oryza sativa*.)

cultivation Rice takes 150–200 days to mature in warm, wet conditions. During its growing period, it needs to be flooded either by the heavy monsoon rains or by irrigation. This restricts the

RHUBARB COMPENDIUM

<http://www.clark.net/pub/dan/rhubarb/rhubarb.html>

Pictures, history, recipes, the list of information included at this site goes on an on; it even includes a section on rhubarb being a possible key to CFC control. It is impossible to believe you would need to know something about rhubarb that this site doesn't tell you.

cultivation of swamp rice, the usual kind, to level land and terraces. A poorer variety, known as hill rice, is grown on hillsides. Outside Asia, there is some rice production in the Po Valley in Italy and in Louisiana, the Carolinas, and California in the USA.

In 1994 the International Rice Research Institute announced a new rice variety that can potentially increase rice yields by 25%. It produces more seed heads than the standard crop and each seed head contains 200 rice grains, compared with the present 100. The plant is also more compact, enabling it to be planted more densely.

nutrition Rice contains 8–9% protein. Brown, or unhusked, rice has valuable B-vitamins that are lost in husking or polishing. Most of the rice eaten in the world is, however, sold in the polished white form.

history Rice has been cultivated since prehistoric days in the East. New varieties with greatly increased protein content have been developed by gamma radiation for commercial cultivation, and yields are now higher than ever before (see *Green revolution*).

by-products Rice husks when burned provide a (silica ash that, mixed with lime, produces an excellent cement.

Richter scale scale based on measurement of seismic waves, used to determine the magnitude of an earthquake at its epicenter. The magnitude of an earthquake differs from its intensity, measured by the Mercalli scale, which is subjective and varies from place to place for the same earthquake. The scale is named after US seismologist Charles Richter.

An earthquake's magnitude is a function of the total amount of energy released, and each point on the Richter scale represents a thirtyfold increase in energy over the previous point. The greatest earthquake ever recorded, in 1920 in Gansu, China, measured 8.6 on the Richter scale.

rich text format in computing, file format usually abbreviated to *RTF*.

ricin extremely poisonous extract from the seeds of the castor-oil plant. When incorporated into monoclonal antibodies, ricin can attack cancer cells, particularly in the treatment of lymphoma and leukaemia.

rickets defective growth of bone in children due to an insufficiency of calcium deposits. The bones, which do not harden adequately, are bent out of shape. It is usually caused by a lack of vitamin D and insufficient exposure to sunlight. Renal rickets, also a condition of malformed bone, is associated with kidney disease.

rift valley valley formed by the subsidence of a block of the Earth's crust between two or more parallel faults. Rift valleys are steep-sided and form where the crust is being pulled apart, as at oceanic ridges, or in the Great Rift Valley of E Africa.

The Richter scale

The Richter scale is based on measurement of seismic waves, used to determine the magnitude of an earthquake at its epicenter. The magnitude of an earthquake differs from its intensity, measured by the Mercalli scale, which is subjective and varies from place to place for the same earthquake. The Richter scale was named after US seismologist Charles Richter (1900–1985).

| Magnitude | Relative amount of energy released | Examples | Year |
|-----------|------------------------------------|-------------------------------------------|------|
| 1 | 1 | | |
| 2 | 31 | | |
| 3 | 960 | | |
| 4 | 30,000 | Carlisle, England (4.7) | 1979 |
| 5 | 920,000 | Wrexham, Wales (5.1) | 1990 |
| 6 | 29,000,000 | San Fernando (CA) (6.5) | 1971 |
| | | northern Armenia (6.8) | 1988 |
| 7 | 890,000,000 | Loma Prieta (CA) (7.1) | 1989 |
| | | Kobe, Japan (7.2) | 1995 |
| | | Rasht, Iran (7.7) | 1990 |
| | | San Francisco (CA) (7.7–7.9) ¹ | 1906 |
| 8 | 28,000,000,000 | Tangshan, China (8.0) | 1976 |
| | | Gansu, China (8.6) | 1920 |
| | | Lisbon, Portugal (8.7) | 1755 |
| 9 | 850,000,000,000 | Prince William Sound (AK) (9.2) | 1964 |

¹ Richter's original estimate of a magnitude of 8.3 has been revised by two recent studies carried out by the California Institute of Technology and the US Geological Survey.

Rigel or *Beta Orionis* brightest star in the constellation Orion. It is a blue-white supergiant, with an estimated diameter 50 times that of the Sun. It is 900 light years from Earth, and is intrinsically the brightest of the first-magnitude stars, its luminosity being about 100,000 times that of the Sun. It is the seventh-brightest star in the sky.

right-angled triangle triangle in which one of the angles is a right angle (90°). It is the basic form of triangle for defining trigonometrical ratios (for example, sine, cosine, and tangent) and for which Pythagoras' theorem holds true. The longest side of a right-angled triangle is called the hypotenuse; its area is equal to half the product of the lengths of the two shorter sides.

Any triangle constructed with its hypotenuse as the diameter of a circle, with its opposite vertex (corner) on the circumference, is a

rift valley The subsidence of rock resulting from two or more parallel rocks moving apart is known as a graben. When this happens on a large scale, with tectonic plates moving apart, a rift valley is created.

right-angled triangle. This is a fundamental theorem in geometry, first credited to the Greek mathematician Thales about 580 BC.

right ascension in astronomy, the coordinate on the celestial sphere that corresponds to longitude on the surface of the Earth. It is measured in hours, minutes, and seconds eastwards from the point where the Sun's path, the ecliptic, once a year intersects the celestial equator; this point is called the **vernal equinox**.

right click in computing, on IBM-compatible PCs, a click on the right-hand button of the mouse that brings up a context-sensitive menu presenting a range of options relevant to the user's current activity.

right-hand rule in physics, a memory aid used to recall the relative directions of motion, magnetic field, and current in an electric generator. It was devised by English physicist John Fleming. See **Fleming's rules**.

rigor medical term for shivering or rigidity. **Rigor mortis** is the stiffness that ensues in a corpse soon after death, owing to chemical changes in muscle tissue.

ring circuit household electrical circuit in which appliances are connected in series to form a ring with each end of the ring connected to the power supply. It superseded the radial circuit.

ring ouzel mountain songbird *Turdus torquatus* with brownish-black plumage and a broad white patch on the throat. It nests in heather or on banks in moorland districts. It belongs to the thrush family Muscicapidae, order Passeriformes.

ringworm any of various contagious skin infections due to related kinds of fungus, usually resulting in circular, itchy, discoloured patches covered with scales or blisters. The scalp and feet (athlete's foot) are generally involved. Treatment is with antifungal preparations.

RIP (abbreviation for **raster image processor**) program in a laser printer (or other high-resolution printer) that converts the stream of printing instructions from a computer into the pattern of dots that make up the printed page. A separate program is required for each type of printer and for each page description language (such as **PostScript** or **PCL**).

RIPs are very demanding programs because of the complexity of a typical printed page. It is not unusual for RIPs to run on extremely fast and powerful **RISC** microprocessors, which are sometimes more powerful than the processor in the computer attached to the printer.

RiPEM (contraction of **Riordan's Internet Privacy Enhanced Mail**) in computing, **OpenPublic** domain software for sending and receiving e-mail using **Pretty Good Privacy (PGP)** for improved security. The name refers to Mark Riordan, who wrote most of the program.

ripple tank in physics, shallow water-filled tray used to demonstrate various properties of waves, such as reflection, refraction, diffraction, and interference.

RISC (acronym for **reduced instruction-set computer**) in computing, a microprocessor (processor on a single chip) that carries out fewer instructions than other (CISC) microprocessors in common use in the 1990s. Because of the low number and the regularity of machine code instructions, the processor carries out those instructions very quickly.

ritualization in ethology, a stereotype that occurs in certain behaviour patterns when these are incorporated into displays. For example, the exaggerated and stylized head toss of the goldeneye drake during courtship is a ritualization of the bathing movement used to wet the feathers; its duration and form have become fixed. Ritualization may make displays clearly recognizable, so ensuring that individuals mate only with members of their own species.

river large body of water that flows down a slope along a channel restricted by adjacent banks and **cléves**. A river originates at a point called its source, and enters a sea or lake at its mouth. Along

Longest Rivers in the World

| River | Location | Approximate length km | mi |

| Orange | South Africa | 2,092 | 1,300 |

its length it may be joined by smaller rivers called **tributaries**; a river and its tributaries are contained within a drainage basin. The point at which two rivers join is called the confluence.

Major rivers of the world include the Ganges, the Mississippi, and the Nile, the world's longest river. A river follows the path of least resistance downhill, and deepens, widens and lengthens its channel by **erosion**.

river red gum large tree *Eucalyptus camaldulensis* found lining the banks of Australian inland rivers. It usually branches low and is often wide spreading, with smooth bark on the upper trunk and branches. It is one of Australia's best-known and most valuable timber trees.

riveting method of joining metal plates. A hot metal pin called a **rivet**, which has a head at one end, is inserted into matching holes in two overlapping plates, then the other end is struck and formed into another head, holding the plates tight. Riveting is used in building construction, boilermaking, and shipbuilding.

river The course of a river from its source of a spring or melting glacier, through to maturity where it flows into the sea.

RL (abbreviation of *real life*) in computing, the opposite of ψ virtual reality.

rlogin (contraction of *remote login*) in computing, ψ UNIX program that enables users to log in on another computer via the Internet. Compare ψ Telnet.

rms in physics, abbreviation for ψ root-mean-square.

RNA (abbreviation for *ribonucleic acid*) nucleic acid involved in the process of translating the genetic material ψ DNA into proteins. It is usually single-stranded, unlike the double-stranded DNA, and consists of a large number of nucleotides strung together, each of which comprises the sugar ribose, a phosphate group, and one of four bases (uracil, cytosine, adenine, or guanine). RNA is copied from DNA by the formation of ψ base pairs, with uracil taking the place of thymine.

To remember that although DNA and RNA are both nucleic acids, they do different jobs in the cell:

DNA DELIVERS THE BLUEPRINT, RNA READS IT

RNA occurs in three major forms, each with a different function in the synthesis of protein molecules. Messenger RNA (mRNA) acts as the template for protein synthesis. Each ψ codon (a set of three bases) on the RNA molecule is matched up with the corresponding amino acid, in accordance with the ψ genetic code. This process (translation) takes place in the ribosomes, which are made up of proteins and ribosomal RNA (rRNA). Transfer RNA (tRNA) is responsible for combining with specific amino acids, and then matching up a special 'anticodon' sequence of its own with a codon on the mRNA.

This is how the genetic code is translated.

Although RNA is normally associated only with the process of protein synthesis, it makes up the hereditary material itself in some viruses, such as ψ retroviruses.

roach any freshwater fish of the Eurasian genus *Rutilus*, of the carp family, especially *R. rutilus* of N Europe. It is dark green above, whitish below, with reddish lower fins; it grows to 35 cm/1.2 ft.

road specially constructed route for wheeled vehicles to travel on.

Reinforced tracks became necessary with the invention of wheeled vehicles in about 3000 BC and most ancient civilizations

had some form of road network. The Romans developed engineering techniques that were not equalled for another 1,400 years.

Until the late 18th century most European roads were haphazardly maintained, making winter travel difficult. In the UK the turnpike system of collecting tolls created some improvement. The Scottish engineers Thomas Telford and John McAdam introduced sophisticated construction methods in the early 19th century. Recent developments have included durable surface compounds and machinery for rapid ground preparation.

roadrunner crested North American ground-dwelling bird *Geococcyx californianus* of the *Geococcyx* family, found in the SW USA and Mexico. It can run at a speed of 25 kph/15 mph.

robin migratory songbird *Erithacus rubecula* of the thrush family Muscicapidae, order Passeriformes, found in Europe, W Asia, Africa, and the Azores. About 13 cm/5 in long, both sexes are olive brown with a red breast. Two or three nests are constructed during the year in sheltered places, and from five to seven white freckled eggs are laid.

The larger North American robin *Turdus migratorius* belongs to the same family. In Australia members of several unrelated genera are called robins, and may have white, yellowish, or red breasts.

robot any computer-controlled machine that can be programmed to move or carry out work. Robots are often used in industry to transport materials or to perform repetitive tasks. For instance, robotic arms, fixed to a floor or workbench, may be used to paint machine parts or assemble electronic circuits. Other robots are designed to work in situations that would be dangerous to humans – for example, in defusing bombs or in space and deep-sea exploration.

Some robots are equipped with sensors, such as touch sensors and video cameras, and can be programmed to make simple decisions based on the sensory data received. As robots do not suffer from fatigue or become distracted, researchers in robotics aim to produce robots that can carry out sophisticated tasks more efficiently than humans, for example a voice-operated robot able to carry out some heart operations was tested successfully on a cow in the USA in 1998.

ROBOT

The word 'robot' originated in the theatre. It was invented by the Czech playwright Karel Capek in his 1921 play *R.U.R.* (Rossum's Universal Robots).

Roche limit in astronomy, the distance from a planet within which a large moon would be torn apart by the planet's gravitational force, creating a set of rings. The Roche limit lies at approximately 2.5 times the planet's radius (the distance from its centre to its surface).

rock constituent of the Earth's crust composed of minerals or materials of organic origin that have consolidated into hard masses as igneous, sedimentary, or metamorphic rocks. Rocks are formed from a combination (or aggregate) of minerals, and the property of a rock will depend on its components. Where deposits of economically valuable minerals occur they are termed *ores*. As a result of weathering, rock breaks down into very small particles that combine with organic materials from plants and animals to form *soil*. In geology the term 'rock' can also include unconsolidated materials such as sand, mud, clay, and peat.

Igneous rock is formed by the cooling and solidification of magma, the molten rock material that originates in the lower part of the Earth's crust, or mantle, where it reaches temperatures as high as 1,000°C. The rock may form on or below the Earth's surface and is usually crystalline in texture. Larger crystals are more

common in rocks such as granite which have cooled slowly within the Earth's crust; smaller crystals form in rocks such as basalt which have cooled more rapidly on the surface. Because of their acidic composition, igneous rocks such as granite are particularly susceptible to acid rain.

Sedimentary rocks are formed by the compression of particles deposited by water, wind, or ice. They may be created by the erosion of older rocks, the deposition of organic materials, or they may be formed from chemical precipitates. For example, sandstone is derived from sand particles, limestone from the remains of sea creatures, and gypsum is precipitated from evaporating sea water. Sedimentary rocks are typically deposited in distinct layers or strata and many contain fossils.

Metamorphic rocks are formed through the action of high pressure or heat on existing igneous or sedimentary rocks, causing changes to the composition, structure, and texture of the rocks. For example, marble is formed by the effects of heat and pressure on limestone, while granite may be metamorphosed into gneiss, a coarse-grained foliated rock.

rock crawler wingless insects with long antennae and either reduced eyes or none. Rock crawlers are generally found only at higher altitudes (450–2,000 m/1,480–6,550 ft), in the mountains of Japan, western North America and eastern Siberia, and prefer low temperature conditions. They live under logs and stones and are omnivorous and nocturnal.

Rock crawlers were discovered in the Canadian Rockies, as late as 1914. Their order, Grylloblattodea, contains three genera and only 16 species, and appears to exemplify the only modern representatives of the primitive insects from which the cockroaches (Blattodea) and grasshoppers and crickets (Orthoptera) have evolved.

long lifespan Eggs have an incubation period of approximately one year; the eight nymphal stages occupy a further five years; and the adult female then lives a further year before laying eggs.

classification Rock crawlers are in order Grylloblattodea in subclass Pterygota, class Insecta, phylum Arthropoda.

rocket projectile driven by the reaction of gases produced by a fast-burning fuel. Unlike jet engines, which are also reaction engines, modern rockets carry their own oxygen supply to burn their fuel and do not require any surrounding atmosphere. For warfare, rocket heads carry an explosive device.

Rockets have been valued as fireworks over the last seven centuries, but their intensive development as a means of propulsion to high altitudes, carrying payloads, started only in the interwar years with the state-supported work in Germany (primarily by Werner von Braun) and of Robert Hutchings Goddard (1882–1945) in the USA. Being the only form of propulsion available that can function in a vacuum, rockets are essential to exploration in outer space. Multistage rockets have to be used, consisting of a number of rockets joined together.

Two main kinds of rocket are used: one burns liquid propellants, the other solid propellants. The fireworks rocket uses gunpowder as a solid propellant. The space shuttle's solid rocket boosters use a mixture of powdered aluminium in a synthetic rubber binder. Most rockets, however, have liquid propellants, which are more powerful and easier to control. Liquid hydrogen and kerosene are common fuels, while liquid oxygen is the most common oxygen provider, or oxidizer. One of the biggest rockets ever built, the Saturn V Moon rocket, was a three-stage design, standing 111 m/365 ft high. It weighed more than 2,700 tonnes/3,000 tons

ONLINE ROCKETRY

<http://www.rocketryonline.com/>

Searchable site with reference materials, organizations, clubs, upcoming launches, products, books, and clubs devoted to rocketry.

on the launch pad, developed a takeoff thrust of some 3.4 million kg/7.5 million lb, and could place almost 140 tonnes/150 tons into low Earth orbit. In the early 1990s, the most powerful rocket system was the Soviet Energiya, capable of placing 100 tonnes/110 tons into low Earth orbit. The US space shuttle can put only 24 tonnes/26 tons into orbit. See *missile*.

rocket The three-stage Saturn V rocket used in the Apollo moonshots of the 1960s and 1970s. It stood 111 m/365 ft high, as tall as a 30-storey skyscraper, weighed 2,700 tonnes/3,000 tons when loaded with fuel, and developed a power equivalent to 50 Boeing 747 jumbo jets.

rock salmon another name for *dogfish*.

Rocky Mountain goat species of ruminant that occurs in North America. It is intermediate in position between a goat and an antelope. It resembles a goat in size and has long white hair with woolly undercoat, black, hollow horns, compressed at the base, and short ears.

classification The Rocky Mountain goat *Oreamnos americanus* is a member of the family Bovidae, order Artiodactyla.

rod a type of light-sensitive cell in the retina of most vertebrates. Rods are highly sensitive and provide only black and white vision. They are used when lighting conditions are poor and are the only type of visual cell found in animals active at night.

rodent any mammal of the worldwide order Rodentia, making up nearly half of all mammal species. Besides ordinary 'cheek teeth', they have a single front pair of incisor teeth in both upper and lower jaw, which continue to grow as they are worn down.

RODENT

Once attached to their mother's nipple, the young of some rodent species simply do not let go. This prevents any rival sibling from muscling in on the young rodent's food supply, and also enables it to hang on if the mother is forced to run away from a predator. Tenacious clinging is characteristic of 44 rodent species, all in the mouse family.

roe buck male of the Eurasian roe *doe*.

roe deer or **roe buck** small deer (the buck stands about 66 cm/26 in at the shoulder, and is 1.2 m/4 ft in length from the nose to the tiny tail). Roe deer are reddish-brown in summer (in winter the redness disappears), and the underparts are yellowish-grey. The horns average about 20 cm/8 in in length.

The mating season is in July to August and the young are born in the following May and June. They are at first reddish-brown with white spots.

Roe deer occur over central and southern Europe, and other races range as far east as China.

classification The roe deer *Capreolus capreolus* is in family Cervidae, order Artiodactyla.

roentgen or **röntgen** unit (symbol R) of radiation exposure, used for X-rays and gamma rays. It is defined in terms of the number of ions produced in one cubic centimetre of air by the radiation. Exposure to 1,000 roentgens gives rise to an absorbed dose of about 870 rads (8.7 grays), which is a dose equivalent of 870 rems (8.7 sieverts).

rogue value in computing, another name for *data terminator*.

roller any brightly coloured bird of the Old World family Coraciidae, resembling crows but in the same order as kingfishers and hornbills. Rollers grow up to 32 cm/13 in long. The name is derived from the habit of some species of rolling over in flight.

rolling common method of shaping metal. Rolling is carried out by giant mangles, consisting of several sets, or stands, of heavy rollers positioned one above the other. Red-hot metal slabs are rolled into sheet and also (using shaped rollers) girders and rails. Metal sheets are often cold-rolled finally to impart a harder surface.

roll-on/roll-off or **ro-ro** method of loading and unloading cargo ships. Lorries drive straight on board a specially designed vessel and then drive off at the ship's destination without unloading their cargo. This saves time and money, although valuable cargo space is taken up by the lorries and special port facilities are needed. Ro-ro is best suited to shorter journeys where handling costs are proportionately higher. Cross-Channel traffic between the UK and France and Belgium is an example.

Rolls-Royce industrial company manufacturing cars and aero-plane engines, founded 1906 by Henry Royce and Charles Rolls. The Silver Ghost car model was designed 1906, and produced until 1925, when the Phantom was introduced. In 1914 Royce designed the Eagle aircraft engine, used extensively in World War I. Royce also designed the Merlin engine, used in Spitfires and Hurricanes in World War II. Jet engines followed, and became an important part of the company.

From 1994, BMW of Germany were to build a percentage of the engines for Rolls-Royce and Bentley cars, as well as providing engineering consultation.

ROM (acronym for *read-only memory*) in computing, a memory device in the form of a collection of integrated circuits (chips), frequently used in microcomputers. ROM chips are loaded with data and programs during manufacture and, unlike ζ RAM (random-access memory) chips, can subsequently only be read, not written to, by computer. However, the contents of the chips are not lost when the power is switched off, as happens in RAM.

ROM is used to form a computer's permanent store of vital information, or of programs that must be readily available but protected from accidental or deliberate change by a user. For example, a microcomputer operating system is often held in ROM memory.

Roman numerals ancient European number system using symbols different from Arabic numerals (the ordinary numbers 1, 2, 3, 4, 5, and so on). The seven key symbols in Roman numerals, as represented today, are I (1), V (5), X (10), L (50), C (100), D (500), and M (1,000). There is no zero, and therefore no place-value as is fundamental to the Arabic system. The first ten Roman numerals are I, II, III, IV (or IIID), V, VI, VII, VIII, IX, and X. When a Roman symbol is preceded by a symbol of equal or greater value, the values of the symbols are added (XVI = 16).

When a symbol is preceded by a symbol of less value, the values are subtracted (XL = 40). A horizontal bar over a symbol indicates a multiple of 1,000 (X̄ = 10,000). Although addition and subtraction are fairly straightforward using Roman numerals, the absence of a zero makes other arithmetic calculations (such as multiplication) clumsy and difficult.

TO REMEMBER THE VALUES OF ROMAN NUMERALS:

X SHALL STAND FOR PLAYMATES TEN, V FOR FIVE STOUT
STALWART MEN, I FOR ONE, AS I'M ALIVE, C FOR HUNDRED
AND D FOR FIVE, M FOR A THOUSAND SOLDIERS TRUE, AND
L FOR FIFTY, I'LL TELL YOU.

röntgen alternative spelling for ζ roentgen, unit of X- and gamma-ray exposure.

rook gregarious European ζ crow *Corvus frugilegus*. The plumage is black and lustrous and the face bare; the legs, toes, and claws are also black. A rook can grow to 45 cm/18 in long. Rooks nest in colonies (rookeries) at the tops of trees. They feed mainly on invertebrates found just below the soil surface. The last 5 mm/0.2 in of beak tip is mostly cartilage containing lots of nerve endings to enable the rook to feel for hidden food.

The nest is a large structure made of twigs and straw, and in it are laid four to six bluish-green eggs blotched with greenish-brown. Feathers round the base of the beak are present in young birds but do not grow again after the second moult.

root in computing, the account used by system administrators and other superusers in ζ UNIX systems. Users logged in as root (or in some systems, avatar) have permission to access and change all the files in the system.

root the part of a plant that is usually underground, and whose primary functions are anchorage and the absorption of water and dissolved mineral salts. Roots usually grow downwards and towards water (that is, they are positively geotropic and hydrotropic; see

Röntgen, Wilhelm Konrad (1845–1923)

(or Roentgen) German physicist. He discovered X-rays 1895. While investigating the passage of electricity through gases, he noticed the fluorescence of a barium platinocyanide screen. This radiation passed through some substances opaque to light, and affected photographic plates. Developments from this discovery revolutionized medical diagnosis. He won the Nobel Prize for Physics 1901.

Mary Evans Picture Library

ζ tropism). Plants such as epiphytic orchids, which grow above ground, produce aerial roots that absorb moisture from the atmosphere. Others, such as ivy, have climbing roots arising from the stems, which serve to attach the plant to trees and walls.

The absorptive area of roots is greatly increased by the numerous slender root hairs formed near the tips. A calyptra, or root cap, protects the tip of the root from abrasion as it grows through the soil.

Symbiotic associations occur between the roots of certain plants, such as clover, and various bacteria that fix nitrogen from the air (see ζ nitrogen fixation). Other modifications of roots include ζ contractile roots, pneumatophores, taproots, and ζ prop roots.

evolution The evolution of root systems by land plants was very fast, in evolutionary terms. The earliest plants (410 million years ago) had tiny roots only a few millimetres in length, but within 20 million years, roots were as long as 50 cm/20 in.

root of an equation, a value that satisfies the equality. For example, $x = 0$ and $x = 5$ are roots of the equation $x^2 - 5x = 0$.

root cap cap at the tip of a growing root. It gives protection to the zone of actively dividing cells as the root pushes through the soil.

root crop plant cultivated for its swollen edible root (which may or may not be a true root). Potatoes are the major temperate root crop; the major tropical root crops are cassava, yams, and sweet potatoes. Root crops are second in importance only to cereals as human food. Roots have a high carbohydrate content, but their protein content rarely exceeds 2%. Consequently, communities relying almost exclusively upon roots may suffer from protein deficiency. Food production for a given area from roots is greater than from cereals.

In the mid-1980s, world production of potatoes, cassava, and yams was just under 600 million tonnes. Root crops are also used as animal feed, and may be processed to produce starch, glue, and alcohol. Sugar beet has largely replaced sugar cane as a source of sugar in Europe.

root directory in computing, the top directory in a ζ tree-and-branch filing system. It contains all the other directories.

root hair tiny hairlike outgrowth on the surface cells of plant roots that greatly increases the area available for the absorption of water and other materials. It is a delicate structure, which survives for a few days only and does not develop into a root.

New root hairs are continually being formed near the root tip, one of the places where plants show the most active growth to replace the ones that are lost. The majority of land plants have

root Types of root. Many flowers (dandelion) and vegetables (carrot) have swollen tap roots with smaller lateral roots. The tuberous roots of the cassava are swollen parts of an underground stem modified to store food. The fibrous roots of the grasses are all of equal size. Prop roots grow out from the stem and then grow down into the ground to support a heavy plant. Aerial roots grow from stems but do not grow into the ground; many absorb moisture from the air.

root hairs. The layer of the root's epidermis that produces root hairs is known as the piliferous layer.

root mean square (rms) in mathematics, value obtained by taking the square root of the mean of the squares of a set of values; for example the rms value of four quantities a , b , c , and d is $\sqrt{[(a^2 + b^2 + c^2 + d^2)/4]}$.

root-mean-square (rms) measure of the effective magnitude of a cyclic or randomly varying quantity whose average value is zero. For a cyclic quantity, it is equal to the square root of the average of the squares of the quantity at each instant over a complete cycle; where the variation is a (sine wave, the rms value is equal to the peak value divided by $\sqrt{2}$. In electrical engineering, for example, the rms value of the current or voltage in an AC circuit is used in power calculations. The rms value is also used as measure of the amplitude of randomly varying quantities, such as the noise in a telecommunications channel.

root nodule clearly visible swelling that develops in the roots of members of the bean family, the Leguminosae. The cells inside this tumorous growth have been invaded by the bacteria *Rhizobium*, a soil microbe capable of converting gaseous nitrogen into nitrate. The nodule is therefore an association between a plant and a bacterium, with both partners benefiting. The plant obtains nitrogen compounds while the bacterium obtains nutrition and shelter.

Nitrogen fixation by bacteria is one of the main ways by which the nitrogen in the atmosphere is cycled back into living things. The economic value of the process is so great that research has been carried out into the possibility of stimulating the formation of root nodules in crops such as wheat, which do not normally form an association with *Rhizobium*.

rootstock another name for rhizome, an underground plant organ.

rope stout cordage with circumference over 2.5 cm/1 in. Rope is made similarly to thread or twine, by twisting yarns together to

form strands, which are then in turn twisted around one another in the direction opposite to that of the yarns. Although hemp is still used to make rope, nylon is increasingly used.

rorqual any of a family (Balaenopteridae) of baleen whales, especially the genus *Balaenoptera*, which includes the blue whale *B. musculus*, the largest of all animals, measuring 30 m/100 ft and more. The common rorqual or fin whale *B. physalus* is slate-colored and not quite so long.

The sei whale *B. borealis*, the minke whale *B. acutorostrata*, Bryde's whale *B. edeni*, and the humpback whale *Megaptera novaeangliae* also belong to this family. All are long-bodied whales with pleated throats.

Rorschach test in psychology, a method of diagnosis involving the use of inkblot patterns that subjects are asked to interpret, to help indicate personality type, degree of intelligence, and emotional stability. It was invented by the Swiss psychiatrist Hermann Rorschach (1884-1922).

ROSAT joint US/German/UK satellite launched 1990 to study cosmic sources of X-rays and extremely short ultraviolet wavelengths, named after Wilhelm Röntgen, the discoverer of X-rays.

rose any shrub or climbing plant belonging to the rose family, with prickly stems and fragrant flowers in many different colours. Numerous cultivated forms have been derived from the sweetbrier or eglantine (*R. rubiginosa*) and dogrose (*R. canina*) native to Europe and Asia. There are many climbing varieties, but the forms most commonly grown in gardens are bush roses and standards (cultivated roses grafted on to a brier stem). (Genus *Rosa*, family Rosaceae.)

rosebay willowherb common perennial weed. See willowherb.

rose beetle another name for rose chafer.

rose chafer or **rose beetle** brightly coloured insect occurring mainly in the tropics.

In the adult stage rose chafers feed on tender shoots and floral parts of plants or on the sap exuded from trees. In contrast, the larvae are generally found in soil, where they attack the roots of most plants, and hence are agricultural pests. Some also inhabit decaying wood, leaf litter, and other plant refuse. There are about 2,500 species.

classification The rose chafer is in subfamily Cetoniinae, family Scarabaeidae, order Coleoptera, class Insecta, phylum Arthropoda.

rosemary evergreen shrub belonging to the mint family, native to the Mediterranean and W Asia, with small, narrow, scented leaves and clusters of pale blue or purple flowers. It is widely cultivated as a herb for use in cooking and for its aromatic oil, used in perfumery and pharmaceuticals. Rosemary is a traditional symbol of remembrance. (*Rosemarinus officinalis*, family Labiatae.)

Rosetta in astronomy, a project of the European Space Agency, due for launch in 2003, to send a spacecraft to Comet Wirtanen. *Rosetta* is expected to go into orbit around the comet in 2011 and land two probes on the nucleus a year later. The spacecraft will stay with the comet as it makes its closest approach to the Sun in October 2013.

rotation in geometry, a transformation in which a figure is turned about a given point, known as the **centre of rotation**. A rotation of 180° is known as a half turn.

rotifer any of the tiny invertebrates, also called 'wheel animalcules', of the phylum Rotifera. Mainly freshwater, some marine, rotifers have a ring of cilia that carries food to the mouth and also provides propulsion. They are the smallest of multicellular animals – few reach 0.05 cm/0.02 in.

Rottweiler breed of dog originally developed in Rottweil, Germany, as a herding and guard dog, and subsequently used as a police dog. Powerfully built, the dog is about 63–66 cm/25–27 in high at the shoulder, black with tan markings. It has a short coat and docked tail.

roughage alternative term for dietary fibre, material of plant origin that cannot be digested by enzymes normally present in the human gut.

rough collie breed of herding dog originating in Scotland. It has a long, thick coat which may be sable, blue merle, or tri-coloured, all with white markings. Its head is narrow, with a pointed muzzle and pricked ears that fold down at the tips. Of slender build, it grows to about 62 cm/24 in. The smooth collie is identical, except that its coat is short.

rounding process by which a number is approximated to the nearest above or below with one or more fewer decimal places. For example, 34.3583 might be rounded to 34.358, whereas 34.3587 would be rounded to 34.359. Similarly, 3.587 might be rounded to the nearest thousand, giving 4,000. When unwanted decimals are simply left out, the process is known as **truncating**.

Rounding can produce considerable errors, especially when the rounded numbers are multiplied by other rounded numbers. For example, if the volume of a cuboid is calculated as 3 x 4 x 5 when the true dimensions are 3.4 x 4.4 x 5.4, the rounding error is 20.784 out of 80.784, an error of over 25%.

roundworm parasitic nematode worm, genus *Toxocara*, found in dogs, cats, and other animals.

router in computing, a device that pushes traffic through a packet-switched network. On the Internet, traffic travels through a series of routers that relay each packet of data to its destination by the best possible route.

rove beetle any of a number of beetles with characteristic very short elytra (wing cases) that conceal large, well developed wings that are intricately folded away. When required the wings can unfold very rapidly, for almost instantaneous flight. The family includes some 20,000 species.

classification The rove beetle is in family Staphylinidae in order Coleoptera class Insecta, phylum Arthropoda.

Most of these beetles are small and inconspicuous, except the devil's coach horse, which is about 3 cm/1.2 in. Some species are predatory; others live in association with ant and termite colonies.

rowan another name for the European mountain ash tree.

Royal Aeronautical Society oldest British aviation body, formed in 1866. Its members discussed and explored the possibilities of flight long before its successful achievement.

royal antelope small nocturnal African antelope, inhabitants of dense jungle. They are the smallest of all antelopes, being no more than 30 cm/12 in high, and are slenderly built with very thin legs, no thicker than a pencil; they are generally brown in colour.

classification The royal antelope *Neotragus pygmaeus* is in family Bovidae, in order Artiodactyla.

ROYAL BOTANIC GARDENS, KEW

<http://www.rbgbkew.org.uk/>

Kew Gardens' home page, with general visitor information, a history of the gardens, a guide to the main plant collections, and a searchable database.

Royal Botanic Gardens, Kew botanic gardens in Richmond, Surrey, England, popularly known as Kew Gardens.

The history of the living world can be summarised as the elaboration of ever more perfect eyes within a cosmos in which there is always something more to be seen.

PIERRE TEILHARD DE CHARDIN French Jesuit theologian, palaeontologist, and philosopher.

The Phenomenon of Man 1955

Royal Greenwich Observatory the national astronomical observatory of the UK, founded in 1675 at Greenwich, SE London, England, to provide navigational information for sailors. After World War II it was moved to Herstmonceux Castle, Sussex; in 1990 it was transferred to Cambridge. It also operates telescopes on La Palma in the Canary Islands, including the 4.2-m/165-in William Herschel Telescope, commissioned 1987.

In 1998 the Particle Physics and Astronomy Research Council decided to return some of the Royal Observatory's work back to the original Greenwich site from Cambridge (other technical work will go to a new UK Astronomy Technology Centre in Edinburgh).

The observatory was founded by King Charles II. The eminence of its work resulted in Greenwich Time and the Greenwich Meridian being adopted as international standards of reference in 1884.

ROYAL GREENWICH OBSERVATORY

<http://www.ast.cam.ac.uk/RGO/>

Official and searchable site of the world's most famous observatory.

In addition to an excellent history and guide for visitors to the observatory's museum, there are comprehensive details of current RGO research (no longer carried out in Greenwich). This is an important site both for students of astronomy and for those seeking information on latest research.

Royal Horticultural Society British society established in 1804 for the improvement of horticulture. The annual Chelsea Flower Show, held in the grounds of the Royal Hospital, London, is also a social event, and another flower show is held at Vincent Square.

ROYAL HORTICULTURAL SOCIETY

http://www.rhs.org.uk/index_f.html

Large source of information on horticulture in the UK. The contents include a guide to RHS gardens, the society's scientific and educational work, RHS publications, and information about the annual Chelsea Flower Show and other events.

London. There are gardens, orchards, and trial grounds at Wisley, Surrey, and the Lindley Library has one of the world's finest horticultural collections.

Royal Institution of Great Britain organization for the promotion, diffusion, and extension of science and knowledge, founded in London 1799 by the Anglo-American physicist Count Rumford (1753-1814).

Royal Society oldest and premier scientific society in Britain, originating in 1645 and chartered in 1662; Robert Boyle, Christopher Wren, and Isaac Newton were prominent early members. Its Scottish equivalent is the Royal Society of Edinburgh 1783.

Royal Society of Chemistry society formed in the UK in 1980, merging the Chemical Society (founded 1841) and the Royal Institute of Chemistry (founded 1877). The society's object, as stated in its royal charter, is the general advancement of chemical science and its applications, serving to that end as a learned society, a professional body, and a representative body. It is recognized in the UK and internationally as an authoritative voice of chemistry and chemists.

RS-232 interface standard type of computer vinteface used to connect computers to serial devices. It is used for modems, mice, screens, and serial printers.

RSA in computing, name of both an encryption valgorithm and the company (RSA Inc) set up to exploit that algorithm in commercial encryption products. First described 1977 by its inventors, Ronald Rivest, Adi Shamir, and Leonard Adelman, and published in *Scientific American*, the RSA algorithm is used in the free program *CPretty Good Privacy* (PGP) and in commercial products released by RSA Laboratories.

RSI (abbreviation for *repetitive strain injury*), a condition affecting workers, such as typists, who repeatedly perform certain movements with their hands and wrists.

RSPB abbreviation for *Royal Society for the Protection of Birds*

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS

<http://birdcare.com/bin/showpage/birdaction/rspb>

Home page of the RSPB. The Web site includes a vast amount of information on birds and bird watching in the UK, with descriptions, sketches and photographs of very common UK bird. The site also holds information on how to join the society, and lists the society's sites and activities around the country.

RSUP (abbreviation for *Reliable SAP Update Protocol*) in computing, bandwidth-saving protocol for Novell networks developed by router manufacturer Cisco Systems.

RTF (abbreviation for *Rich Text Format*) in computing, file format designed to facilitate the exchange of documents between different word processing programs. RTF text files make it possible to trans-

fer formatting such as font styles or paragraph indents from one program to another.

RU486 another name for *ö*mifepristone, an abortion pill.

rubber slang term for a *ö*condom.

rubber coagulated latex of a variety of plants, mainly from the New World. Most important is Para rubber, which comes from the tree *Hevea brasiliensis*, belonging to the spurge family. It was introduced from Brazil to SE Asia, where most of the world supply is now produced, the chief exporters being Peninsular Malaysia, Indonesia, Sri Lanka, Cambodia, Thailand, Sarawak, and Brunei. At about seven years the tree, which may grow to 20 m/60 ft, is ready for tapping. Small cuts are made in the trunk and the latex drips into collecting cups. In pure form, rubber is white and has the formula $(C_5H_8)_n$. **plant rubber** Other sources of rubber are the Russian dandelion *Taraxacum koksagyz*, which grows in temperate climates and can yield about 45 kg/100 lb of rubber per tonne of roots, and guayule *Parthenium argentatum*, a small shrub which grows in the southwestern USA and Mexico.

treatment Early uses of rubber were limited by its tendency to soften on hot days and harden on colder ones, a tendency that was eliminated by Charles Goodyear's invention of *ö*vulcanization 1839. **synthetic rubber** In the 20th century, world production of rubber increased a hundredfold, and World War II stimulated the production of synthetic rubber to replace the supplies from Malaysian sources overrun by the Japanese. There are an infinite variety of synthetic rubbers adapted to special purposes, but economically foremost is SBR (styrene-butadiene rubber). Cheaper than natural rubber, it is preferable for some purposes, for example in car tyres, where its higher abrasion resistance is useful, and it is either blended with natural rubber or used alone for industrial moulding and extrusions, shoe soles, hoses, and latex foam.

rubber plant Asiatic tree belonging to the mulberry family, native to Asia and N Africa, which produces latex in its stem. It has shiny, leathery, oval leaves, and young specimens are grown as house plants. (*Ficus elastica*, family Moraceae.)

rubella technical term for *ö*German measles.

rubidium Latin *rubidus* 'red' soft, silver-white, metallic element, symbol Rb, atomic number 37, relative atomic mass 85.47. It is one of the alkali metals, ignites spontaneously in air, and reacts violently with water. It is used in photocells and vacuum-tube filaments.

Rubidium was discovered spectroscopically by German physicists Robert Bunsen and Gustav Kirchhoff 1861, and named after the red lines in its spectrum.

ruby the red transparent gem variety of the mineral *ö*corundum Al_2O_3 , aluminium oxide. Small amounts of chromium oxide, Cr_2O_3 , substituting for aluminium oxide, give ruby its colour. Natural rubies are found mainly in Myanmar (Burma), but rubies can also be produced artificially and such synthetic stones are used in *ö*lasers.

ruby-tailed cuckoo wasp or **ruby-tailed fly** insect in the family Chrysididae.

rudd or **red eye** freshwater bony fish allied to the *ö*roach. It is tinged with bronze, and has reddish fins, the dorsal being farther back than that of the roach. It is found in British and European lakes and sluggish streams. The largest weigh over 1 kg/2.2 lb and may be as much as 45 cm/18 in long.

classification The rudd *Scardinius erythrophthalmus* belongs to the order Cypriniformes, class Osteichthyes.

rue shrubby perennial herb native to S Europe and temperate Asia. It bears clusters of yellow flowers. An oil extracted from the strongly scented blue-green leaves is used in perfumery. (*Ruta graveolens*, family Rutaceae.)

ruff bird *Philomachus pugnax* of the sandpiper family Scolopacidae. The name is taken from the frill of erectile purple-black feathers developed in the breeding season around the neck

of the male. The females (reeves) have no ruff; they lay four spotted green eggs in a nest of coarse grass made amongst reeds or rushes. The ruff is found across N Europe and Asia, and migrates south in winter. It is a casual migrant throughout North America.

ruffe or pope European freshwater perchlike fish. The dorsal fin is continuous in the ruffe, whereas in the perch there are two separate fins.

classification The ruff *Acerina cernua* is in family Percidae in order Perciformes, class Osteichthyes.

ruminant any even-toed hoofed mammal with a rumen, the 'first stomach' of its complex digestive system. Plant food is stored and fermented before being brought back to the mouth for chewing (chewing the cud) and then is swallowed to the next stomach. Ruminants include cattle, antelopes, goats, deer, and giraffes, all with a four-chambered stomach. Camels are also ruminants, but they have a three-chambered stomach.

Rumpler Berlin aircraft company which made aircraft for the German Army in World War I.

runner or stolon in botany, aerial stem that produces new plants.

runner A runner, or stolon, grows horizontally near the base of some plants, such as the strawberry. It produces roots along its length and new plants grow at these points.

run-time system in computing, programs that must be stored in memory while an application is executed.

run-time version in computing, copy of a program that is provided with another application, so that the latter can be run, although it does not provide the full functionality of the program. An example is the provision of run-time versions of Microsoft Windows with Windows applications for those users who do not have the full version of Windows.

rupture in medicine, another name for *hernia*.

rush any of a group of grasslike plants found in wet places in cold and temperate regions. The round stems and flexible leaves of some species have been used for making mats and baskets since ancient times. (Genus *Juncus*, family Juncaceae.)

Three passions, simple but overwhelmingly strong, have governed my life: the longing for love, the search for knowledge, and unbearable pity for the suffering of mankind.

BERTRAND RUSSELL English philosopher and mathematician.
Autobiography, Prologue

Russian Academy of Sciences society founded 1725 by Catherine the Great in St Petersburg. The academy has been responsible for such achievements as the *Sputnik* satellite, and

Russell, Bertrand Arthur William (1872–1970)

3rd Earl Russell British philosopher and mathematician. He contributed to the development of modern mathematical logic and wrote about social issues. His works include *Principia Mathematica* 1910–13 (with A N Whitehead), in which he attempted to show that mathematics could be reduced to a branch of logic; *The Problems of Philosophy* 1912; and *A History of Western Philosophy* 1946. He was an outspoken liberal pacifist. Earl 1931. Nobel Prize for Literature 1950.

Russell was born in Monmouthshire, the grandson of Prime Minister John Russell. He studied mathematics and philosophy at Trinity College, Cambridge, where he became a lecturer in 1910. His pacifist attitude in World War I lost him the lectureship, and he was imprisoned for six months for an article he wrote in a pacifist journal. His *Introduction to Mathematical Philosophy* 1919 was written in prison. He and his wife ran a progressive school 1927–32. After visits to the USSR and China, he went to the USA in 1938 and taught at many universities. In 1940, a US court disqualified him from teaching at City College of New York because of his liberal moral views. He later returned to England and resumed his fellowship at Trinity College.

Russell was a life-long pacifist except during World War II. From 1949 he advocated nuclear disarmament and until 1963 was on the Committee of 100, an offshoot of the Campaign for Nuclear Disarmament.

Among his other works are *Principles of Mathematics* 1903, *Principles of Social Reconstruction* 1917, *Marriage and Morals* 1929, *An Enquiry into Meaning and Truth* 1940, *New Hopes for a Changing World* 1951, and *Autobiography* 1967–69.

Mary Evans Picture Library

has daughter academies in the Ukraine (welding, cybernetics), Armenia (astrophysics), and Georgia (mechanical engineering).

Russian Blue breed of domestic shorthaired cat, probably not of Russian origin. Long and elegant in form, it has a flatish head and broad face, and its slanting eyes are green. The undercoat is thick and upstanding, and its blue-grey colour is slightly silvered by light grey tips to the overlying guard hairs.

russula any of a large group of fungi (see *fungus*), containing many species. They are medium-to-large mushrooms with flattened caps, and many are brightly coloured. (Genus *Russula*.)

R. emetica is a common species found in damp places under conifer trees. Up to 9 cm/3.5 in across, the cap is scarlet, fading to cherry, and the gills are white. This mushroom tastes acrid and causes vomiting eaten raw, but some russulas are edible.

rust in botany, common name for a group of minute parasitic fungi (see *fungus*) that appear on the leaves of their hosts as orange-red spots, later becoming darker. The commonest is the wheat rust (*Puccinia graminis*). (Order Uredinales.)

rust reddish-brown oxide of iron formed by the action of moisture and oxygen on the metal. It consists mainly of hydrated iron(III) oxide ($\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$) and iron(III) hydroxide ($\text{Fe}(\text{OH})_3$).

Paints that penetrate beneath any moisture, and plastic compounds that combine with existing rust to form a protective coating, are used to avoid rusting.

Rutherford, Ernest, 1st Baron Rutherford of Nelson (1871–1937)

New Zealand-born British physicist. He was a pioneer of modern atomic science. His main research was in the field of radioactivity, and he discovered alpha, beta, and gamma rays. He was the first to recognize the nuclear nature of the atom 1911. Nobel prize 1908. Knighted 1914, Baron 1931.

Rutherford produced the first artificial transformation, changing one element to another, 1919, bombarding nitrogen with alpha particles and getting hydrogen and oxygen. After further research he announced that the nucleus of any atom

must be composed of hydrogen nuclei; at Rutherford's suggestion, the name 'proton' was given to the hydrogen nucleus 1920. He speculated that uncharged particles (neutrons) must also exist in the nucleus.

In 1934, using heavy water, Rutherford and his co-workers bombarded deuterium with deuterons and produced tritium. This may be considered the first nuclear fusion reaction.

Mary Evans Picture Library

ruthenium hard, brittle, silver-white, metallic element, symbol Ru, atomic number 44, relative atomic mass 101.07. It is one of the so-called platinum group of metals; it occurs in platinum ores as a free metal and in the natural alloy osmiridium. It is used as a hardener in alloys and as a catalyst; its compounds are used as colouring agents in glass and ceramics.

rutherfordium synthesized, radioactive, metallic element, symbol Rf. It is the first of the transactinide series, atomic number 104, relative atomic mass 262. It is produced by bombarding californium with carbon nuclei and has ten isotopes, the longest-lived of which, Rf-262, has a half-life of 70 seconds.

Two institutions claim to be the first to have synthesized it: the Joint Institute for Nuclear Research in Dubna, Russia, in 1964; and the University of California at Berkeley, USA, in 1969.

rutile titanium oxide mineral, TiO_2 , a naturally occurring ore of titanium. It is usually reddish brown to black, with a very bright (adamantine) surface lustre. It crystallizes in the tetragonal system. Rutile is common in a wide range of igneous and metamorphic rocks and also occurs concentrated in sands; the coastal sands of E and W Australia are a major source. It is also used as a pigment that gives a brilliant white to paint, paper, and plastics.

Rydberg constant in physics, a constant that relates atomic spectra to the ϕ spectrum of hydrogen. Its value is 1.0977×10^7 per metre.

rye tall annual cereal grass grown extensively in N Europe and other temperate regions. The flour is used to make dark-coloured ('black') breads. Rye is grown mainly as a food crop for animals, but the grain is also used to make whisky and breakfast cereals. (*Secale cereale*.)

S

S abbreviation for *south*.

SAA abbreviation for ϕ systems application architecture.

sabin unit of sound absorption, used in acoustical engineering. One sabin is the absorption of one square foot (0.093 square metre) of a perfectly absorbing surface (such as an open window).

Sabin, Albert Bruce (1906–1993)

Russian-born US microbiologist who developed a highly effective, live vaccine against polio. The earlier vaccine, developed by physicist Jonas Salk, was based on heat-killed viruses. Sabin was convinced that a live form would be longer-lasting and more effective, and in 1957 he succeeded in weakening the virus so that it lost its virulence. The vaccine can be given by mouth.

sable marten *Martes zibellina*, about 50 cm/20 in long and usually brown. It is native to N Eurasian forests, but now found mainly in E Siberia. The sable has diminished in numbers because of its valuable fur, which has long attracted hunters.

Conservation measures and sable farming have been introduced to save it from extinction.

saccharide another name for a ϕ sugar molecule.

saccharin or *ortho-sulpho benzimide* $C_7H_5NO_2S$ sweet, white, crystalline solid derived from coal tar and substituted for sugar. Since 1977 it has been regarded as potentially carcinogenic. Its use is not universally permitted and it has been largely replaced by other sweetening agents.

Sachs, Julius von (1832–1897)

German botanist and plant physiologist who developed several important experimental techniques and showed that photosynthesis occurs in the chloroplasts (the structure in a plant cell containing the green pigment chlorophyll) and produces oxygen. He was especially gifted in his experimental approach; some of his techniques are still in use today, such as the simple iodine test, which he used to show the existence of starch in a whole leaf.

sacred baboon or *hamadryas* medium-sized ϕ baboon *Papio hamadryas* that was once sacred in Egypt but has since become extinct there owing to competition for land. It occurs in troops of up to 500. It is still found in Ethiopia on dry savannah where there are rocky cliffs and hillsides, but is threatened by habitat changes and perhaps also hunting.

sadism tendency to derive pleasure (usually sexual) from inflicting physical or mental pain on others. The term is derived from the Marquis de Sade.

sadomasochism sexual behaviour that combines ϕ sadism and ϕ masochism. The term was coined 1907 by sexologist Richard von Krafft-Ebing.

safety glass glass that does not splinter into sharp pieces when smashed. **Toughened glass** is made by heating a glass sheet and then rapidly cooling it with a blast of cold air; it shatters into rounded pieces when smashed. **Laminated glass** is a 'sandwich' of a clear plastic film between two glass sheets; when this is struck, it simply cracks, the plastic holding the glass in place.

safety lamp portable lamp designed for use in places where flammable gases such as methane may be encountered; for example, in coal mines. The electric head lamp used as a miner's working light has the bulb and contacts in protected enclosures. The safety lamp, now used primarily for gas detection, has the wick enclosed within a strong glass cylinder surmounted by wire gauzes. English chemist Humphrey Davy 1815 and English engineer George ϕ Stephenson each invented flame safety lamps.

Saffir–Simpson damage-potential scale scale of potential damage from wind and sea when a hurricane is in progress: 1 is minimal damage, 5 is catastrophic.

safflower thistlelike Asian plant with large orange-yellow flowers. It is widely grown for the oil from its seeds, which is used in cooking, margarine, and paints and varnishes; the leftovers are used as cattle feed. (*Carthamus tinctorius*, family Compositae.)

saffron crocus plant belonging to the iris family, probably native to SW Asia, and formerly widely cultivated in Europe; also the dried orange-yellow ϕ stigmas of its purple flowers, used for colouring and flavouring in cookery. (*Crocus sativus*, family Iridaceae.)

sage perennial herb belonging to the mint family, with grey-green aromatic leaves used for flavouring in cookery. It grows up to 50 cm/20 in high and has bluish-lilac or pink flowers. (*Salvia officinalis*, family Labiatae.)

Sagittarius bright zodiac constellation in the southern hemisphere, represented as a centaur aiming a bow and arrow at neighbouring Scorpius. The Sun passes through Sagittarius from mid-Dec to mid-Jan, including the winter solstice, when it is farthest south of the Equator. The constellation contains many nebulae and ϕ globular clusters, and open ϕ star clusters. Kaus Australis and Nunki are its brightest stars. The centre of our Galaxy, the ϕ Milky Way, is marked by the radio source Sagittarius A. In astrology, the dates for Sagittarius are about 22 Nov–21 Dec (see ϕ precession).

sago starchy material obtained from the pith of the sago palm *Metroxylon sagu*. It forms a nutritious food and is used for manufacturing glucose and sizing textiles.

Sahel Arabic *sahil* 'coast' marginal area to the south of the Sahara, from Senegal to Somalia, which experiences desert-like conditions during periods of low rainfall. The desertification is partly due to climatic fluctuations but has also been caused by the pressures of a rapidly expanding population, which has led to overgrazing and the destruction of trees and scrub for fuelwood. In recent years many famines have taken place in the area.

saiga antelope *Saiga tatarica* of E European and W Asian steppes and deserts. Buff-coloured, whitish in winter; it stands 75 cm/30 in at the shoulder, with a body about 1.5 m/5 ft long. Its nose is unusually large and swollen, an adaptation which may help warm and moisten the air inhaled, and keep out the desert dust. The saiga can run at 80 kph/50 mph.

Only the male has horns, which are straight and up to 30 cm/1 ft long. The saiga is threatened by the demand for its horn for use in traditional Chinese medicine. Once a vanishing species, it is now protected; in 1994 it was listed in Appendix II of ϕ CITES, requiring a special permit for trade. The total 1995 population was about 1 million.

The Miner's Safety lamp

BY PETER LAFFERTY

In 1793, the headmaster at Penzance Grammar School, Cornwall, England, told Humphry Davy that he was lazy. Yet Davy went on to become one of the best-known chemists of his time. He discovered six previously unknown elements, sodium, potassium, magnesium, calcium, barium, and strontium. He won many scientific honours, and was knighted in 1812 by Prince Regent – the King, George III, and was insane and could not carry out the investiture. He was even awarded a prize established by Napoleon Bonaparte, at a time when England and France were at war. He became wealthy – in 1811 he was paid a very large sum of money for a course of lectures in Ireland. Not bad for a lazy schoolboy!

Davy became a household name when he solved the problem of explosions in coal mines. The only illumination in the coal mines of the time was naked flames in lamps. The danger of explosions in some mines was very real, especially as mines were worked at deeper levels underground. The heat of the flame would ignite the mixture of air, coal dust and fire damp (methane) found in the mines, causing an explosion. In 1815, within six months of being asked to devise a safe lamp, Davy had the solution. He discovered that the heat of a candle flame would not pass along a narrow metal tube, as the metal conducted the heat away. This meant that a mixture of air and coal dust at one end of the tube could not be ignited by a candle at the other end. Applying this discovery, Davy completely surrounded the flame of a lamp with a piece of metal gauze. The gauze acted as a huge number of short metal tubes and conducted the heat of the flame away from the explosive gas outside the lamp. The gas was not heated by the lamp and did not explode. The gauze did not block the light from the lamp. The new lamp was adopted widely and saved many lives. In appreciation, the mine owners of Tyne and Wear in Northeast England honoured Davy with a valuable gold plate. The Davy lamp meant that they could work coal seams previously thought too dangerous.

Numerous other achievements can be attributed to this great scientist. He investigated the effect of breathing the gas nitrous oxide. It was thought at the time that the gas had the power to spread diseases. Davy decided to test the gas on himself and

breathed two quarts from a silk bag. He found that the gas made him feel drunk, in a pleasant sort of way. When his friends breathed the gas, some laughed uncontrollably, so the gas became known as laughing gas. Davy also noticed that the gas eased the pain of a toothache he had been suffering. He commented: 'as nitrous oxide appears to destroy pain it may probably be used to advantage during surgical operations'. This suggestion was not taken up for another 45 years, when it was used by an American dentist, Horace Wells, as an anaesthetic.

Davy also introduced a chemical approach to agriculture, the tanning industry and mineralogy; he designed an arc lamp for illumination, an electrolytic process for the desalination of sea water and a method of cathodic protection for the copper-clad ships of the day by connecting them to zinc plates. But his genius has been described as flawed. At his best, he was a scientist of great perception, a painstaking laboratory worker and a brilliant lecturer. At other times, he was disorganized, readily distracted and prone to hasty decisions and arguments. He was snobbish, over-excitable, suspicious and ungenerous to those he saw as scientific rivals. In 1824 he tried to block the election of his protégé Michael Faraday to the Royal Society, even after Faraday had demonstrated his genius by devising the first simple electric motor and discovering benzene. Ironically, many regard Faraday as Davy's finest discovery.

In 1824, the people of Penzance decided to honour Davy. The local newspaper reported: 'At the general meeting in Penzance it was unanimously resolved that a public dinner be given to Sir Humphry Davy at the Union Hotel in Chapel Street, and that the Mayor be required to wait on him forthwith.' Later they wrote: 'Every heart, tongue and eye were as one to do honour to him who had not only rendered the name of their town as famous and imperishable as science itself, but (who had added lustre to the intellectual character of their country and)... who is one of the happy few who can claim to be permanent benefactors to the human race.' It is not recorded whether his old headmaster was present!

sailfish marine bony fish. The snout is long and pointed and the dorsal fin is unusually large. It is blue above, silver below, and over 3 m/10 ft long. It can swim up to 100 km/60 mi in pursuit of the fish it eats.

classification Sailfish belong to genus *Istiophorus* in the order Perciformes, class Osteichthyes.

St Bernard breed of large, heavily built dog, named after the monks of Grand St Bernard Hospice, Switzerland, who kept them for finding lost travellers in the Alps and to act as guides. They are 70 cm/30 in high at the shoulder, and weigh about 70 kg/154 lb. They have pendulous ears and lips, large feet, and drooping lower eyelids. They are usually orange and white.

St Elmo's fire bluish, flame-like electrical discharge that sometimes occurs above ships' masts and other pointed objects or about aircraft in stormy weather. Although high voltage, it is low current and therefore harmless. St Elmo (or St Erasmus) is the patron saint of sailors.

saki New World tree-dwelling monkey with a long, non-prehensile tail. There are four species: the white-faced saki, monk saki, black bearded saki, and white-nosed bearded saki. They are found only in the Amazon valley and Guiana.

classification Sakis are in the genera *Pithecia* and *Chiropotes* (bearded sakis) in the family Cebidae, order Primates.

salamander tailed amphibian of the order Urodela. They are sometimes confused with lizards, but unlike lizards they have no

Sakharov, Andrei Dmitrievich (1921–1989)

Soviet physicist. He was an outspoken human-rights campaigner, who with Igor Tamm (1895–1971) developed the hydrogen bomb. He later protested against Soviet nuclear tests and was a founder of the Soviet Human Rights Committee 1970, winning the Nobel Peace Prize 1975. For criticizing Soviet action in Afghanistan, he was in internal exile 1980–86.

Sakharov was elected to the Congress of the USSR People's Deputies 1989, where he emerged as leader of its radical reform grouping before his death later the same year.

Mary Evans Picture Library

scales or claws. Salamanders have smooth or warty moist skin. The order includes some 300 species, arranged in nine families, found mainly in the northern hemisphere. Salamanders include hellbenders, *amphibians*, olms, waterdogs, sirens, mole salamanders, *newts*, and lungless salamanders (dusky, woodland, and spring salamanders).

They eat insects and worms, and live in water or in damp areas in the northern temperate regions, mostly feeding at night and hiding during the day, and often hibernating during the winter. Fertilization is either external or internal, often taking place in water. The larvae have external gills. Some remain in the larval form, although they become sexually mature and breed; this is called neoteny. The Mexican *axolotl* and the mud puppy *Necturus maculosus* of North America are neotenic.

According to fossil evidence, giant salamanders were once common throughout Europe, and reached up to 2.3 m in length.

sal ammoniac former name for ammonium chloride.

salicylic acid $\text{HOOC}_6\text{H}_4\text{COOH}$ the active chemical constituent of aspirin, an analgesic drug. The acid and its salts (salicylates) occur naturally in many plants; concentrated sources include willow bark and oil of wintergreen.

When purified, salicylic acid is a white solid that crystallizes into prismatic needles at $318^\circ\text{F}/159^\circ\text{C}$. It is used as an antiseptic, in food preparation and dyestuffs, and in the preparation of aspirin.

saliva in vertebrates, an alkaline secretion from the salivary glands that aids the swallowing and digestion of food in the mouth. In mammals, it contains the enzyme amylase, which converts starch to sugar. The salivary glands of mosquitoes and other blood-sucking insects produce anticoagulants.

SALIVA

The Chinese delicacy of bird's nest soup is in fact a bowl of coagulated swiftlet saliva. Asian cave swiftlets make their tiny cup-shaped nests from layer upon layer of their quick drying saliva.

salivary gland or **parotid gland** in mammals, one of two glands situated near the mouth responsible for the manufacture of saliva and its secretion into the mouth. The salivary glands are stimulated to produce saliva during a meal. Saliva contains an enzyme, ptyalin, and mucous which are essential for the mastication and initial digestion of food.

Salk, Jonas Edward (1914–1995)

US physician and microbiologist. In 1954 he developed the original vaccine that led to virtual eradication of paralytic polio in industrialized countries. He was director of the Salk Institute for Biological Studies, University of California, San Diego, 1963–75.

sally certain Australian eucalypts and wattles thought to resemble the willow (genus *Salix*) in habit or foliage. Two species recognized in the timber industry are the black sally *Eucalyptus stellulata* found in New South Wales and Victoria and the white sally *Eucalyptus pauciflora* of South Australia, Tasmania, Victoria, and New South Wales.

salmon any of the various bony fishes of the family Salmonidae. More specifically the name is applied to several species of game fishes of the genera *Salmo* and *Oncorhynchus* of North America and Eurasia that mature in the ocean but, to spawn, return to the

freshwater streams where they were born. Their normal colour is silvery with a few dark spots, but the colour changes at the spawning season.

life cycle The spawning season is between Sept and Jan, although they occasionally spawn at other times. The orange eggs, about 6 mm/0.25 in in diameter, are laid on the river bed, fertilized by the male, and then covered with gravel by the female. The incubation period is from five weeks to five months. The young hatched fish are known as alevins, and when they begin feeding they are called parr. At about two years old, the coat becomes silvery, and they are then smolts. Depending on the species, they may spend up to four years at sea before returning to their home streams to spawn (at this stage called grilse), often overcoming great obstacles to get there and die.

salmon farming Salmon are increasingly farmed in cages, and 'ranching' (selectively bred, hatched, and fed before release to the sea). Stocking rivers indiscriminately with hatchery fish may destroy the precision of their homing instinct by interbreeding between those originating in different rivers.

salmonella any of a very varied group of bacteria, genus *Salmonella* that colonize the intestines of humans and some animals. Some strains cause typhoid and paratyphoid fevers, while others cause salmonella (food poisoning), which is characterized by stomach pains, vomiting, diarrhoea, and headache. It can be fatal in elderly people, but others usually recover in a few days without antibiotics. Most cases are caused by contaminated animal products, especially poultry meat.

Human carriers of the disease may be well themselves but pass the bacteria on to others through unhygienic preparation of food. Domestic pets can also carry the bacteria while appearing healthy.

Salmonidae important family of fishes, with a small adipose fin, without fin rays, between the dorsal fin and the tail. Many species live in the sea, but enter fresh water to spawn, afterwards returning to the sea. The salmon, trout, char, and whitefish are included in this family.

classification Salmonidae are in order Salmoniformes, class Osteichthyes.

salsify or **vegetable oyster** hardy biennial plant native to the Mediterranean region. Its white fleshy roots and spring shoots are cooked and eaten; the roots are said to taste like oysters. (*Tragopogon porrifolius*, family Compositae.)

salt in chemistry, any compound formed from an acid and a base through the replacement of all or part of the hydrogen in the acid by a metal or electropositive radical. Common salt is sodium chloride (see *csalt*, common).

A salt may be produced by chemical reaction between an acid and a base, or by the displacement of hydrogen from an acid by a metal (see *displacement activity*). As a solid, the ions normally adopt a regular arrangement to form crystals. Some salts only form stable crystals as hydrates (when combined with water). Most inorganic salts readily dissolve in water to give an electrolyte (a solution that conducts electricity).

TO CREATE A SALT:

IF A SOLUBLE SALT YOU WISH TO PROVIDE, YOU FIRST ON THE ACID SETTLE; THEN NEUTRALIZE WITH THE PROPER OXIDE, HYDROXIDE, CARBONATE OR METAL BUT IF THE SALT WILL NOT DISSOLVE, A SIMPLER MEANS YOU'LL TRY: PRECIPITATE IT, YOU RESOLVE, THEN FILTER, WASH AND DRY

saltation Latin *saltare* 'to leap' in biology, the idea that an abrupt genetic change can occur in an individual, which then gives rise to a new species. The idea has now been largely discredited, although the appearance of polyploid individuals can be considered an example.

saltbush any of a group of drought-resistant plants belonging to the goosefoot family, especially the widespread genus *Atriplex*, used as grazing plants in arid, saline, and alkaline parts of North America, Australia, and S Africa, and the Australian and New Zealand genus *Rhagodia*. Where saltbush is the predominant vegetation, as in SW South Australia, the whole area is referred to as the saltbush. (Family Chenopodiaceae.)

salt, common or **sodium chloride** NaCl white crystalline solid, found dissolved in sea water and as rock salt (the mineral halite) in large deposits and salt domes. Common salt is used extensively in the food industry as a preservative and for flavouring, and in the chemical industry in the making of chlorine and sodium.

salt marsh wetland with halophytic vegetation (tolerant to sea water). Salt marshes develop around estuaries and on the sheltered side of sand and shingle spits. Salt marshes usually have a network of creeks and drainage channels by which tidal waters enter and leave the marsh.

saltpetre former name for potassium nitrate (KNO₃), the compound used in making gunpowder (from about 1500). It occurs naturally, being deposited during dry periods in places with warm climates, such as India.

saluki ancient breed of hunting dog resembling the greyhound. It is about 65 cm/26 in high and has a silky coat, which is usually fawn, cream, or white.

The saluki is a gazehound (hunts by sight) and is descended from the hound of the African desert Bedouins.

Salvarsan historical proprietary name for arsphenamine (technical name 3,3-diamino-4,4-dihydroxyarsenobenzene dichloride), the first specific antibacterial agent, discovered by German bacteriologist Paul Ehrlich in 1909. Because of its destructive effect on *Spirochaeta pallida*, it was used in the treatment of syphilis before the development of antibiotics.

salt volatile another name for smelling salts.

Salyut Russian 'salute' series of seven space stations launched by the USSR 1971-82. Salyut was cylindrical in shape, 15 m/50 ft long, and weighed 19 tonnes/21 tons. It housed two or three cosmonauts at a time, for missions lasting up to eight months.

Salyut 1 was launched 19 April 1971. It was occupied for 23 days in June 1971 by a crew of three, who died during their return to Earth when their Soyuz ferry craft depressurized. In 1973 *Salyut 2* broke up in orbit before occupation. The first fully successful Salyut mission was a 14-day visit to *Salyut 3* July 1974. In 1984-85 a team of three cosmonauts endured a record 237-day flight in *Salyut 7*. In 1986 the Salyut series was superseded by *Mir*, an improved design capable of being enlarged by additional modules sent up from Earth.

samara in botany, a winged fruit, a type of achene.

samarium hard, brittle, grey-white, metallic element of the lanthanide series, symbol Sm, atomic number 62, relative atomic mass 150.4. It is widely distributed in nature and is obtained commercially from the minerals monazite and bastnaesite. It is used only occasionally in industry, mainly as a catalyst in organic reactions. Samarium was discovered by spectroscopic analysis of the mineral samarskite and named 1879 by French chemist Paul Lecoq de Boisbaudran (1838-1912) after its source.

samoyed breed of dog originating in Siberia. It weighs about 25 kg/60 lb and is 58 cm/23 in tall. It resembles a Chow Chow, but has a more pointed face and a white or cream coat.

sapphire or **glasswort** or **sea asparagus** perennial plant found on sea cliffs and coastlines in Europe. The aromatic, salty leaves are fleshy and sharply pointed; the flowers grow in yellow-green open clusters. Sapphire is used in salads, or pickled. (*Crithmum maritimum*, family Umbelliferae.)

sampling measurement of an analogue signal (such as an audio or video signal) at regular intervals. The result of the mea-

surement can be converted into a digital signal that can be electronically enhanced, edited or processed.

San Andreas fault geological fault stretching for 1,125 km/700 mi NW-SE through the state of California, USA. It marks a conservative plate margin, where two plates slide past each other (see *plate tectonics*).

Friction is created as the coastal Pacific plate moves northwest, rubbing against the American continental plate, which is moving slowly southeast. The relative movement is only about 5 cm/2 in a year, which means that Los Angeles will reach San Francisco's latitude in 10 million years. The friction caused by the tectonic movement gives rise to frequent, destructive earthquakes. For example, in 1906 an earthquake originating from the fault almost destroyed San Francisco and killed about 700 people.

SAN ANDREAS FAULT AND BAY AREA

http://sepwww.stanford.edu/oldsep/joe/fault_images/BayAreaSanAndreasFault.html

Detailed tour of the San Andreas Fault and the San Francisco Bay area, with information on the origin of the fault. The site is supported by a full range of area maps.

sand loose grains of rock, sized 0.0625-2.00 mm/0.0025-0.08 in in diameter, consisting most commonly of quartz, but owing their varying colour to mixtures of other minerals. Sand is used in cement-making, as an abrasive, in glass-making, and for other purposes.

Sands are classified into marine, freshwater, glacial, and terrestrial. Some 'light' soils contain up to 50% sand. Sands may eventually consolidate into sandstone.

sandalwood fragrant heartwood of any of several Asiatic and Australian trees, used for ornamental carving, in perfume, and burned as incense. (Genus *Santalum*, family Santalaceae.)

sandbar ridge of sand built up by the currents across the mouth of a river or bay. A sandbar may be entirely underwater or it may form an elongated island that breaks the surface. A sandbar stretching out from a headland is a sand spit.

Coastal bars can extend across estuaries to form bay bars.

sand eel small, carnivorous fish found near the coasts of temperate seas of the northern hemisphere. Their bodies are covered with small scales, the swimbladder is absent, and they have long, sharply pointed snouts with which they bury themselves in the sand.

classification Sand eels are in genus *Ammodytes* in the family Ammodytidae, belonging to the order Perciformes, class Osteichthyes.

sandflea another name for *Cigger*.

sandgrouse any bird of the family Pteroclididae, order Columbiformes. They look like long-tailed grouse, but are actually closely related to pigeons. They live in warm, dry areas of Europe,

SANDGROUSE

A sandgrouse can hold about 9,000 seeds in its crop (that part of its anatomy used to store food). This is useful, as ground-feeding is a risky business and the birds need to feed rapidly as they move about.

Asia, and Africa and have long wings, short legs and bills, a wedge-shaped tail, and thick skin. They are sandy coloured and feed on vegetable matter and insects.

Sandgrouse may travel long distances to water to drink, and some carry water back to their young by soaking the breast feathers. The pin-tailed sandgrouse *Pterocles alchata* is a desert bird living in southern Europe, Africa, and Asia.

sand hopper or *beach flea* any of various small crustaceans belonging to the order Amphipoda, with laterally compressed bodies, that live in beach sand and jump like fleas. The eastern sand hopper *Orchestia agilis* of North America is about 1.3 cm/0.5 in long.

sand lizard lizard found on sandy heaths in Britain and central Europe, growing to nearly 20 cm/8 in in length. The male is brownish above, and in the spring a bright green on the flanks and belly. The female is brownish or greyish and mottled all over. They are active burrowers.

classification The sand lizard *Lacerta agilis* is in the suborder Sauria, order Squamata, class Reptilia.

sandpiper shorebird with a long, slender bill, which is compressed and grooved at the tip. They belong to the family Scolopacidae, which includes godwits, curlews, and snipes, order Charadriiformes.

sandstone sedimentary rocks formed from the consolidation of sand, with sand-sized grains (0.0625–2 mm/0.0025–0.08 in) in a matrix or cement. Their principal component is quartz. Sandstones are commonly permeable and porous, and may form freshwater aquifers. They are mainly used as building materials.

Sandstones are classified according to the matrix or cement material (whether derived from clay or silt; for example, as calcareous sandstone, ferruginous sandstone, siliceous sandstone).

sans-serif font typeface, such as Helvetica or Gill Sans, the strokes of which terminate in plain ends. Such fonts are very clear – hence their use in posters and signposts – but many designers believe that in running text, serif fonts are easier to read.

sap the fluids that circulate through vascular plants, especially woody ones. Sap carries water and food to plant tissues. Sap contains alkaloids, protein, and starch; it can be milky (as in rubber trees), resinous (as in pines), or syrupy (as in maples).

saponification in chemistry, the hydrolysis (splitting) of an ester by treatment with a strong alkali, resulting in the liberation of the alcohol from which the ester had been derived and a salt of the constituent fatty acid. The process is used in the manufacture of soap.

sapphire deep-blue, transparent gem variety of the mineral $\text{corundum Al}_2\text{O}_3$, aluminium oxide. Small amounts of iron and titanium give it its colour. A corundum gem of any colour except red (which is a ruby) can be called a sapphire; for example, yellow sapphire.

saprophyte in botany, an obsolete term for a saprotroph, an organism that lives in dead or decaying matter.

saprotroph (formerly *saprophyte*) organism that feeds on the excrement or the dead bodies or tissues of others. They include most fungi (the rest being parasites); many bacteria and protozoa; animals such as dung beetles and vultures; and a few unusual plants, including several orchids. Saprotrophs cannot make food for themselves, so they are a type of heterotroph. They are useful scavengers, and in sewage farms and refuse dumps break down organic matter into nutrients easily assimilable by green plants.

Sarcodina subphylum of protozoa containing the amoebae.

sarcoidosis chronic disease of unknown cause involving enlargement of the lymph nodes and the formation of small fleshy nodules in the lungs. It may also affect the eyes, and skin, and (rarely) other tissue. Many cases resolve spontaneously or may be successfully treated using corticosteroids.

sarcoma malignant tumour arising from the fat, muscles, bones, cartilage, or blood and lymph vessels and connective tissues. Sarcomas are much less common than carcinomas.

sardine common name for various small fishes (pilchards) in the herring family.

sarin poison gas 20 times more lethal to humans than potassium cyanide. It cripples the central nervous system, blocking the action of an enzyme that removes acetylcholine, the chemical that transmits signals. Sarin was developed in Germany during World War II.

Sarin was used in 1995 in a terrorist attack on the Tokyo underground by a Japanese sect. It is estimated that the USA had a stockpile of 15,000 tonnes of sarin, and more than 1,000 US rockets with sarin warheads were found to be leaking in 1995. There are no known safe disposal methods.

SARIN

<http://www.outbreak.org/cgi-unreg/dynaserve.exe/cb/sarin.html>

Outbreak page on the nerve agent sarin. The Website contains sections on the characteristics of sarin, its toxicology, symptoms it causes, cautions and precautions, first aid therapy for victims of the gas, and a list of neutralization and decontamination methods.

The human race has today the means for annihilating itself.

MAX BORN German-born British physicist.
Bulletin of the Atomic Scientists June 1957

satellite any small body that orbits a larger one, either natural or artificial. Natural satellites that orbit planets are called moons. The first artificial satellite, *Sputnik 1*, was launched into orbit around the Earth by the USSR in 1957. Artificial satellites are used for scientific purposes, communications, weather forecasting, and military applications. The brightest artificial satellites can be seen by the naked eye.

At any time, there are several thousand artificial satellites orbiting the Earth, including active satellites, satellites that have ended their working lives, and discarded sections of rockets. Artificial satellites eventually re-enter the Earth's atmosphere. Usually they burn up by friction, but sometimes debris falls to the Earth's surface, as with *Skylab* and *Salut 7*. In 1997 there were 300 active artificial satellites in orbit around Earth, the majority used in communications.

satellite applications the uses to which artificial satellites are put. These include:

scientific experiments and observation Many astronomical observations are best taken above the disturbing effect of the atmosphere. Satellite observations have been carried out by *IRAS* (*Infrared Astronomical Satellite*, 1983) which made a complete infrared survey of the skies, and *Solar Max* 1980, which observed solar flares. The *Hipparcos* satellite, launched 1989, measured the positions of many stars. The *ROSAT* (Roentgen Satellite), launched June 1990, examined UV and X-ray radiation. In 1992, the COBE (Cosmic Background Explorer) satellite detected details of the Big Bang that mark the first stage in the formation of galaxies. Medical experiments have been carried out aboard crewed satellites, such as the Soviet *Mir* and the US *Skylab*.

reconnaissance, land resource, and mapping applications Apart from military use and routine mapping, the US *Landsat*, the French *SPOT*, and equivalent USSR satellites have provided much useful information about water sources and drainage, vegetation, land use, geological structures, oil and mineral locations, and snow and ice.

weather monitoring The US NOAA series of satellites, and others launched by the European space agency, Japan, and India, provide continuous worldwide observation of the atmosphere.

navigation The US Global Positioning System uses 24 Navstar satellites that enable users (including walkers and motorists) to find their position to within 100 m/328 ft. The US military can make full use of the system, obtaining accuracy to within 1.5 m/4 ft 6 in. The Transit system, launched in the 1960s, with 12 satellites in orbit, locates users to within 100 m/328 ft.

communications A complete worldwide communications network is now provided by satellites such as the US-run Intelsat system.

satellite television transmission of broadcast signals through artificial communications satellites. Mainly positioned in geostationary orbit, satellites have been used since the 1960s to relay television pictures around the world.

Higher-power satellites have more recently been developed to broadcast signals to cable systems or directly to people's homes.

saturated compound organic compound, such as propane, that contains only single covalent bonds. Saturated organic compounds can only undergo further reaction by substitution reactions, as in the production of chloropropane from propane.

saturated fatty acid fatty acid in which there are no double bonds in the hydrocarbon chain.

saturated solution in physics and chemistry, a solution obtained when a solvent (liquid) can dissolve no more of a solute (usually a solid) at a particular temperature. Normally, a slight fall in temperature causes some of the solute to crystallize out of solution. If this does not happen the phenomenon is called supercooling, and the solution is said to be supersaturated.

Saturn in astronomy, the second-largest planet in the Solar System, sixth from the Sun, and encircled by bright and easily visible equatorial rings. Viewed through a telescope it is ochre. Its polar diameter is 12,000 km/7,450 mi smaller than its equatorial diameter, a result of its fast rotation and low density, the lowest of any planet. Its mass is 95 times that of Earth, and its magnetic field 1,000 times stronger.

mean distance from the Sun 1.427 billion km/0.886 billion mi

equatorial diameter 120,000 km/75,000 mi

rotational period 10 hr 14 min at equator, 10 hr 40 min at higher latitudes

year 29.46 Earth years

atmosphere visible surface consists of swirling clouds, probably made of frozen ammonia at a temperature of $-170^{\circ}\text{C}/-274^{\circ}\text{F}$, although the markings in the clouds are not as prominent as Jupiter's. The space probes *Voyager 1* and 2 found winds reaching 1,800 kph/1,100 mph

surface Saturn is believed to have a small core of rock and iron, encased in ice and topped by a deep layer of liquid hydrogen

satellites 18 known moons, more than for any other planet. The largest moon, Titan, has a dense atmosphere. Other satellites include Epimetheus, Janus, Pandora, and Prometheus. The rings visible from Earth begin about 14,000 km/9,000 mi from the planet's cloudtops and extend out to about 76,000 km/47,000 mi. Made of small chunks of ice and rock (averaging 1 m/3 ft across), they are 275,000 km/170,000 mi rim to rim, but only 100 m/300 ft thick. The *Voyager* probes showed that the rings actually consist of thousands of closely spaced ringlets, looking like the grooves in a gramophone record.

SATURN

<http://www.hawastsoc.org/solar/eng/saturn.htm>

How many rings does Saturn have? How many satellites? Find out this and more at this site, which also features a video of a storm in the planet's atmosphere.

Saturn rocket family of large US rockets, developed by Wernher von Braun (1912-1977) for the Apollo project. The two-stage *Saturn IB* was used for launching Apollo spacecraft into orbit around the Earth. The three-stage *Saturn V* sent Apollo spacecraft to the Moon, and launched the *Skybolt* space shuttle. The liftoff thrust of a *Saturn V* was 3,500 tonnes. After Apollo and *Skybolt*, the Saturn rockets were retired in favour of the space shuttle.

sausage tree tropical African tree, which grows up to 12 m/40 ft tall and has purplish flowers. Its gourdlike fruits hang from stalks and look like thick sausages; they can be up to 60 cm/2 ft long and weigh 2-5 kg/5-12 lb. (*Kigelia pinnata*, family Bignoniaceae.)

savanna or **savannah** extensive open tropical grasslands, with scattered trees and shrubs. Savannas cover large areas of Africa, North and South America, and N Australia. The soil is acidic and sandy and generally considered suitable only as pasture for low-density grazing.

A new strain of rice suitable for savanna conditions was developed 1992. It not only grew successfully under test conditions in Colombia but also improved pasture quality so grazing numbers could be increased twentyfold.

sawfish any fish of the order Pristiformes of large, sharklike rays, characterized by a flat, sawlike snout edged with teeth. The common sawfish *Pristis pectinatus*, also called the smalltooth, is more than 6 m/19 ft long. It has some 24 teeth along an elongated snout (2 m/6 ft) that can be used as a weapon.

sawfly any of several families of insects of the order Hymenoptera, related to bees, wasps, and ants, but lacking a 'waist' on the body. The egg-laying tube (ovipositor) of the female is surrounded by a pair of sawlike organs, which it uses to make a slit in a plant stem to lay its eggs. Hornets are closely related.

sawshark member of two genera of sharks. They grow to 1 m/3.3 ft long including the long, sawlike, toothed snout, which is used to attack prey. They are not dangerous to humans.

Although they resemble the sawfish, a ray, their gill-slits are on the sides of the head instead of underneath, and the front edge of the pectoral fins are free, not fused to the head and body.

classification *Pliotrema* and *Pristiophorus*, are in the family Pristiophoridae of order Pristiophoriformes, subclass Elasmobranchii, class Chondrichthyes.

saxifrage any of a group of plants belonging to the saxifrage family, found growing in rocky, mountainous, and alpine areas in the northern hemisphere. They are low plants with groups of small white, pink, or yellow flowers. (Genus *Saxifraga*, family Saxifragaceae.)

SCABIES

<http://biomed.nus.sg/nsc/scabies.html>

Well-presented information about scabies from Singapore's National Skin Centre. There is a picture of the condition and information on its transmission and treatment.

scabies contagious infection of the skin caused by the parasitic itch mite *Sarcoptes scabiei*, which burrows under the skin to deposit eggs. Treatment is by antiparasitic creams and lotions.

scabious any of a group of plants belonging to the teasel family, native to Europe and Asia, with many small, usually purplish-blue flowers borne in a single head on a tall stalk. The small scabious (*S. columbaria*) and the Mediterranean sweet scabious (*S. atropurpurea*) are often cultivated. (Genus *Scabiosa*, family Dipsacaceae.)

scalable font font that can be used at any size and any resolution, on a screen or hard-copy device, such as a laser printer or image setter. Scalable fonts are always outline fonts.

scalar quantity in mathematics and science, a quantity that has magnitude but no direction, as distinct from a vector quantity, which has a direction as well as a magnitude. Temperature, mass, and volume are scalar quantities.

scale the numerical relationship, expressed as a ratio, between the actual size of an object and the size of an image that represents it on a map, plan, or diagram.

scale in chemistry, calcium carbonate deposits that form on the inside of a kettle or boiler as a result of boiling hard water.

scale insect any small plant-sucking insect, order Homoptera, of the superfamily Coccoidea. Some species are major pests – for example, the citrus mealy bug (genus *Pseudococcus*), which attacks citrus fruits in North America. The female is often wingless and legless, attached to a plant by the head and with the body covered with a waxy scale. The rare males are winged.

scaler instrument that counts the number of radioactive particles passing through a radiation detector such as a Geiger-Müller tube (the scaler and tube together form a Geiger counter). It gives the total, or cumulative, number of particles counted whereas a ratemeter gives the number of particles detected in a unit of time.

scallop any marine bivalve mollusc of the family Pectinidae, with a fan-shaped shell. There are two 'ears' extending from the sock-like hinge. Scallops use water-jet propulsion to move through the water to escape predators such as starfish. The giant Pacific scallop found from Alaska to California can reach 20 cm/s in width.

scaly anteater another name for the pangolin.

scandium silver-white, metallic element of the lanthanide series, symbol Sc, atomic number 21, relative atomic mass 44.956.

Its compounds are found widely distributed in nature, but only in minute amounts. The metal has little industrial importance.

Scandium is relatively more abundant in the Sun and other stars than on Earth. Scandium oxide (scandia) is used as a catalyst, in making crucibles and other ceramic parts, and scandium sulphate (in very dilute aqueous solution) is used in agriculture to improve seed germination.

scanner in computing, a device that can produce a digital image of a document for input and storage in a computer. It uses technology similar to that of a photocopier. Small scanners can be passed over the document surface by hand; larger versions have a flat bed, like that of a photocopier, on which the input document is placed and scanned.

Scanners are widely used to input graphics for use in desktop publishing. If text is input with a scanner, the image captured is seen by the computer as a single digital picture rather than as separate characters. Consequently, the text cannot be processed by, for example, a word processor unless suitable optical character-recognition software is available to convert the image to its constituent characters. Scanners vary in their resolution, typical hand-held scanners ranging from 75 to 300 dpi. Types include flat-bed, drum, and overhead.

scanner device, usually electronic, used to sense and reproduce an image.

Magnetic resonance imaging (MRI) was being used in 1990 to tell stale food from fresh: the image of a fresh vegetable is different from that of one frozen and thawed. It is also used in medical diagnosis.

scanning in medicine, the noninvasive examination of body organs to detect abnormalities of structure or function. Detectable waves – for example, ultrasound, gamma, or X-rays – are passed through the part to be scanned. Their absorption pattern is recorded, analysed by computer, and displayed pictorially on a screen.

scanning electron microscope (SEM) electron microscope that produces three-dimensional images, magnified 10–200,000 times. A fine beam of electrons, focused by electromagnets, is moved, or scanned, across the specimen. Electrons reflected from the specimen are collected by a detector, giving rise to an electrical signal, which is then used to generate a point of brightness on a television-like screen. As the point moves rapidly over the screen, in phase with the scanning electron beam, an image of the specimen is built up.

The resolving power of an SEM depends on the size of the electron beam – the finer the beam, the greater the resolution. Present-day instruments typically have a resolution of 7–10 nm.

The first scanning electron picture was produced in 1935 by Max Knoll of the German company Telefunken, though the first commercial SEM (produced by the Cambridge Instrument Company in the UK) did not go on sale until 1965.

scanning transmission electron microscope (STEM) electron microscope that combines features of the scanning electron microscope (SEM) and the transmission electron microscope (TEM). First built in the USA in 1966, the microscope has both the SEM's contrast characteristics and lack of aberrations and the high resolution of the TEM. Magnifications of over 90 million times can be achieved, enough to image single atoms.

A fine beam of electrons, 0.3 nm in diameter, moves across the specimen, as in an SEM. However, because the specimen used is a thin slice, the beam also passes through the specimen (as in a TEM). The reflected electrons and those that penetrated the specimen are collected to form an electric signal, which is interpreted by computer to form an image on screen.

scanning tunnelling microscope (STM) microscope that produces a magnified image by moving a tiny tungsten probe across the surface of the specimen. The tip of the probe is so fine that it may consist of a single atom, and it moves so close to the specimen surface that electrons jump (or tunnel) across the gap between the tip and the surface.

The magnitude of the electron flow (current) depends on the distance from the tip to the surface, and so by measuring the current, the contours of the surface can be determined. These can be used to form an image on a computer screen of the surface, with individual atoms resolved. Magnifications up to 100 million times are possible.

The STM was invented 1981 by Gerd Binnig from Germany and Heinrich Rohrer from Switzerland at the IBM Zurich Research Laboratory. With Ernst Ruska, who invented the transmission electron microscope in 1933, they were awarded the Nobel Prize for Physics in 1986.

scapula or **shoulder blade** large, flat, triangular bone which lies over the second to seventh ribs on the back, forming part of the pectoral girdle, and assisting in the articulation of the arm with the chest region. Its flattened shape allows a large region for the attachment of muscles.

scarab any of a family Scarabaeidae of beetles, often brilliantly coloured, and including cockchafer, June beetles, and dung beetles. The *Scarabaeus sacer* was revered by the ancient Egyptians as the symbol of resurrection.

scarlet fever or **scarlatina** acute infectious disease, especially of children, caused by the bacteria in the *Streptococcus pyogenes* group. It is marked by fever, vomiting, sore throat, and a bright red rash spreading from the upper to the lower part of the body. The rash is followed by the skin peeling in flakes. It is treated with antibiotics.

scarp and dip in geology, the two slopes formed when a sedimentary bed outcrops as a landscape feature. The scarp is the slope that cuts across the bedding plane; the dip is the opposite slope which follows the bedding plane. The scarp is usually steep, while the dip is a gentle slope.

scatter diagram or **scattergram** diagram whose purpose is to establish whether or not a relationship or correlation exists between two variables; for example, between life expectancy and

gross national product. Each observation is marked with a dot in a position that shows the value of both variables. The pattern of dots is then examined to see whether they show any underlying trend by means of a line of best fit (a straight line drawn so that its distance from the various points is as short as possible).

scattering in physics, the random deviation or reflection of a stream of particles or of a beam of radiation such as light, by the particles in the matter through which it passes.

alpha particles Alpha particles scattered by a thin gold foil provided the first convincing evidence that atoms had very small, very dense, positive nuclei. From 1906 to 1908 Ernest Rutherford carried out a series of experiments from which he estimated that the closest approach of an alpha particle to a gold nucleus in a head-on collision was about 10^{-14} m. He concluded that the gold nucleus must be no larger than this. Most of the alpha particles fired at the gold foil passed straight through undeviated; however, a few were scattered in all directions and a very small fraction bounced back towards the source. This result so surprised Rutherford that he is reported to have commented: 'It was almost as if you fired a 15-inch shell at a piece of tissue paper and it came back and hit you'. **light** Light is scattered from a rough surface, such as that of a sheet of paper, by random reflection from the varying angles of each small part of the surface. This is responsible for the dull, flat appearance of such surfaces and their inability to form images (unlike mirrors). Light is also scattered by particles suspended in a gas or liquid. The red and yellow colours associated with sunrises and sunsets are due to the fact that red light is scattered to a lesser extent than is blue light by dust particles in the atmosphere. When the Sun is low in the sky, its light passes through a thicker, more dusty layer of the atmosphere, and the blue light radiated by it is scattered away, leaving the red sunlight to pass through to the eye of the observer.

scent gland gland that opens onto the outer surface of animals, producing odorous compounds that are used for communicating between members of the same species (pheromones), or for discouraging predators.

scheltopusik another name for the vglase snake.

schipperke Dutch 'little boatman' from its use on canal barges breed of small dog originally bred in Flanders as a hunter of rats. It has a short, thick, bristly, all-black coat. Of sturdy build, it has a small head with pointed ears; its tail is often completely docked. Schipperkes come in two sizes, the smaller weighing up to 5 kg/11 lb, the larger up to 9 kg/20 lb.

schist metamorphic rock containing mica or another platy or elongate mineral, whose crystals are aligned to give a foliation (planar texture) known as schistosity. Schist may contain additional minerals such as garnet.

schizocarp dry fruit that develops from two or more carpels and splits, when mature, to form separate one-seeded units known as mericarps.

The mericarps may be dehiscent, splitting open to release the seed when ripe, as in *Geranium*, or indehiscent, remaining closed once mature, as in mallow *Malva* and plants of the Umbelliferae family, such as the carrot *Daucus carota* and parsnip *Pastinaca sativa*.

schizophrenia mental disorder, a psychosis of unknown origin, which can lead to profound changes in personality, behaviour, and perception, including delusions and hallucinations. It is more common in males and the early-onset form is more severe than when the illness develops in later life. Modern treatment approaches include drugs, family therapy, stress reduction, and rehabilitation.

Schizophrenia implies a severe divorce from reality in the patient's thinking. Although the causes are poorly understood, it is now recognized as an organic disease, associated with structural anomalies in the brain. Canadian researchers 1995 identified a protein in the brain, PSA-NCAM, that plays a part in filtering sensory information. The protein is significantly reduced in the brains

of schizophrenics, supporting the idea that schizophrenia occurs when the brain is overwhelmed by sensory information.

There is some evidence that early trauma, either in the womb or during delivery, may play a part in causation. There is also a genetic contribution.

There is an enormous inter-country variation in the symptoms of schizophrenia and in the incidence of the main forms of the disease, according to a 1997 report by American investigators. **Paranoid schizophrenia**, characterized by feeling of persecution, is 50% more common in developed countries, whereas **catatonic schizophrenia**, characterized by total immobility, is six times more frequent in developing countries. **Hebephrenic schizophrenia**, characterized by disorganized behaviour and speech and emotional bluntness, is four times more prevalent in developed countries overall but is rare in the USA.

SCHIZOPHRENIA

<http://www.pslgroup.com/schizophr.htm>

Facts about schizophrenia – causes and symptoms, the different types of the disease, how it affects sufferers' family members, available treatments, and new developments. It includes a list of available support resources.

Schmidt Telescope reflecting telescope used for taking wide-angle photographs of the sky. Invented 1930 by Estonian astronomer Bernhard Schmidt (1879–1935), it has an added corrector lens to help focus the incoming light. Examples are the 1.2-m/48-in Schmidt telescope on Mount Palomar and the UK Schmidt telescope, of the same size, at Siding Spring.

schнауzer breed of dog originating in Germany and now found in three sizes: miniature, standard, and giant. All have a coarse coat, either all black or pepper and salt in colour, with a strong, square muzzle and bristly hair on the face. The standard schnauzer (about 48 cm/18 in tall) is used as a general-purpose guard and farm dog; the giant (up to 65 cm/25.5 in) is used as a police and guard dog; the miniature (under 35 cm/14 in) is kept as a pet.

Schneider Trophy aviation trophy presented by Jacques Schneider in 1913 for competition between seaplanes of any nation. From the first holder, M Prévost in 1913, who averaged 73.62 kph/45.75 mph, the trophy changed hands several times before being won outright by Britain, after victories in 1927, 1929 and 1931, the last creating a world record of 547.30 kph/340.08 mph.

Schwarzschild radius in astrophysics, the radius of the event horizon surrounding a black hole within which light cannot escape its gravitational pull.

For a black hole of mass M , the Schwarzschild radius R_s is given by $R_s = 2gm/c^2$, where g is the gravitational constant and c is the speed of light. The Schwarzschild radius for a black hole of solar mass is about 3 km/1.9 mi. It is named after Karl Schwarzschild, the German mathematician who deduced the possibility of black holes from Einstein's general theory of relativity in 1916.

sciatica persistent pain in the back and down the outside of one leg, along the sciatic nerve and its branches. Causes of sciatica include inflammation of the nerve or pressure of a displaced disc on a nerve root leading out of the lower spine.

[Science doesn't deal with facts; indeed] fact is an emotion-loaded word for which there is little place in scientific debate. Science is above all a cooperative enterprise.

HERMANN BONDI Austrian-born British scientist and mathematician.
Nature 1977

science Latin *scientia* 'knowledge' any systematic field of study or body of knowledge that aims, through experiment, observation, and deduction, to produce reliable explanations of phenomena, with reference to the material and physical world.

history Activities such as healing, star-watching, and engineering have been practised in many societies since ancient times. Pure science, especially physics (formerly called natural philosophy), had traditionally been the main area of study for philosophers. The European scientific revolution between about 1650 and 1800 replaced speculative philosophy with a new combination of observation, experimentation, and rationality.

philosophy of science Today, scientific research involves an interaction between tradition, experiment and observation, and deduction. The subject area called philosophy of science investigates the nature of this complex interaction, and the extent of its ability to gain access to the truth about the material world. It has long been recognized that induction from observation cannot give explanations based on logic. In the 20th century Karl Popper has described ϕ scientific method as a rigorous experimental testing of a scientist's ideas or ϕ hypotheses (see hypothesis). The origin and role of these ideas, and their interdependence with observation, have been examined, for example, by the US thinker Thomas S Kuhn, who places them in a historical and sociological setting.

sociology of science The sociology of science investigates how scientific theories and laws are produced, and questions the possibility of objectivity in any scientific endeavour. One controversial point of view is the replacement of scientific realism with scientific relativism, as proposed by Paul K Feyerabend. Questions concerning the proper use of science and the role of science education are also restructuring this field of study.

MAD SCIENTIST NETWORK

<http://medinfo.wustl.edu/~ysp/MSN/>

Indispensable resource for school science teachers and children in need of answers to scientific questions. The Mad Scientist network is a group of scientists prepared to field queries on a vast range of subjects. There is an excellent online archive of previous questions and answers, and helpful guides to accessing other general interest Web science sites.

science park site near a university on which high-technology industrial businesses are housed, so that they can benefit from the research expertise of the university's scientists. Science parks originated in the USA in the 1950s.

scientific law in science, principles that are taken to be universally applicable.

Laws (for instance, ϕ Boyle's law and ϕ Newton's laws of motion) form the basic theoretical structure of the physical sciences, so that the rejection of a law by the scientific community is an almost inconceivable event. On occasion a law may be modified, as was the case when Einstein showed that Newton's laws of motion do not apply to objects travelling at speeds close to that of light.

scientific method in science, the belief that experimentation and observation, properly understood and applied, can avoid the influence of cultural and social values and so build up a picture of a reality independent of the observer.

Techniques and mechanical devices that improve the reliability of measurements may seem to support this theory; but the realization that observations of subatomic particles influence their behaviour has undermined the view that objectivity is possible in science (see ϕ uncertainty principle).

scientific notation alternative term for ϕ standard form.

scilla any of a group of bulbous plants belonging to the lily family, with blue, pink, or white flowers; they include the spring *Scilla* (*S. verna*). (Genus *Scilla*, family Liliaceae.)

scimitar oryx medium-sized ϕ oryx *Oryx dammah*. Its startling, swept-back horns have made it a prime target for hunters. It was once found over virtually the whole of the Sahel. Numbers started to decline sharply in the 1950s and the animals were reduced to scattered groups by the 1970s, then reached the edge of extinction by the 1980s. The initial cause of decline was the destruction of grasslands, but savage hunting annihilated the remainder. There are captive breeding herds and plans to reintroduce the species in Tunisia.

scintillation counter instrument for measuring very low levels of radiation. The radiation strikes a scintillator (a device that emits a unit of light when a charged elementary particle collides with it), whose light output is 'amplified' by a ϕ photomultiplier; the current pulses of its output are in turn counted or added by a scaler to give a numerical reading.

sclerenchyma plant tissue whose function is to strengthen and support, composed of thick-walled cells that are heavily lignified (toughened). On maturity the cell inside dies, and only the cell walls remain.

Sclerenchyma may be made up of one or two types of cells: *sclereids*, occurring singly or in small clusters, are often found in the hard shells of fruits and in seed coats, bark, and the stem cortex; *fibres*, frequently grouped in bundles, are elongated cells, often with pointed ends, associated with the vascular tissue (ϕ xylem and ϕ phloem) of the plant.

Some fibres provide useful materials, such as flax from *Linum usitatissimum* and hemp from *Cannabis sativa*.

sclerosis any abnormal hardening of body tissues, especially the nervous system or walls of the arteries. See ϕ multiple sclerosis and *vatherosclerosis*.

scoliosis lateral (sideways) deviation of the spine. It may be congenital or acquired (through bad posture, illness, or other deformity); or it may be idiopathic (of unknown cause). Treatments include mechanical or surgical correction, depending on the cause.

Scombridae important family of bony fish, which include the bonito, mackerel, tuna or tunny, and wahoo.

Fossil forms of Scombridae are found in the Eocene and Miocene strata.

classificati Scombridae is in order Perciformes, class Osteichthyes.

Scorpio alternative term for ϕ Scorpius.

SCORPION

If disturbed, whip scorpions emit a spray that is 84% acetic acid (the acid in vinegar). The spray also contains a powerful solvent to ensure that the irritant acid penetrates its target fully.

scorpion any arachnid of the order Scorpiones, common in the tropics and subtropics. Scorpions have four pairs of walking legs, large pincers, and long tails ending in upcurved poisonous stings.

WELCOME TO THE SCORPION EMPORIUM

<http://wrbu.si.edu/www/stockwell/emporium/emporium.html>

Complete source of information on the nippy creepy crawlies. There is an interesting list of frequently asked questions about scorpions. A gallery of photos aids identification of a particular species. There is advice on looking after scorpions and even what to do if they turn on you.

though the venom is not usually fatal to a healthy adult human. Some species reach 25 cm/10 in. There are about 600 different species.

They are nocturnal in habit, hiding during the day beneath stones and under the loose bark of trees. The females are viviparous (producing live young), the eggs being hatched in the enlarged oviducts. Scorpions sometimes prey on each other, but their main food is the woodlouse. They seize their prey with their powerful claws or palpi. They are also able to survive for a long time without eating; one scorpion managed to survive for 17 months on a single housefly.

scorpion fly any insect of the order Mecoptera. They have a characteristic downturned beak with jaws at the tip, and many males have a scorpion-like upturned tail, giving them their common name. Most feed on insects or carrion. They are an ancient group with relatively few living representatives.

Scorpius bright zodiacal constellation in the southern hemisphere between ♏Libra and ♐Sagittarius, represented as a scorpion. The Sun passes briefly through Scorpius in the last week of Nov. The heart of the scorpion is marked by the bright red supergiant star ♀Antares. Scorpius contains rich ♀Milky Way star fields, plus the strongest X-ray source in the sky, Scorpius X-1. The whole area is rich in clusters and nebulae. In astrology, the dates for Scorpius are about 24 Oct–21 Nov (see ♀precession).

Scottish Fold cat breed of domestic shorthaired cat with distinctive folded ears. Developed in Scotland in the 1960s from a mutation, it was imported into the USA from the early 1970s. The folded ear flaps either droop forward or forward and downward with the tip almost touching the head. The head is round and set on a well rounded body. The coat, which is short and dense, is acceptable in almost any colour.

The breed was recognized in Britain 1976.

Scottish terrier breed of short-legged terrier used originally to kill foxes and rodents. Its coarse, thick coat is usually black, but may also be brindle or wheaten, and grows long underneath the body; the long bristling hairs around its muzzle and over its eyes are characteristic. It stands about 28 cm/11 in at the shoulder and carries its ears and thick, pointed tail upright.

scrambling circuit in radiotelephony, a transmitting circuit that renders signals unintelligible unless received by the corresponding unscrambling circuit.

scraper earth-moving machine used in road construction. Self-propelled or hauled by a ♀bulldozer, a scraper consists of an open bowl, with a cutting blade at the lower front edge. When moving, the blade bites into the soil, which is forced into the bowl.

scrapie fatal disease of sheep and goats that attacks the central nervous system, causing deterioration of the brain cells, and leading to the characteristic staggering gait and other behavioural abnormalities, before death. It is caused by the presence of an abnormal version of the brain protein PrP and is related to ♀bovine spongiform encephalopathy, the disease of cattle known as 'mad cow disease', and Creutzfeldt-Jakob disease in humans. It is a transmissible spongiform encephalopathy.

In 1996 Dutch researchers announced a test for detecting abnormal PrP in the tonsils of affected sheep before the symptoms of scrapie become apparent.

screeamer any South American marsh-dwelling bird of the family Anhimidae, order Anseriformes; there are only three species, all in the genus *Anhimus*. They are about 80 cm/30 in long, with short curved beaks, long toes, dark plumage, spurs on the fronts of the wings, and a crest or horn on the head.

Screeamers wade in wet forests and marshes, although their feet are scarcely webbed. They are related to ducks and are placed in the same order. The horned screeamer *A. cornuta* is found in certain parts of Central and South America, and has glossy black plumage with a white abdomen; it has a long, slender, yellowish horn on its head.

scree pile of rubble and sediment that collects at the foot of a mountain range or cliff. The rock fragments that form scree are usually broken off by the action of frost (♀freeze-thaw weathering).

With time, the rock waste builds up into a heap or sheet of rubble that may eventually bury even the upper cliffs, and the growth of the scree then stops. Usually, however, erosional forces remove the rock waste so that the scree stays restricted to lower slopes.

screen in computing, another name for monitor.

screen dump in computing, the process of making a printed copy of the current VDU screen display. The screen dump is sometimes stored as a data file instead of being printed immediately.

screen grabber in computing, software which can take a snapshot of the contents of a computer screen and save it as a picture file. Screen grabbers are useful for creating the screen shots seen in many computer magazines to illustrate software reviews and instructions.

screening or health screening the systematic search for evidence of a disease, or of conditions that may precede it, in people who are at risk but not suffering from any symptoms. The aim of screening is to try to limit ill health from preventable diseases that might otherwise go undetected in the early stages. Examples are hypothyroidism and phenylketonuria, for which all newborn babies in Western countries are screened; breast cancer (♀mammography) and cervical cancer; and stroke, for which high blood pressure is a known risk factor.

The criteria for a successful screening programme are that the disease should be important and treatable, the population at risk identifiable, the screening test acceptable, accurate, and cheap, and that the results of screening should justify the costs involved.

screen saver in computing, program designed to prevent a static image from 'burning' itself into the phosphor screen of an idle computer monitor. If the user leaves the computer alone for more than a few minutes, the screen saver automatically displays a moving or changing image – perhaps a sequence of random squiggles, or an animation of flying toasters – on the screen. When the user touches any key, the computer returns to its previous state.

screw in construction, cylindrical or tapering piece of metal or plastic (or formerly wood) with a helical groove cut into it. Each turn of a screw moves it forward or backwards by a distance equal to the pitch (the spacing between neighbouring threads).

Its mechanical advantage equals $2\pi/P$, where P is the pitch and r is the radius of the thread. Thus the mechanical advantage of a tapering wood screw, for example, increases as it is rotated into the wood.

script in communications, a series of instructions for a computer. For example, when users log on to an ISP (Internet Service Provider) or other service, their computers follow a script containing passwords and other information to tell the ISP's server who they are.

scrollback in computing, the automatic scrolling of messages down the screen as they are received in ♀Internet Relay Chat (IRC), ♀bulletin boards or similar forums.

scrollbar in computing, a narrow box along two sides of a ♀window, enabling users to move its contents up, down, left or right. Each end of the scrollbar represents the same end of the document on display, and the ♀mouse is used to move a small 'scroll-box' up and down the bar to scroll the contents or to click on the directional arrows.

scrolling in computing, the action by which data displayed on a VDU screen are automatically moved upwards and out of sight as new lines of data are added at the bottom.

scrub bird one of two Australian birds of the genus *Atrichornis*, order Passeriformes. Both are about 18 cm/7 in long, rather wren-like but long-tailed. Scrub birds are good mimics.

The noisy scrub bird *Atrichornis clamosus* was feared to be extinct, but has been rediscovered, although numbers are still low. The other species is the rufous scrub bird *A. rufescens*.

SCSI (abbreviation for *small computer system interface*) in computing, standard method for connecting peripheral devices (such as printers, scanners and CD-ROM drives) to a computer. A group of peripherals linked in series to a single SCSI port is called a daisy-chain.

scuba (acronym for *self-contained underwater breathing apparatus*) another name for *aqualung*.

scurvy disease caused by deficiency of vitamin C (ascorbic acid), which is contained in fresh vegetables and fruit. The signs are weakness and aching joints and muscles, progressing to bleeding of the gums and other spontaneous haemorrhage, and drying-up of the skin and hair. It is reversed by giving the vitamin.

scurvy grass plant found growing in salt marshes and on banks by the sea in the northern hemisphere. Shoots may grow low, or more upright, up to 50 cm/20 in, with fleshy heart-shaped lower leaves; the flowers are white and have four petals. The edible, sharp-tasting leaves are a good source of vitamin C and were formerly eaten by sailors as a cure for the disease scurvy. (*Cochlearia officinalis*, family Cruciferae.)

scythe harvesting tool with long wooden handle and sharp, curving blade.

It is similar to a sickle. The scythe was in common use in the Middle East and Europe from the dawn of agriculture until the early 20th century, by which time it had generally been replaced by machinery.

Until the beginning of the 19th century, the scythe was used in the hayfield for cutting grass, but thereafter was applied to cereal crops as well, because it was capable of a faster work rate than the sickle. One person could mow 0.4 hectares/1 acre of wheat in a day with a scythe. Next came a team of workers to gather and bind the crop into sheaves and stand them in groups, or stooks, across the field.

SDK (abbreviation for *software development kit*) in computing, suite of programs supplied to software developers to help them develop applications for environments such as Microsoft Windows and Microsoft Office.

sea anemone invertebrate marine animal of the phylum Cnidaria with a tubelike body attached by the base to a rock or shell. The other end has an open 'mouth' surrounded by stinging tentacles, which capture crustaceans and other small organisms. Many sea anemones are beautifully coloured, especially those in tropical waters.

sea anemone Distributed along the west coasts of the British Isles, the snakelocks anemone *Anemonia sulcata* is found on the middle and lower shores. Along with the common beaded anemone, it is the sea anemone most likely to be discovered by the casual observer. Premaphotos Wildlife

sea bass any marine fish of the family Serranidae, of perchlike appearance. Striped bass *Roccus saxatilis* of the E North American coast, is the best known.

seaborgium synthesized radioactive element of the α transactinide series, symbol Sg, atomic number 106, relative atomic mass 263. It was first synthesized 1974 in the USA and given the temporary name unilhexium. The discovery was not confirmed until 1993. It was officially named 1997 after US nuclear chemist Glenn Seaborg.

The University of California, Berkeley, bombarded californium with oxygen nuclei to get isotope 263; the Joint Institute for Nuclear Research, Dubna, Russia, bombarded lead with chromium nuclei to obtain isotopes 259 and 260.

sea butterfly or *pteropod* member of a group of molluscs comprising about 100 species that swim freely in the ocean, having a pair of fins developed from the sides of the mouth and neck, enabling the animal to progress by flapping.

classification Sea butterflies belong to order Tectosomata in subclass Opisthobranchia, class Gastropoda, phylum Mollusca.

sea cucumber any echinoderm of the class Holothuroidea with a cylindrical body that is tough-skinned, knobbed, or spiny. The body may be several feet in length. Sea cucumbers are sometimes called 'cotton-spinners' from the sticky filaments they eject from the anus in self-defence.

The dried flesh of sea cucumbers is a delicacy in Japan and Taiwan, and overfishing has threatened some populations. A high density is vital to sustain a population as they reproduce by releasing sperm or ova into the water; other sea cucumbers must also be releasing sperm or ova nearby.

seafloor spreading growth of the ocean crust outwards (sideways) from ocean ridges. The concept of seafloor spreading has been combined with that of continental drift and incorporated into plate tectonics.

Seafloor spreading was proposed 1960 by US geologist Harry Hess (1906-1969), based on his observations of ocean ridges and the relative youth of all ocean beds. In 1963, British geophysicists Fred Vine and Drummond Matthews observed that the floor of the Atlantic Ocean was made up of rocks that could be arranged in strips, each strip being magnetized either normally or reversely (due to changes in the Earth's polarity when the North Pole becomes the South Pole and vice versa, termed *polar reversal*). These strips were parallel and formed identical patterns on both sides of the ocean ridge. The implication was that each strip was formed at some stage in geological time when the magnetic field was polarized in a certain way. The seafloor magnetic-reversal patterns could be matched to dated magnetic reversals found in terrestrial rock. It could then be shown that new rock forms continuously and spreads away from the ocean ridges, with the oldest rock located farthest away from the midline. The observation was made independently 1963 by Canadian geologist Lawrence Morley, studying an ocean ridge in the Pacific near Vancouver Island.

seagull common name for a number of gull species.

sea hare marine mollusc widely distributed around Britain that occurs offshore amongst kelps.

The sea hare comes on shore during the summer to spawn. The shell is greatly reduced and internal and the animal relies for protection on its cryptic coloration (matching the background) that it acquires from the algae upon which it feeds. When disturbed, it releases a purple fluid that acts as a smoke screen and allows it to escape, either by crawling, or swimming by means of winglike projections developed from the mantle.

classification Sea hares are in order Anaspidea in the subclass Opisthobranchia, class Gastropoda, phylum Mollusca.

sea horse any marine fish of several related genera, especially *Hippocampus*, of the family Syngnathidae, which includes the pipefishes. The body is small and compressed and covered with bony plates raised into tubercles or spines. The tail is prehensile, and the tubular mouth sucks in small shellfish and larvae as food.

The head and foreparts, usually carried upright, resemble those of a horse. They swim vertically and beat their fins up to 70 times a second.

Unusually for fish, sea horses are monogamous and have a relatively long courtship, from 3–7 days. The female deposits her eggs, from dozens to hundreds, in a special pouch in the male. The male fertilizes the eggs whilst they are in his pouch, and nourishes them for six weeks or so until they are finally released as young fish.

SEA HORSE

The largest sea horse is the Australian leafy sea horse, which grows to 30 cm/12 in.

seakale perennial European coastal plant with broad, fleshy leaves and white flowers; it is cultivated in Europe and the young shoots are eaten as a vegetable. (*Crambe maritima*, family Cruciferae.)

seal aquatic carnivorous mammal of the families Otariidae and Phocidae (sometimes placed in a separate order, the Pinnipedia). The eared seals or sea lions (Otariidae) have small external ears, unlike the true seals (Phocidae). Seals have a streamlined body with thick blubber for insulation, and front and hind flippers. They are able to close their nostrils as they dive, and obtain oxygen from their blood supply while under water. They feed on fish, squid, or crustaceans, and are commonly found in Arctic and Antarctic seas, but also in Mediterranean, Caribbean, and Hawaiian waters.

sea lily any *echinoderm* of the class Crinoidea. In most, the rayed, cuplike body is borne on a sessile stalk (permanently attached to a rock) and has feathery arms in multiples of five encircling the mouth. However, some sea lilies are free-swimming and unattached.

sea lion any of several genera of seals of the family Otariidae (eared seals), which also includes the fur seals. These streamlined animals have large fore flippers which they use to row themselves through the water. The hind flippers can be turned beneath the body to walk on land.

There are two species of sea lion in the northern hemisphere, and three in the south. They feed on fish, squid, and crustaceans. Steller's sea lion *Eumetopias jubatus* lives in the N Pacific, large numbers breeding on the Aleutian Islands. Males may be up to 3.4 m/11 ft long, with a thick neck with a characteristic mane, and

weigh up to one tonne. Females are one-third the weight. The Californian sea lion *Zalophus californianus* only reaches 2.3 m/7 ft, and is the species most often seen in zoos and as a 'performing seal'.

The Australian sea lion *Neophoca cinerea* is found only in southern Australian waters, especially on offshore islands such as Kangaroo Island. It is one of the larger sea lions; males weigh up to 300 kg/660 lb, three times as much as females, and are 2 m/6.5 ft long. The New Zealand sea lion *Phocartos hookeri*, of similar size, is found mainly on Auckland Island, 322 km/200 mi S of New Zealand.

Sealyham breed of terrier dog, named after the place in Pembrokeshire, Wales, where it originated in the 19th century as a cross between the Welsh and Jack Russell terriers. It has a coarse white coat and reaches a height of 30 cm/12 in.

sea mouse any of a genus *Aphrodite* of large marine annelid worms (polychaetes), with oval bodies covered in bristles and usually found on muddy sea floors.

seaplane aeroplane capable of taking off from, and landing on, water. There are two major types, floatplanes and flying boats. The floatplane is similar to an ordinary aeroplane but has floats in place of wheels; the flying boat has a broad hull shaped like a boat and may also have floats attached to the wing tips.

Seaplanes depend on smooth water for a good landing, and since World War II few have been built, although they were widely used in both world wars and the first successful international airlines, such as Pan Am, relied on a fleet of flying boats in the 1920s and 1930s.

sea potato yellow-brown sea urchin *Echinocardium cordatum* covered in short spines, and found burrowing in sand from the lower shore downwards.

search engine in computing, remotely accessible program to help users find information on the Internet. Commercial search engines such as AltaVista and Lycos comprise databases of documents, URLs, USENET articles and more, which can be searched by keying in a key word or phrase. The databases are compiled by a mixture of automated agents (spiders) and webmasters registering their sites. However, only about 50% of Web pages can be accessed by search engines.

searching in computing, extracting a specific item from a large body of data, such as a file or table. The method used depends on how the data are organized. For example, a binary search, which requires the data to be in sequence, involves first deciding which half of the data contains the required item, then which quarter, then which eighth, and so on until the item is found.

season The cause of the seasons. As the Earth orbits the Sun, its axis of rotation always points in the same direction. This means that, during the northern hemisphere summer solstice (21 June), the Sun is overhead in the northern hemisphere. At the northern hemisphere winter solstice (22 December), the Sun is overhead in the southern hemisphere.

search request in computing, a structured request by a user for information from a database. This may be a simple request for all the entries that have a single field meeting a certain condition. For example, a user searching a file of car-registration details might request a list of all the records that have 'VOLKSWAGEN' in the field recording the make of car. In more complex examples, the user may construct a search request using operators like AND, OR, NOT, CONTAINING, and BETWEEN.

sea robin any of a family (Triglidae) of spine-finned coastal fishes, especially the slender sea robin *Prionotus scitulus* of the Gulf and SE North American coast. They have large heads and creep along the sea bottom by means of three fingerlike appendages detached from the pectoral fins.

Sears Tower skyscraper in Chicago, USA, rising 110 storeys to a height of 443 m/1,454 ft. Topped out in 1973, it was then the world's tallest building. It was built as the headquarters of Sears, Roebuck & Co, to provide office accommodation for more than 16,000 people.

sea slug any of an order (Nudibranchia) of marine gastropod molluscs in which the shell is reduced or absent. The order includes some very colourful forms, especially in the tropics. They are largely carnivorous, feeding on hydroids and sponges.

Most are under 2.5 cm/1 in long, and live on the sea bottom or on vegetation, although some live in open waters. Tentacles on the back help take in oxygen.

sea snake one of a number of aquatic venomous snakes. Their tails are compressed laterally, and form powerful swimming organs. The eyes are extremely small, have round pupils, and the snakes are practically blind when out of water. The poison secreted by the animals is very virulent, and is used by them to kill the fish on which they feed.

All the species are viviparous (the young develop inside the mother), and inhabit the Indian and Pacific Oceans. A considerable number of human deaths each year are caused by these animals, particularly in the Indian Ocean.

classification Sea snakes are all members of family Hydrophiidae, order Squamata, class Reptilia.

season period of the year having a characteristic climate. The change in seasons is mainly due to the change in attitude of the Earth's axis in relation to the Sun, and hence the position of the Sun in the sky at a particular place. In temperate latitudes four seasons are recognized: spring, summer, autumn (fall), and winter. Tropical regions have two seasons – the wet and the dry. Monsoon areas around the Indian Ocean have three seasons: the cold, the hot, and the rainy.

The northern temperate latitudes have summer when the southern temperate latitudes have winter, and vice versa. During winter, the Sun is low in the sky and has less heating effect because of the oblique angle of incidence and because the sunlight has further to travel through the atmosphere. The differences between the seasons are more marked inland than near the coast, where the sea has a moderating effect on temperatures. In polar regions the change between summer and winter is abrupt; spring and autumn are hardly perceivable. In tropical regions, the belt of rain associated with the trade winds moves north and south with the Sun, as do the dry conditions associated with the belts of high pressure near the tropics. The monsoon's three seasons result from the influence of the Indian Ocean on the surrounding land mass of Asia in that area.

seasonal affective disorder (SAD) form of depression that occurs in winter and is relieved by the coming of spring. Its incidence decreases closer to the Equator. One type of SAD is associated with increased sleeping and appetite.

It has been suggested that SAD may be caused by changes in the secretion of melatonin, a hormone produced by the pineal body in the brain. Melatonin secretion is inhibited by bright daylight.

sea squirt or *uniculate* any solitary or colonial-dwelling saclike chordate of the class Ascidacea. A pouch-shaped animal attached to a rock or other base, it draws in food-carrying water through

one siphon and expels it through another after straining it through numerous gill slits. The young are free-swimming tadpole-shaped organisms, which, unlike the adults, have a notochord.

Sea squirts have transparent or translucent tunics made of cellulose. They vary in size from a few millimetres to 30 cm/12 in in length and are cylindrical, circular, or irregular in shape. Their defences against predators include sulphuric acid secretion and the accumulation of vanadium, a toxic heavy metal.

seat belt safety device in a motor vehicle or aeroplane that is designed to reduce the risk of injury to a passenger from sudden changes in velocity, such as during a collision or when brakes are applied sharply. In an emergency, it extends the time over which the decelerating force acts on a passenger thereby reducing that force to a safe level. It also spreads the force over a broad band across the chest and over the hip bone, reducing the pressure applied to the person.

sea urchin any of various orders of the class Echinoidea among the phlechinoderms. They all have a globular body enclosed with plates of lime and covered with spines. Sometimes the spines are anchoring organs, and they also assist in locomotion. Sea urchins feed on seaweed and the animals frequenting them, and some are edible, as is their roe.

sea water the water of the seas and oceans, covering about 70% of the Earth's surface and comprising about 97% of the world's water (only about 3% is fresh water). Sea water contains a large amount of dissolved solids, the most abundant of which is sodium chloride (almost 3% by mass); other salts include potassium chloride, bromide, and iodide, magnesium chloride, and magnesium sulphate. It also contains a large amount of dissolved carbon dioxide, and thus acts as a carbon 'sink' that may help to reduce the greenhouse effect.

seaweed any of a vast group of simple multicellular plant forms belonging to the algae and found growing in the sea, brackish estuaries, and salt marshes, from about the high-tide mark to depths of 100–200 m/300–600 ft. Many seaweeds have holdfasts (attaching them to rocks or other surfaces), stalks, and fronds, sometimes with air bladders to keep them afloat, and are green, blue-green, red, or brown.

Some have traditionally been gathered for food, such as purple laver (*Porphyra umbilicalis*), green laver (*Ulva lactuca*), and carragheen (*Chondrus crispus*). From the 1960s, seaweeds have been farmed, and the alginates (salts) which are extracted are used in convenience foods, ice cream, and animal feeds, as well as in toothpaste, soap, and the manufacture of iodine and glass.

sea urchin The bony skeleton of the sea urchin is often washed up in large numbers on beaches. Known as a test, and often sold as an ornament, it has a relatively smooth surface as the urchin's spines are quickly detached once the animal dies. Premaphotos Wildlife

The ribbonlike seaweed *Undaria*, which arrived in the Mediterranean in the 1980s from Japan attached to imported oysters, is now being grown by the French for export to the Asian market.

seborrhoeic eczema common skin disease affecting any sebaceous (natural oil) producing area of the skin. It is thought to be caused by the yeast *Pityrosporum*, and is characterized by yellowish-red, scaly areas on the skin, and dandruff. Antidandruff shampoos are often helpful.

sebum oily secretion from the sebaceous glands that acts as a skin lubricant. A acne is caused by inflammation of the sebaceous glands and over-secretion of sebum.

sec or **s** abbreviation for second, a unit of time.

SECAM (acronym for *Système Electronique Couleur Avec Mémoire*) television and video standard used in France, some states in Eastern Europe, and a few other countries. It is broadly similar to the PAL system used in most of Europe.

secant in trigonometry, the function of a given angle in a right-angled triangle, obtained by dividing the length of the hypotenuse (the longest side) by the length of the side adjacent to the angle. It is the reciprocal of the cosine (sec = 1/cos). See illustration on page 672.

second basic SI unit (symbol sec or s) of time, one-sixtieth of a minute. It is defined as the duration of 9,192,631,770 cycles of regulation (periods of the radiation corresponding to the transition between two hyperfine levels of the ground state) of the caesium-133 isotope. In mathematics, the second is a unit (symbol ') of angular measurement, equalling one-sixtieth of a minute, which in turn is one-sixtieth of a degree.

secondary data information that has been collected by another agency. Examples of secondary data include government reports and statistics, company reports and accounts, and weather reports in newspapers.

secondary emission in physics, an emission of electrons from the surface of certain substances when they are struck by high-speed electrons or other particles from an external source. It can be detected with a photomultiplier.

secondary growth or **secondary thickening** increase in diameter of the roots and stems of certain plants (notably shrubs and trees) that results from the production of new cells by the cambium. It provides the plant with additional mechanical support and new conducting cells, the secondary xylem and phloem. Secondary growth is generally confined to gymnosperms and,

among the angiosperms, to the dicotyledons. With just a few exceptions, the monocotyledons (grasses, lilies) exhibit only primary growth, resulting from cell division at the apical meristems.

secondary sexual characteristic in biology, an external feature of an organism that is indicative of its gender (male or female), but not the reproductive organs themselves. They include facial hair in men and breasts in women, combs in cockerels, brightly coloured plumage in many male birds, and manes in male lions. In many cases, they are involved in displays and contests for mates and have evolved by sexual selection. Their development is stimulated by sex hormones.

secretary bird ground-hunting, long-legged, mainly grey-plumaged bird of prey *Sagittarius serpentarius*. It is about 1.2 m/4 ft tall, with an erectile head crest tipped with black. It is protected in southern Africa because it eats poisonous snakes.

It gets its name from the fact that its head crest supposedly looks like a pen behind a clerk's ear. It is the only member of the family Sagittariidae, in the same order (Falconiformes) as vultures, eagles, and hawks.

secretin hormone produced by the small intestine of vertebrates that stimulates the production of digestive secretions by the pancreas and liver.

secretion in biology, any substance (normally a fluid) produced by a cell or specialized gland, for example, sweat, saliva, enzymes, and hormones. The process whereby the substance is discharged from the cell is also known as secretion.

sector in computing, part of the magnetic structure created on a disc surface during disc formatting so that data can be stored on it. The disc is first divided into circular tracks and then each circular track is divided into a number of sectors.

sector in geometry, part of a circle enclosed by two radii and the arc that joins them.

secure HTTP in computing, communications protocol that provides the basis for privacy-enhanced or encrypted communications between a Web browser and a server. Secure HTTP enables users to send private information such as credit card numbers and addresses over the Internet.

secure socket layer (SSL) in computing, standard protocol built into Web browsers such as Netscape and Internet Explorer, which provides an encrypted channel for private information such as credit card numbers and passwords.

Considered a key technology to allow commerce across the World Wide Web, SSL began appearing on the Net in 1995.

security protection against loss or misuse of data; see vdata security.

sedative any drug that has a calming effect, reducing anxiety and tension.

Sedatives will induce sleep in larger doses. Examples are barbiturates, narcotics, and benzodiazepines.

sedge any of a group of perennial grasslike plants, usually with three-cornered solid stems, common in low water or on wet and marshy ground. (Genus *Carex*, family Cyperaceae.)

$$\sec(\text{ant}) \beta = \frac{1}{\cos \beta} = \frac{\text{hypotenuse}}{\text{adjacent}} = \frac{AB}{BC}$$

secant The secant of an angle is a function used in the mathematical study of the triangle. If the secant of angle B is known, then the hypotenuse can be found given the length of the adjacent side, or the adjacent side can be found from the hypotenuse.

TO TELL THE DIFFERENCE BETWEEN GRASSES AND SEDGES:

'SEDGES HAVE EDGES'. UNLIKE GRASSES, SEDGES HAVE THREE-SIDED STEMS IN CROSS-SECTION; ALSO, SEDGES GROW IN WET SPOTS, OFTEN ALONG MARSH EDGES WHEREAS GRASSES PREFER DRIER UPLAND AREAS

sediment any loose material that has 'settled' - deposited from suspension in water, ice, or air, generally as the water current or wind speed decreases. Typical sediments are, in order of

increasing coarseness, clay, mud, silt, sand, gravel, pebbles, cobbles, and boulders.

Sediments differ from sedimentary rocks in which deposits are fused together in a solid mass of rock by a process called lithification. Pebbles are cemented into conglomerates; sands become sandstones; muds become mudstones or shales; peat is transformed into coal.

sedimentary rock rock formed by the accumulation and cementation of deposits that have been laid down by water, wind, ice, or gravity. Sedimentary rocks cover more than two-thirds of the Earth's surface and comprise three major categories: clastic, chemically precipitated, and organic (or biogenic). Clastic sediments are the largest group and are composed of fragments of pre-existing rocks; they include clays, sands, and gravels.

Chemical precipitates include some limestones and evaporated deposits such as gypsum and halite (rock salt). Coal, oil shale, and limestone made of fossil material are examples of organic sedimentary rocks.

Most sedimentary rocks show distinct layering (stratification), caused by alterations in composition or by changes in rock type. These strata may become folded or fractured by the movement of the Earth's crust, a process known as deformation.

Seebeck effect in physics, the generation of a voltage in a circuit containing two different metals, or semiconductors, by keeping the junctions between them at different temperatures. Discovered by the German physicist Thomas Seebeck (1770-1831), it is also called the thermoelectric effect, and is the basis of the thermocouple. It is the opposite of the Peltier effect (in which current flow causes a temperature difference between the junctions of different metals).

seed the reproductive structure of higher plants (angiosperms and gymnosperms). It develops from a fertilized ovule and consists of an embryo and a food store, surrounded and protected by an outer seed coat, called the testa. The food store is contained either in a specialized nutritive tissue, the endosperm, or in the cotyledons of the embryo itself. In angiosperms the seed is enclosed within a fruit, whereas in gymnosperms it is usually naked and unprotected, once shed from the female cone.

castor-oil plant
(dicotyledon)

corn
(monocotyledon)

seed The structure of seeds. The castor is a dicotyledon, a plant in which the developing plant has two leaves, developed from the cotyledon. In maize, a monocotyledon, there is a single leaf developed from the scutellum.

Following germination the seed develops into a new plant.

Seeds may be dispersed from the parent plant in a number of different ways. Agents of dispersal include animals, as with burrs and fleshy edible fruits, and wind, where the seed or fruit may be winged or plumed. Water can disperse seeds or fruits that float, and various mechanical devices may eject seeds from the fruit, as in the pods of some leguminous plants (see legume).

There may be a delay in the germination of some seeds to ensure that growth occurs under favourable conditions (see after-ripening, dormancy). Most seeds remain viable for at least 15 years if dried to about 5% water and kept at $-20^{\circ}\text{C}/-4^{\circ}\text{F}$, although 20% of them will not survive this process.

SEEDS OF LIFE

<http://www.vol.it/mirror/SeedsOfLife/home.html>

Wealth of information about seeds and fruits, with information about the basic structure of a seed, fruit types, how seeds are dispersed, and seeds and humans, plus a mystery seed contest.

seed plant any seed-bearing plant; also known as a **spermatophyte**.

The seed plants are subdivided into two classes: the angiosperms, or flowering plants, and the gymnosperms, principally the cycads and conifers.

Together, they comprise the major types of vegetation found on land.

Angiosperms are the largest, most advanced, and most successful group of plants at the present time, occupying a highly diverse range of habitats. There are estimated to be about 250,000 different species. Gymnosperms differ from angiosperms in their ovules which are borne unprotected (not within an ovary) on the scales of their cones.

The arrangement of the reproductive organs, and their more simplified internal tissue structure, also distinguishes them from the flowering plants. In contrast to the gymnosperms, the ovules of angiosperms are enclosed within an ovary and many species have developed highly specialized reproductive structures associated with pollination by insects, birds, or bats.

seek time in computing, time taken for a read-write head to reach a particular item of data on a disc track.

Sega Japanese games console and software manufacturer. Sega's most successful game is *Sonic the Hedgehog*.

segment in geometry, part of a circle cut off by a straight line or chord, running from one point on the circumference to another. All angles in the same segment are equal.

seismic wave energy wave generated by an earthquake or an artificial explosion. There are two types of seismic waves: **body waves** that travel through the Earth's interior, and **surface waves** that travel through the surface layers of the crust and can be felt as the shaking of the ground, as in an earthquake.

body waves There are two types of body waves: P-waves and S-waves, so-named because they are the primary and secondary waves detected by a seismograph. P-waves are longitudinal waves (wave motion in the direction the wave is travelling), whose compressions and rarefactions resemble those of a sound wave. S-waves are transverse waves or shear waves, involving a back-and-forth shearing motion at right angles to the direction the wave is travelling (see wave).

Because liquids have no resistance to shear and cannot sustain a shear wave, S-waves cannot travel through liquid material. The Earth's outer core is believed to be liquid because S-waves disappear at the mantle-core boundary, while P-waves do not.

surface waves Surface waves travel in the surface and subsurface layers of the crust. **Rayleigh waves** travel along the free surface (the uppermost layer) of a solid material. The motion of particles is

seismograph A seismogram, or recording made by a seismograph. Such recordings are used to study earthquakes and in prospecting.

elliptical, like a water wave, creating the rolling motion often felt during an earthquake. Love waves are transverse waves trapped in a subsurface layer due to different densities in the rock layers above and below. They have a horizontal side-to-side shaking motion transverse (at right angles) to the direction the wave is travelling.

seismograph instrument used to record the activity of an earthquake. A heavy inert weight is suspended by a spring and attached to this is a pen that is in contact with paper on a rotating drum. During an earthquake the instrument moves causing the pen to record a zigzag line on the paper; the pen doesn't move.

seismology study of earthquakes and how their shock waves travel through the Earth. By examining the global pattern of waves produced by an earthquake, seismologists can deduce the nature of the materials through which they have passed. This leads to an understanding of the Earth's internal structure.

On a smaller scale, artificial earthquake waves, generated by explosions or mechanical vibrators, can be used to search for subsurface features in, for example, oil or mineral exploration. Earthquake waves from underground nuclear explosions can be distinguished from natural waves by their shorter wavelength and higher frequency.

seismosaurus plant-eating sauropod dinosaur, *Seismosaurus hallorum*, related to *diplodocus*. It is believed to be the longest dinosaur, with a length of 39–52 m, and a mass of around 100 tonnes. One incomplete skeleton was discovered in the New Mexican desert 1985.

selenium Greek *Selene* 'Moon' grey, nonmetallic element, symbol Se, atomic number 34, relative atomic mass 78.96. It belongs to the sulphur group and occurs in several allotropic forms that differ in their physical and chemical properties. It is an essential trace element in human nutrition.

Obtained from many sulphide ores and selenides, it is used as a red colouring for glass and enamel.

Because its electrical conductivity varies with the intensity of light, selenium is used extensively in photoelectric devices. It was discovered in 1817 by Swedish chemist Jöns Berzelius and named after the Moon because its properties follow those of tellurium, whose name derives from Latin *Tellus* 'Earth'.

self-inductance or **self-induction** in physics, the creation of an electromotive force opposing the current. See *inductance*.

Sellafield site of a nuclear power station on the coast of Cumbria, NW England. It was known as Windscale until 1971, when the management of the site was transferred from the UK Atomic Energy Authority to British Nuclear Fuels Ltd. It reprocesses more than 1,000 tonnes of spent fuel from nuclear reactors annually. The plant is the world's greatest discharger of radioactive waste: between 1968 and 1979, 180 kg/400 lb of plutonium was discharged into the Irish Sea.

In 1996, British Nuclear Fuels was fined £25,000 after admitting 'serious and significant' failures in safety that left a Sellafield plant worker contaminated with radioactivity.

In 1998, the Norwegian environment minister called for a ban on the release of technetium-99 into the sea. It is being released from Sellafield and causing raised concentrations along the coast of Norway.

For accidents, see *nuclear safety*.

semelparity in biology, the occurrence of a single act of reproduction during an organism's lifetime. Most semelparous species produce very large numbers of offspring when they do reproduce, and normally die soon afterwards. Examples include the Pacific salmon and the pine looper moth. Many plants are semelparous, or *ömonocarpic*. Repeated reproduction is called *öteroparity*.

semen fluid containing *ösperm* from the testes and secretions from various sex glands (such as the prostate gland) that is ejaculated by male animals during copulation. The secretions serve to nourish and activate the sperm cells, and prevent them clumping together.

semicircular canal one of three looped tubes that form part of the labyrinth in the inner ear. They are filled with fluid and detect changes in the position of the head, contributing to the sense of balance.

semiconductor material with electrical conductivity intermediate between metals and insulators and used in a wide range of electronic devices. Certain crystalline materials, most notably silicon and germanium, have a small number of free electrons that have escaped from the bonds between the atoms. The atoms from which they have escaped possess vacancies, called holes, which are

similarly able to move from atom to atom and can be regarded as positive charges. Current can be carried by both electrons (negative carriers) and holes (positive carriers). Such materials are known as **intrinsic semiconductors**.

Conductivity of a semiconductor can be enhanced by doping the material with small numbers of impurity atoms which either release free electrons (making an **n-type semiconductor** with more electrons than holes) or capture them (a **p-type semiconductor** with more holes than electrons). When p-type and n-type materials are brought together to form a p-n junction, an electrical barrier is formed which conducts current more readily in one direction than the other. This is the basis of the **semiconductor diode**, used for rectification, and numerous other devices including transistors, rectifiers, and integrated circuits (silicon chips).

semiconductor diode or **p-n junction diode** in electronics, a two-terminal semiconductor device that allows electric current to flow in only one direction, the **forward-bias** direction. A very high resistance prevents current flow in the opposite, or **reverse-bias**, direction. It is used as a **rectifier**, converting alternating current (AC) to direct current (DC).

seminiferous tubule in male vertebrates, one of a number of tightly packed, highly coiled tubes in the testis. The tubes are lined with germinal epithelium cells, from which **sperm** are produced by cell division (**meiosis**) and in the midst of which the sperm mature, nourished and protected in the folds of large Sertoli cells. After maturation, the sperm are stored in a long tube called the **epididymis**.

sendmail in computing, UNIX program for sending e-mail via **TCP/IP** (Transport Control Protocol/Internet Protocol) using **SMTP** (simple mail transfer protocol).

senescence in biology, the deterioration in physical and (sometimes) mental capacities that occurs with ageing.

senile dementia ϕ dementia associated with old age, often caused by ϕ Alzheimer's disease.

sense in mathematics, the orientation of a vector. Each vector has an equivalent vector of the opposite sense. The combined effect of two vectors of opposite sense is a zero vector.

sense organ any organ that an animal uses to gain information about its surroundings. All sense organs have specialized receptors (such as light receptors in the eye) and some means of translating their response into a nerve impulse that travels to the brain. The main human sense organs are the eye, which detects light and colour (different wavelengths of light); the ear, which detects sound (vibrations of the air) and gravity; the nose, which detects some of the chemical molecules in the air; and the tongue, which detects some of the chemicals in food, giving a sense of taste. There are also many small sense organs in the skin, including pain, temperature, and pressure sensors, contributing to our sense of touch.

animal senses Research suggests that our noses may also be sensitive to magnetic forces, giving us an innate sense of direction. This sense is well developed in other animals, as are a variety of senses that we do not share. Some animals can detect small electrical discharges, underwater vibrations, minute vibrations of the ground, or sounds that are below (infrasound) or above (ultrasound) our range of hearing. Sensitivity to light varies greatly. Most mammals cannot distinguish different colours, whereas some birds can detect the polarization of light. Many insects can see light in the ultraviolet range, which is beyond our spectrum, while snakes can form images of infrared radiation (radiant heat). In many animals, light is also detected by another organ, the pineal body, which 'sees' light filtering through the skull, and measures the length of the day to keep track of the seasons.

Science is nothing but trained and organized common sense.

THOMAS HENRY HUXLEY English biologist.
Collected Essays, 'The Method of Zadiq'

sensitivity the ability of an organism, or part of an organism, to detect changes in the environment. Although all living things are capable of some sensitivity, evolution has led to the formation of highly complex mechanisms for detecting light, sound, chemicals, and other stimuli. It is essential to an animal's survival that it can process this type of information and make an appropriate response.

sensor in computing, a device designed to detect a physical state or measure a physical quantity, and produce an input signal for a computer. For example, a sensor may detect the fact that a printer has run out of paper or may measure the temperature in a kiln.

The signal from a sensor is usually in the form of an analogue voltage, and must therefore be converted to a digital signal, by means of an **analogue-to-digital converter**, before it can be input.

sepal part of a flower, usually green, that surrounds and protects the flower in bud. The sepals are derived from modified leaves, and are collectively known as the **calyx**.

In some plants, such as the marsh marigold *Caltha palustris*, where true petals are absent, the sepals are brightly coloured and petal-like, taking over the role of attracting insect pollinators to the flower.

sepsis general term for infectious change in the body caused by bacteria or their toxins.

septicaemia general term for any form of blood poisoning.

septic shock life-threatening fall in blood pressure caused by blood poisoning (septicaemia). Toxins produced by bacteria infecting the blood induce a widespread dilation of the blood vessels throughout the body, and it is this that causes the patient's collapse (see shock). Septic shock can occur following bowel surgery, after a penetrating wound to the abdomen, or as a consequence of infection of the urinary tract. It is usually treated in an intensive care unit and has a high mortality rate.

sequence-control register or **program counter** in computing, a special memory location used to hold the address of the next instruction to be fetched from the immediate access memory for execution by the computer (see **fetch-execute cycle**). It is located in the control unit of the **central processing unit**.

sequencing in biochemistry, determining the sequence of chemical subunits within a large molecule. Techniques for sequencing amino acids in proteins were established in the 1950s, insulin being the first for which the sequence was completed. The ϕ Human Genome Project is attempting to determine the sequence of the 3 billion base pairs within human ϕ DNA.

sequential file in computing, a file in which the records are arranged in order of a **key** field and the computer can use a searching technique, like a **binary** search, to access a specific record. See **file access**.

sequoia either of two species of ϕ conifer tree belonging to the redwood family, native to the western USA. The redwood (*Sequoia sempervirens*) is a long-living timber tree, and one specimen, the Howard Libbey Redwood, is the world's tallest tree at 110 m/361 ft, with a trunk circumference of 13.4 m/44 ft. The giant sequoia (*Sequoiadendron giganteum*) reaches up to 30 m/100 ft in circumference at the base of the trunk, and grows almost as tall as the redwood. It is also (except for the bristlecone pine) the oldest living tree, some specimens being estimated at over 3,500 years of age. (Family Taxodiaceae.)

sere plant ϕ succession developing in a particular habitat. A **lithosere** is a succession starting on the surface of bare rock. A **hydrosere** is a succession in shallow freshwater, beginning with planktonic vegetation and the growth of pondweeds and other aquatic plants, and ending with the development of swamp. A **plagiosere** is the sequence of communities that follows the clearing of the existing vegetation.

serial device in computing, a device that communicates binary data by sending the bits that represent each character one by one along a single data line, unlike a **parallel** device.

serial file in computing, a file in which the records are not stored in any particular order and therefore a specific record can be accessed only by reading through all the previous records. See *file access*.

serial interface in computing, an interface through which data is transmitted one bit at a time.

Serial Line Internet Protocol in computing, method of connecting a computer to the Internet; usually abbreviated to *SLIP*.

seriema flesh-eating bird of the order *Gruiformes*, found in the grasslands of northern Argentina, eastern Bolivia, Paraguay, and parts of Brazil. There are two species: the red-legged seriema *Cariacus cristata* and the black-legged or Burmeister's seriema *Chunga burmeisteri*.

The birds are about 0.7m/2.3 ft tall with long legs and neck. They are poor fliers but excellent runners, reaching speeds of about 60 kph/37 mph. They eat small mammals, reptiles, insects, and other birds. Prey is beaten on the ground until senseless, then swallowed whole.

series circuit electrical circuit in which the components are connected end to end, so that the current flows through them all one after the other. See illustration on page 676.

series circuit In a series circuit, the components of the circuit are connected end to end, so that the current passes through each component one after the other, without division or branching into parallel circuits.

serif font typeface, such as Times or Palatino, the strokes of which terminate in ornamental curves or cross-strokes. These are said to aid legibility.

Serpens constellation on the celestial equator (see *celestial sphere*), represented as a serpent coiled around the body of *Ophiuchus*. It is the only constellation divided into two halves: *Serpens Caput*, the head (on one side of *Ophiuchus*), and *Serpens Cauda*, the tail (on the other side). Its main feature is the Eagle nebula.

serpentine group of minerals, hydrous magnesium silicate, $Mg_3Si_2O_5(OH)_4$, occurring in soft metamorphic rocks and usually dark green. The fibrous form *chrysotile* is a source of asbestos; other forms are *antigorite* and *lizardite*. Serpentine minerals are formed by hydration of ultramafic rocks during metamorphism. Rare snake-patterned forms are used in ornamental carving.

serum clear fluid that separates out from clotted blood. It is blood plasma with the anticoagulant proteins removed, and contains antibodies and other proteins, as well as the fats and sugars of the blood. It can be produced synthetically, and is used to protect against disease.

serval African wild cat *Felis serval*. It is a slender, long-limbed cat, about 1 m/3 ft long, with a yellowish-brown, black-spotted coat. It has large, sensitive ears, with which it locates its prey, mainly birds and rodents.

Servals weigh about 11–13 kg/24–28 lb. They are solitary animals, except for females with young. The young are born (after a gestation of 65–75 days) in litters of four to six and are independent after a year. Sexual maturity is reached at the age of about 2 years, and lifespan is 13–20 years.

server computer used as a store of software and data for use by other computers on a network. See *file server*.

service tree deciduous tree (*S. domestica*) with alternate pinnate leaves (leaflets growing either side of the stem), creamy white flowers, and small, brown, edible, oval fruits, native to Europe and Asia. The European wild service tree (*S. torminalis*) has oblong rather than pointed leaflets. It is related to the ymountain ash. (Genus *Sorbus*, family Rosaceae.)

servomechanism automatic control system used in aircraft, motor cars, and other complex machines. A specific input, such as moving a lever or joystick, causes a specific output, such as feeding current to an electric motor that moves, for example, the rudder of the aircraft. At the same time, the position of the rudder is detected and fed back to the central control, so that small adjustments can continually be made to maintain the desired course.

sesame annual herbaceous plant, probably native to SE Asia, and widely cultivated in India. It produces oily seeds used in cooking and soap making. (*Sesamum indicum*, family Pedaliaceae.)

sessile in botany, a leaf, flower, or fruit that lacks a stalk and sits directly on the stem, as with the sessile acorns of certain oaks. In zoology, it is an animal that normally stays in the same place, such as a barnacle or mussel. The term is also applied to the eyes of crustaceans when these lack stalks and sit directly on the head.

set or **class** in mathematics, any collection of defined things (elements), provided the elements are distinct and that there is a rule to decide whether an element is a member of a set. It is usually denoted by a capital letter and indicated by curly brackets {}.

For example, *L* may represent the set that consists of all the letters of the alphabet. The symbol \in stands for 'is a member of'; thus $p \in L$ means that *p* belongs to the set consisting of all letters, and $4 \notin L$ means that 4 does not belong to the set consisting of all letters.

There are various types of sets. A finite set has a limited number of members, such as the letters of the alphabet; an infinite set has an unlimited number of members, such as all whole numbers; an empty or null set has no members, such as the number of people who have swum across the Atlantic Ocean, written as {} or \emptyset ; a single-element set has only one member, such as days of the week beginning with M, written as {Monday}. Equal sets have the same members; for example, if *W* = {days of the week} and *S* = {Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday}, it can be said that *W* = *S*. Sets with the same number of members are **equivalent sets**. Sets with some members in common are **intersecting sets**; for example, if *R* = {red playing cards} and *F* = {face cards}, then *R* and *F* share the members that are red face cards. Sets with no members in common are **disjoint sets**. Sets contained within others are **subsets**; for example, *V* = {vowels} is a subset of *L* = {letters of the alphabet}.

Sets and their interrelationships are often illustrated by a Venn diagram.

SETI (abbreviation for *search for extra-terrestrial intelligence*) in astronomy, a programme originally launched by NASA in 1992, using powerful radio telescopes to search the skies for extra-terrestrial signals. NASA cancelled the SETI project in 1993, but other privately funded SETI projects continue.

setter any of various breeds of gun dog, called 'setters' because they were trained to crouch or 'set' on the sight of game to be pursued. They stand about 66 cm/26 in high and weigh about 25 kg/55 lb. They have a long, smooth coat, feathered tails, and spaniel-like faces.

The Irish setter is a rich red, the English setter is usually white with black, tan, or liver markings, and the Gordon setter is black and brown.

set-top box box containing decoding equipment for satellite or cable television broadcasts. Such boxes represent a means of linking television sets to a network such as the Internet, enabling people to browse the World Wide Web using their televisions as the monitor, or to view video-on-demand.

Seven Wonders of the World In antiquity, the ϕ pyramids of Egypt, the Hanging Gardens of Babylon, the temple of Artemis at Ephesus, the Greek sculptor Phidias' chryselephantine statue of Zeus at Olympia, the Mausoleum at Halicarnassus, the Colossus of Rhodes, and the lighthouse on the island of Pharos in the Bay of Alexandria.

sewage disposal the disposal of human excreta and other waterborne waste products from houses, streets, and factories. Conveyed through sewers to sewage works, sewage has to undergo a series of treatments to be acceptable for discharge into rivers or the sea, according to various local laws and ordinances. Raw sewage, or sewage that has not been treated adequately, is one serious source of water pollution and a cause of eutrophication.

In the industrialized countries of the West, most industries are responsible for disposing of their own wastes. Government agencies establish industrial waste-disposal standards. In most countries, sewage works for residential areas are the responsibility of local authorities. The solid waste (sludge) may be spread over fields as a fertilizer or, in a few countries, dumped at sea. A significant proportion of bathing beaches in densely populated regions have unacceptably high bacterial content, largely as a result of untreated sewage being discharged into rivers and the sea. This can, for example, cause stomach upsets in swimmers.

The use of raw sewage as a fertilizer (long practised in China) has the drawback that disease-causing microorganisms can survive in the soil and be transferred to people or animals by consumption of subsequent crops. Sewage sludge is safer, but may contain dangerous levels of heavy metals and other industrial contaminants.

sewing machine apparatus for the mechanical sewing of cloth, leather, and other materials by a needle, powered by hand, treadle, or belted electric motor. The popular lockstitch machine, using a double thread, was invented independently in the USA by both Walter Hunt in 1834 and Elias Howe in 1846. Howe's machine was the basis of the machine patented in 1851 by US inventor Isaac ϕ Singer.

In modern microprocessor-controlled sewing machines, as many as 25 different stitching patterns can be selected by push button.

sex chromosome chromosome that differs between the sexes and that serves to determine the sex of the individual. In humans, females have two X chromosomes and males have an X and a Y chromosome.

sex determination process by which the sex of an organism is determined. In many species, the sex of an individual is dictated by the two sex chromosomes (X and Y) it receives from its parents. In mammals, some plants, and a few insects, males are XY, and females XX; in birds, reptiles, some amphibians, and butterflies the reverse is the case. In bees and wasps, males are produced from unfertilized eggs, females from fertilized eggs.

Environmental factors can affect some fish and reptiles, such as turtles, where sex is influenced by the temperature at which the eggs develop. In 1991 it was shown that maleness is caused by a single gene, 14 base pairs long, on the Y chromosome.

sex hormone steroid hormone produced and secreted by the gonads (testes and ovaries). Sex hormones control development and reproductive functions and influence sexual and other behaviour.

sex linkage in genetics, the tendency for certain characteristics to occur exclusively, or predominantly, in one sex only. Human examples include red-green colour blindness and haemophilia, both found predominantly in males. In both cases, these characteristics are ϕ recessive and are determined by genes on the ϕ X chromosome.

Since females possess two X chromosomes, any such recessive ϕ allele on one of them is likely to be masked by the corresponding allele on the other. In males (who have only one X chromosome paired with a largely inert ϕ Y chromosome) any gene on the X chromosome will automatically be expressed. Colour blindness and haemophilia can appear in females, but only if they are ϕ homozygous for these traits, due to inbreeding, for example.

sextant The geometry of the sextant. When the light from a star can be seen at the same time as light from the horizon, the angle A can be read from the position of the index arm on the angle scale.

sextant navigational instrument for determining latitude by measuring the angle between some heavenly body and the horizon. It was invented in 1730 by John Hadley (1682–1744) and can be used only in clear weather.

female reproductive system

male reproductive system

sexual reproduction The human reproductive organs. In the female, gametes called ova are released regularly in the ovaries after puberty. The Fallopian tubes carry the ova to the uterus or womb, in which the baby will develop. In the male, sperm is produced inside the testes after puberty; about 10 million sperm cells are produced each day, enough to populate the world in six months. The sperm duct or vas deferens, a continuation of the epididymis, carries sperm to the urethra during ejaculation.

sexual reproduction Reproductive organs in flowering plants. The stamens are the male parts of the plant. Each consists of a stalklike filament topped by an anther. The anther contains four pollen sacs which burst to release tiny grains of pollen, the male sex cells. The carpels are the female reproductive parts. Each carpel has a stigma which catches the pollen grain. The style connects the stigma to the ovary. The ovary contains one or more ovules, the female sex cells. Buttercups have many ovaries; the lupin has only one.

When the horizon is viewed through the right-hand side horizon glass, which is partly clear and partly mirrored, the light from a star can be seen at the same time in the mirrored left-hand side by adjusting an index mirror. The angle of the star to the horizon can then be read on a calibrated scale.

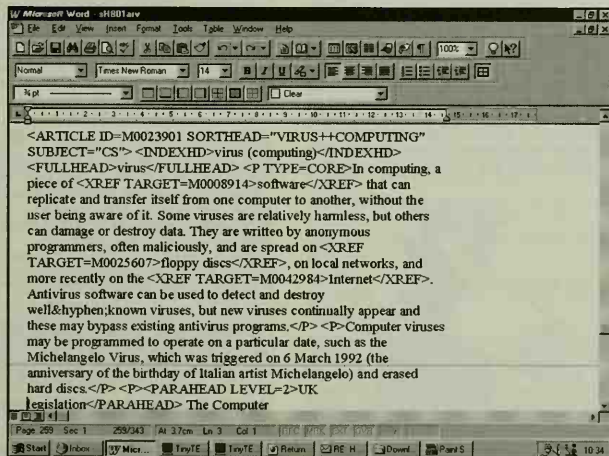

sexton beetle or **burying beetle** carrion-feeding orange and black beetle of the genus *Nicrophorus*. Before laying eggs, sexton beetles must locate an animal carcass and bury it. Once buried, the beetles construct a 'crypt' around the carcass. After laying their eggs in the surrounding soil, they roll the carcass into a ball and coat it with antibacterial secretions. When the larvae hatch 2–3 days later their parents guide them to the carrion that is their food source.

The beetles can bury a mouse carcass within an hour. If the soil beneath the carcass is too hard, the beetles must move the carcass, as they bury the carcass by displacing the soil beneath it. Though the larvae can usually complete their development unassisted, the

parents remain and help them to feed by regurgitating food.

sexually transmitted disease (STD) any disease transmitted by sexual contact, involving transfer of body fluids. STDs include not only traditional venereal disease, but also a growing list of conditions, such as AIDS and scabies, which are known to be spread primarily by sexual contact. Other diseases that are transmitted sexually include viral hepatitis. The WHO estimate that there are 356,000 new cases of STDs daily worldwide (1995).

sexual reproduction reproductive process in organisms that requires the union, or fertilization, of gametes (such as eggs and sperm). These are usually produced by two different individuals, although self-fertilization occurs in a few hermaphrodites such as tapeworms. Most organisms other than bacteria and cyanobacteria (blue-green algae) show some sort of sexual process. Except in some lower organisms, the gametes are of two distinct types called eggs and sperm. The organisms producing the eggs are called

SGML An example of an SGML source file. No on-screen formatting is used; headings and paragraphs are tagged as such and only appear in a different typeface in the final display.

females, and those producing the sperm, males. The fusion of a male and female gamete produces a *zygote*, from which a new individual develops.

sexual selection process similar to (natural selection but relating exclusively to success in finding a mate for the purpose of sexual reproduction and producing offspring. Sexual selection occurs when one sex (usually but not always the female) invests more effort in producing young than the other. Members of the other sex compete for access to this limited resource (usually males competing for the chance to mate with females).

Sexual selection often favours features that increase a male's attractiveness to females (such as the peacock's tail) or enable males to fight with one another (such as a deer's antlers). More subtly, it can produce hormonal effects by which the male makes the female unresponsive to other males, causes the abortion of fetuses already conceived, or removes the sperm of males who have already mated with a female.

Seyfert galaxy galaxy whose small, bright centre is caused by hot gas moving at high speed around a massive central object, possibly a black hole. Almost all Seyferts are spiral galaxies. They seem to be closely related to quasars, but are about 100 times fainter. They are named after their discoverer Carl Seyfert (1911–1960).

SGML (abbreviation for *Standard Generalized Markup Language*) (International Standards Organization standard describing how the structure (features such as headers, columns, margins, and tables) of a text can be identified so that it can be used, probably via filters, in applications such as desktop publishing and electronic publishing. HTML and VRML are both types of SGML.

shackle obsolete unit of length, used at sea for measuring cable or chain. One shackle is 15 fathoms (90 ft/27 m).

shad any of several marine fish, especially the genus *Alosa*, the largest (60 cm/2 ft long and 2.7 kg/6 lb in weight) of the herring family (Clupeidae). They migrate in shoals to breed in rivers.

shadoof or *shaduf* machine for lifting water, consisting typically of a long, pivoted wooden pole acting as a lever, with a weight at one end. The other end is positioned over a well, for example. The shadoof was in use in ancient Egypt and is still used in Arab countries today.

shadow area of darkness behind an opaque object that cannot be reached by some or all of the light coming from a light source in front. Its presence may be explained in terms of light rays travelling in straight lines and being unable to bend round obstacles. A point source of light produces an umbra, a completely black shadow with sharp edges. An extended source of light produces both a central umbra and a penumbra, a region of semidarkness with blurred edges where darkness gives way to light.

shadow Shadows are created as light travels in straight lines and so cannot bend around objects, and is therefore blocked.

(Eclipses are caused by the Earth passing into the Moon's shadow or the Moon passing into the Earth's shadow.)

shag waterbird *Phalacrocorax aristotelis*, order Pelecaniformes, related to the cormorant. It is smaller than the cormorant, with a green tinge to its plumage and in the breeding season has a crest. Its food consists mainly of sand eels for which it dives, staying underwater for up to 54 seconds. It breeds on deeply fissured cliffs, and on rocky parts of isolated islands.

shale fine-grained and finely layered sedimentary rock composed of silt and clay. It is a weak rock, splitting easily along bedding planes to form thin, even slabs (by contrast, mudstone splits into irregular flakes). Oil shale contains kerogen, a solid bituminous material that yields petroleum when heated.

shallot small onion in which bulbs are clustered like garlic; it is used for cooking and in pickles. (*Allium ascalonicum*, family Liliaceae.)

shamrock any of several leguminous plants (see (legume) whose leaves are divided into three leaflets, including clovers. St Patrick is said to have used one to illustrate the doctrine of the Holy Trinity, and it was made the national badge of Ireland. (Family Leguminosae.)

sharecropping farming someone else's land, where the farmer gives the landowner a proportion of the crop instead of money. This system of rent payment was common in the USA, especially the South, until after World War II. It is still common in parts of the developing world; for example, in India. Often the farmer is left with such a small share of the crop that he or she is doomed to poverty.

shared memory bus architecture (SMBA) in computing, system of buses that allows parallel computers to share RAM for greater processing power.

SHAREWARE.COM

<http://www.shareware.com/>

Access to a whole host of add-ons, new applications, upgrades, and games available as free downloads from the Internet. There is a wide variety here, so fortunately, as well as a list of new items and a search engine, the shareware is also organized by the most popular requests from the previous week.

shareware software distributed free via the Internet or on discs given away with magazines. Users have the opportunity to test its functionality and ability to meet their requirements before paying a small registration fee directly to the author. This may bring additional functionality, documentation, and occasional upgrades. Shareware is not copyright-free. Compare with public-domain software.

SHARK

Despite their reputation, about 90% of all species of shark present no threat to humans. They are too small, have inadequate teeth, or live at too great a depth beneath the water.

shark any member of various orders of cartilaginous fish (class Chondrichthyes), found throughout the oceans of the world. There are about 400 known species of shark. They have tough, usually grey skin covered in denticles (small toothlike scales). A shark's

streamlined body has side pectoral fins, a high dorsal fin, and a forked tail with a large upper lobe. Five open gill slits are visible on each side of the generally pointed head. They shed and replace their teeth continually, even before birth. Teeth may be replaced as frequently as every week. Most sharks are fish-eaters, and a few will attack humans. They range from several feet in length to the great white shark *Carcharodon carcharias*, 9 m/30 ft long, and the harmless plankton-feeding whale shark *Rhincodon typus*, over 15 m/50 ft in length.

Relatively few attacks on humans lead to fatalities, and research suggests that the attacking sharks are not searching for food, but attempting to repel perceived rivals from their territory. **endangered species** An estimated 100 million sharks are killed each year for their meat, skin, and oil (basking shark). Some species, such as the great white shark, the tiger shark, and the hammerhead, are now endangered and their killing has been banned in US waters since July 1991. Other species will be protected by catch quotas. The Convention on International Trade in Endangered Species (CITES) agreed in 1994 to investigate the extent of the shark trade.

The fins of 90% of sharks caught are traded, almost all destined for Asia, to be made into soup. Many sharks are 'finned': the fins are sliced from live sharks, which are then thrown back to die. Finning was banned in US Atlantic waters in 1993, and by Canada in 1994. As most sharks tend to be long-lived, not reaching sexual maturity till the age of almost 30, and produce small numbers of young with a high juvenile mortality rate, they are ill-equipped to withstand high levels of fishing.

SHARK

http://www.seaworld.org/animal_bytes/sharkab.html

Illustrated guide to the shark including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

shearwater any sea bird of the genus *Puffinus*. All the species are oceanic, and either dark above and white below or all dark. Shearwaters are members of the same family (Procellariidae), as the diving petrels, order Procellariiformes. They get their name from their habit of skimming low over the sea on still winds.

The sooty shearwater *P. griseus* is common on both North Atlantic coasts. The muttonbird or whalebird *P. tenuirostris* breeds in Australia but for the rest of the year moves over the Pacific; it is killed for meat and oil. The shearwater population around the Californian coast declined by 90% between 1987 and 1994. In a 1997 report, US biologists attributed the loss of the majority of four million birds to global warming because increased water temperatures affect the plankton that shearwaters feed on.

sheath another name for a ϕ condom.

sheathbill white-plumaged shore bird of the southern hemisphere, family Chionidae. The snowy or greater sheathbill *Chionis alba* occurs in the Antarctic region and grows to a length of 39 cm/15 in. It feeds on penguin and seal excrement, and by stealing what it can from penguins feeding their young with half-digested krill.

At breeding times, sheathbills eat unattended penguin eggs. Their own nests are conglomerations of litter – bone, guano, and the remains of dead chicks. They lay two or three eggs but only raise a single chick, probably sacrificing the weaker chick as food for the stronger. Sheathbills are unique as Antarctica's only genuine land-bird, spending most of their time scavenging in penguin colonies.

sheep any of several ruminant, even-toed, hoofed mammals of the family Bovidae. Wild species survive in the uplands of central and eastern Asia, North Africa, southern Europe and North America. The domesticated breeds are all classified as *Ovis aries*.

Various breeds of sheep are reared worldwide for meat, wool, milk, and cheese, and for rotation on arable land to maintain its fertility.

sheepdog any of several breeds of dog, bred originally for herding sheep. The dog now most commonly used by shepherds and farmers in Britain to tend sheep is the ϕ border collie. Non-pedigree dogs of the border collie type, though more variable in size and colour, are referred to as working sheepdogs. Other recognized British breeds are the Old English and ϕ Shetland sheepdogs. Many countries have their own breeds of sheepdog, such as the ϕ Belgian sheepdog, Australian ϕ kelpie, and Hungarian puli.

sheep ked wingless insect that is an external parasite of sheep, feeding on their blood.

Adult keds are particularly well-adapted to clinging to their hosts; they are flattened dorso-ventrally and their legs end in claws. The female fly, which lacks wings, deposits 10–15 larvae which she cements to the sheep's fleece. The oval-shaped, non-motile larvae pupate almost instantaneously while still attached to the host. The newly emerged adults suck the sheep's blood. The sheep react to these irritations by scratching and thus damage their wool. In addition the keds defecate on the wool, which lowers its quality. Dipping the sheep regularly removes the keds.

classification The sheep ked *Melophagus ovinus* is in family Hippoboscidae, suborder Cyclorhapha, order Diptera, class Insecta, phylum Arthropoda.

sheep scab highly contagious disease of sheep, caused by mites that penetrate the animal's skin. Painful irritation, infection, loss of fleece, and death may result. The disease is notifiable in the UK.

shelduck duck *Tadorna tadorna* of family Anatidae, order Anseriformes. It has a dark-green head and red bill, with the rest of the plumage strikingly marked in black, white, and chestnut. The drake is about 60 cm/24 in long. Widely distributed in Europe and Asia, it lays 10–12 white eggs in rabbit burrows on sandy coasts, and is usually seen on estuary mudflats.

shelf sea relatively shallow sea, usually no deeper than 200 m/650 ft, overlying the continental shelf around the coastlines. Most fishing and marine mineral exploitations are carried out in shelf seas.

shell in computing, program that mediates access to a particular system or server. Windows 95 is a shell that interposes a ϕ graphical user interface and other utilities between the operator and ϕ MS-DOS. In DOS itself, the file COMMAND.COM is a shell that makes the operating system display a ϕ prompt and enables it to interpret user instructions. Shells can also be used to improve computer security.

shell the hard outer covering of a wide variety of invertebrates. The covering is usually mineralized, normally with large amounts of calcium. The shell of birds' eggs is also largely made of calcium.

shellac resin derived from secretions of the ϕ lac insect.

shell account in computing, cheap method of accessing the ϕ Internet via another computer, usually a ϕ UNIX machine. Users with a shell account are given text-only access (via the telephone) to another computer connected to the Net.

shellfish popular name for molluscs and crustaceans, including the whelk and periwinkle, mussel, oyster, lobster, crab, and shrimp.

shell script in computing, the UNIX equivalent of batch files created for a program's shell. Essentially, shell scripts allow users to create their own commands by creating a file that contains the sequence of commands they want to run and then designating the file as executable. Thereafter, typing the name of the file executes the sequence of commands.

shell shock or *combat neurosis* or *battle fatigue* any of the various forms of mental disorder that affect soldiers exposed to heavy explosions or extreme ϕ stress. Shell shock was first diagnosed during World War I.

Sheltie breed of dog. See *Shetland sheepdog*.

shepherd's purse annual plant distributed worldwide in temperate zones. It is a persistent weed with white flowers followed by heart-shaped, seed-containing pouches, which give the plant its name. (*Capsella bursa-pastoris*, family Cruciferae.)

Shetland sheepdog or *Sheltie* breed of small herding dog native to the Shetland islands of Scotland. Similar to a rough collie, it has a long coat with a variety of colours and markings, narrow head, pricked ears folded at the tips, and dainty build, but reaches only 36 cm/14 in in height.

SHF in physics, abbreviation for *superhigh frequency*. SHF radio waves have frequencies in the range 3–30 GHz.

shiatsu in alternative medicine, Japanese method of massage derived from *acupuncture* and sometimes referred to as 'acupressure', which treats organic or physiological dysfunctions by applying finger or palm pressure to parts of the body remote from the affected part.

SHIATSU – JAPANESE MASSAGE

http://www1.tip.nl/~t283083/e_index.htm

Well-written introduction to the theoretical underpinnings and the practice of shiatsu. The origins of this ancient Japanese pressure technique are explained with reference to the theory of yin and yang. Diagrams are used to explain techniques. There is a bibliography and list of addresses of shiatsu therapists, services and legal assistance.

shield in geology, alternative name for *craton*, the ancient core of a continent.

shield in technology, any material used to reduce the amount of radiation (electrostatic, electromagnetic, heat, nuclear) reaching from one region of space to another, or any material used as a protection against falling debris, as in tunnelling.

Electrical conductors are used for electrostatic shields, soft iron for electromagnetic shields, and poor conductors of heat for heat shields. Heavy materials, such as lead, and concrete are used for protection against X-rays and nuclear radiation. See also *biological shield* and *cheat shield*.

shifting cultivation farming system where farmers move on from one place to another when the land becomes exhausted. The most common form is *slash-and-burn* agriculture: land is cleared by burning, so that crops can be grown. After a few years, soil fertility is reduced and the land is abandoned. A new area is cleared while the old land recovers its fertility.

Slash-and-burn is practised in many tropical forest areas, such as the Amazon region, where yams, cassava, and sweet potatoes can be grown. This system works well while population levels are low, but where there is overpopulation, the old land will be reused before soil fertility has been restored. A variation of this system, found in parts of Africa, is *rotational bush fallowing* that involves a more permanent settlement and crop rotation.

shih tzu breed of small dog originating in China. It has short legs and a maximum height of 26 cm/10.5 in. Its long, dense coat may be any colour, and it carries its plummy tail over its back. The long hair growing from the top of its muzzle and falling either side of its face gives it its characteristic expression.

Shimbel index a mathematical measurement of the accessibility of a transportation network. It is the total of the number of links or edges that form the shortest path between each node (junctions or places) and all other nodes in the network.

shingles common name for *herpes zoster*, a disease characterized by infection of sensory nerves, with pain and eruption of blisters along the course of the affected nerves.

SHINGLES

<http://biomed.nus.sg/nsc/shingles.html>

Excellent guide to diagnosing and treating herpes zoster from Singapore's National Skin Centre. There are pictures to illustrate the condition.

Shinkansen Japanese 'new trunk line' fast railway network operated by Japanese Railways, on which the 'bullet' trains run. The network, opened 1964, uses specially built straight and level track, on which average speeds of 160 kph/100 mph are attained.

The Shinkansen between Tokyo and Osaka carried 270,000 passengers a day by 1990.

The new Japanese bullet train, *Nozomi-503*, March 1997 hit an average speed of 261.8 kph/163 mph between Hiroshima and Kokura, breaking the current rail speed record. Equipped with a long-nose lead carriage and new sound-proofing for a faster, quieter ride, the *Nozomi-503* carried 1,300 passengers in 16 carriages from Osaka to Fukuoka, hitting speeds of up to 300 kph/187 mph. The official record for average speed between two stations of 252.6 kph/157 mph had been held by the French TGV. The *Nozomi* also matched the top speed reached by the TGV.

ship large seagoing vessel. The Greeks, Phoenicians, Romans, and Vikings used ships extensively for trade, exploration, and warfare. The 14th century was the era of European exploration by sailing ship, largely aided by the invention of the compass. In the 15th century Britain's Royal Navy was first formed, but in the 16th–19th centuries Spanish and Dutch fleets dominated the shipping lanes of both the Atlantic and Pacific.

The ultimate sailing ships, the fast US and British tea clippers, were built in the 19th century. Also in the 19th century, iron was first used for some shipbuilding instead of wood. Steam-propelled ships of the late 19th century were followed by compound engine and turbine-propelled vessels from the early 20th century.

origins The earliest vessels were rafts or dug-out canoes, many of which have been found in Britain, and date from prehistoric times. The Greeks and Phoenicians built wooden ships, propelled by oar or sail. The Romans and Carthaginians built war galleys equipped with rams and several tiers of rowers. The double-ended oak ships of the Vikings were built for rough seas.

development of sailing ships The invention of the stern rudder during the 12th century, together with the developments made in sailing during the Crusades, enabled the use of sails to almost completely supersede that of oars. Following the invention of the compass, and with it the possibilities of exploration, the development of sailing ships advanced quickly during the 14th century. In the 15th century Henry VIII built the *Great Harry*, the first double-decked English warship.

In the 16th century ships were short and high-sterned, and despite Pett's three-decker in the 17th century, English ships did not bear comparison with the Spanish and Dutch until the early 19th century. In the 1840s iron began replacing wood in shipbuilding, pioneered by British engineer Isambard Kingdom Brunel's *Great Britain* in 1845. Throughout the 19th century, improvements were made in warships, including the evolution of the elliptical stern. However, increased rivalry between US and British owners for possession of the Chinese and Indian tea trade led to improvements also being made to the merchant vessel.

The first clipper, the *Ann McKim*, was built in Baltimore in 1832, and Britain soon adopted this type of fast-sailing ship. One of the finest of the tea clippers, the *Sir Launelot*, was built in 1865 and marked the highest development of the sailing ship. The US ship *Champion of the Seas* was one of the fastest of its time, averaging speeds of 20 knots.

Ships: chronology

| | | | |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8000-7000 BC | Reed boats were developed in Mesopotamia and Egypt; dugout canoes were used in northwest Europe. | 1886 | German engineer Gottlieb Daimler built the first boat powered by an internal-combustion engine. |
| 4000-3000 | The Egyptians used single-masted square-rigged ships on the Nile. | 1897 | English engineer Charles Parson fitted a steam turbine to <i>Turbinia</i> , making it the fastest boat of the time. |
| 1200 | The Phoenicians built keeled boats with hulls of wooden planks. | 1900 | Irish-American John Philip Holland designed the first modern submarine <i>Holland VI</i> , fitted with an electric motor for underwater sailing and an internal-combustion engine for surface travel; E. Forlanini of Italy built the first hydrofoil. |
| 1st century BC | The Chinese invented the rudder. | 1902 | The French ship <i>Petit-Pierre</i> became the first boat to be powered by a diesel engine. |
| AD 200 | The Chinese built ships with several masts. | 1955 | The first nuclear-powered submarine, <i>Nautilus</i> , was built in the USA; the hovercraft was patented by British inventor Christopher Cockerell. |
| 200-300 | The Arabs and Romans developed fore-and-aft rigging that allowed boats to sail across the direction of wind. | 1959 | The first nuclear-powered surface ship, the Soviet ice-breaker <i>Lenin</i> , was commissioned; the US <i>Savannah</i> became the first nuclear-powered merchant (passenger and cargo) ship. |
| 800-900 | Square-rigged Viking longboats crossed the North Sea to Britain, the Faroe Islands, and Iceland. | 1980 | Launch of the first wind-assisted commercial ship for half a century, the Japanese tanker <i>Shin-Aitoku-Maru</i> . |
| 1090 | The Chinese invented the magnetic compass. | 1983 | German engineer Ortwin Fries invented a hinged ship designed to bend into a V-shape in order to scoop up oil spillages in its jaws. |
| 1400-1500 | Three-masted ships were developed in western Europe, stimulating voyages of exploration. | 1989 | <i>Gentry Eagle</i> set a record for the fastest crossing of the Atlantic in a power vessel, taking 2 days, 14 hours, and 7 minutes. |
| 1620 | Dutch engineer Cornelius Drebbel invented the submarine. | 1990 | <i>Hoverspeed Great Britain</i> , a wave-piercing catamaran, crossed the Atlantic in 3 days, 7 hours, and 52 minutes, setting a record for the fastest crossing by a passenger vessel. The world's largest car and passenger ferry, the <i>Silja Serenade</i> , entered service between Stockholm and Helsinki, carrying 2,500 passengers and 450 cars. |
| 1776 | US engineer David Bushnell built a hand-powered submarine, <i>Turtle</i> , with buoyancy tanks. | 1992 | Japanese propellerless ship <i>Yamato</i> driven by magnetohydrodynamics completes its sea trials. The ship uses magnetic forces to suck in and eject sea water like a jet engine. |
| 1777 | The first boat with an iron hull was built in Yorkshire, England. | 1997 | The biggest cruise ship ever, the <i>Carnival Destiny</i> , was launched. It is as long as three football pitches, taller than the Statue of Liberty, and too wide to pass through the Panama Canal. US researchers tested a new type of submersible (small submarine) with wings, which can turn, dive, and roll like an aeroplane. |
| 1783 | Frenchman Joffroy d'Abbas built the first paddle-driven steamboat. | | |
| 1802 | Scottish engineer William Symington launched the first stern paddle-wheel steamer, the <i>Charlotte Dundas</i> . | | |
| 1807 | The first successful steamboat, the <i>Clermont</i> , designed by US engineer and inventor Robert Fulton, sailed between New York and Albany. | | |
| 1836 | The screw propeller was patented, by Francis Pettit Smith in the UK. | | |
| 1838 | British engineer Isambard Kingdom Brunel's <i>Great Western</i> , the first steamship built for crossing the Atlantic, sailed from Bristol to New York in 15 days. | | |
| 1845 | <i>Great Britain</i> , also built by Isambard Kingdom Brunel, became the first propeller-driven iron ship to cross the Atlantic. | | |
| 1845 | The first clipper ship, <i>Rainbow</i> , was launched in the USA. | | |
| 1863 | <i>Plongeur</i> , the first submarine powered by an air-driven engine, was launched in France. | | |
| 1866 | The British clippers <i>Taeping</i> and <i>Ariel</i> sailed, laden with tea, from China to London in 99 days. | | |

steamships Early steamers depended partly on sails for auxiliary power. In 1802 the paddle-wheel steamer *Charlotte Dundas*, constructed by William Symington, was launched on the Forth and Clyde Canal, Scotland. However, the effort was halted amid fears that the wash produced by the paddle would damage the canal banks. In 1812 the *Comet*, built in Scotland 1804 by Bell, Napier, and Robertson, was launched. This ship, which had a paddle on each side, was a commercial success, and two others were built for service from Glasgow. From this time the steamship-building industry rapidly developed on the banks of the Clyde.

The first steamship to cross the Atlantic was the Dutch vessel *Curaçao*, a wooden paddler built at Dover 1826, which left Rotterdam in April 1827, and took one month to cross. The next transatlantic steamer, the *Royal William*, crossed from Quebec to London in 17 days in 1833. Britain's entry into the transatlantic efforts began with Brunel's *Great Western* paddle-steamer, which achieved recognition when it completed the journey from Bristol to New York in 15 days—three days faster than a clipper.

The first great iron steamship, *Rainbow*, was launched 1838. In the following year, Pettit Smith designed the *Archimedes*, the first steamer to use a screw propeller, followed quickly by Brunel's *Great Britain*, which crossed from Liverpool to New York in 14.5 days 1845.

In 1862 the Cunard Company obtained permission to fit mail steamers with propellers, which suffered less from the rolling of the ship, and the paddle-wheel was relegated to comparatively smooth

water. The opening of the Suez Canal in 1869, together with the simultaneous introduction of the compound engine, raised steamships to superiority over sailing ships. In 1902 the turbine engine was employed on passenger steamers on the Clyde, and in 1905 was applied to the transatlantic service. This was followed by the introduction of the internal combustion engine.

the Blue Riband of the Atlantic The trophy for the fastest Atlantic crossing, the 'Blue Riband', has been held by many passenger liners, including the Cunarder *Mauretania* (1909-30), the *Queen Mary* (1938-52), and the *United States* (1952-89).

tankers Following World War II, when reconstruction and industrial development created a great demand for oil, the tanker was developed to carry supplies to the areas of consumption. The shipyards of the world were flooded with orders for tankers; due to economic demands, the size of the tankers became increasingly large. The Suez Canal crisis 1956, with its disruption of the free flow of the world's oil supplies, focused attention on the possibility of working giant tankers over the Cape route. The prolonged closure of the Suez Canal after 1967 and the great increase in oil consumption led to the development of the very large tanker, or 'supertanker'.

shock In medicine, circulatory failure marked by a sudden fall of blood pressure and resulting in pallor, sweating, fast (but weak) pulse, and sometimes complete collapse. Causes include disease, injury, and psychological trauma.

In shock, the blood pressure falls below that necessary to supply the tissues of the body, especially the brain. Treatment depends on the cause. Rest is needed, and, in the case of severe blood loss, restoration of the normal circulating volume.

shock absorber in technology, any device for absorbing the shock of sudden jarring actions or movements. Shock absorbers are used in conjunction with coil springs in most motor-vehicle suspension systems and are usually of the telescopic type, consisting of a piston in an oil-filled cylinder. The resistance to movement of the piston through the oil creates the absorbing effect.

shock wave narrow band or region of high pressure and temperature in which the flow of a fluid changes from subsonic to supersonic.

Shock waves are produced when an object moves through a fluid at a supersonic speed. See *sonic boom*.

Shockwave in computing, application that enables interactive and multimedia features, such as movies, sounds, and animations, to be embedded in Web pages. Unlike *Java*, which achieves these effects by using a special programming language, Shockwave allows developers to add items created with conventional authoring tools such as *Director* or *Freehand*.

shoebill or *whale-headed stork* large, grey, long-legged, swamp-dwelling African bird *Balaeniceps rex*. Up to 1.5 m/5 ft tall, it has a large wide beak 20 cm/8 in long, with which it scoops fish, molluscs, reptiles, and carrion out of the mud. It is the only species in the family Balaenicipitidae of the order Ciconiiformes.

shoot in botany, the parts of a vascular plant growing above ground, comprising a stem bearing leaves, buds, and flowers. The shoot develops from the plumule of the embryo.

shooting star another name for a *meteor*.

Short British aircraft manufacturers. The Type 184 seaplane in 1914 was the first aircraft to carry a torpedo and, during the World War I Gallipoli campaign, was the first aircraft to sink an enemy ship with a torpedo.

The firm began by making balloons in 1898 and only turned to aircraft in 1908. The company also manufactured a number of airships for the Royal Flying Corps and Royal Naval Air Service in their Bedford factory.

short circuit unintended direct connection between two points in an electrical circuit.

Its relatively low resistance means that a large current flows through it, bypassing the rest of the circuit, and this may cause the circuit to overheat dangerously.

shortcut in computing, keyboard combination or icon which activates a procedure otherwise available only through pull-down menus and dialog boxes. Most commercial software comes with built-in keyboard shortcuts and pushbuttons, and many allow users to create their own custom shortcuts. In Windows 95, a shortcut is an icon that launches a program direct from the desktop.

short-sightedness nontechnical term for *myopia*.

shoveler fresh-water duck *Anas clypeata*, family Anatidae, order Anseriformes, so named after its long and broad flattened beak used for filtering out small organisms from sand and mud. The male has a green head, white and brown body plumage, black and white wings, greyish bill, orange feet, and can grow up to 50 cm/20 in long. The female is speckled brown. Spending the summer in N Europe or North America, it winters further south.

shovelware in computing, material used to fill (usually) a large-capacity disc, such as a CD-ROM, by 'shovelling it in' without changing or updating it to suit the new format. The term is also used for a disc that is full of old or low-cost material, such as shareware programs or the texts of out-of-copyright books

shredder machine for disposing of confidential documents or computer discs. Paper is shredded into strips or, in high-security machines, into confetti; magnetic discs are cut to pieces or pulverized.

SHREW

The number of chromosomes in the cells of common shrews varies from 20–25 in females and 21–27 in males. They are the only mammals not to have a constant number of chromosomes.

shrew insectivorous mammal of the family Soricidae, order Insectivora, found in the Americas and Eurasia. It is mouse-like, but with a long nose and pointed teeth. Its high metabolic rate means that it must eat almost constantly.

The common shrew *Sorex araneus* is about 7.5 cm/3 in long with a long, supple, pointed snout bearing numerous stiff hairs projecting beyond the lower jaw; its fur is reddish-grey above and greyish beneath. It has glands which secrete a strong, unpleasant odour as a means of defence. It feeds on insects, worms, and often on members of its own kind killed after a fight.

SHREW-(ISTS) SITE

<http://members.vienna.at/shrew/index.html>

Splendid site for the shrew enthusiast that includes images, details of current research, a newsletter, and facts, stories and myths about this animal. There is even a shrew gift shop!

shrike or *butcher-bird* bird of the family Laniidae, of which there are over 70 species, living mostly in Africa, but also in Eurasia and North America. They often impale insects and small vertebrates on thorns. They can grow to 35 cm/14 in long, have grey, black, or brown plumage, sharply clawed feet, and hooked beaks.

shrimp crustacean related to the *crayfish*. It has a cylindrical, semi-transparent body, with ten jointed legs. Some shrimps grow as large as 25 cm/10 in long.

The European common shrimp *Crangon vulgaris* is greenish, translucent, has its first pair of legs ending in pincers, possesses no rostrum (the beaklike structure which extends forwards from the head in some crustaceans), and has comparatively shorter antennae than the prawn. *Squilla regalis*, a shrimp that lives within sponges in the coral reefs of Belize, was discovered in 1996 to live in social colonies with a structure resembling that of social insects, such as ants. All are the offspring of a single reproductive female; care of young is cooperative; and larger individuals act to defend the colony.

shrub perennial woody plant that typically produces several separate stems, at or near ground level, rather than the single trunk of most trees. A shrub is usually smaller than a tree, but there is no clear distinction between large shrubs and small trees.

shunt in electrical engineering, a conductor of very low resistance that is connected in parallel to an ammeter in order to enable it to measure larger electric currents. Its low resistance enables it to act like a bypass, diverting most of the current through itself and away from the ammeter.

SI (abbreviation for *Système International d'Unités*) (French 'International System of Metric Units'); see *SI units*.

sial in geochemistry and geophysics, the substance of the Earth's continental crust, as distinct from the *sim*a of the ocean crust.

The name, now used rarely, is derived from silica and alumina, its two main chemical constituents. Sial is often rich in granite.

siamang the largest gibbon *Symphalangus syndactylus*, native to Malaysia and Sumatra. Siamangs have a large throat pouch to amplify the voice, making the territorial 'song' extremely loud.

They are black-haired, up to 90 cm/3 ft tall, with very long arms (a span of 150 cm/5 ft).

Siamese cat breed of domestic shorthaired cat originating in Thailand. Siamese were imported into Britain in the 1880s and into the US shortly afterwards. It has large pointed ears on a wedge-shaped head, blue eyes, and a long, slender body. In the Seal-point, the original and most popular variety, the fur is cream with dark brown ears, face, tail, legs, and feet. There are now many varieties.

Developed from a Siamese mutant, the Balinese differs from the original only in the length of its coat, which is long. It appeared first in the USA in the late 1940s and recognized there in 1970.

Siamese fighting fish beautiful freshwater fish noted for its colour and elaborate behavioural displays. The male builds a nest of bubbles and looks after the eggs.

classification The Siamese fighting fish *Betta splendens* is in family Belontiidae, order Perciformes, class Osteichthyes.

sick building syndrome malaise diagnosed in the early 1980s among office workers and thought to be caused by such pollutants as formaldehyde (from furniture and insulating materials), benzene (from paint), and the solvent trichloroethene, concentrated in air-conditioned buildings. Symptoms include headache, sore throat, tiredness, colds, and flu. Studies have found that it can cause a 40% drop in productivity and a 30% rise in absenteeism.

Work on improving living conditions of astronauts showed that the causes were easily and inexpensively removed by potplants in which interaction is thought to take place between the plant and microorganisms in its roots. Among the most useful are chrysanthemums (counteracting benzene), English ivy and the peace lily (trichloroethene), and the spider plant (formaldehyde).

sickle harvesting tool of ancient origin characterized by a curving blade with serrated cutting edge and short wooden handle. It was widely used in the Middle East and Europe for cutting wheat, barley, and oats from about 10,000 BC to the 19th century.

sickle-cell disease hereditary chronic blood disorder common among people of black African descent; also found in the E Mediterranean, parts of the Persian Gulf, and in NE India. It is characterized by distortion and fragility of the red blood cells, which are lost too rapidly from the circulation. This often results in anaemia.

People with this disease have abnormal red blood cells (sickle cells), containing a defective haemoglobin. The presence of sickle cells in the blood is called **sicklemia**.

The disease is caused by a recessive allele. Those with two copies of the allele suffer debilitating anaemia; those with a single copy paired with the normal allele, suffer with only mild anaemia and have a degree of protection against malaria because fewer normal red blood cells are available to the parasites for infection.

In the US there were approximately 65,000 African Americans suffering from sickle-cell disease in 1996; there were about 5,500 British sufferers. Worldwide, 100,000 babies are born with the disease annually. Those born in developing countries are unlikely to survive for long.

Bone marrow transplantation can provide a cure, but the risks (a fatality rate of 10% and a complications rate of 20% are so great that it is only an option for the severely ill. US researchers announced in April 1995 that patients treated with a drug called hydroxyurea showed a reduction in the number of sickle cells. The drug works by reducing the amount of defective haemoglobin produced, and reviving the production of fetal haemoglobin. Fetal haemoglobin is not affected by sickling.

sidereal period the orbital period of a planet around the Sun, or a moon around a planet, with reference to a background star. The sidereal period of a planet is in effect a 'year'. A synodic period is a full circle as seen from Earth.

sidereal time in astronomy, time measured by the rotation of the Earth with respect to the stars. A sidereal day is the time taken by the Earth to turn once with respect to the stars, namely 23 h 56 min 4 s. It is divided into sidereal hours, minutes, and seconds, each of which is proportionally shorter than the corresponding SI unit.

sidewinder rattlesnake *Crotalus cerastes* that lives in the deserts of the SW USA and Mexico, and moves by throwing its coils into a sideways 'jump' across the sand. It can grow up to 75 cm/30 in long.

Siding Spring Mountain peak 400 km/250 mi NW of Sydney, site of the UK Schmidt Telescope, opened 1973, and the 3.9-m/154-in Anglo-Australian Telescope, opened in 1975, which was the first big telescope to be fully computer-controlled. It is one of the most powerful telescopes in the southern hemisphere.

SIDS (acronym for **sudden infant death syndrome**) the technical name for cot death.

siemens SI unit (symbol S) of electrical conductance, the reciprocal of the resistance of an electrical circuit. One siemens equals one ampere per volt. It was formerly called the mho or reciprocal ohm.

Siemens multinational industrial empire founded in Germany by Ernst Werner von Siemens and expanded by his brothers, William (Karl Wilhelm) (1823-1883) moved to the UK in 1843; he perfected the open-hearth production of steel, pioneered the development of the electric locomotive and the laying of transoceanic cables, and improved the electric generator. The company now operates in the electrical and electronic sector.

sievert SI unit (symbol Sv) of radiation dose equivalent. It replaces the rem (1 Sv equals 100 rem). Some types of radiation do more damage than others for the same absorbed dose - for example, an absorbed dose of alpha radiation causes 20 times as much biological damage as the same dose of beta radiation. The equivalent dose in sieverts is equal to the absorbed dose of radiation in grays multiplied by the relative biological effectiveness. Humans can absorb up to 0.25 Sv without immediate ill effects; 1 Sv may produce radiation sickness; and more than 8 Sv causes death.

sight the detection of light by an eye, which can form images of the outside world.

Sigma Octantis the star closest to the south celestial pole (see celestial sphere), in effect the southern equivalent of Polaris, although far less conspicuous. Situated just less than 1° from the south celestial pole in the constellation Octans, Sigma Octantis is 120 light years away.

signal any sign, gesture, sound, or action that conveys information. Examples include the use of flags (semaphore), light (traffic and railway signals), radio telephony, radio telegraphy (Morse code), and electricity (telecommunications and computer networks).

The International Code of Signals used by shipping was drawn up by an international committee and published 1931. The codes and abbreviations used by aircraft are dealt with by the International Civil Aviation Organization, established in 1944.

signal processing in computing, the digitizing of an analogue signal such as a voice stream.

signal-to-noise ratio ratio of the power of an electrical signal to that of the unwanted noise accompanying the signal. It is expressed in decibels.

In general, the higher the signal-to-noise ratio, the better. For a telephone, an acceptable ratio is 40 decibels; for television, the acceptable ratio is 50 decibels.

signature (or *sig*) in computing, personal information appended to a message by the sender of an e-mail message or USENET posting in order to add a human touch. Signatures, which are optional, usually carry the sender's real name and e-mail address, and may also include the writer's occupation, telephone number,

and the URL of his or her home page. Many have a short quote, motto or slogan, and a few incorporate ASCII art. .Sig is the name of the file in which signature information is stored on a UNIX system.

significant figures the figures in a number that, by virtue of their place value, express the magnitude of that number to a specified degree of accuracy. The final significant figure is rounded up if the following digit is greater than 5. For example, 5,463,254 to three significant figures is 5,460,000; 3,462,891 to four significant figures is 3,463; 0.00347 to two significant figures is 0.0035.

silage fodder preserved through controlled fermentation in a silo, an airtight structure that presses green crops. It is used as a winter feed for livestock. The term also refers to stacked crops that may be preserved indefinitely.

Silbury Hill artificial mound of the Neolithic (New Stone Age) period, around 2800 BC, situated just south of Avebury, Wiltshire, England. Steep and rounded, it towers 40 m/130 ft high with a surrounding ditch approximately 6 m/20 ft deep, made when quarrying for the structure. It is the largest ancient artificial mound in Europe.

Excavation has revealed that it is not a burial mound, as was previously thought, but its purpose is still unclear. The main mound was built in a series of horizontal layers over a primary mound about 25 m/82 ft in diameter. It may have initially been about a third higher and the sides were originally terraced.

The mound is estimated to have required 18 million hours of labour to complete, which suggests considerable organization of workforce in keeping with a social structure regarded as later Neolithic, with a paramount chief in control of the territory.

silencer (North American *muffler*) device in the exhaust system of cars and motorbikes. Gases leave the engine at supersonic speeds, and the exhaust system and silencer are designed to slow them down, thereby silencing them.

Some silencers use baffle plates (plates with holes, which disrupt the airflow), others use perforated tubes and an expansion box (a large chamber that slows down airflow).

silica silicon dioxide, SiO_2 , the composition of the most common mineral group, of which the most familiar form is quartz. Other silica forms are chalcedony, chert, opal, tridymite, and cristobalite.

Common sand consists largely of silica in the form of quartz.

silicate one of a group of minerals containing silicon and oxygen in tetrahedral units of SiO_4 , bound together in various ways to form specific structural types. Silicates are the chief rock-forming minerals. Most rocks are composed, wholly or in part, of silicates (the main exception being limestones). Glass is a manufactured complex polysilicate material in which other elements (boron in borosilicate glass) have been incorporated.

Generally, additional cations are present in the structure, especially Al^{3+} , Fe^{2+} , Mg^{2+} , Ca^{2+} , Na^+ , K^+ , but quartz and other polymorphs of SiO_2 are also considered to be silicates; stishovite (a high-pressure form of SiO_2) is a rare exception to the usual tetrahedral coordination of silica and oxygen.

In **orthosilicates**, the oxygens are all ionically bonded to cations such as Mg^{2+} or Fe^{2+} (as olivines), and are not shared between tetrahedra. All other silicate structures involve some degree of oxygen sharing between adjacent tetrahedra. For example, beryl is a ring silicate based on tetrahedra linked by sharing oxygens to form a circle. Pyroxenes are single chain silicates, with chains of linked tetrahedra extending in one direction through the structure; amphiboles are similar but have double chains of tetrahedra. In micas, which are sheet silicates, the tetrahedra are joined to form continuous sheets that are stacked upon one another. **Framework silicates**, such as feldspars and quartz, are based on three-dimensional frameworks of tetrahedra in which all oxygens are shared.

silicon Latin *silex* 'flint' brittle, nonmetallic element, symbol Si, atomic number 14, relative atomic mass 28.086. It is the second-most abundant element (after oxygen) in the Earth's crust and occurs in amorphous and crystalline forms. In nature it is found only in combination with other elements, chiefly with oxygen in sil-

ica (silicon dioxide, SiO_2) and the silicates. These form the mineral quartz, which makes up most sands, gravels, and beaches.

Pottery glazes and glassmaking are based on the use of silica sands and date from prehistory. Today the crystalline form of silicon is used as a deoxidizing and hardening agent in steel, and has become the basis of the electronics industry because of its semiconductor properties, being used to make 'silicon chips' for microprocessors.

The element was isolated by Swedish chemist Jöns Berzelius in 1823, having been named in 1817 by Scottish chemist Thomas Thomson by analogy with boron and carbon because of its chemical resemblance to these elements.

silicon chip integrated circuit with microscopically small electrical components on a piece of silicon crystal only a few millimetres square.

One chip may contain more than a million components. A chip is mounted in a rectangular plastic package and linked via gold wires to metal pins, so that it can be connected to a printed circuit board for use in electronic devices, such as computers, calculators, television sets, car dashboards, and domestic appliances.

Silicon Glen area in central Scotland, around Glenrothes new town, where there are many electronics firms. By 1986 Glenrothes had over 21% of its workforce employed in electrical engineering, especially high-tech firms. Many of the firms here are owned by US and other foreign companies.

Silicon Graphics, Inc (SGI) manufacturer of high-performance workstations and software designed primarily for graphics and image processing.

Silicon Valley nickname given to a region of S California, approximately 32 km/20 mi long, between Palo Alto and San Jose. It is the site of many high-technology electronic firms, whose prosperity is based on the silicon chip.

SILICON VALLEY

<http://www.internetvalley.com/introduction.html>

Brief exploration of the history of California's Silicon Valley, which was named after the brittle metalloid used in the manufacture of microprocessors.

silicosis chronic disease of miners and stone cutters who inhale silica dust, which makes the lung tissues fibrous and less capable of aerating the blood. It is a form of pneumoconiosis.

silk-screen printing or **serigraphy** method of printing based on stencilling. It can be used to print on most surfaces, including paper, plastic, cloth, and wood. An impermeable stencil (either paper or photosensitized gelatin plate) is attached to a finely meshed silk screen that has been stretched on a wooden frame, so that the ink passes through to the area beneath only where an image is required. The design can also be painted directly on the screen with varnish. A series of screens can be used to add successive layers of colour to the design.

The process was developed in the early 20th century for commercial use and adopted by many artists from the 1930s onwards, most notably Andy Warhol.

silkworm usually the larva of the common silkworm moth *Bombyx mori*. After hatching from the egg and maturing on the leaves of white mulberry trees (or a synthetic substitute), it spins a protective cocoon of fine silk thread 275 m/900 ft long. To keep the thread intact, the moth is killed before emerging from the cocoon, and several threads are combined to form the commercial silk thread woven into textiles.

Other moths produce different fibres, such as tussah from *Antheraea mylitta*. The raising of silkworms is called **sericulture**.

and began in China about 2000 BC. Chromosome engineering and artificial selection practised in Japan have led to the development of different types of silkworm for different fibres.

SILKWORM

It takes about 1,700 silkworm cocoons to make a silk dress and 350 to make a pair of stockings.

silo in farming, an airtight tower in which ϕ silage is made by the fermentation of freshly cut grass and other forage crops. In military technology, a silo is an underground chamber for housing and launching a ballistic missile.

Silurian period of geological time 439–409 million years ago, the third period of the Palaeozoic era. Silurian sediments are mostly marine and consist of shales and limestone. Luxuriant reefs were built by coral-like organisms. The first land plants began to evolve during this period, and there were many ostracoderms (armoured jawless fishes). The first jawed fishes (called acanthodians) also appeared.

silver white, lustrous, extremely malleable and ductile, metallic element, symbol Ag (from Latin *argentum*), atomic number 47, relative atomic mass 107.868. It occurs in nature in ores and as a free metal; the chief ores are sulphides, from which the metal is extracted by smelting with lead. It is one of the best metallic conductors of both heat and electricity; its most useful compounds are the chloride and bromide, which darken on exposure to light and are the basis of photographic emulsions.

Silver is used ornamentally, for jewellery and tableware, for coinage, in electroplating, electrical contacts, and dentistry, and as a solder. It has been mined since prehistory; its name is an ancient non-Indo-European one, *silubr*, borrowed by the Germanic branch as *silver*.

silverberry North American shrub *Eleagnus commutata* of the oleaster family, having twigs marked with brown and silver scales and bearing silvery yellow, fragrant flowers. The silvery berrylike fruits are edible.

silverfish wingless insect, a type of ϕ bristletail.

silver plate silverware made by depositing a layer of silver on another metal, usually copper, by the process of ϕ electroplating.

sima in geochemistry and geophysics, the substance of the Earth's oceanic ϕ crust, as distinct from the ϕ sial of the continental crust. The name, now used rarely, is derived from silica and magnesia, its two main chemical constituents.

simple harmonic motion (SHM) oscillatory or vibrational motion in which an object (or point) moves so that its acceleration towards a central point is proportional to its distance from it. A simple example is a pendulum, which also demonstrates another feature of SHM, that the maximum deflection is the same on each side of the central point.

A graph of the varying distance with respect to time is a sine curve, a characteristic of the oscillating current or voltage of an alternating current (AC), which is another example of SHM.

Simple Mail Transfer Protocol in computing, protocol for transferring electronic mail between computers, commonly abbreviated to ϕ SMTP.

Simple Network Management Protocol in computing, agreed method of managing a computer network, commonly abbreviated to ϕ SNMP.

simplify of a fraction, to reduce to lowest terms by dividing both numerator and denominator by any number that is a factor of both, until there are no common factors between the numerator and denominator. Also, in algebra, to condense an algebraic expression

by grouping similar terms and reducing constants to their lowest terms. For example, the expression $a + 2b + b + 2a - 2(a + b)$ can be simplified to $a + b$.

Science may be described as the art of systematic oversimplification.

KARL POPPER Austrian philosopher of science.
Remark, Aug 1982

simulation short for ϕ computer simulation.

simultaneous equations in mathematics, one of two or more algebraic equations that contain two or more unknown quantities that may have a unique solution. For example, in the case of two linear equations with two unknown variables, such as (i) $x + 3y = 6$ and (ii) $3y - 2x = 4$, the solution will be those unique values of x and y that are valid for both equations. Linear simultaneous equations can be solved by using algebraic manipulation to eliminate one of the variables, ϕ coordinate geometry, or matrices (see ϕ matrix).

For example, by using algebra, both sides of equation (i) could be multiplied by 2, which gives $2x + 6y = 12$. This can be added to equation (ii) to get $9y = 16$, which is easily solved: $y = \frac{16}{9}$. The variable x can now be found by inserting the known y value into either original equation and solving for x . Another method is by plotting the equations on a graph, because the two equations represent straight lines in coordinate geometry and the coordinates of their point of intersection are the values of x and y that are true for both of them. A third method of solving linear simultaneous equations involves manipulating matrices. If the equations represent either two parallel lines or the same line, then there will be no solutions or an infinity of solutions respectively.

sine in trigonometry, a function of an angle in a right-angled triangle which is defined as the ratio of the length of the side opposite the angle to the length of the hypotenuse (the longest side).

Various properties in physics vary sinusoidally; that is, they can be represented diagrammatically by a sine wave (a graph obtained by plotting values of angles against the values of their sines). Examples include ϕ simple harmonic motion, such as the way alternating current (AC) electricity varies with time.

$$\sin(\theta) \beta = \frac{\text{opposite}}{\text{hypotenuse}} = \frac{AC}{AB}$$

sine (left) The sine of an angle; (right) constructing a sine wave. The sine of an angle is a function used in the mathematical study of the triangle. If the sine of angle β is known, then the hypotenuse can be found given the length of the opposite side, or the opposite side can be found from the hypotenuse. Within a circle of unit radius (left), the height P_1A_1 equals the sine of angle P_1OA_1 . This fact and the equalities below the circle allow a sine curve to be drawn, as on the right.

the sine rule states that

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}$$

or

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}$$

sine rule The sine rule relates the sides and angles of a triangle, stating that the ratio of the length of each side and the sine of the angle opposite is constant.

sine rule in trigonometry, a rule that relates the sides and angles of a triangle, stating that the ratio of the length of each side and the sine of the angle opposite is constant (twice the radius of the circumscribing circle). If the sides of a triangle are a , b , and c , and the angles opposite are A , B , and C , respectively, then the sine rule may be expressed as

$$a/\sin A = b/\sin B = c/\sin C.$$

Singer, Isaac Merrit (1811–1875)

US inventor of domestic and industrial sewing machines. Within a few years of opening his first factory in 1851, he became the world's largest sewing-machine manufacturer (despite infringing the patent of Elias Howe), and by the late 1860s more than 100,000 Singer sewing machines were in use in the USA alone.

Single European Act 1986 update of the Treaty of Rome (signed in 1957) that provides a legal basis for action by the European Union in matters relating to the environment. The act requires that environmental protection shall be a part of all other Union policies. Also, it allows for agreement by a qualified majority on some legislation, whereas before such decisions had to be unanimous.

single-sideband transmission radio-wave transmission using either the frequency band above the carrier wave frequency, or below, instead of both (as now).

singularity in astrophysics, the point in space-time at which the known laws of physics break down. Singularity is predicted to exist at the centre of a black hole, where infinite gravitational forces compress the infalling mass of a collapsing star to infinite density. It is also thought, according to the Big Bang model of the origin of the universe, to be the point from which the expansion of the universe began.

sinusitis painful inflammation of one of the sinuses, or air spaces, that surround the nasal passages. Most cases clear with antibiotics and nasal decongestants, but some require surgical drainage.

Sinusitis most frequently involves the maxillary sinuses, within the cheek bones, producing pain around the eyes, toothache, and a nasal discharge.

SIPC (abbreviation for *simply interactive PC*) in computing, easy-to-use and cheaply-priced computer planned by ©Microsoft, Intel, and Toshiba for release 1997. The SIPC will be a sealed unit that can be connected to the telephone, television, hi-fi and other domestic electronic appliances.

siphon tube in the form of an inverted U with unequal arms. When it is filled with liquid and the shorter arm is placed in a tank or reservoir, liquid flows out of the longer arm provided that its exit is below the level of the surface of the liquid in the tank.

The liquid flows through the siphon because low pressure develops at the apex as liquid falls freely down the long arm. The difference between the pressure at the tank surface (atmospheric pressure) and the pressure at the apex causes liquid to rise in the short arm to replace that falling from the long arm.

siphonogamy plant reproduction in which a pollen tube grows to enable male gametes to pass to the ovary without leaving the protection of the plant.

Siphonogamous reproduction is found in all angiosperms and most gymnosperms, and has enabled these plants to reduce their dependency on wet conditions for reproduction, unlike the zoidogamous plants (see *zoidogamy*).

Sirius or *Dog Star* or *Alpha Canis Majoris* the brightest star in the night sky, 8.6 light years from Earth in the constellation Canis Major. Sirius is a white star with a mass 2.3 times that of the Sun, a diameter 1.8 times that of the Sun, and a luminosity of 23 Suns. It is orbited every 50 years by a white dwarf, Sirius B, also known as the Pup.

Sirius is a double star with an orbital period of 50 years. Its eighth-magnitude companion is sometimes known as 'the Dark Companion' as it was first detected by Friedrich Bessel from its gravitational effect on the proper motion of Sirius. It was seen for the first time in 1862 but it was only in the 1920s that it was recognized as the first known example of a white dwarf.

sirocco hot, normally dry and dust-laden wind that blows from the deserts of N Africa across the Mediterranean into S Europe. It occurs mainly in the spring. The name 'sirocco' is also applied to any hot oppressive wind.

sisal strong fibre made from various species of agave, such as *Agave sisalana*.

siskin North American finch *Carduelis pinus* with yellow markings or greenish-yellow bird *Carduelis spinus* about 12 cm/5 in long, found in Eurasia. They are members of the finch family Fringillidae, order Passeriformes.

sitatunga herbivorous antelope *Tragelaphus spekei* found in several swamp regions in Central Africa. Its hooves are long and splayed to help progress on soft surfaces. It grows to about 1.2 m/4 ft high at the shoulder; the male has thick horns up to 90 cm/3 ft long.

Males are dark greyish-brown, females and young are chestnut, all with whitish markings on the rather shaggy fur.

site location at which computers are used. If a company uses only ©IBM computers, for example, it is known as an IBM site. The term is also used for a computer which acts as a server for files that can be accessed via the ©World Wide Web, also called a Web site.

site licence in computing, licence issued with commercial software entitling the purchaser to install the program on a fixed number of computers.

site of special scientific interest (SSSI) in the UK, land that has been identified as having animals, plants, or geological features that need to be protected and conserved. From 1991 these sites were designated and administered by English Nature, Scottish

Natural Heritage, and the Countryside Council for Wales.

Numbers fluctuate, but there were over 5,000 SSSIs in 1991, covering about 6% of Britain. Although SSSIs enjoy some legal protection, this does not in practice always prevent damage or destruction; during 1992, for example, 40% of SSSIs were damaged by development, farming, public access, and neglect. A report by English Nature estimated that a quarter of the total area of SSSIs, over 1 million acres, had been damaged by acid rain. Around 1% of SSSIs are irreparably damaged each year. In 1995-96 7% of Welsh SSSIs and 4.2% of English SSSIs experienced damage.

SI units (French *Système International d'Unités*) standard system of scientific units used by scientists worldwide.

Originally proposed in 1960, it replaces the ϕ m.k.s., ϕ c.g.s., and ϕ f.p.s. systems. It is based on seven basic units: the metre (m) for length, kilogram (kg) for mass, second (s) for time, ampere (A) for electrical current, kelvin (K) for temperature, mole (mol) for amount of substance, and candela (cd) for luminosity.

16-bit in computing, term describing the ability to process 16 ϕ bits at a time. The Intel 286 series of microprocessors are examples of 16-bit processors.

The term is used slightly differently to specify the quality of the sound produced by ϕ sound cards, where it refers to digital audio resolution; the quality of sound produced by a 16-bit sound card is roughly equivalent to that produced by a compact disc.

64-bit in computing, term describing the ability to process 64 ϕ bits simultaneously. DEC's Alpha processor is the best known 64-bit chip. However, Intel and Hewlett-Packard are jointly developing new 32-bit and 64-bit processors, code-named Merced, that will be compatible with the 32-bit Pentium range.

Sizewell nuclear power station in Suffolk, eastern England, 3 km/2 mi east of Leiston. Sizewell A, a Magnox nuclear power station, came into operation in 1966. Sizewell B, Britain's first pressurized-water nuclear reactor (PWR) and among the most advanced nuclear power stations in the world, reached full load in June

skeleton The human skeleton is made up of 206 bones and provides a strong but flexible supportive framework for the body.

1995. Plans to build Sizewell C were abandoned by the British government in December 1995.

Sizewell B has an electrical output of 1,188 MW. It cost £2,030 million to construct (in 1987).

skate any of several species of flatfish of the ray group. The common skate *Raja batis* is up to 1.8 m/6 ft long and greyish, with black specks. Its egg cases ('mermaids' purses') are often washed ashore by the tide.

skeleton the rigid or semirigid framework that supports and gives form to an animal's body, protects its internal organs, and provides anchorage points for its muscles. The skeleton may be composed of bone and cartilage (vertebrates), chitin (arthropods), calcium carbonate (molluscs and other invertebrates), or silica (many protists). The human skeleton is composed of 206 bones, with the (vertebral) column (spine) forming the central supporting structure.

A skeleton may be internal, forming an *endoskeleton*, or external, forming an *exoskeleton*, as in the shells of insects or crabs. Another type of skeleton, found in invertebrates such as earthworms, is the hydrostatic skeleton. This gains partial rigidity from fluid enclosed within a body cavity. Because the fluid cannot be compressed, contraction of one part of the body results in extension of another part, giving peristaltic motion. See illustration on page 687.

skew distribution in statistics, a distribution in which frequencies are not balanced about the mean. For example, low wages are earned by a great number of people, while high wages are earned by very few. However, because the high wages can be very high they pull the average up the scale, making the average wage look unrepresentatively high.

skew lines straight lines that are not parallel and yet do not meet since they lie in a different plane. Every pair of skew lines has a minimum distance between them, which is the length of their common perpendicular.

skin the covering of the body of a vertebrate. In mammals, the outer layer (epidermis) is dead and its cells are constantly being rubbed away and replaced from below; it helps to protect the body from infection and to prevent dehydration. The lower layer (dermis) contains blood vessels, nerves, hair roots, and sweat and sebaceous glands, and is supported by a network of fibrous and elastic cells. The medical speciality concerned with skin diseases is called dermatology.

Skin grafting is the repair of injured skin by placing pieces of skin, taken from elsewhere on the body, over the injured area.

SKIN

Each person sheds an average of 18 kg/40lb of skin in a lifetime. The outer layer of skin – the epidermis – consists entirely of dead cells that fall off and are replaced by the level below.

skink lizard of the family Scincidae, a large family of about 700 species found throughout the tropics and subtropics. The body is usually long and the legs are reduced. Some skinks are legless and rather snakelike. Many are good burrowers, or can 'swim' through sand, like the sandfish genus *Scincus* of North Africa. Some skinks lay eggs, others bear live young.

Skinks include the three-toed skink *Chalcides chalcides* of S Europe and northwest Africa, up to 40 cm/16 in long, of which half is tail, and the stump-tailed skink *Tiliqua rugosa* of Australia, which stores fat in its triangular tail, looks the same at either end, and feeds on fruit as well as small animals. A new skink genus was identified in the rainforest of the Philippine Islands and described

skin The skin is composed of two layers: the epidermis, a layer of dead cells; and the living dermis. The skin of an adult man covers about 1.9 sq m/20 sq ft; a woman's skin covers about 1.6 sq m/17 sq ft.

in 1997. There are two species of moist forest skink *Parvoscinus*. They lack external ear openings and females have only one oviduct and lay a single egg.

skua dark-coloured gull-like seabird, living in Arctic and Antarctic waters. Skuas can grow up to 60 cm/2 ft long, with long, well-developed wings and short, stout legs; in colour they are greyish above and white below. They are aggressive scavengers, and seldom fish for themselves but force gulls to disgorge their catch, and also eat chicks of other birds. Skuas are in the family Stercorariidae, order Charadriiformes.

The largest species is the great skua *Stercorarius skua* of the N Atlantic, 60 cm/2 ft long and dark brown on the upper parts.

Antarctic skuas *Catharacta antarctica* nest near the penguin colonies they feed on, and are as aggressive in defending their own nests as they are in defending their local penguin colony from other predators. They fly north during the Antarctic winter.

skull in vertebrates, the collection of flat and irregularly shaped bones (or cartilage) that enclose the brain and the organs of sight, hearing, and smell, and provide support for the jaws. In most mammals, the skull consists of 22 bones joined by fibrous immobile joints called sutures. The floor of the skull is pierced by a large hole (*foramen magnum*) for the spinal cord and a number of smaller apertures through which other nerves and blood vessels pass.

The skull comprises the cranium (brain case) and the bones of the face, which include the upper jaw, enclosing the sinuses, and form the framework for the nose, eyes, and the roof of the mouth cavity. The lower jaw is hinged to the middle of the skull at its lower edge. The opening to the middle ear is located near the jaw hinge. The plate at the back of the head is jointed at its lower edge with the upper section of the spine. Inside, the skull has various shallow cavities into which fit different parts of the brain.

TO REMEMBER THE BONES OF THE SKULL:

OLD PEOPLE FROM TEXAS EAT SPIDERS

OCCIPITAL, PARIETAL, FRONTAL, TEMPORAL, ETHMOID, SPHENOID

skull The skull is a protective box for the brain, eyes, and hearing organs. It is also a framework for the teeth and flesh of the face. The cranium has eight bones: occipital, two temporal, two parietal, frontal, sphenoid, and ethmoid. The face has 14 bones, the main ones being two maxillae, two nasal, two zygoma, two lacrimal, and the mandible.

SKUNK AND OPOSSUM PAGE

<http://elvis.neep.wisc.edu/~firmiss/mephitis-didelphis.html>

Lively site providing all the information you could possibly want about skunks and opossums – photos, a guide to identifying their tracks, common misconceptions, advice on keeping them as pets, stories featuring the animals, and even a recipe!

skunk cabbage either of two disagreeably smelling North American plants of the arum family Araceae: *Symplocarpus foetidus*, of the E, growing in wet soils and having large, cabbage-like leaves and a fleshy blunt spike of tiny flowers in a purple, hooded sheath; or *Lysichiton americanum* of the W, having similar appearance except that the sheath enclosing a more elongated flower spike is yellow.

Skye terrier breed of short-legged terrier from the island of Skye and adjoining areas of Scotland, bred originally as a killer of rodents. Its long, thick coat may be black, grey, fawn, or cream. It is about 25 cm/10 in at the shoulder and its body is long in proportion.

Skylab US space station, launched 14 May 1973, made from the adapted upper stage of a Saturn V rocket. At 75 tonnes/82.5 tons, it was the heaviest object ever put into space, and was 25.6 m/84 ft long. *Skylab* contained a workshop for carrying out experiments in weightlessness, an observatory for monitoring the Sun, and cameras for photographing the Earth's surface.

Damaged during launch, it had to be repaired by the first crew of astronauts. Three crews, each of three astronauts, occupied *Skylab* for periods of up to 84 days, at that time a record duration

for human spaceflight. *Skylab* finally fell to Earth on 11 July 1979, dropping debris on Western Australia.

PROJECT SKYLAB

<http://www.ksc.nasa.gov/history/skylab/skylab.html>

Official NASA archive of the project that launched the USA's first experimental space station. There are comprehensive details (technical and of general interest) on all the experiments included in the project. There is also a selection of photos and videos and a search engine

skylark a type of *clark*.

slag in chemistry, the molten mass of impurities that is produced in the smelting or refining of metals.

The slag produced in the manufacture of iron in a blast furnace floats on the surface above the molten iron. It contains mostly silicates, phosphates, and sulphates of calcium. When cooled, the solid is broken up and used as a core material in the foundations of roads and buildings.

slaked lime $\text{Ca}(\text{OH})_2$ (technical name *calcium hydroxide*) substance produced by adding water to quicklime (calcium oxide, CaO). Much heat is given out and the solid crumbles as it absorbs water. A solution of slaked lime is called *limewater*.

slash and burn simple agricultural method whereby natural vegetation is cut and burned, and the clearing then farmed for a few years until the soil loses its fertility, whereupon farmers move on and leave the area to regrow. Although this is possible with a small, widely dispersed population, it becomes unsustainable with more people and is now a cause of deforestation.

slate fine-grained, usually grey metamorphic rock that splits readily into thin slabs along its cleavage planes. It is the metamorphic equivalent of shale.

Slate is highly resistant to atmospheric conditions and can be used for writing on with chalk (actually gypsum). Quarrying slate takes such skill and time that it is now seldom used for roof and sill material except in restoring historic buildings.

sleep state of natural unconsciousness and activity that occurs at regular intervals in most mammals and birds, though there is considerable variation in the amount of time spent sleeping. Sleep differs from hibernation in that it occurs daily rather than seasonally, and involves less drastic reductions in metabolism. The function of sleep is unclear. People deprived of sleep become irritable, uncoordinated, forgetful, hallucinatory, and even psychotic.

In humans, sleep is linked with hormone levels and specific brain electrical activity, including delta waves, quite different from the brain's waking activity. REM (rapid eye movement) phases, associated with dreams, occur at regular intervals during sleep, when the eyes move rapidly beneath closed lids.

SLEEP

The koala sleeps on average 22 hours a day. It is the only animal more slothful than the sloth, which sleeps only 20 hours a day. Some say that the koala's diet of eucalyptus leaves means that it is in an almost permanently drugged sleep.

sleeping pill any sedative that induces sleep; in small doses, such drugs may relieve anxiety.

sleeping sickness infectious disease of tropical Africa, a form of trypanosomiasis. Early symptoms include fever, headache, and chills, followed by anaemia and joint pains. Later, the disease attacks the central nervous system, causing drowsiness, lethargy, and, if left untreated, death. Sleeping sickness is caused by either of two trypanosomes, *Trypanosoma gambiense* or *T. rhodesiense*. Control is by eradication of the tsetse fly, which transmits the disease to humans.

Sleeping sickness in cattle is called nagana.

slide rule mathematical instrument with pairs of logarithmic sliding scales, used for rapid calculations, including multiplication, division, and the extraction of square roots. It has been largely superseded by the electronic calculator.

It was invented in 1622 by the English mathematician William Oughtred. A later version was devised by the French army officer Amédée Mannheim (1831–1906).

slide show in computing presentation graphics programs, facility to display a presentation electronically instead of outputting it onto film or paper. The program displays the images ('slides') using the computer's full screen or an overhead projector. Slide shows are a versatile display method: presenters can customize timings to suit what they have to say and incorporate sound and movies into their presentations.

slime mould or *myxomycete* extraordinary organism that shows some features of fungus and some of protozoa. Slime moulds are not closely related to any other group, although they are often classed, for convenience, with the fungi. There are two kinds, cellular slime moulds and plasmodial slime moulds, differing in their complex life cycles.

Cellular slime moulds go through a phase of living as single cells, looking like amoebae, and feed by engulfing the bacteria found in rotting wood, dung, or damp soil. When a food supply is exhausted, up to 100,000 of these amoebae form into a colony resembling a single sluglike animal and migrate to a fresh source of bacteria. The colony then takes on the aspect of a fungus, and forms long-stalked fruiting bodies which release spores. These germinate to release amoebae, which repeat the life cycle.

Plasmodial slime moulds have a more complex life cycle involving sexual reproduction. They form a slimy mass of protoplasm with no internal cell walls, which slowly spreads over the bark or branches of trees.

SLIME MOULD

Single-celled slime moulds can clump together to form a multicellular organism when times get tough. If food is becoming scarce, the unicellular slime mould releases a chemical to attract others. As they group together, they begin to produce spores that can then be dispersed to more fruitful areas.

SLIP (abbreviation for *serial line Internet protocol*) in computing, the older of two standard methods for connecting a computer to the Internet via a modem and telephone line. Unlike PPP (Point-to-Point Protocol), a SLIP connection needs to have its IP address reset every time it is used, and offers no error detection.

sloe fruit of the blackthorn bush.

slope another name for *gradient*.

sloth slow-moving South American mammal, about 70 cm/2.5 ft long, family Bradypodidae, order Edentata. Sloths are greyish brown and have small rounded heads, rudimentary tails, and prolonged forelimbs. Each foot has long curved claws adapted to clinging upside down from trees. On the ground the animals cannot walk, but drag themselves along. They are vegetarian.

The hair is brown, long, coarse and shaggy. An alga lives in it, and in damp weather turns the hair green, which helps the animal

to blend in with its leafy background. Sloths are nocturnal animals. They usually live alone in the treetops, eating leaves. They give birth to one young at a time, which spends its first few weeks clinging to its mother's hair.

slow-worm harmless species of lizard *Anguis fragilis*, once common in Europe, now a protected species in Britain. Superficially resembling a snake, it is distinguished by its small mouth and movable eyelids. It is about 30 cm/1 ft long, and eats worms and slugs.

SLR (abbreviation for *single-lens reflex*) a type of camera in which the image can be seen through the lens before a picture is taken. A small mirror directs light entering the lens to the viewfinder.

When a picture is taken the mirror moves rapidly aside to allow the light to reach the film. The SLR allows different lenses, such as close-up or zoom lenses, to be used because the photographer can see exactly what is being focused on.

slug obsolete unit of mass, equal to 14.6 kg/32.17 lb. It is the mass that will have an acceleration of one foot per second when under a force of one pound weight.

slug soft-bodied land-living gastropod (type of mollusc) related to the snails, but without a shell, or with a much reduced shell. All slugs have a protective coat of slime and a distinctive head with protruding tentacles. The eyes are at the end of the tentacles, which are also used to smell and locate food. Slugs eat dead animal matter and plants; some species are carnivorous and eat other slugs, snails, and earthworms. Slugs are hermaphrodites (having both male and female organs). They can fertilize themselves, but usually mate with another. Slugs can live for up to three years, and are invertebrates (animals without backbones).

behaviour Water can quickly be lost from the slug's body, so, to prevent drying out, slugs normally come out to feed only at night or when it is wet. During dry weather they shelter in crevices, hidden under rocks or go underground. The slug moves by gliding its flattened body (foot) over the ground, leaving a slimy mucus trail.

types of slug Land slugs belong to two groups, the roundbacks and the keeled slugs. Roundbacks, such as the slugs found in gardens, are usually about 2–3 cm/0.7–1 in long and have soft fleshy sausage-shaped bodies. Keeled slugs, such as the great grey slug, are usually longer, growing up to 20 cm/6.4 in long, and they have a ridge or keel along their backs.

classification Slugs belong to the animal phylum Mollusca (molluscs), class Gastropoda (slugs and snails). There are over 40,000 species of gastropod and most land and freshwater slugs belong to a group called the pulmonates. The great number of land species include the common garden slug (*Arion hortensis*) and the great grey slug (*Limax maximus*).

slurry form of manure composed mainly of liquids. Slurry is collected and stored on many farms, especially when large numbers of animals are kept in factory units (see factory farming). When slurry tanks are accidentally or deliberately breached, large amounts can spill into rivers, killing fish and causing eutrophication. Some slurry is spread on fields as a fertilizer.

smack slang term for heroin, an addictive depressant drug.

small arms one of the two main divisions of firearms: guns that can be carried by hand. The first small arms were portable handguns in use in the late 14th century, supported on the ground and ignited by hand. Today's small arms range from breech-loading single-shot rifles and shotguns to sophisticated automatic and semiautomatic weapons. In 1990, 10,567 people were killed by handguns in the USA, compared with 91 in Switzerland, 87 in Japan, 68 in Canada, and 13 in Sweden. From 1988 guns accounted for more deaths among teenage US males than all other causes put together.

The matchlock, which evolved during the 15th century, used a match of tow and saltpetre gripped by an S-shaped lever, which was rocked towards the touch hole with one finger, enabling the gun to be held, aimed, and fired in much the same way as today. Front and back sights, followed by a curved stock that could be held against the shoulder (in the hackbut or Hookgun), gave increased precision. The difficulty of keeping a matchlight alive

wet weather was overcome by the introduction of the wheel lock, in about 1515, in which a shower of sparks was produced by a spring-drawn steel wheel struck by iron pyrites. This cumbersome and expensive mechanism evolved into the simpler flintlock in about 1625, operated by flint striking steel and in general use for 200 years until a dramatic advance, the 'percussion cap', invented in 1810 by a sport-loving Scottish cleric, Alexander Forsyth (1769–1843), removed the need for external igniters. From then on, weapons were fired by a small explosive detonator placed behind or within the base of the bullet, struck by a built-in hammer.

The principles of rifling, breech-loading, and the repeater, although known since the 16th century, were not successfully exploited until the 19th century. It was known that imparting a spin made the bullet's flight truer, but the difficulty of making the bullet bite the grooves had until then prevented the use of rifling. The Baker rifle, issued to the British Rifle Brigade in 1800, was loaded from the front of the barrel (muzzle) and had a mallet for hammering the bullets into the grooves. The first breechloader was von Dreyse's 'needle gun', issued to the Prussian army in 1842, in which the detonator was incorporated with the cartridge. By 1870 breech-loading was in general use, being quicker, and sweeping the barrel out after each firing. An early rifle with bolt action was the Lee-Metford of 1888, followed by the Lee-Enfield, both having a magazine beneath the breech, containing a number of cartridges. A modified model is still used by the British army. US developments favoured the repeater (such as the Winchester) in which the fired case was extracted and ejected, the hammer cocked, and a new charge inserted into the chamber, all by one reciprocation of a finger lever. In the semiautomatic, part of the explosion energy performs the same operations: the Garand, long used by the US army, is of this type. Completely automatic weapons were adopted during World War II. Improvements since then have concentrated on making weapons lighter and faster-firing, as with the M-16, extensively used by US troops in the Vietnam War.

SMALLPOX

<http://www.outbreak.org/cgi-unreg/dynaserve.exe/Smallpox.html>

Story of the eradication of the smallpox virus. The Web site covers the eradication program from its earliest stages to the final destruction of the virus, described by the WHO as 'Man's greatest achievement'. A photograph of the virus is included on the Web site via a hypertext link, and an interview with John Scott Porterfield, one of the workers responsible for the virus' destruction, is also available here.

smallpox acute, highly contagious viral disease, marked by aches, fever, vomiting, and skin eruptions leaving pitted scars. Widespread vaccination programmes have eradicated this often fatal disease.

It was endemic in Europe until the development of vaccination by Edward Jenner about 1800, and remained so in Asia, where a virulent form of the disease (variola major) entailed a fatality rate of 30% until the World Health Organization (WHO) campaign from 1967, which resulted in its virtual eradication by 1980. The campaign was estimated to have cost \$300 million/£200 million, and was the organization's biggest health success to date.

The deviation of man from the state in which he was originally placed by nature seems to have proved him to be a prolific source of diseases.

EDWARD JENNER English physician.
An Inquiry into the Causes and Effects of the Variolae Vaccinae, or Cow-pox

Smalltalk the first high-level programming language used in object-oriented applications.

smart in computing, term for any piece of equipment that works with the help of a microprocessor: a 'smart' carburettor, for example, maintains the correct proportion of air-to-petrol vapour in a car engine by electronically monitoring engine temperature, acceleration, and other variables. Designers are incorporating smart technology into an increasing range of products, such as smart toasters, which can prevent toast from burning. Smart furniture, such as chairs with cushions that adjust themselves according to the size and weight of the person sitting in them, is a typical area of current research.

Architects are already making smart buildings, especially large office blocks and hospitals. Such buildings are wired with sensors to monitor heating, lighting, and air quality. A central computer automatically performs simple tasks such as turning lights out when there is nobody in a room, adjusting air conditioning and even darkening photoelectric windows to counteract bright sunlight.

smart card plastic card with an embedded microprocessor and memory. It can store, for example, personal data, identification, and bank-account details, to enable it to be used as a credit or debit card. The card can be loaded with credits, which are then spent electronically, and reloaded as needed. Possible other uses range from hotel door 'keys' to passports.

The smart card was invented by French journalist Juan Moreno in 1974. It is expected that by the year 2000 it will be possible to make cards with as much computing power as the leading personal computers of 1990.

smart drug any drug or combination of nutrients (vitamins, amino acids, minerals, and sometimes herbs) said to enhance the functioning of the brain, increase mental energy, lengthen the span of attention, and improve the memory. As yet there is no scientific evidence to suggest that these drugs have any significant effect on healthy people.

Some smart drugs consist of food additives which are precursors of the neurotransmitter acetylcholine. Most, however, are experimental drugs devised by pharmaceutical companies to treat aspects of dementia, in particular, memory loss. The description is also applied to existing drugs claimed to improve mental performance but which are legally prescribed for other purposes. These include beta-blockers (prescribed for some heart disease), phenytoin (epilepsy), and L-dopa (Parkinson's disease).

smart fluid or *electrorheological fluid* liquid suspension that solidifies to form a jellylike solid when a high-voltage electric field is applied across it and that returns to the liquid state when the field is removed. Most smart fluids are zeolites or metals coated with polymers or oxides.

SMELL

The great white shark is so sensitive to the smell of blood that it can detect a single drop in 4,600,000 litres of water. Two-thirds of the shark's brain governs sense of smell.

smell sense that responds to chemical molecules in the air. It works by having receptors for particular chemical groups, into which the airborne chemicals must fit to trigger a message to the brain.

A sense of smell is used to detect food and to communicate with other animals (see *pheromone* and *oscent gland*). Humans can distinguish between about 10,000 different smells. Aquatic animals can sense chemicals in water, but whether this sense should be described as 'smell' or 'taste' is debatable. See also *snose*.

MYSTERY OF SMELL

<http://www.hhmi.org/senses/d/d110.htm>

As part of a much larger site called 'Seeing, Hearing, and Smelling the World', here is a page examining the way our sense of smell works. It is divided into four sections called 'the vivid world of odours', 'finding the odourant receptors', 'how rats and mice – and probably humans – recognize odours', and 'the memory of smells'. This site makes good use of images and animations to help with the explanations, so it is best viewed with an up-to-date browser.

smelling salts or *sal volatile* a mixture of ammonium carbonate, bicarbonate, and carbamate together with other strong-smelling substances, formerly used as a restorative for dizziness or fainting.

smelt small fish, usually marine, although some species are freshwater.

They occur in Europe and North America. The most common European smelt is the sparring *Osmerus eperlanus*.

smelting processing a metallic ore in a furnace to produce the metal. Oxide ores such as iron ore are smelted with coke (carbon), which reduces the ore into metal and also provides fuel for the process.

A substance such as limestone is often added during smelting to facilitate the melting process and to form a slag, which dissolves many of the impurities present.

smiley alternative term for *phemicon*, named after the original smiling face :-).

Smithsonian Institution academic organization in Washington DC, USA, founded in 1846 with money left by British chemist and mineralogist James Smithson. The Smithsonian Institution, 'an establishment for the increase and diffusion of knowledge', undertakes scientific research but is also the parent organization of a collection of museums.

The Smithsonian Institution's second curator, the naturalist Spencer Baird (1823–87), at the expense of research, increased funds for collection and exploration, thereby securing its role as a leading museum.

smog natural fog containing impurities, mainly nitrogen oxides (NO_x) and volatile organic compounds (VOCs) from domestic fires, industrial furnaces, certain power stations, and internal-combustion engines (petrol or diesel). It can cause substantial illness and loss of life, particularly among chronic bronchitics, and damage to wildlife.

photochemical smog is mainly prevalent in the summer as it is caused by chemical reaction between strong sunlight and vehicle exhaust fumes. Such smogs create a build-up of ozone and nitrogen oxides which cause adverse symptoms, including coughing and eye irritation, and in extreme cases can kill.

The London smog of 1952 lasted for five days and killed more than 4,000 people from heart and lung diseases. The use of smokeless fuels, the treatment of effluent, and penalties for excessive smoke from poorly maintained and operated vehicles can be effective in reducing smog but it still occurs in many cities throughout the world.

smokeless fuel fuel that does not give off any smoke when burned, because all the carbon is fully oxidized to carbon dioxide (CO₂). Natural gas, oil, and coke are smokeless fuels.

smoking method of preserving fresh oily meats (such as pork and goose) or fish (such as herring and salmon). Before being smoked, the food is first salted or soaked in brine, then hung to dry. Meat is hot-smoked over a fast-burning wood fire, which is covered with sawdust, producing thick smoke and partly cooking the meat. Fish may be hot-smoked or cold-smoked over a slow-burning wood fire.

which does not cook it. Modern refrigeration techniques mean that food does not need to be smoked to help it keep, so factory-smoked foods tend to be smoked just enough to give them a smoky flavour, with colours added to give them the appearance of traditionally smoked food.

smoking inhaling the fumes from burning substances, generally tobacco in the form of cigarettes. The practice is habit-forming and is dangerous to health, since carbon monoxide and other toxic materials result from the combustion process. A direct link between lung cancer and tobacco smoking was established in 1950; the habit is also linked to respiratory and coronary heart diseases. In the West, smoking is now forbidden in many public places because even passive smoking – breathing in fumes from other people's cigarettes – can be harmful.

smooth collie breed of dog. See rough collie.

smoothing capacitor large electronic capacitor connected across the output of a rectifier circuit that has the effect of smoothing out the voltage variations to give a nearly steady DC voltage supply.

The voltage and current output from a rectifier circuit fitted with a smoothing capacitor is similar to that provided by a battery.

smooth muscle involuntary muscle capable of slow contraction over a period of time. It is present in hollow organs, such as the intestines, stomach, bladder, and blood vessels. Its presence in the wall of the alimentary canal allows slow rhythmic movements known as peristalsis, which cause food to be mixed and forced along the gut. Smooth muscle has a microscopic structure distinct from other forms.

smooth snake common nonvenomous snake found in southern and central Europe. It grows to a length of 60 cm/24 in, and it is brownish-red or grey in colour, with dark-brown spots along its back. It is ovoviviparous, producing live young that free themselves from their shells immediately.

classification The smooth snake *Coronella austriaca* is in family Colubridae, suborder Serpentes, order Squamata, class Reptilia.

SMPTE (abbreviation for the *Society of Motion Picture and Television Engineers*) US organization founded 1916 to advance the theory and application of motion-imaging technology including film, television, video, computer imaging, and telecommunications.

The SMPTE has 8,500 members in 72 countries, including engineers, executives, technical directors, camerapeople, editors, and consultants. It is based in White Plains, New York.

SMTP (abbreviation for *simple mail transfer protocol*) in computing, the basic protocol for transferring electronic mail between computers. SMTP is an agreed procedure for identifying the host, sending and receiving data and checking e-mail addresses.

smut in botany, any of a group of parasitic fungi (see fungus) that infect flowering plants, particularly cereal grasses. (Order Ustilaginales.)

SNA abbreviation for IBM's S/Systems Network Architecture.

snail air-breathing gastropod mollusc with a spiral shell. There are thousands of species, on land and in water. The typical snails of the genus *Helix* have two species in Europe. The common garden snail *H. aspersa* is very destructive to plants.

snail mail in the computing community, nickname for the conventional postal service. E-mail can deliver messages within minutes while conventional postal services take at least a day. One's postal address is therefore a 'snail mail address'.

snake reptile of the suborder Serpentes of the order Squamata, which also includes lizards. Snakes are characterized by an elongated limbless body, possibly evolved because of subterranean ancestors. However, a team of US and Israeli palaeontologists rediscovered a fossil collection in 1996 which suggested that snakes evolved from sea-dwelling predators.

One of the striking internal modifications is the absence or greatly reduced size of the left lung. The skin is covered in scales, which are markedly wider underneath where they form. There are

SNAKES AND OTHER SLITHERING THINGS

<http://fovea.retina.net/~gecko/herps/snakes/>

Guide to different snakes and tips on keeping them as pets. Emergency guidelines in case of being bitten by a snake are given, and light relief is provided in the form of an ode to snakes.

3,000 species found in the tropical and temperate zones, but none in New Zealand, Ireland, Iceland, and near the poles. Only three species are found in Britain: the adder, smooth snake, and grass snake.

locomotion In all except a few species, scales are an essential aid to locomotion. A snake is helpless on glass where scales can effect no 'grip' on the surface; progression may be undulant, 'concertina', or creeping, or a combination of these.

senses Detailed vision is limited at a distance, though movement is immediately seen; hearing is restricted to ground vibrations (sound waves are not perceived); the sense of touch is acute; besides the sense of smell through the nasal passages, the flicking tongue picks up airborne particles which are then passed to special organs in the mouth for investigation; and some (rattlesnakes) have a cavity between eye and nostril which is sensitive to infrared rays (useful in locating warm-blooded prey in the dark).

reproduction Some are oviparous and others ovoviviparous, that is, the eggs are retained in the oviducts until development is complete; in both cases the young are immediately self-sufficient.

species The majority of snakes belong to the Colubridae, chiefly harmless, such as the common grass snake of Europe, but including the deadly African boomslang *Dispholidus typus*. The venomous families include the Elapidae, comprising the true cobras, the New World coral snakes, and the Australian taipan, copperhead, and death adder; the Viperidae (see viper); and the Hydrophiidae, aquatic sea-snakes.

Among the more primitive snakes are the Boidae, which still show links with the lizards and include the boa constrictor, anaconda, and python. These kill by constriction but their victims are usually comparatively small animals.

All snakes are carnivorous, and often camouflaged for better concealment in hunting as well as for their own protection.

treatment of snakebite The serums used to treat snakebites are called antivenins. Antivenins are produced by injecting animals (horses and sheep are used) with venom, extracting their blood, now containing antibodies to the venom, and removing the red blood cells. However, in addition to the desired venom antibodies, many other antibodies and proteins are contained within the serum. These often cause 'serum sickness' in the patient, as a result of a severe allergic reaction.

As antivenins are expensive to produce and store, and specific to one snake species, experiments have been carried out using more widely valid treatments, for example, trypsin, a powerful protein-degrading enzyme, effective against the cobra/mamba group.

In 1993 Japanese and Brazilian researchers independently identified a protein in the blood of a venomous snake that neutralizes its own venom. In laboratory tests in Australia, this protein, named *Notechis scutatus* inhibitor (NSI) after the tiger snake from the whose blood it was isolated, was effective against the venom of six other snakes.

snake fly elongate insect found in wooded regions, among flowers or tree-trunks. More than 80 species are known.

The adult insects have an unusually long prothorax (region immediately behind the head) which forms a kind of 'neck' and the entire body is elongate, ending in a drawn out slender egg-laying apparatus (ovipositor), hence their name. The female inserts the eggs, with its long ovipositor, into slits in the bark of trees, especially of conifers. The larva forages under the loose bark, preying on soft-bodied insects.

classification The snake fly is in family Raphidiidae, in suborder Megaloptera of order Neuroptera, class Insecta, phylum Arthropoda.

snapdragon perennial herbaceous plant belonging to the figwort family, with spikes of brightly coloured two-lipped flowers. (*Antirrhinum majus*, family Scrophulariaceae.)

snapper one of a number of tropical, carnivorous fish, about 60 cm/24 in or more in length. Many are red, but the species come in many colours. They are valuable edible fishes, especially the red snapper *Lutjanus blackfordi*.

classification Snappers are in the family Lutjanidae of order Perciformes, class Osteichthyes.

snellen unit expressing the visual power of the eye.

Snell's law of refraction in optics, the rule that when a ray of light passes from one medium to another, the sine of the angle of incidence divided by the sine of the angle of refraction is equal to the ratio of the indices of refraction in the two media. For a ray passing from medium 1 to medium 2: by $\frac{n_2}{n_1} = \frac{\sin i}{\sin r}$ where n_1 and n_2 are the refractive indices of the two media. The law was devised by the Dutch physicist Willebrord Snell.

sniffer in computing, software tool that analyses the transport data attached to packets sent across a network, used to monitor the network's efficiency and level of usage. Hackers (see phacking) also use sniffers to collect people's passwords for Telnet connections.

snipe marsh bird of the family Scolopacidae, order Charadriiformes closely related to the woodcock. Snipes use their long, straight bills to probe marshy ground for worms, insects, and molluscs. Their nests are made on the grass, and they lay four eggs.

The cry of the birds resembles the sound 'scape-scape', and during the breeding season they make a peculiar drumming or bleating noise in their downward flight. A gamebird, the snipe has a swift and darting flight, making it a difficult target.

SNMP (abbreviation for *Simple Network Management Protocol*) in computing, agreed method of managing a computer network. SNMP governs the overall structure of the Internet, in particular its arrangement around hubs and nodes.

snook or **robalo** or **sea pike** US bony fish found in coastal and brackish waters. They can reach up to 1.4 m/4.6 ft and feed mainly on fish and crustaceans.

classification The snook *Centropomus undecimalis* is in the family Serranidae, order Perciformes and so is closely related to the perches.

snoring loud noise during sleep made by vibration of the soft palate (the rear part of the roof of the mouth), caused by streams of air entering the nose and mouth at the same time. It is most common when the nose is partially blocked.

Sleep apnoea causes loud snoring that wakes the sufferer repeatedly throughout the night, causing chronic tiredness.

snowdrop small bulbous European plant; its white bell-shaped hanging flowers, tinged with green, are among the first to appear in early spring. (*Galanthus nivalis*, family Amaryllidaceae.)

snow gum small to medium eucalypt growing at high altitudes in Australia with white smooth bark and open habit, especially *Eucalyptus pauciflora*.

snow leopard a type of leopard.

SNR (abbreviation for *supernova remnant*) in astronomy, the glowing remains of a star that has been destroyed in an supernova explosion. The brightest and most famous example is the Crab Nebula.

sodium mixture of the sodium salts of various fatty acids: palmitic, stearic, and oleic acid. It is made by the action of sodium hydroxide (caustic soda) or potassium hydroxide (caustic potash) on fats of animal or vegetable origin. Soap makes grease and dirt disperse in water in a similar manner to a detergent.

Soap was mentioned by Galen in the 2nd century for washing the body, although the Romans seem to have washed with a mixture of

sand and oil. Soap was manufactured in Britain from the 14th century, but better-quality soap was imported from Castile or Venice. The Soapmakers' Company, London, was incorporated in 1638. Soap was taxed in England from the time of Cromwell in the 17th century to 1853.

soapstone compact, massive form of impure talc.

social behaviour in zoology, behaviour concerned with altering the behaviour of other individuals of the same species. Social behaviour allows animals to live harmoniously in groups by establishing hierarchies of dominance to discourage disabling fighting. It may be aggressive or submissive (for example, covering and other signals of appeasement), or designed to establish bonds (such as social grooming or preening).

The social behaviour of mammals and birds is generally more complex than that of lower organisms, and involves relationships with individually recognized animals. Thus, courtship displays allow individuals to choose appropriate mates and form the bonds necessary for successful reproduction. In the social systems of bees, wasps, ants, and termites, an individual's status and relationships with others are largely determined by its biological form, as a member of a caste of workers, soldiers, or reproductives; see eusociality.

It is his ability to communicate with his fellows and train his offspring that has probably been the chief agency in the rapid social evolution of man.

THOMAS HUNT MORGAN US geneticist.
The Scientific Basis of Evolution 1932

sociobiology study of the biological basis of all social behaviour, including the application of population genetics to the evolution of behaviour. It builds on the concept of inclusive fitness, contained in the notion of the 'selfish gene'. Contrary to some popular interpretations, it does not assume that all behaviour is genetically determined.

socket in computing, mechanism for creating a connection to an application on another computer. A socket combines an IP address (denoting the host computer on a network) with a port number describing the application (perhaps FTP or SMTP) the user requires.

soda ash former name for sodium carbonate.

soda lime powdery mixture of calcium hydroxide and sodium hydroxide or potassium hydroxide, used in medicine and as a drying agent.

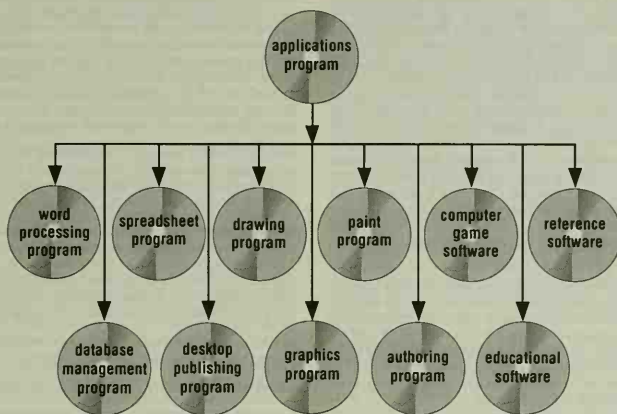

sodium soft, waxlike, silver-white, metallic element, symbol Na (from Latin *natrum*), atomic number 11, relative atomic mass 22.989. It is one of the alkali metals and has a very low density, being light enough to float on water. It is the sixth-most abundant element (the fourth-most abundant metal) in the Earth's crust. Sodium is highly reactive, oxidizing rapidly when exposed to air and reacting violently with water. Its most familiar compound is sodium chloride (common salt), which occurs naturally in the oceans and in salt deposits left by dried-up ancient seas.

Sir Humphrey Davy detested gravity. He lived in the odium of having discovered sodium.

EDMUND CLERHEW BENTLEY English author.
Biography for Beginners 1925

sodium carbonate or **soda ash** Na_2CO_3 anhydrous white solid. The hydrated, crystalline form ($\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$) is also known as washing soda.

It is made by the Solvay process and used as a mild alkali, as it is hydrolysed in water.

software The various types of software application program that are available for computer systems.

It is used to neutralize acids, in glass manufacture, and in water softening.

sodium chloride or *common salt* or *table salt* NaCl white, crystalline compound found widely in nature. It is a typical ionic solid with a high melting point (801°C/1,474°F); it is soluble in water, insoluble in organic solvents, and is a strong electrolyte when molten or in aqueous solution. Found in concentrated deposits, it is widely used in the food industry as a flavouring and preservative, and in the chemical industry in the manufacture of sodium, chlorine, and sodium carbonate.

sodium hydrogen carbonate chemical name for bicarbonate of soda.

sodium hydroxide or *caustic soda* NaOH the commonest alkali. The solid and the solution are corrosive. It is used to neutralize acids, in the manufacture of soap, and in oven cleaners. It is prepared industrially from sodium chloride by the electrolysis of concentrated brine.

soft-sectored disc another name for an unformatted blank disc; see disc formatting.

software in computing, a collection of programs and procedures for making a computer perform a specific task, as opposed to hardware, the physical components of a computer system. Software is created by programmers and is either distributed on a suitable medium, such as the floppy disc, or built into the computer in the form of firmware. Examples of software include operating systems, compilers, and applications programs such as payrolls or word processors. No computer can function without some form of software.

To function, computers need two types of software: application software and systems software. Application software, such as a payroll system or a word processor, is designed for the benefit of the end user. Systems software performs tasks related to the operation and performance of the computer system itself. For example, a systems program might control the operation of the display screen, or control and organize backing storage.

software agent in computing, see intelligent agent

software piracy in computing, unauthorized duplication of computer software. Although some software piracy is done by companies for financial gain, most piracy is done by private individuals who lend discs to friends or copy programs from the workplace to their computers at home.

Software manufacturers' attempts to protect their property – for example, by using special codes to prevent programs from being installed more than once from each set of discs – have proved unpopular with users and bypassable by determined copiers. Because computer data is so easy to duplicate, and the use of unauthorized software is so hard to detect, it appears nigh impossible to enforce anti-piracy law. The only sure way to prevent it appears to be for manufacturers to sell each copy of their software with a dongle – a coded plug that must actually be fitted to the computer for the software to function.

software project life cycle various stages of development in the writing of a major program (software), from the identification of a requirement to the installation, maintenance, and support of the finished program. The process includes systems analysis and systems design.

software suite in computing, a set of complementary programs which can be bought separately, or (at a considerable saving) as a bundled package. Office suites are an especially common form of software suite.

Examples include: Adobe's graphics software which includes Photoshop (for processing photographs), Pagemaker (for page layout), and Illustrator (for creating illustrations); and Macromedia's multimedia software, which comprises Director (for creating presentations), xRes2 (for editing images), SoundEdit (for editing sound) and Extreme 3D (for 3D modelling and animation).

soft water water that contains very few dissolved metal ions such as calcium (Ca²⁺) or magnesium (Mg²⁺). It lathers easily with soap, and no scale is formed inside kettles or boilers. It has been found that the incidence of heart disease is higher in soft-water areas.

softwood any coniferous tree (see conifer), or the wood from it. In general this type of wood is softer and easier to work, but in some cases less durable, than wood from flowering (or angiosperm) trees.

SOHO (abbreviation for Solar and Heliospheric Observatory) space probe launched in 1995 by the European Space Agency to

study the \odot solar wind of atomic particles streaming towards the Earth from the Sun. It also observes the Sun in ultraviolet and visible light, and measures slight oscillations on the Sun's surface that can reveal details of the structure of the Sun's interior. It is positioned 1.5 million km/938,000 mi from Earth towards the Sun. SOHO is operated jointly with NASA and costs \$1.2 billion.

Soho carries equipment for 11 separate experiments, including the study of the Sun's corona, measurement of its magnetic field, and of solar winds. The **Coronal Diagnostic Spectrometer (CDS)** detects radiation at extreme ultraviolet wavelengths and allows the study of the Sun's atmosphere. The **Michelson Doppler Imager (MDI)** measures Doppler shifts in light wavelengths and can detect winds caused by convection beneath the Sun's surface. The **Extreme-Ultraviolet Imaging Telescope (EIT)** investigates the mechanisms that heat the Sun's corona. The **Large-Angle Spectroscopic Coronagraph (LASCO)** images the corona by detecting sunlight scattered by the coronal gases.

soil loose covering of broken rocky material and decaying organic matter overlying the bedrock of the Earth's surface. Various types of soil develop under different conditions: deep soils form in warm wet climates and in valleys; shallow soils form in cool dry areas and on slopes. **Pedology**, the study of soil, is significant because of the relative importance of different soil types to agriculture.

The organic content of soil is widely variable, ranging from zero in some desert soils to almost 100% in peats.

TO REMEMBER THE CHIEF CONSTITUENTS OF SOIL:

ALL HAIRY MEN WILL BUY RAZORS.

AIR / HUMUS / MINERAL SALTS / WATER / BACTERIA / ROCK PARTICLES

SOIL PH - WHAT IT MEANS

<http://www.esf.edu/pubprog/brochure/soilph/soilph.htm>

Explanation of soil pH. The Web site also describes how to measure the pH of soil using simple experimental equipment, and goes on to describe methods that may be used to modify the acidity or alkalinity of your soil.

soil creep gradual movement of soil down a slope in response to gravity. This eventually results in a mass downward movement of soil on the slope.

Evidence of soil creep includes the formation of terracettes (steplike ridges along the hillside), leaning walls and telegraph poles, and trees that grow in a curve to counteract progressive leaning.

soil erosion the wearing away and redistribution of the Earth's soil layer.

It is caused by the action of water, wind, and ice, and also by improper methods of \odot agriculture. If unchecked, soil erosion results in the formation of deserts (\odot desertification). It has been estimated that 20% of the world's cultivated topsoil was lost between 1950 and 1990.

If the rate of erosion exceeds the rate of soil formation (from rock and decomposing organic matter), then the land will become infertile. The removal of forests (\odot deforestation) or other vegetation often leads to serious soil erosion, because plant roots bind soil, and without them the soil is free to wash or blow away, as in the American \odot dust bowl. The effect is worse on hillsides, and there has been devastating loss of soil where forests have been cleared from mountainsides, as in Madagascar.

Improved agricultural practices such as contour ploughing are needed to combat soil erosion. Windbreaks, such as hedges or

strips planted with coarse grass, are valuable, and organic farming can reduce soil erosion by as much as 75%.

Soil degradation and erosion are becoming as serious as the loss of the rainforest. It is estimated that more than 10% of the world's soil lost a large amount of its natural fertility during the latter half of the 20th century. Some of the worst losses are in Europe, where 17% of the soil is damaged by human activity such as mechanized farming and fallout from acid rain. Mexico and Central America have 24% of soil highly degraded, mostly as a result of deforestation.

soil mechanics branch of engineering that studies the nature and properties of the soil. Soil is investigated during construction work to ensure that it has the mechanical properties necessary to support the foundations of dams, bridges, and roads.

Sokoke scops owl small African \odot owl *Otus inaeae* thought to be entirely confined to the threatened Arabuko Sokoke Forest in Kenya. Only discovered in 1965, the owl is typical of many of the continent's little-known species, confined to a few limited and specialized habitats and thus extremely vulnerable to change. There are currently efforts to establish a national park in the forest.

sol \odot colloid of very small solid particles dispersed in a liquid that retains the physical properties of a liquid.

solan goose another name for the \odot gannet.

Solar and Heliospheric Observatory (SOHO) European Space Agency spacecraft usually abbreviated to \odot SOHO.

solar cycle in astronomy, the variation of activity on the \odot Sun over an 11-year period indicated primarily by the number of \odot sunspots visible on its surface. The next period of maximum activity is expected around 2001.

solar energy energy derived from the Sun's radiation. The amount of energy falling on just 1 sq km/0.3861 sq mi is about 4,000 megawatts, enough to heat and light a small town. In one second the Sun gives off 13 million times more energy than all the electricity used in the USA in one year. **Solar heaters** have industrial or domestic uses. They usually consist of a black (heat-absorbing) panel containing pipes through which air or water, heated by the Sun, is circulated, either by thermal convection or by a pump.

Solar energy may also be harnessed indirectly using **solar cells** (photovoltaic cells) made of panels of \odot semiconductor material (usually silicon), which generate electricity when illuminated by sunlight. Although it is difficult to generate a high output from solar energy compared to sources such as nuclear or fossil fuels, it is a major nonpolluting and renewable energy source used as far north as Scandinavia as well as in the SW USA and in Mediterranean countries.

A solar furnace, such as that built in 1970 at Odeillo in the French Pyrenees, had thousands of mirrors to focus the Sun's rays; it produced uncontaminated intensive heat (up to 3,000°C/5,400°F) for industrial and scientific or experimental purposes. The world's first solar power station connected to a national grid opened in 1991 at Adriano in Sicily. Scores of giant mirrors move to follow the Sun throughout the day, focusing the rays into a boiler. Steam from the boiler drives a conventional turbine. The plant generates up to 1 megawatt. A similar system, called Solar 1, has been built in the Mojave Desert near Daguerre, California, USA. It consists of 1,818 computer-controlled mirrors arranged in circles around a central boiler tower 91 m/300 ft high. Advanced schemes have been proposed that would use giant solar reflectors in space to harness solar energy and beam it down to Earth in the form of \odot microwaves.

In March 1996 the first solar power plant capable of storing heat was switched on in California's Mojave Desert. Solar 2, part of a three-year government-sponsored project, consists of 2,000 motorized mirrors that will focus the Sun's rays on to a 91-m/300 ft metal tower containing molten nitrate salt. When the salt reaches 565°C/1049°F it boils water to drive a 10-megawatt steam turbine. The molten salt retains its heat for up to 12 hours.

Despite their low running costs, their high installation cost and low power output have meant that solar cells have found few applications outside space probes and artificial satellites. Solar heating

is, however, widely used for domestic purposes in many parts of the world, and is an important renewable source of energy.

If sunbeams were weapons of war, we would have had solar energy long ago.

GEORGE PORTER British physical chemist.
Observer 1973

Solar Maximum Mission satellite launched by the US agency NASA in 1980 to study solar activity, which discovered that the Sun's luminosity increases slightly when sunspots are most numerous. It was repaired in orbit by astronauts from the space shuttle in 1984 and burned up in the Earth's atmosphere in 1989.

solar pond natural or artificial 'pond', such as the Dead Sea, in which salt becomes more soluble in the Sun's heat. Water at the bottom becomes saltier and hotter, and is insulated by the less salty water layer at the top. Temperatures at the bottom reach about 100°C/212°F and can be used to generate electricity.

solar radiation radiation given off by the Sun, consisting mainly of visible light, ultraviolet radiation, and infrared radiation, although the whole spectrum of electromagnetic waves is present, from radio waves to X-rays. High-energy charged particles, such as electrons, are also emitted, especially from solar flares. When these reach the Earth, they cause magnetic storms (disruptions of the Earth's magnetic field), which interfere with radio communications.

Solar System the Sun (a star) and all the bodies orbiting it: the nine planets (Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto), their moons, the asteroids, and the comets. The Sun contains 99.86% of the mass of the Solar System.

The Solar System gives every indication of being a strongly unified system having a common origin and development. It is isolated in space; all the planets go round the Sun in orbits that are nearly circular and coplanar, and in the same direction as the Sun itself rotates; moreover this same pattern is continued in the regular system of satellites that accompany Jupiter, Saturn, and Uranus. It is thought to have formed by condensation from a cloud of gas and dust in space about 4.6 billion years ago.

SOLAR SYSTEM

<http://www.hawastsoc.org/solar/eng/>

Educational tour of the Solar System. It contains information and statistics about the Sun, Earth, planets, moons, asteroids, comets, and meteorites found within the Solar System, supported by images.

solar time in astronomy, the time of day as determined by the position of the Sun in the sky.

Apparent solar time, the time given by a sundial, is not uniform because of the varying speed of the Earth in its elliptical orbit. **Mean solar time** is a uniform time that coincides with apparent solar time at four instants through the year. The difference between them is known as the equation of time, and is greatest in early November when the Sun is more than 16 minutes fast on mean solar time. Mean solar time on the Green meridian is known as Greenwich Mean Time and is the basis of civil timekeeping.

solar wind stream of atomic particles, mostly protons and electrons, from the Sun's corona, flowing outwards at speeds of between 300 kps/200 mps and 1,000 kps/600 mps.

The fastest streams come from 'holes' in the Sun's corona that lie over areas where no surface activity occurs. The solar wind pushes the gas of comets' tails away from the Sun, and 'gusts' in the solar wind cause geomagnetic disturbances and aurorae on Earth.

solder any of various alloys used when melted for joining metals such as copper, its common alloys (brass and bronze), and tin-plated steel, as used for making food cans.

Soft solders (usually alloys of tin and lead, sometimes with added antimony) melt at low temperatures (about 200°C/392°F), and are widely used in the electrical industry for joining copper wires. Hard (or brazing) solders, such as silver solder (an alloy of copper, silver, and zinc), melt at much higher temperatures and form a much stronger joint. Printed circuit boards for computers are assembled by soldering.

A necessary preliminary to making any solder joint is thorough cleaning of the surfaces of the metal to be joined (to remove oxide) and the use of a flux (to prevent the heat applied to melt the solder from reoxidizing the metal).

soldier beetle reddish beetle with soft, black elytra (wing cases) and a black patch and black legs. It reaches a length of 15 mm/0.5 in and can be found in the daytime during the months of April to July on field, garden, and forest plants. It feeds particularly on aphids. Its larvae are black, and are to be found in the soil or among moss.

classification The soldier beetle is in family Cantharidae, order Coleoptera, class Insecta, phylum Arthropoda.

sole flatfish found in temperate and tropical waters. The common sole *Solea solea*, also called Dover sole, is found in the southern seas of NW Europe. Up to 50 cm/20 in long, it is a prized food fish, as is the sand or French sole *Pegusa lascaris* further south.

solenodon rare insectivorous shrewlike mammal, genus *Solenodon*. There are two species, one each on Cuba and Hispaniola. They are about 30 cm/12 in long with a 25 cm/10 in naked tail, shaggy hair, long, pointed snouts, and strong claws, and they produce venomous saliva. They are slow-moving, come out mostly at night, and eat insects, worms, and other invertebrate animals. They are threatened with extinction owing to introduced predators.

solenoid coil of wire, usually cylindrical, in which a magnetic field is created by passing an electric current through it (see electromagnet). This field can be used to move an iron rod placed on its axis.

Mechanical valves attached to the rod can be operated by switching the current on or off, so converting electrical energy into mechanical energy. Solenoids are used to relay energy from the battery of a car to the starter motor by means of the ignition switch.

solid in physics, a state of matter that holds its own shape (as opposed to a liquid, which takes up the shape of its container, or a gas, which totally fills its container). According to kinetic theory, the atoms or molecules in a solid are not free to move but merely vibrate about fixed positions, such as those in crystal lattices.

solidification change of state from liquid (or vapour) to solid that occurs at the freezing point of a substance.

solid-state circuit electronic circuit where all the components (resistors, capacitors, transistors, and diodes) and interconnections are made at the same time, and by the same processes, in or on one piece of single-crystal silicon. The small size of this construction accounts for its use in electronics for space vehicles and aircraft.

soliton solitary wave that maintains its shape and velocity, and does not widen and disperse in the normal way. The mathematical equations that sum up the behaviour of solitons are being used to further research in nuclear fusion and superconductivity.

Solomon's seal any of a group of perennial plants belonging to the lily family, native to Europe and found growing in moist, shady woodland areas. They have drooping bell-like white or greenish-white flowers which appear just above the point where the leaves join the arching stems, followed by blue or black berries. (Genus *Polygonatum*, family Liliaceae.)

solstice either of the days on which the Sun is farthest north or south of the celestial equator each year. The summer solstice,

when the Sun is farthest north, occurs around 21 June; the **winter solstice** around 22 December.

solubility measure of the amount of solute (usually a solid or gas) that will dissolve in a given amount of solvent (usually a liquid) at a particular temperature. Solubility may be expressed as grams of solute per 100 grams of solvent or, for a gas, in parts per million (ppm) of solvent.

comparative solubility curves for copper (II) sulphate and potassium nitrate

solubility

solubility curve graph that indicates how the solubility of a substance varies with temperature. Most salts increase their solubility with an increase in temperature, as they dissolve endothermically. These curves can be used to predict which salt, and how much of it, will crystallize out of a mixture of salts.

solute substance that is dissolved in another substance (see *solution*).

solution two or more substances mixed to form a single, homogeneous phase. One of the substances is the solvent and the others (solute) are said to be dissolved in it.

The constituents of a solution may be solid, liquid, or gaseous. The solvent is normally the substance that is present in greatest quantity; however, if one of the constituents is a liquid this is considered to be the solvent even if it is not the major substance.

solution in earth science, the dissolving in water of minerals within a rock. It may result in weathering (for example, when weakly acidic rainfall causes carbonation) and erosion (when flowing water passes over rocks).

Solution commonly affects limestone and chalk, and may be responsible for forming features such as sink holes.

solution in algebra, the value of a variable that satisfies a given equation; see *root*.

solution set the set of values that satisfies an inequality relationship, or equation(s).

Solvay process industrial process for the manufacture of sodium carbonate.

It is a multistage process in which carbon dioxide is generated from limestone and passed through brine saturated with ammonia. Sodium hydrogen carbonate is isolated and heated to yield sodium carbonate. All intermediate by-products are recycled so that the only ultimate by-product is calcium chloride.

solvent substance, usually a liquid, that will dissolve another substance (see *solution*). Although the commonest solvent is water, in popular use the term refers to low-boiling-point organic liquids, which are harmful if used in a confined space. They can give rise to respiratory problems, liver damage, and neurological complaints.

Typical organic solvents are petroleum distillates (in glues), xylol (in paints), alcohols (for synthetic and natural resins such as shellac), esters (in lacquers, including nail varnish), ketones (in cellulose lacquers and resins), and chlorinated hydrocarbons (as paint stripper and dry-cleaning fluids). The fumes of some solvents, when inhaled (glue-sniffing), affect mood and perception. In addition to damaging the brain and lungs, repeated inhalation of solvent from a plastic bag can cause death by asphyxia.

sonar (acronym for *sound navigation and ranging*) method of locating underwater objects by the reflection of ultrasonic waves. The time taken for an acoustic beam to travel to the object and back to the source enables the distance to be found since the velocity of sound in water is known. Sonar devices, or *echo sounders*, were developed in 1920, and are the commonest means of underwater navigation.

sone unit of subjective loudness. A tone of 40 decibels above the threshold of hearing with a frequency of 1,000 hertz is defined as one sone; any sound that seems twice as loud as this has a value of two sones, and so on. A loudness of one sone corresponds to 40 ϕ phons.

sonic boom noise like a thunderclap that occurs when an aircraft passes through the sound barrier, or begins to travel faster than the speed of sound. It happens when the cone-shaped shock wave caused by the plane touches the ground.

sonochemistry branch of chemistry based on the properties of chemicals when subjected to high-intensity ultrasound. The ultrasound causes bubbles to form, grow, and implode. The implosion generates intense local heat and extreme pressure, but for less than a millionth of a second. Light is also emitted (*sonoluminescence*).

Applications include the production of amorphous metals, molten metals cooled so fast they freeze before crystals have a chance to form properly. This gives them unique electromagnetic properties and resistance to corrosion.

sonoluminescence emission of light by a liquid that is subjected to high-frequency sound waves. The rapid changes of pressure induced by the sound cause minute bubbles to form in the liquid, which then collapse. Light is emitted at the final stage of the collapse, probably because it squeezes and heats gas inside the bubbles.

Sony Japanese electronics company that produced the *Walkman*, the first easily portable cassette player with headphones, in 1980. It diversified into entertainment by the purchase of CBS Records 1988 and Columbia Pictures in 1989. Sony made the 3.5 in disc drives for the Apple Macintosh in 1984, and also manufactures microchips and *Q*games consoles, amongst other things.

During the 1970s Sony developed the Betamax video-cassette format, which technicians rated as more advanced than the rival VHS system developed by the *Matsumita Corporation*, but the latter eventually triumphed in the marketplace. Sony's former chair, Akio Morita, is co-author of *A Japan That Can Say No* 1989 and sequel.

Sony Corporation's sales for the year to March 31 1997 were 5,663 billion yen (\$45,670 million), at which time it had 22,000 employees.

sorbic acid $\text{CH}_3\text{CH}=\text{CHCH}=\text{CHCOOH}$ tasteless acid found in the fruit of the mountain ash (genus *Sorbus*) and prepared synthetically. It is widely used in the preservation of food – for example, cider, wine, soft drinks, animal feeds, bread, and cheese.

sorghum or *great millet* or *Guinea corn* any of a group of *Cerealia* grasses native to Africa but cultivated widely in India, China, the USA, and S Europe. The seeds are used for making bread. *Q*durra is a member of the genus. (Genus *Sorghum*.)

Around 58 million tonnes of sorghum are grown worldwide on 44 million hectares. It is vulnerable to the fungus *ergot*, which can destroy whole crops. In 1994 a simple fungicidal spray of garlic and water was found to be nearly 100% successful in combatting ergot.

sorrel Old French *sur 'sour'* any of several plants belonging to the buckwheat family. *R. acetosa* is grown for its bitter salad leaves. ♀Dock plants are of the same genus. (Genus *Rumex*, family Polygonaceae.)

sorting in computing, arranging data in sequence. When sorting a collection, or file, of data made up of several different fields, one must be chosen as the key field used to establish the correct sequence. For example, the data in a company's mailing list might include fields for each customer's first names, surname, address, and telephone number. For most purposes the company would wish the records to be sorted alphabetically by surname; therefore, the surname field would be chosen as the key field.

The choice of sorting method involves a compromise between running time, memory usage, and complexity. Those used include selection sorting, in which the smallest item is found and exchanged with the first item, the second smallest exchanged with the second item, and so on; bubble sorting, in which adjacent items are continually exchanged until the data are in sequence; and insertion sorting, in which each item is placed in the correct position and subsequent items moved down to make a place for it.

sorus in ferns, a group of sporangia, the reproductive structures that produce spores. They occur on the lower surface of fern fronds.

sound physiological sensation received by the ear, originating in a vibration that communicates itself as a pressure variation in the air and travels in every direction, spreading out as an expanding sphere. All sound waves in air travel with a speed dependent on the temperature; under ordinary conditions, this is about 330 m/1,070 ft per second. The pitch of the sound depends on the number of vibrations imposed on the air per second, but the speed is unaffected. The loudness of a sound is dependent primarily on the amplitude of the vibration of the air.

The lowest note audible to a human being has a frequency of about 20 hertz (vibrations per second), and the highest one of about 20,000 Hz; the lower limit of this range varies little with the person's age, but the upper range falls steadily from adolescence onwards.

sound absorption in acoustics, the conversion of sound energy to heat energy when sound waves strike a surface. The process reduces the amplitude of each reflected sound wave (echo) and thus the degree to which reverberation takes place. Materials with good sound-absorbing properties are often fitted on walls and ceilings in buildings such as offices, factories, and concert halls in order to reduce or control sound levels.

sound barrier concept that the speed of sound, or sonic speed (about 1,220 kmph/760 mph at sea level), constitutes a speed limit to flight through the atmosphere, since a badly designed aircraft suffers severe buffeting at near sonic speed owing to the formation of shock waves. US test pilot Chuck Yeager first flew through the 'barrier' in 1947 in a Bell X-1 rocket plane. Now, by careful design, such aircraft as Concorde can fly at supersonic speed with ease, though they create in their wake a sonic boom.

SoundBlaster in computing, the most popular type of sound card for IBM-compatible PCs. SoundBlaster cards are made by Creative Labs.

sound card printed circuit board that, coupled with a set of speakers, enables a computer to reproduce music and sound effects. 16-bit sound cards give better reproduction than 8-bit sound cards, and usually offer stereo sound.

sound-level indicator instrument used to measure the intensity or loudness of sound.

Readings are given on a decibel (dB) scale that compares the sound level with the threshold of human hearing (standardized as an intensity of 1.0×10^{-12} watts per square metre). A specialised scale called the dBA scale gives a weighted reading that takes into account the ear's sensitivity to different frequencies.

sound synthesis the generation of sound (usually music) by electronic synthesizer.

sorus Heaps of bright yellow spore-producing sporangia grouped to form sori are clearly visible beneath this frond of common polypody fern. Premaphotos Wildlife

soundtrack band at one side of a cine film on which the accompanying sound is recorded. Usually it takes the form of an optical track (a pattern of light and shade). The pattern is produced on the film when signals from the recording microphone are made to vary the intensity of a light beam. During playback, a light is shone through the track on to a photo cell, which converts the pattern of light falling on it into appropriate electrical signals. These signals are then fed to loudspeakers to recreate the original sounds.

sound wave the longitudinal wave motion with which sound energy travels through a medium. It carries energy away from the source of the sound without carrying the material itself with it. Sound waves are mechanical; unlike electromagnetic waves, they require vibration of their medium's molecules or particles, and this is why sound cannot travel through a vacuum.

source code in computing, the original instructions written by computer programmers. Before these instructions can be understood, they must be processed by a compiler and turned into machine code.

source language in computing, the language in which a program is written, as opposed to machine code, which is the form in which the program's instructions are carried out by the computer. Source languages are classified as either high-level languages or low-level languages, according to whether each notation in the source language stands for many or only one instruction in machine code.

Programs in high-level languages are translated into machine code by either a compiler or an interpreter program. Low-level programs are translated into machine code by means of an assembler program. The program, before translation, is called the source program; after translation into machine code it is called the object program.

source program in computing, a program written in a source language.

source resistance alternative term for internal resistance, the resistance inside an electric power supply.

souring change that occurs to wine on prolonged exposure to air. The ethanol in the wine is oxidized by the air (oxygen) to ethanoic acid. It is the presence of the ethanoic (acetic) acid that produces the sour taste.

The Year in Space – 1997

BY TIM FURNISS

Space in 1997 has been dominated by three events: the landing on the planet Mars of the NASA *Mars Pathfinder* and its tiny rover, the Sojourner, on 4 July; the hyped-up, infamous incidents on the Russian *Mir* space station; and the successful test flight of Europe's *Ariane 5* rocket.

Mars Pathfinder Lands

The landing of the low-cost *Mars Pathfinder* and the images it returned – 21 years after the last touchdowns on the Red Planet by the *Vikings 1* and 2 – was made all the more spectacular by the access to its pictures by users of the Internet. The Web revolution even resulted in home-based addicts getting daily weather reports from Mars. The Sojourner, about the size of a microwave oven and the precursor of slightly larger and more sophisticated rovers on future missions in the Mars Surveyor programme, caught the imagination of the public with its explorations and analysis of rocks with such names as Yogi and Barnacle Bill.

Both craft continued to operate well beyond their design lives and provided more evidence that water once flowed across the now barren, ruddy coloured, rocky surface. The mission formally ended in November after four months.

Mir Space Station

Closer to home, the remarkable Russian *Mir 1* space station continued manned operations – also beyond its design life – providing a wealth of data and experience about operating larger space stations. The Russians' invaluable expertise in this area of space utilization was sadly underplayed by the extraordinary media reaction to certain incidents on the station, which were highlighted because US astronauts were on board at the time.

A fire that broke out in February was not the first to occur on the station, but the collision of the *Progress* tanker craft with the *Spekt* module in June could have been a disaster. The collision was more of a glancing blow, but the *Spekt* module lost the use of a solar panel and was depressurized as a result. The incident was a reminder that space travel is dangerous, and risks have to be accepted. Most of the media attention was given to the age of the *Mir* station, and the fact that it was apparently a 'wreck'. In fact, while the core module of *Mir* was launched in 1986, the final module of the space complex was launched in 1996! Running a space station for that long is bound to involve things breaking down, but part of the Russian way of working is to treat these events as operational, not emergency, situations, which is a different culture altogether from NASA Space Shuttle missions. Regular spacewalks and maintenance on the *Mir* station will contribute towards keeping the *Mir* in working order and ready to house many more crews until it is retired, perhaps in 1999.

During spacewalks in 1997 and early 1998, the veteran Russian cosmonaut Anatoli Solovyov became the first to make 14 spacewalks, all outside the *Mir* station on various missions. He has accumulated 63 hours of spacewalk time, compared with the individual US record of 29 hours. Another *Mir* spacewalk marked the first by a Russian and US astronaut together, an occasion later repeated aboard the Space Shuttle. Once the International Space Station is operational, NASA and the other partners will owe a debt to the operational space-station experience database provided by Russia.

Ariane 5 Launched

The successful flight of the *Ariane 5* from Kourou on 31 October was a great relief to the European space industry. The first *Ariane 5* failed dramatically in an explosion in June 1996, and another problem could have been a disaster. It is now hoped that *Ariane 5* can go on to forge a successful commercial career, allowing the old

workhorse, the *Ariane 4*, to retire in about 2003. Eleven *Ariane 4*s made successful commercial flights in 1997.

Notable Satellite Launches

Brazil, making its first attempt to join the 'space league' of nations that have launched national satellites on indigenously-developed boosters, failed when its VLS booster had to be destroyed after an engine fault. A spectacular failure of a US Delta rocket, which had people running for cover at Cape Canaveral in January, illustrated that losses can be experienced by veteran space nations as well. Another Delta featured in the successful launch of the first in a series of satellites, opening a new era in communications. Sixty-six Iridium satellites will eventually enable users of mobile telephones to make a call from anywhere in the world to anywhere in the world. By the end of the year, 41 Iridiums had been launched, and the network should be completed in mid-1998.

Successes and Some Failures

A new era in planetary exploration began in 1997, too, with the launch in November of the first spacecraft, the *Cassini/Huygens*, to orbit the planet Saturn in 2004 after its long route around the solar system. The *Huygens* lander is to touch down on the surface of the Saturnian moon, Titan. Another planetary spacecraft, the Mars Global Surveyor, reached Mars orbit in September, but its manoeuvring to operational mapping orbit was interrupted by some malfunctions and, as a result, its mission may be limited.

The launch of a new crew to operate a shift aboard the *Mir* space station in July marked the 200th manned spaceflight launch in history since April 1961 (not including the failed Challenger Shuttle mission in 1986). The USA also launched eight Space Shuttle missions in 1997, three of them to dock with the *Mir* space station to deliver a new astronaut and return one home. As the year closed, the US resident *Mir* astronaut was David Wolf, who clambered aboard the *Mir* in October and was replaced by another astronaut early in 1998.

The year also marked a Shuttle record. One mission, STS 83, had to be aborted after three days due to a fuel cell failure but was reflown in July with the entire crew returning to space in a record 84 days. The Russian *Proton* launcher completed its second commercial launch in May 1997, carrying a *Telesat* satellite into orbit for the joint US/Russian International Launch Services (ILS). The company's link-up with the USA has transformed the commercial career of the *Proton*, which is now fully booked until 2001 for commercial launches but the *Proton* blotted the copy book by failing on the 25 December. Overall, in 1997, there were 86 satellite launches, 38 by the USA, 28 by Russia, 12 by Europe, 6 by China, 2 by Japan and 1 by India, involving almost 140 satellites.

Not all the satellites performed well, however. A Japanese earth-observation satellite suffered a solar panel malfunction and was lost, too US Earth observation satellites were also lost, and a communications satellite stranded in the wrong orbit.

One of the 28 Russian satellite launches inaugurated a new launch site at Svobodny in far-eastern Russia. The former top-secret military base and missile launch complex has been converted into a launch base for small satellites into low earth orbit, using converted military missiles. In the business world, the proposed merger of the UK/French Matra Marconi Space company and Germany's Daimler-Benz Aerospace space division, announced in 1997, will result in the formation of a large pan-European company to compete on equal terms with the giant US satellite manufacturers, Hughes, Lockheed Martin, and Space Systems Loral. 1998 promises to be a very significant year in the history of space exploration – the start of the assembly of the first International Space Station.

Space Flight: chronology

| | | | |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1903 | Russian scientist Konstantin Tsiolkovsky published the first practical paper on astronautics. | 1986 | Space shuttle <i>Challenger</i> (USA) exploded shortly after take-off, killing all seven crew members. |
| 1926 | US engineer Robert Goddard launched the first liquid-fuel rocket. | 1988 | US shuttle programme resumed with launch of <i>Discovery</i> . Soviet shuttle <i>Buran</i> was launched from the rocket <i>Energia</i> . Soviet cosmonauts Musa Manarov and Vladimir Titov in space station <i>Mir</i> spent a record 365 days 59 min in space. |
| 1937-45 | In Germany, Wernher von Braun developed the V2 rocket. | 1990 | April: Hubble Space Telescope (USA) was launched from Cape Canaveral. |
| 1957 | 4 Oct: The first space satellite, <i>Sputnik 1</i> (USSR, Russian 'fellow-traveller'), orbited the Earth at a height of 229-898 km/142-558 mi in 96.2 min. 3 Nov: <i>Sputnik 2</i> was launched carrying a dog, 'Laika'; it died on board seven days later. | 1991 | 5 April: The Gamma Ray Observatory was launched from the space shuttle <i>Atlantis</i> to survey the sky at gamma-ray wavelengths. 18 May: Astronaut Helen Sarmann, the first Briton in space, was launched with Anatoli Artsebarsky and Sergei Krikalev to <i>Mir</i> space station, returning to Earth 26 May in <i>Soyuz TM-11</i> with Viktor Afanasyev and Musa Manarov. Manarov set a record for the longest time spent in space, 541 days, having also spent a year aboard <i>Mir</i> 1988. |
| 1958 | 31 Jan: <i>Explorer 1</i> , the first US satellite, discovered the Van Allen radiation belts. | 1992 | European satellite <i>Hipparcos</i> , launched 1989 to measure the position of 120,000 stars, failed to reach geostationary orbit and went into a highly elliptical orbit, swooping to within 500 km/308 mi of the Earth every ten hours. The mission was later retrieved. 16 May: Space shuttle <i>Endeavour</i> returned to Earth after its first voyage. During its mission, it circled the Earth 141 times and travelled 4 million km/2.5 million mi. 23 Oct: <i>LAGEOS II</i> (Laser Geodynamics Satellite) was released from the space shuttle <i>Columbia</i> into an orbit so stable that it will still be circling the Earth in billions of years. Dec: Space shuttle <i>Endeavour</i> successfully carried out mission to replace the Hubble Space Telescope's solar panels and repair its mirror. |
| 1961 | 12 April: the first crewed spaceship, <i>Vostok 1</i> (USSR), with Yuri Gagarin on board, was recovered after a single orbit of 89.1 min at a height of 142-175 km/88-109 mi. | 1994 | 4 Feb: Japan's heavy-lifting <i>H-2</i> rocket was launched successfully, carrying an uncrewed shuttle craft. |
| 1962 | 20 Feb: John Glenn in <i>Friendship 7</i> (USA) became the first American to orbit the Earth. <i>Telstar</i> (USA), a communications satellite, sent the first live television transmission between the USA and Europe. | 1995 | June: the US space shuttle <i>Atlantis</i> docked with <i>Mir</i> , exchanging crew members. |
| 1963 | 16-19 June: Valentina Tereshkova in <i>Vostok 1</i> (USSR) became the first woman in space. | 1996 | 4 June: the <i>Ariane 5</i> rocket disintegrated almost immediately after takeoff, destroying the four Cluster satellites. |
| 1967 | 27 Jan: US astronauts Virgil Grissom, Edward White, and Roger Chaffee were killed during a simulated countdown when a flash fire swept through the cabin of <i>Apollo 1</i> . 24 April: Vladimir Komarov was the first person to be killed on a mission, when his ship, <i>Soyuz 1</i> (USSR), crash-landed on the Earth. | 1997 | April: NASA ceased operations using the space probe <i>Pioneer 10</i> after 25 years of sending signals from the edge of the Solar System. July: <i>Mir</i> underwent increasing difficulties, following a collision with a cargo ship in June that depressurized one of its modules, Spektr. |
| 1969 | 20 July: Neil Armstrong of <i>Apollo 11</i> (USA) was the first person to walk on the Moon. | | |
| 1970 | 10 Nov: <i>Luna 17</i> (USSR) was launched; its space probe, <i>Lunokhod</i> , took photographs and made soil analyses of the Moon's surface. | | |
| 1971 | 19 April: <i>Salyut 1</i> (USSR), the first orbital space station, was established; it was later visited by the <i>Soyuz 11</i> crewed spacecraft. | | |
| 1973 | <i>Skylab 2</i> , the first US orbital space station, was established. | | |
| 1975 | 15-24 July: <i>Apollo 18</i> (USA) and <i>Soyuz 19</i> (USSR) made a joint flight and linked up in space. | | |
| 1979 | The European Space Agency's satellite launcher, <i>Ariane 1</i> , was launched. | | |
| 1981 | 12 April: The first reusable crewed spacecraft, the space shuttle <i>Columbia</i> (USA), was launched. | | |

South African Astronomical Observatory national observatory of South Africa at Sutherland, founded 1973 after the merger of the Royal Observatory, Cape Town, and the Republic Observatory, Johannesburg, and operated by the Council for Scientific and Industrial Research of South Africa. Its main telescope is a 1.88-m/74-in reflector formerly at the Radcliffe Observatory, Pretoria.

Southern Cross popular name for the constellation δ Crux.

southern lights common name for the δ aurora australis, coloured light in southern skies.

Southern Ocean corridor linking the Pacific, Atlantic, and Indian oceans, all of which receive cold polar water from the world's largest ocean surface current, the Antarctic Circumpolar Current, which passes through the Southern Ocean.

soya bean leguminous plant (see δ legume) native to E Asia, in particular Japan and China. Originally grown as a food crop for animals, it is increasingly used for human consumption in cooking oils and margarine, as a flour, soya milk, soya sauce, or processed into tofu, miso, or textured vegetable protein (δ TVP). (*Glycine max.*)

Soya is the richest natural vegetable food. The dried bean is 18-22% fat, 35% carbohydrate, and one hectare of soya beans

yields 162 kg/357 lb of protein (compared with 9 kg/20 lb per hectare for beef). There are more than 1,000 varieties. The plant has been cultivated in Asia for about 5,000 years, and first became known in Europe when brought back from Japan by German botanist Engelbert Kaenfer in 1692. Today the USA produces more soya beans than Asia.

Miso is soya beans fermented with cereal grains, water, and salt, used in soups and sauces; **soy sauce** is beans fermented with salt; and **tamari** is similar to soy sauce but stronger, having been matured for up to two years.

Soyuz Russian 'union' Soviet series of spacecraft, capable of carrying up to three cosmonauts. Soyuz spacecraft consist of three parts: a rear section containing engines; the central crew compartment; and a forward compartment that gives additional room for working and living space. They are now used for ferrying crews up to space stations, though they were originally used for independent space flight.

space or **outer space** the void that exists beyond Earth's atmosphere. Above 120 km/75 mi, very little atmosphere remains, so objects can continue to move quickly without extra energy. The space between the planets is not entirely empty, but filled with the tenuous gas of the δ solar wind as well as dust specks.

Space Probe: chronology

| | | | |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1959 | (13 Sept) <i>Luna 2</i> (USSR) hit the Moon, the first craft to do so. (10 Oct) <i>Luna 3</i> photographed the far side of the Moon. | 1990 | (10 Aug) <i>Magellan</i> arrived at Venus and transmitted its first pictures 16 Aug 1990. (6 Oct) <i>Ulysses</i> (European Space Agency) launched from space shuttle <i>Discovery</i> , to study the Sun. |
| 1962 | (14 Dec) <i>Mariner 2</i> (USA) flew past Venus; launch date 26 Aug 1962. | 1991 | (29 Oct) <i>Galileo</i> made the closest-ever approach to an asteroid, Gaspra, flying within 1,600 km/990 mi. |
| 1964 | (31 July) <i>Ranger 7</i> (USA) hit the Moon, having sent back 4,316 pictures before impact. | 1992 | (8 Feb) <i>Ulysses</i> flew past Jupiter at a distance of 380,000 km/236,000 mi from the surface, just inside the orbit of Io and closer than 11 of Jupiter's 16 moons. (10 July) <i>Giotto</i> (ESA) flew at a speed of 14 km/8.5 mps to within 200 km/124 mi of comet Grigg-Skellerup, 12 light years (240 million km/150 mi) away from Earth. |
| 1965 | (14 July) <i>Mariner 4</i> flew past Mars; launch date 28 Nov 1964. | | (25 Sept) <i>Mars Observer</i> (USA) launched from Cape Canaveral, the first US mission to Mars for 17 years. |
| 1966 | (3 Feb) <i>Luna 9</i> achieved the first soft landing on the Moon, having transmitted 27 close up panoramic photographs; launch date 31 Jan 1966. (2 June) <i>Surveyor 1</i> (USA) landed softly on the Moon and returned 11,150 pictures; launch date 30 May 1965. | | (10 Oct) <i>Pioneer-Venus 1</i> burned up in the atmosphere of Venus. |
| 1971 | (13 Nov) <i>Mariner 9</i> entered orbit of Mars; launch date 30 May 1971. | 1993 | (21 Aug) <i>Mars Observer</i> disappeared three days before it was due to drop into orbit around Mars. (28 Aug) <i>Galileo</i> flew past the asteroid Ida. |
| 1973 | (3 Dec) <i>Pioneer 10</i> (USA) flew past Jupiter; launch date 3 March 1972. | 1995 | (Dec) <i>Galileo's</i> probe entered the atmosphere of Jupiter. It radioed information back to the orbiter for 57 minutes before it was destroyed by atmospheric pressure. |
| 1974 | (29 March) <i>Mariner 10</i> flew past Mercury; launch date 3 Nov 1973. | 1996 | NASA's Near Earth Asteroid Rendezvous (NEAR) was launched to study Eros. |
| 1975 | (22 Oct) <i>Venera 9</i> (USSR) landed softly on Venus and returned its first pictures; launch date 8 June 1975. | 1997 | The US spacecraft <i>Mars Pathfinder</i> landed on Mars. Two days later the probe's rover <i>Sojourner</i> , a six-wheeled vehicle that was controlled by an Earth-based operator, began to explore the area around the spacecraft. |
| 1976 | (20 July) <i>Viking 1</i> (USA) first landed on Mars; launch date 20 Aug 1975. (3 Sept) <i>Viking 2</i> transmitted data from the surface of Mars. | 1997 | The US space probe <i>Galileo</i> began orbiting Jupiter's moons. It took photographs of Europa for a potential future landing site, and detected molecules containing carbon and nitrogen on Callisto, suggesting that life once existed there. |
| 1977 | (20 Aug) <i>Voyager 2</i> (USA) launched. (5 Sept) <i>Voyager 1</i> launched. | 1997 | The US Near Earth Asteroid Rendezvous (NEAR) spacecraft flew within 1,200 km/746 mi of the asteroid Mathilde, taking high-resolution photographs and revealing a 25-km/15.5-mi crater covering the 53-km/33-mi asteroid. |
| 1978 | (4 Dec) <i>Pioneer-Venus 1</i> (USA) orbited Venus; launch date 20 May 1978. | 1997 | The US spacecraft <i>Mars Global Surveyor</i> went into orbit around Mars to conduct a detailed photographic survey of the planet, commencing in March 1998, and reported the discovery of bacteria on Mars. |
| 1979 | (5 March and 9 July) <i>Voyager 1</i> and <i>Voyager 2</i> encountered Jupiter, respectively. | 1998 | The US probe <i>Lunar Prospector</i> was launched to go into low orbits around the Moon and transmit data on the composition of its crust, record gamma rays, and map its magnetic field. The satellite detected 11 million tonnes of water on the Moon in the form of ice. |
| 1980 | (12 Nov) <i>Voyager 1</i> reached Saturn. | 1998 | Analysis of high resolution images from the <i>Galileo</i> spacecraft suggested that the icy crust of Europa, Jupiter's fourth largest moon, may have a vast ocean warm enough to support life. |
| 1981 | (25 Aug) <i>Voyager 2</i> flew past Saturn. | 1998 | (4 July) Japan's Planet-B was launched to study Mars. |
| 1982 | (1 March) <i>Venera 13</i> transmitted its first colour pictures of the surface of Venus; launch date 30 Oct 1981. | | |
| 1983 | (10 Oct) <i>Venera 15</i> mapped the surface of Venus from orbit; launch date 2 June 1983. | | |
| 1985 | (2 July) <i>Giotto</i> (European Space Agency) launched to Halley's comet. | | |
| 1986 | (24 Jan) <i>Voyager 2</i> encountered Uranus. (13-14 March) <i>Giotto</i> met Halley's comet, closest approach 596 km/370 mi, at a speed 50 times faster than that of a bullet. | | |
| 1989 | (4 May) <i>Magellan</i> (USA) launched from space shuttle <i>Atlantis</i> on a 15-month cruise to Venus across 15 million km/9 million mi of space. (25 Aug) <i>Voyager 2</i> reached Neptune (4,400 million km/2,700 million mi from Earth), approaching it to within 4,850 km/3,010 mi. (18 Oct) <i>Galileo</i> (USA) launched from space shuttle <i>Atlantis</i> for six-year journey to Jupiter. | | |

Space isn't remote at all. It's only an hour's drive away if your car could go straight upwards.

FRED HOYLE English astronomer and writer.
Observer Sept 1979

Spacelab small space station built by the European Space Agency, carried in the cargo bay of the US space shuttle, in which it remains throughout each flight, returning to Earth with the shuttle. Spacelab consists of a pressurized module in which astronauts can work, and a series of pallets, open to the vacuum of space, on which equipment is mounted.

Spacelab is used for astronomy, Earth observation, and experiments utilizing the conditions of weightlessness and vacuum in

orbit. The pressurized module can be flown with or without pallets, or the pallets can be flown on their own, in which case the astronauts remain in the shuttle's own crew compartment. All the sections of Spacelab can be reused many times. The first Spacelab mission, consisting of a pressurized module and pallets, lasted ten days November-December 1983.

space probe any instrumented object sent beyond Earth to collect data from other parts of the Solar System and from deep space. The first probe was the Soviet *Luik 1*, which flew past the Moon in 1959. The first successful planetary probe was the US *Mariner 2*, which flew past Venus in 1962, using transfer orbit. The first space probe to leave the Solar System was *Pioneer 10* in 1983. Space probes include *Galileo*, *Giotto*, *Magellan*, *Mars Observer*, *Ulysses*, the Moon probes, and the Mariner, Pioneer, Viking, and Voyager series.

space programme the systematic exploration and utilization of space; see *space probe* and *space shuttle*.

space shuttle reusable crewed spacecraft. The first was launched 12 April 1981 by the USA. It was developed by NASA to reduce the cost of using space for commercial, scientific, and military purposes. After leaving its payload in space, the space-shuttle orbiter can be flown back to Earth to land on a runway, and is then available for reuse.

Four orbiters were built: *Columbia*, *Challenger*, *Discovery*, and *Atlantis*. *Challenger* was destroyed in a midair explosion just over a minute after its tenth launch 28 January 1986, killing all seven crew members, the result of a failure in one of the solid rocket boosters. Flights resumed with redesigned boosters in Sept 1988. A replacement orbiter, *Endeavour*, was built, which had its maiden flight in May 1992. At the end of the 1980s, an average of \$375 million had been spent on each space-shuttle mission.

The USSR produced a shuttle of similar size and appearance to the US one. The first Soviet shuttle, *Buran*, was launched without a crew by the Energiya rocket 15 Nov 1988. In Japan, development of a crewless shuttle began in 1986.

NASA SHUTTLE WEB

<http://shuttle.nasa.gov/reference/>

Official NASA site for all shuttle missions. There is extensive technical and nontechnical information, both textual and graphic. Questions can be sent to shuttle crew members during missions. If they are not answered there is an extensive list of frequently asked questions.

There are helpful links to related sites and even a plain English explanation of NASA's bewildering jargon and acronyms.

space sickness or **space adaptation syndrome** feeling of nausea, sometimes accompanied by vomiting, experienced by about 40% of all astronauts during their first few days in space. It is akin to travel sickness, and is thought to be caused by confusion of the body's balancing mechanism, located in the inner ear, by weightlessness. The sensation passes after a few days as the body adapts.

space station any large structure designed for human occupation in space for extended periods of time. Space stations are used for carrying out astronomical observations and surveys of Earth, as well as for biological studies and the processing of materials in weightlessness. The first space station was *Salyut 1*, and the USA has launched *SkyLab*.

NASA plans to build a larger space station, to be called *Alpha* in cooperation with other countries, including the European Space Agency, which is building a module called *Columbus*; Russia and Japan are also building modules.

space suit protective suit worn by astronauts and cosmonauts in space. It provides an insulated, air-conditioned cocoon in which people can live and work for hours at a time while outside the spacecraft. Inside the suit is a cooling garment that keeps the body at a comfortable temperature even during vigorous work. The suit provides air to breathe, and removes exhaled carbon dioxide and moisture. The suit's outer layers insulate the occupant from the extremes of hot and cold in space (-150°C – 240°F in the shade to $+180^{\circ}\text{C}$ – $+350^{\circ}\text{F}$ in sunlight), and from the impact of small meteorites. Some space suits have a jet-propelled backpack, which the wearer can use to move about.

space-time in physics, combination of space and time used in the theory of relativity. When developing relativity, Albert Einstein showed that time was in many respects like an extra dimension (or direction) to space. Space and time can thus be considered as entwined into a single entity, rather than two separate things.

Space-time is considered to have four dimensions: three of space and one of time. In relativity theory, events are described as occurring at points in space-time. The general theory of relativity

spadix The numerous tiny stalkless flowers on the spadix of the sweet flag *Acorus calamus*. A plant of watersides, the sweet flag is native to S Asia and North America but is now widely naturalized in Europe, including the British Isles. Premaphotos Wildlife

describes how space-time is distorted by the presence of material bodies, an effect that we observe as gravity.

spadix in botany, an inflorescence consisting of a long, fleshy axis bearing many small, stalkless flowers. It is partially enclosed by a large bract or spathe. A spadix is characteristic of plants belonging to the family Araceae, including the arum lily *Zantedeschia aethiopica*.

spamming advertising on the Internet by broadcasting to many or all newsgroups regardless of relevance. Spamming is contrary to netiquette, the Net's conduct code, and is likely to result in the advertiser being bombarded by flames (angry messages), and 'dumping' (the downloading of large, useless files).

spaniel any of several breeds of small and medium-sized gundog, characterized by large, drooping ears and a wavy, long, silky coat. Spaniels are divided into two groups: those that are still working gundogs – *Clumber*, *cocker*, *Irish water*, *springer*, and *Sussex* – and the toy breeds that are kept as pets – including the *Japanese*, *King Charles*, *papillon*, and *Tibetan*.

The working breeds usually have docked tails.

Spanish fly alternative name for a European blister beetle *Lytta resicatoria*, once used in powdered form as a dangerous diuretic and supposed aphrodisiac.

spark chamber electronic device for recording tracks of charged subatomic particles, decay products, and rays. In combination with a stack of photographic plates, a spark chamber enables the point where an interaction has taken place to be located, to within a cubic centimetre. At its simplest, it consists of two smooth threadlike (electrodes that are positioned 1–2 cm/0.5–1 in apart, the space between being filled by an inert gas such as neon. Sparks jump through the gas along the ionized path created by the radiation. See *particle detector*.

spark plug plug that produces an electric spark in the cylinder of a petrol engine to ignite the fuel mixture. It consists essentially of two electrodes insulated from one another. High-voltage (18,000 V) electricity is fed to a central electrode via the distributor. At the base of the electrode, inside the cylinder, the electricity jumps to another electrode earthed to the engine body, creating a spark. See also *ignition coil*.

sparrow any of a family (Passeridae) of small Old World birds of the order Passeriformes with short, thick bills, but applied particularly to the different members of the genus *Passer* in the family *Ploceidae*, order *Passeriformes*.

Many numbers of the New World family *Emberizidae*, which includes warblers, orioles, and buntings, are also called sparrows; for example, the North American song sparrow *Melospiza melodia*.

sparrow hawk small woodland hawk *Accipiter nisus*, of the family *Falconidae*, order *Falconiformes*, found in Eurasia and N Africa. It is bluish-grey, with brown and white markings, and has a long tail and short wings. The male grows to 28 cm/11 in long, and the female to 38 cm/15 in. It hunts small birds and mice.

spastic term applied generally to limbs with impaired movement, stiffness, and resistance to passive movement, and to any body part (such as the colon) affected with spasm.

spathe in flowers, the single large bract surrounding the type of inflorescence known as a *spadix*. It is sometimes brightly coloured and petal-like, as in the brilliant scarlet spathe of the flamingo plant *Anthurium andreanum* from South America; this serves to attract insects.

spawn extruded egg mass of such egg-laying animals as fish, amphibians, and molluscs.

Spawn is produced in very variable quantities (for example, the cling lays about 150,000,000 eggs, and the American oyster 60,000,000 eggs) and is much preyed upon, even, as in the case of the stickleback, by the female herself. A variety of means have been devised for its protection.

In fish, spawning is the reproductive phase, variously involving aggregation of the fish, courtship, extrusion of eggs and sperm into the water, and fertilization of the eggs. Large migrations may precede spawning, as in salmon and herring. In some groups the spawn is not released, fertilization being internal.

The name is also sometimes given to the mycelium of mushrooms and other fungi, seen as white threads in decaying matter.

spearmint perennial herb belonging to the mint family, with aromatic leaves and spikes of purple flowers; the leaves are used for flavouring in cookery. (*Mentha spicata*, family *Labiatae*.)

speciation emergence of a new species during evolutionary history. One cause of speciation is the geographical separation of populations of the parent species, followed by reproductive isolation and selection for different environments so that they no longer produce viable offspring when they interbreed. Other causes are assortative mating and the establishment of a *polyploid* population.

species in biology, a distinguishable group of organisms that resemble each other or consist of a few distinctive types (as in *polymorphism*), and that can all interbreed to produce fertile offspring. Species are the lowest level in the system of biological classification.

Related species are grouped together in a genus. Within a species there are usually two or more separate populations, which may in time become distinctive enough to be designated subspecies or varieties, and could eventually give rise to new species through speciation. Around 1.4 million species have been identified so far, of which 750,000 are insects, 250,000 are plants, and 41,000 are vertebrates. In tropical regions there are roughly two species for each temperate-zone species. It is estimated that one species becomes extinct every day through habitat destruction.

specific gravity alternative term for *relative density*.

specific heat capacity in physics, quantity of heat required to raise unit mass (1 kg) of a substance by one kelvin (1 K). The unit of specific heat capacity in the SI system is the joule per kilogram kelvin ($\text{J kg}^{-1} \text{K}^{-1}$).

specific latent heat in physics, the heat that changes the physical state of a unit mass (one kilogram) of a substance without causing any temperature change.

The specific latent heat of fusion of a solid substance is the heat required to change one kilogram of it from solid to liquid without any temperature change. The specific latent heat of vaporization of a liquid substance is the heat required to change one kilogram of it from liquid to vapour without any temperature change.

speckle interferometry technique whereby large telescopes can achieve high resolution of astronomical objects despite the adverse effects of the atmosphere through which light from the object under study must pass. It involves the taking of large numbers of images, each under high magnification and with short exposure times. The pictures are then combined to form the final picture. The technique was introduced by the French astronomer Antoine Labeyrie in 1970.

spectacles pair of lenses fitted in a frame and worn in front of the eyes to correct or assist defective vision. Common defects of the eye corrected by spectacle lenses are short sight (myopia) by using concave (spherical) lenses, long sight (hypermetropia) by using convex (spherical) lenses, and astigmatism by using cylindrical lenses.

Spherical and cylindrical lenses may be combined in one lens. Bifocal spectacles correct vision both at a distance and for reading by combining two lenses of different curvatures in one piece of glass. Varifocal spectacles have the same effect without any visible line between the two types of lens.

Spectacles are said to have been invented in the 13th century by a Florentine monk. Few people found the need for spectacles until printing was invented, when the demand for them increased rapidly. Using photosensitive glass, lenses can be produced that darken in glare and return to normal in ordinary light conditions. Lightweight plastic lenses are also common. The alternative to spectacles is contact lenses.

spectator ion in a chemical reaction that takes place in solution, an ion that remains in solution without taking part in the chemical change. For example, in the precipitation of barium sulphate from barium chloride and sodium sulphate, the sodium and chloride ions are spectator ions.

spectral classification in astronomy, the classification of stars according to their surface temperature and luminosity, as determined from their spectra. Stars are assigned a spectral type (or class) denoted by the letters O, B, A, F, G, K, and M, where O stars (about 40,000 K) are the hottest and M stars (about 3,000 K) are the coolest.

Each letter may be further divided into ten subtypes, B0, B1, B2, etc. Stars are also assigned a luminosity class denoted by a Roman numeral attached to the spectral type: I (supergiants), II (bright giants), III (giants), IV (subgiants), V (main sequence), VI (subwarfs), or VII (white dwarfs). The Sun is classified as type G2V. See also *Hertzsprung-Russell diagram*.

spectrometer in physics and astronomy, an instrument used to study the composition of light emitted by a source. The range, or spectrum, of wavelengths emitted by a source depends upon its constituent elements, and may be used to determine its chemical composition.

The simpler forms of spectrometer analyse only visible light. A collimator receives the incoming rays and produces a parallel beam, which is then split into a spectrum by either a diffraction grating or a prism mounted on a turntable. As the turntable is rotated each of the constituent colours of the beam may be seen through a telescope, and the angle at which each has been deviated may be measured on a circular scale. From this information the wavelengths of the colours of light can be calculated.

Spectrometers are used in astronomy to study the electromagnetic radiation emitted by stars and other celestial bodies. The spectral information gained may be used to determine their chemical composition, or to measure the red shift of colours associated with the expansion of the universe and thereby calculate the speed with which distant stars are moving away from the Earth.

spectrometry in analytical chemistry, a technique involving the measurement of the spectrum of energies (not necessarily electromagnetic radiation) emitted or absorbed by a substance.

spectroscopy study of spectra (see *spectrum*) associated with atoms or molecules in solid, liquid, or gaseous phase. Spectroscopy can be used to identify unknown compounds and is an invaluable

tool in science, medicine, and industry (for example, in checking the purity of drugs).

Emission spectroscopy is the study of the characteristic series of sharp lines in the spectrum produced when an element is heated. Thus an unknown mixture can be analysed for its component elements. Related is **absorption spectroscopy**, dealing with atoms and molecules as they absorb energy in a characteristic way. Again, dark lines can be used for analysis. More detailed structural information can be obtained using **infrared spectroscopy** (concerned with molecular vibrations) or **nuclear magnetic resonance (NMR) spectroscopy** (concerned with interactions between adjacent atomic nuclei). **Supersonic jet laser beam spectroscopy** enables the isolation and study of clusters in the gas phase. A laser vaporizes a small sample, which is cooled in helium, and ejected into an evacuated chamber. The jet of clusters expands supersonically, cooling the clusters to near absolute zero, and stabilizing them for study in a mass spectrometer.

spectrum (plural *spectra*) in physics, an arrangement of frequencies or wavelengths when electromagnetic radiations are separated into their constituent parts. Visible light is part of the electromagnetic spectrum and most sources emit waves over a range of wavelengths that can be broken up or 'dispersed'; white light can be separated into red, orange, yellow, green, blue, indigo, and violet. The visible spectrum was first studied by Isaac Newton, who showed in 1672 how white light could be broken up into different colours.

TO REMEMBER THE ORDER OF COLOURS:

RICHARD OF YORK GAINED BATTLES IN VAIN.

OR

ROLL OUT YOUR GUINNESS, BOYS, IN VATS.

OR

REAL OLD YOKELS GUZZLE BEER IN VOLUME.

RED, ORANGE, YELLOW, GREEN, BLUE, INDIGO, VIOLET

speech chip in computing, see **DDSP**.

speech recognition or **voice input** in computing, any technique by which a computer can understand ordinary speech. Spoken words are divided into 'frames', each lasting about one-thirtieth of a second, which are converted to a wave form. These are then compared with a series of stored frames to determine the most likely word. Research into speech recognition started in 1938, but the technology did not become sufficiently developed for commercial applications until the late 1980s.

There are three types: **separate word recognition** for distinguishing up to several hundred separately spoken words; **connected speech recognition** for speech in which there is a short pause between words; and **continuous speech recognition** for normal but carefully articulated speech.

speech synthesis or **voice output** computer-based technology for generating speech. A speech synthesizer is controlled by a computer, which supplies strings of codes representing basic speech sounds (phonemes); together these make up words. Speech-synthesis applications include children's toys, car and aircraft warning systems, and talking books for the blind.

speech writing system computing system that enables data to be input by voice. It includes a microphone, and (sound card that plugs into the computer and converts the analogue signals of the voice to digital signals. Examples include DragonDictate, and IBM's Personal Dictation System released in 1994.

The user must read sample sentences to the computer on first use to familiarize it with individual pronunciation. Early speech writers were very inaccurate and slow but by the mid-1990s speeds of 80 words per minute with 95-99% accuracy were achievable.

speed common name for **amphetamine**, a stimulant drug.

speed the rate at which an object moves. The average speed v of an object may be calculated by dividing the distance s it has travelled by the time t taken to do so, and may be expressed as:

$$v = \frac{s}{t}$$

The usual units of speed are metres per second or kilometres per hour.

Speed is a scalar quantity in which direction of motion is unimportant (unlike the vector quantity **velocity**, in which both magnitude and direction must be taken into consideration). See also **distance-time graph** and **speed-time graph**.

speed of light speed at which light and other electromagnetic waves travel through empty space. Its value is 299,792,458 m/186,281 mi per second. The speed of light is the highest speed possible, according to the theory of relativity, and its value is independent of the motion of its source and of the observer. It is impossible to accelerate any material body to this speed because it would require an infinite amount of energy.

TO REMEMBER THE SPEED OF LIGHT:

THE SPEED OF LIGHT IS 299,792,458 M/S, WHICH CAN BE REMEMBERED FROM THE NUMBER OF LETTERS IN EACH WORD OF THE FOLLOWING PHRASE: WE GUARANTEE CERTAINTY, CLEARLY REFERRING TO THIS LIGHT MNEMONIC

speed of reaction alternative term for **rate of reaction**.

speed of sound speed at which sound travels through a medium, such as air or water. In air at a temperature of 0°C/32°F, the speed of sound is 331 m/1,087 ft per second. At higher temperatures, the speed of sound is greater; at 18°C/64°F it is 342 m/1,123 ft per second.

It is greater in liquids and solids; for example, in water it is around 1,440 m/4,724 ft per second, depending on the temperature.

speedometer instrument attached to the transmission of a vehicle by a flexible drive shaft, which indicates the speed of the vehicle in miles or kilometres per hour on a dial easily visible to the driver.

speed-time graph graph used to describe the motion of a body by illustrating how its speed or velocity changes with time. The gradient of the graph gives the object's acceleration: if the gradient is zero (the graph is horizontal) then the body is moving with constant speed or uniform velocity; if the gradient is constant, the body is moving with uniform acceleration. The area under the graph gives the total distance travelled by the body.

speedwell any of a group of flowering plants belonging to the snapdragon family. Of the many wild species, most are low-growing with small bluish flowers. (Genus *Veronica*, family Scrophulariaceae.)

speleology scientific study of caves, their origin, development, physical structure, flora, fauna, folklore, exploration, mapping, photography, cave-diving, and rescue work. Potholing, which involves following the course of underground rivers or streams, has become a popular sport.

Speleology first developed in France in the late 19th century, where the Société de Spéologie was founded in 1895.

sperm or **spermatozoon** in biology, the male gamete of animals. Each sperm cell has a head capsule containing a nucleus, a middle portion containing mitochondria (which provide energy), and a long tail (flagellum). See **sexual reproduction**.

In most animals, the sperm are motile, and are propelled by a long flagellum, but in some (such as crabs and lobsters) they are nonmotile. Sperm cells are produced in the testes (see **testis**). From there they pass through the sperm ducts via the seminal vesicles and the prostate gland, which produce fluids called semen that give the sperm cells energy and keep them moving after they

leave the body. Hundreds of millions of sperm cells are contained in only a small amount of semen. The human sperm is 0.005 mm/0.0002 in long and can survive inside the female for 2-9 days. Mammalian sperm have receptor cells identical to some of those found in the lining of the nose. These may help in navigating towards the egg.

The term is sometimes applied to the motile male gametes (♂antherozoids) of lower plants.

sperm Only a single sperm is needed to fertilize an egg, or ovum. Yet up to 500 million may start the journey towards the egg. Once a sperm has fertilized an egg, the egg's wall cannot be penetrated by other sperm. The unsuccessful sperm die after about three days.

spermaceti glistening waxlike substance, not a true oil, contained in the cells of the huge, almost rectangular 'case' in the head of the sperm whale, amounting to about 2.8 tonnes/3 tons. It rapidly changes in density with variations in temperature. It was formerly used in lubricants and cosmetics, but in 1980 a blend of fatty acids and esters from tallow and coconut oil was developed as a substitute.

spermatophore small capsule containing ♂sperm and other nutrients produced in invertebrates, newts, and cephalopods.

spermatophyte in botany, another name for a ♂seed plant.

sperm competition competition between the sperm of rival males within the body of the female. This may involve actual removal of a rival's sperm before mating, for example the penis of a male dragonfly is shaped to scoop out existing sperm; or internal competition between rival sperm cells.

spermicide any cream, jelly, pessary, or other preparation that kills the ♂sperm cells in semen. Spermicides are used for contraceptive purposes, usually in combination with a ♂condom or ♂diaphragm. Sponges impregnated with spermicide have been developed but are not yet in widespread use. Spermicide used alone is only 75% effective in preventing pregnancy.

sphalerite mineral composed of zinc sulphide with a small proportion of iron, formula (Zn,Fe)S. It is the chief ore of zinc. Sphalerite is brown with a nonmetallic lustre unless an appreciable amount of iron is present (up to 26% by weight). Sphalerite usually occurs in ore veins in limestones, where it is often associated with galena. It crystallizes in the cubic system but does not normally form perfect cubes.

sphere in mathematics, a perfectly round object with all points on its surface the same distance from the centre. This distance is the radius of the sphere. For a sphere of radius r , the volume $V = 4/3\pi r^3$ and the surface area $A = 4\pi r^2$.

There is geometry in the humming of the strings. There is music in the spacings of the spheres.

PYTHAGORAS

Quoted in Aristotle *Metaphysics*

sphincter ring of muscle, such as is found at various points in the alimentary canal, that contracts and relaxes to open and close the canal and control the movement of food. The **pyloric sphincter**, at the base of the stomach, controls the release of the gastric contents into the duodenum. After release the sphincter contracts, closing off the stomach. The **external anal sphincter** closes the anus; the **internal anal sphincter** constricts the rectum; the **sphincter vesicae** controls the urethral orifice of the bladder. In the eye the **sphincter pupillae** contracts the pupil in response to bright light.

sphygmomanometer instrument for measuring blood pressure. Consisting of an inflatable arm cuff joined by a rubber tube to a pressure-recording device (incorporating a column of mercury with a graduated scale), it is used, together with a stethoscope, to measure arterial blood pressure.

Sphynx cat or **Canadian Hairless** breed of domestic hairless cat bred in Ontario, Canada, since 1966. It is bald apart from a fine down on the face, ears, feet, and tail, and the skin is wrinkled on the face, body, and legs. It has very large ears, a short nose, and no whiskers.

The Sphynx has not yet been recognized by many cat associations. Hairless cats are said to have been bred by the Aztecs and have also been recorded at the turn of the 20th century in New Mexico, USA. However, the 'Mexican Hairless' has now become extinct.

Spica or **Alpha Virginis** the brightest star in the constellation Virgo and the 16th brightest star in the sky. First-magnitude Spica has a true luminosity of over 1,500 times that of the Sun, and is 140 light years from Earth. It is also a spectroscopic binary star, the components of which orbit each other every four days.

spice any aromatic vegetable substance used as a condiment and for flavouring food. Spices are mostly obtained from tropical plants, and include pepper, nutmeg, ginger, and cinnamon. They have little food value but increase the appetite and may help digestion.

spicebush aromatic E North American shrub *Lindera benzoin* of the laurel family Lauraceae, with leathery, elliptical leaves.

Its red, aromatic berries can be dried and crushed for use as a spice and its leaves for tea.

spicules, solar in astronomy, short-lived jets of hot gas in the upper chromosphere of the Sun. Spiky in appearance, they move at high velocities along lines of magnetic force to which they owe their shape, and last for a few minutes each. Spicules appear to disperse material into the corona.

spider any arachnid (eight-legged animal) of the order Araneae. There are about 30,000 known species, mostly a few centimetres

SPIDER

Spider silk is up to 200 times finer than the finest human hair and is highly elastic. It can be stretched to over 20% of its length and retains its elasticity at temperatures as low as -40°C.

in size, although a few tropical forms attain great size, for example, some bird-eating spiders attain a body length of 9 cm/3.5 in. Spiders produce silk, and many spin webs to trap their prey. They are found everywhere in the world except Antarctica. Many species are found in woods and dry commons; a few are aquatic. Spiders are predators; they bite their prey, releasing a powerful toxin from poison glands which causes paralysis, together with digestive juices. They then suck out the juices and soft parts.

spider in computing, program that combs the Internet for new documents such as Web pages and GFTP files. Spiders start their work by retrieving a document such as a Web page and then following all the links and references contained in it. They repeat the process with the followed links, supplying all the references they find to a database that can be searched via a search engine.

spider monkey species of monkey found in Central and South America. Spider monkeys have long and very flexible limbs and a long, prehensile tail that is much used in climbing. The thumb is either absent or vestigial (much reduced).

species There are two species in the genus *Ateles*: the black spider monkey (or coaita) *A. paniscus* lives in Brazil and the long-haired spider monkey (or marimonda) *A. belzebuth* lives in Guiana. The single species in the genus *Brachyteles* is the woolly spider monkey *B. arachnoides*, characterized by its long, woolly hair. It is quite large and varies from grey to brown or even yellow in colour.

classification Spider monkeys are in the family Cebidae, order Primates.

spider plant African plant belonging to the lily family. Two species (*C. comosum* and *C. elatum*) are popular house plants. They have long, narrow, variegated leaves and produce flowering shoots from which the new plants grow, hanging below the main plant. The flowers are small and white. Spider plants absorb toxins from the air and therefore help to purify the atmosphere around them. (Genus *Chlorophytum*, family Liliaceae.)

spikelet in botany, one of the units of a grass inflorescence. It comprises a slender axis on which one or more flowers are borne.

Each individual flower or floret has a pair of scalelike bracts, the glumes, and is enclosed by a membranous lemma and a thin, narrow palea, which may be extended into a long, slender bristle, or awn.

spikenard either of two plants: a Himalayan plant belonging to the valerian family whose underground stems produce a perfume used in Eastern aromatic oils; or a North American plant of the ginseng family, with fragrant roots. (Himalayan *Nardostachys jatamansi*, family Valerianaceae; North American *Aralia racemosa*, family Araliaceae.)

spin in physics, the intrinsic angular momentum of a subatomic particle, nucleus, atom, or molecule, which continues to exist even when the particle comes to rest. A particle in a specific energy state has a particular spin, just as it has a particular electric charge and mass. According to quantum theory, this is restricted to discrete and indivisible values, specified by a spin quantum number. Because of its spin, a charged particle acts as a small magnet and is affected by magnetic fields.

spina bifida congenital defect in which part of the spinal cord and its membranes are exposed, due to incomplete development of the spine (vertebral column). It is a neural tube defect.

Spina bifida, usually present in the lower back, varies in severity. The most seriously affected babies may be paralysed below the waist. There is also a risk of mental retardation and death from hydrocephalus, which is often associated. Surgery is performed to close the spinal lesion shortly after birth, but this does not usually cure the disabilities caused by the condition. Spina bifida can be diagnosed prenatally.

spinach annual plant belonging to the goosefoot family. It is native to Asia and widely cultivated for its leaves, which are eaten as a vegetable. (*Spinacia oleracea*, family Chenopodiaceae.)

spinal cord major component of the central nervous system in vertebrates, encased in the spinal column. It consists of bundles of nerves enveloped in three layers of membrane (the meninges).

spinal tap another term for lumbar puncture, a medical test.

spine backbone of vertebrates. In most mammals, it contains 26 small bones called vertebrae, which enclose and protect the spinal cord (which links the peripheral nervous system to the brain).

The spine articulates with the skull, ribs, and hip bones, and provides attachment for the back muscles.

In humans it is made up of individual vertebrae, separated by intervertebral discs. In the adult there are seven cervical vertebrae in the neck; twelve thoracic in the upper trunk; five lumbar in the lower back; the sacrum (consisting of five rudimentary vertebrae fused together, joined to the hipbones); and the coccyx (four vertebrae, fused into a tailbone). The human spine has four curves (front to rear), which allow for the increased size of the chest and pelvic cavities, and permit springing, to minimize jolting of the internal organs. See illustration on page 708.

spinel any of a group of 'mixed oxide' minerals consisting mainly of the oxides of magnesium and aluminium, $MgAl_2O_4$ and $FeAl_2O_4$. Spinel crystallize in the cubic system, forming octahedral crystals. They are found in high-temperature igneous and metamorphic rocks. The aluminium oxide spinel contains gem varieties, such as the ruby spinels of Sri Lanka and Myanmar (Burma).

spinifex spiny grass chiefly found in Australia, growing on the coastal sand dunes. It is often planted to bind sand along the seashore. The term also refers to porcupine grass, any of a group of spiny-leaved, tussock-forming grasses of inland Australia. (Genus *Spinifex*, porcupine grass genus *Triodia*.)

spinone breed of medium-sized gundog developed in Italy from various ancient hunting breeds. Its rough coat, mainly white with orange-brown patches and flecks, is ideal for hunting in wooded areas. It has a sturdy build and grows to about 65 cm/25.5 in.

spiny anteater alternative name for echidna.

spiracle in insects, the opening of a trachea, through which oxygen enters the body and carbon dioxide is expelled. In cartilaginous fishes (sharks and rays), the same name is given to a circular opening that marks the remains of the first gill slit.

In tetrapod vertebrates, the spiracle of early fishes has evolved into the Eustachian tube, which connects the middle ear cavity with the pharynx.

spiracle The spiracles of this large *Dirphia avia* moth caterpillar from Trinidad are visible as a line of white ovals outlined with a black rim. Premaphotos Wildlife

side view of backbone

vertebral joints

spinal cord

spine The human spine extends every night during sleep. During the day, the cartilage discs between the vertebra are squeezed when the body is in a vertical position, standing or sitting, but at night, with pressure released, the discs swell and the spine lengthens by about 8 mm/0.3 in.

spiraea any of a group of herbaceous plants or shrubs, which includes many cultivated species with ornamental sprays of white or pink flowers; their delicate appearance has given rise to the popular name bridal wreath. (Genus *Spiraea*, family Rosaceae.)

spiral a plane curve formed by a point winding round a fixed point from which it distances itself at regular intervals, for example the spiral traced by a flat coil of rope. Various kinds of spirals can be generated mathematically – for example, an equiangular or logarithmic spiral (in which a tangent at any point on the curve always makes the same angle with it) and an involute. Spirals also occur in nature as a normal consequence of accelerating growth, such as the spiral shape of the shells of snails and some other molluscs.

spiral aloe or *kharetsa* a perennial succulent plant *Aloe polyphylla* confined to mountains in Lesotho. An attractive species valued by the horticultural trade, this succulent has been endangered by uprooting for sale to collectors. It is now legally protected and is known from about 50 localities, but remains vulnerable.

spiral galaxy in astronomy, one of the main classes of galaxy in the Hubble classification comprising up to 30% of known galaxies. Spiral galaxies are characterized by a central bulge surrounded by a flattened disc containing (normally) two spiral arms composed of hot young stars and clouds of dust and gas. In about half of spiral galaxies (barred spirals) the arms originate at the ends of a bar across the central bulge. The bar is not a rigid object but consists of stars in motion about the centre of the galaxy.

spirits of salts former name for hydrochloric acid.

spiritual healing or *psychic healing* transmission of energy from or through a healer, who may practise hand healing or absent healing through prayer or meditation.

In religions worldwide, from shamanism to latter-day charismatic Christianity, healing powers have been attributed to gifted individuals, and sometimes to particular locations (Delphi, Lourdes) or objects (religious relics), and the anecdotal evidence for the reality of spiritual healing is substantial and cross-cultural. Since both healers and beneficiaries can only adduce metaphysical explanations for the effects, medical science remains sceptical, at most allowing that in exceptional cases faith and will may bring about inexplicable cures or remissions, which, however, also occur in cases where no spiritual contribution is claimed.

spirochaete spiral-shaped bacterium. Some spirochaetes are free-living in water, others inhabit the intestines and genital areas of animals. The sexually transmitted disease syphilis is caused by a spirochaete.

spit ridge of sand or shingle projecting from the land into a body of water. It is deposited by waves carrying material from one direction to another across the mouth of an inlet (longshore drift). Deposition in the brackish water behind a spit may result in the formation of a salt marsh.

spittle alternative name for saliva and cuckoo spit.

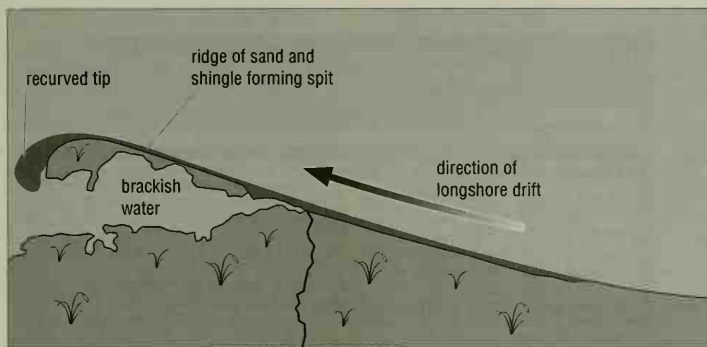

spittlebug alternative name for froghopper.

spleen organ in vertebrates, part of the reticuloendothelial system, which helps to process lymphocytes. It also regulates the number of red blood cells in circulation by destroying old cells, and stores iron. It is situated on the left side of the body, behind the stomach.

sponge any saclike simple invertebrate of the phylum Porifera, usually marine. A sponge has a hollow body, its cavity lined by cells

Formerly, when religion was strong and science weak, men mistook magic for medicine; now, when science is strong and religion weak, men mistake medicine for magic.

THOMAS SZASZ Hungarian-born US psychiatrist.
'Science and Scientism'

spit Longshore drift carries sand and shingle up coastlines. Deposited material gradually builds up over time at headlands forming a new stretch of land called a spit. A spit that extends across a bay is known as a bar.

bearing flagellae, whose whiplike movements keep water circulating, bringing in a stream of food particles. The body walls are strengthened with protein (as in the bath sponge) or small spikes of silica, or a framework of calcium carbonate.

A deep-sea sponge found in 1994 is the first carnivorous sponge to be identified. The 15-mm/0.6-in high sponge, of the family Cladorhizidae, traps small crustaceans by entangling them in thin filaments. Epithelial cells then migrate towards the prey and envelop it.

spontaneous combustion burning that is not initiated by the direct application of an external source of heat. A number of materials and chemicals, such as hay and sodium chlorate, can react with their surroundings, usually by oxidation, to produce so much internal heat that combustion results.

Special precautions must be taken for the storage and handling of substances that react violently with moisture or air. For example, phosphorus ignites spontaneously in the presence of air and must therefore be stored under water; sodium and potassium are stored under kerosene in order to prevent their being exposed to moisture.

spontaneous generation or **abiogenesis** erroneous belief that living organisms can arise spontaneously from nonliving matter. This survived until the mid-19th century, when the French chemist Louis Pasteur demonstrated that a nutrient broth would not generate microorganisms if it was adequately sterilized. The theory of abiogenesis holds that spontaneous generation cannot now occur; it is thought, however, to have played an essential role in the origin of life on this planet 4 billion years ago.

spooling in computing, the process in which information to be printed is stored temporarily in a file, the printing being carried out later. It is used to prevent a relatively slow printer from holding up the system at critical times, and to enable several computers or programs to share one printer.

spoonbill any of several large wading birds of the ibis family Threskiornithidae, order Ciconiiformes, characterized by a long, flat bill, dilated at the tip in the shape of a spoon. Spoonbills are white or pink, and up to 90 cm/3 ft tall. Their feet are adapted for wading, and the birds obtain their food, consisting chiefly of fish, frogs, molluscs, and crustaceans, from shallow water.

sporangium structure in which spores are produced.

spore small reproductive or resting body, usually consisting of just one cell. Unlike a gamete, it does not need to fuse with another cell in order to develop into a new organism. Spores are produced

by the lower plants, most fungi, some bacteria, and certain protozoa. They are generally light and easily dispersed by wind movements.

Plant spores are haploid and are produced by the sporophyte, following meiosis; see alternation of generations.

sporophyte diploid spore-producing generation in the life cycle of a plant that undergoes alternation of generations.

sprat small marine bony fish common around the British Isles. It is 7–15 cm/2.8–6 in long, with smooth scales and a prominent lower jaw. It has a sharp, toothed edge to its belly.

classification The sprat *Clupea sprattus* is a small member of the herring genus, order Clupeiformes, class Osteichthyes.

spreadsheet in computing, a program that mimics a sheet of ruled paper, divided into columns and rows. The user enters values in the sheet, then instructs the program to perform some operation on them, such as totalling a column or finding the average of a series of numbers.

Highly complex numerical analyses may be built up from these simple steps.

Spreadsheets are widely used in business for forecasting and financial control. The first spreadsheet program, Software Arts' VisiCalc, appeared 1979. The best known include Lotus 1–2–3 and Microsoft Excel.

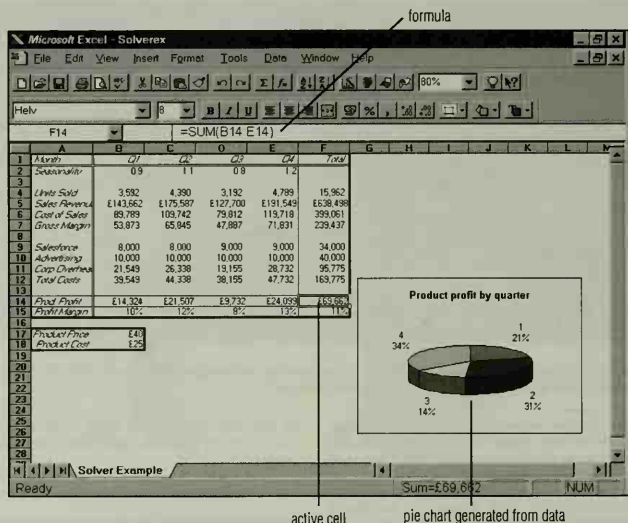

spring device, usually a metal coil, that returns to its original shape after being stretched or compressed. Springs are used in some machines (such as clocks) to store energy, which can be released at a controlled rate. In other machines (such as engines) they are used to close valves.

In vehicle-suspension systems, springs are used to cushion passengers from road shocks. These springs are used in conjunction with shock absorbers to limit their amount of travel. In bedding and upholstered furniture springs add comfort.

spring in geology, a natural flow of water from the ground, formed at the point of intersection of the water table and the ground's surface. The source of water is rain that has percolated through the overlying rocks. During its underground passage, the water may have dissolved mineral substances that may then be precipitated at the spring (hence, a mineral spring).

A spring may be continuous or intermittent, and depends on the position of the water table and the topography (surface features).

spring balance instrument for measuring weight that relates the weight of an object to the extent to which it stretches or

spreadsheet A typical spreadsheet software package. The data it contains may be output in a graphical form, enabling the production of charts and diagrams.

compresses a vertical spring. According to Hooke's law, the extension or compression will be directly proportional to the weight, providing that the spring is not overstretched. A pointer attached to the spring indicates the weight on a scale, which may be calibrated in newtons (the SI unit of force) for physics experiments, or in grams, kilograms, or pounds (units of mass) for everyday use.

springbok South African antelope *Antidorcas marsupialis* about 80 cm/30 in at the shoulder, with head and body 1.3 m/4 ft long. It

may leap 3 m/10 ft or more in the air when startled or playing, and has a fold of skin along the middle of the back which is raised to a crest in alarm. Springboks once migrated in herds of over a million, but are now found only in small numbers where protected.

springer spaniel breed of medium-sized gundog bred in England and Wales for 'springing' (flushing out) game. The Welsh springer is red and white and used mainly for upland game; the English is brown and white, or black and white, or a variety of solid colours,

spring Springs occur where water-laden rock layers (aquifers) reach the surface. Water will flow from a well whose head is below the water table.

and will spring game and retrieve from water. Both types weigh up to about 20 kg/45 lb and stand about 50 cm/20 in tall.

Springfield rifle US Army service rifle, adopted in 1903 and retained in service until the 1940s.

Of 0.30 in calibre, it used a Mauser bolt mechanism and five-shot magazine. The name came from the Springfield, Massachusetts, arsenal where it was designed and originally manufactured.

springtail small wingless insect. The maximum size is 6 mm/0.2 in in length. Springtails are extremely widespread and can be found in soil, decaying vegetable matter, under the bark of trees, in ant and termite nests, and on the surface of fresh water. There are about 1,500 species of springtail and some species are, unusually for insects, marine.

Springtails have mandibulate mouthparts (adapted for chewing), which are withdrawn into the head when not in use. They do not have compound eyes, but simple eyes may be present. The antennae are usually four-segmented, and the abdomen is six-segmented with, usually, three pairs of appendages, the most important being the forked springing organ attached to the under surface of segment number four. There is, usually, no tracheal (respiratory tube) system and the insects breathe through the cuticle. They usually, therefore, inhabit moist situations.

classification Springtails are in order Collembola, class Insecta, phylum Arthropoda.

Sprint US telecommunications company supplying data and long-distance voice connections. It was founded in 1899 as the Brown Telephone Company.

Sprint began offering long distance service under the Sprint brand name in 1986. The company was the first to connect coast-to-coast fibre-optic transmissions.

sprite in computing, a graphics object made up of a pattern of pixels (picture elements) defined by a computer programmer. Some high-level languages and applications programs contain routines that allow a user to define the shape, colours, and other characteristics of individual graphics objects. These objects can then be manipulated and combined to produce animated games or graphic screen displays.

spruce coniferous tree belonging to the pine family, found over much of the northern hemisphere. Pyramidal in shape, spruces have rigid, prickly needles and drooping, leathery cones. Some are important forestry trees, such as the sitka spruce (*P. sitchensis*), native to W North America, and the Norway spruce (*P. abies*), now planted widely in North America. (Genus *Picea*, family Pinaceae.)

Sputnik Russian 'fellow traveller' series of ten Soviet Earth-orbiting satellites. *Sputnik 1* was the first artificial satellite, launched 4 October 1957. It weighed 84 kg/185 lb, with a 58 cm/23 in diameter, and carried only a simple radio transmitter which allowed scientists to track it as it orbited Earth. It burned up in the atmosphere 92 days later. Sputniks were superseded in the early 1960s by the Cosmos series.

Sputnik 2, launched 3 November 1957, weighed about 500 kg/1,100 lb including the dog Laika, the first living creature in space. Unfortunately, there was no way to return the dog to Earth, and it died in space. Later Sputniks were test flights of the Vostok spacecraft.

sq abbreviation for square (measure).

SQL (abbreviation for *structured query language*) high-level computer language designed for use with relational databases. Although it can be used by programmers in the same way as other languages, it is often used as a means for programs to communicate with each other. Typically, one program (called the 'client') uses SQL to request data from a database 'server'.

Although originally developed by IBM, SQL is now widely used on many types of computer.

Squamata order of reptiles comprising the snakes and lizards.

square in geometry, a quadrilateral (four-sided) plane figure with all sides equal and each angle a right angle. Its diagonals bisect each other at right angles. The area *A* of a square is the length *l* of one side multiplied by itself ($A = l \times l$).

Also, any quantity multiplied by itself is termed a square, represented by an exponent of power 2; for example, $4 \times 4 = 4^2 = 16$ and $6.8 \times 6.8 = 6.8^2 = 46.24$.

An algebraic term is squared by doubling its exponent and squaring its coefficient if it has one; for example, $(x^2)^2 = x^4$ and $(6y^3)^2 = 36y^6$. A number that has a whole number as its square root is known as a perfect square; for example, 25, 144 and 54,756 are perfect squares (with roots of 5, 12, and 234, respectively).

square root in mathematics, a number that when squared (multiplied by itself) equals a given number. For example, the square root of 25 (written $\sqrt{25}$) is ± 5 , because $5 \times 5 = 25$, and $(-5) \times (-5) = 25$. As an exponent, a square root is represented by $\frac{1}{2}$, for example, $16^{\frac{1}{2}} = 4$.

Negative numbers (less than 0) do not have square roots that are real numbers. Their roots are represented by complex numbers, in which the square root of -1 is given the symbol *i* (that is, $i^2 = -1$). Thus the square root of -4 is $\sqrt{(-1) \times 4} = \sqrt{-1} \times \sqrt{4} = 2i$.

SQUID

The eyes of the giant squid – at a diameter of 37 cm/15 in – are the size of dustbin lids. They are the largest in the animal kingdom.

squid marine mollusc of the class Cephalopoda. See cephalopod.

IN SEARCH OF GIANT SQUID

http://seawifs.gsfc.nasa.gov/OCEAN_PLANET/HTML/squid_opening.html

Exhibition about the world's largest invertebrates presented by the Smithsonian's National Museum of Natural History. It includes a large number of photos, discussion of stories and myths surrounding giant squid, a fascinating comparison of squid and snails, and informative sections on anatomy, food, movement, and defence systems.

squill bulb-forming perennial plant belonging to the lily family, found growing in dry places near the sea in W Europe. Cultivated species usually bear blue flowers, either singly or in clusters, at the top of the stem. (Genus *Scilla*, family Liliaceae.)

squint or **strabismus** common condition in which one eye deviates in any direction. A squint may be convergent (with the bad eye turned inwards), divergent (outwards), or, in rare cases, vertical. A convergent squint is also called cross-eye.

There are two types of squint: **paralytic**, arising from disease or damage involving the extraocular muscles or their nerve supply; and **nonparalytic**, which may be inherited or due to some refractive error within the eye. Nonparalytic (or concomitant) squint is the typical condition seen in small children. It is treated by corrective glasses, exercises for the eye muscles, or surgery.

squirrel rodent of the family Sciuridae. Squirrels are found worldwide except for Australia, Madagascar, and polar regions. Some are tree dwellers; these generally have bushy tails, and some, with membranes between their legs, are called flying squirrels. Others are terrestrial, generally burrowing forms called ground squirrels; these include chipmunks, gophers, marmots, and prairie dogs.

stable equilibrium

unstable equilibrium

neutral equilibrium

W stands for weight; C stands for contact

stability

squirrel monkey small, tree-dwelling New World monkey that eats mainly fruit, with some insects. They have long, non-prehensile tails and live in groups of as many as 200 individuals.

classification Squirrel monkeys are in genus *Saimiri* family Cebidae, order Primates.

SRAM (acronym for *static random-access memory*) computer memory device in the form of a silicon chip used to provide immediate access memory. SRAM is faster but more expensive than DRAM (dynamic random-access memory).

DRAM loses its contents unless they are read and rewritten every 2 milliseconds or so. This process is called **refreshing** the memory. SRAM does not require such frequent refreshing.

SSSI abbreviation for Site of Special Scientific Interest.

Staaken German heavy bombing aircraft of World War I made by the Zeppelin Werke Staaken.

stability measure of how difficult it is to move an object from a position of balance or equilibrium with respect to gravity.

An object displaced from equilibrium does not remain in its new position if its weight, acting vertically downwards through its centre of mass, no longer passes through the line of action of the contact force (the force exerted by the surface on which the object is resting), acting vertically upwards through the object's new base. If the lines of action of these two opposite but equal forces do not coincide they will form a couple and create a moment (see moment of a force) that will cause the object either to return to its original rest position or to topple over into another position.

An object in **stable equilibrium** returns to its rest position after being displaced slightly. This form of equilibrium is found in objects that are difficult to topple over; these usually possess a relatively wide base and a low centre of mass – for example, a cone resting on its flat base on a horizontal surface. When such an object is tilted slightly its centre of mass is raised and the line of action of its weight no longer coincides with that of the contact force exerted by its new, smaller base area. The moment created will tend to lower the centre of mass and so the cone will fall back to its original position.

An object in **unstable equilibrium** does not remain at rest if displaced, but falls into a new position; it does not return to its original rest position. Objects possessing this form of equilibrium are easily toppled and usually have a relatively small base and a high centre of mass – for example, a cone balancing on its point, or apex, on a horizontal surface. When an object such as this is given the slightest push its centre of mass is lowered and the displacement of the line of action of its weight creates a moment. The moment will tend to lower the centre of mass still further and so the object will fall on to another position.

An object in **neutral equilibrium** stays at rest if it is moved into a new position – neither moving back to its original position nor on any further. This form of equilibrium is found in objects that are able to roll, such as a cone resting on its curved side placed on a horizontal surface. When such an object is rolled its centre of mass remains in the same position, neither rising nor falling, and the line of action of its weight continues to coincide with the contact force; no moment is created and so its equilibrium is maintained.

stabilizer one of a pair of fins fitted to the sides of a ship, especially one governed automatically by a gyroscopic mechanism, designed to reduce side-to-side rolling of the ship in rough weather.

stable equilibrium the state of equilibrium possessed by a body that will return to its original rest position if displaced slightly. See *stability*.

stack in computing, a method of storing data in which the most recent item stored will be the first to be retrieved. The technique is commonly called 'last in, first out'.

Stacks are used to solve problems involving nested structures; for example, to analyse an arithmetical expression containing subexpressions in parentheses, or to work out a route between two points when there are many different paths.

Staffordshire bull terrier breed of dog developed in England as a cross between the bulldog and the terrier. Like the related *bull terrier*, it was formerly used for bull-baiting and is still used for illegal dogfighting. It has a sturdy, muscular build, with a heavy, square head, and powerful jaws. It stands up to about 40 cm/15 in at the shoulder and weighs in the range 10.5–17 kg/24–38 lb. Common colours are red-brown, fawn, or brindle, often with white markings.

stag beetle any of a number of large dark brown beetles, the males of which possess enormous mandibles, or jaws, shaped rather like the antlers of a stag. There are over 900 species within this family.

The males are much bigger than the females and very often the length of their mandibles equals the length of the rest of the body. The mandibles appear to be largely ornamental and cannot be moved by the jaw muscles. Another characteristic feature is the smooth appearance of the chestnut-coloured wing cases, which are devoid of ridges. The larvae inhabit the rotting wood or the roots of trees, such as oak.

classification The stag beetle is in family *Lucanidae* of the

superfamily *Scarabaeoidea*, order *Coleoptera*, class *Insecta*, phylum *Arthropoda*.

stain in chemistry, a coloured compound that will bind to other substances. Stains are used extensively in microbiology to colour microorganisms and in histochemistry to detect the presence and whereabouts in plant and animal tissue of substances such as fats, cellulose, and proteins.

stainless steel widely used alloy of iron, chromium, and nickel that resists rusting. Its chromium content also gives it a high tensile strength. It is used for cutlery and kitchen fittings, and in surgical instruments. Stainless steel was first produced in the UK in 1913 and in Germany in 1914.

stalactite and stalagmite cave structures formed by the deposition of calcite dissolved in ground water. *Stalactites* grow downwards from the roofs or walls and can be icicle-shaped, straw-shaped, curtain-shaped, or formed as terraces. *Stalagmites* grow upwards from the cave floor and can be conical, fir-cone-shaped, or resemble a stack of saucers. Growing stalactites and stalagmites may meet to form a continuous column from floor to ceiling.

Stalactites are formed when ground water, hanging as a drip, loses a proportion of its carbon dioxide into the air of the cave. This reduces the amount of calcite that can be held in solution, and a small trace of calcite is deposited. Successive drips build up the stalactite over many years. In stalagmite formation the calcite comes out of the solution because of agitation – the shock of a drop of water hitting the floor is sufficient to remove some calcite from the drip. The different shapes result from the splashing of the falling water.

stamen male reproductive organ of a flower. The stamens are collectively referred to as the *androecium*. A typical stamen consists of a stalk, or filament, with an anther, the pollen-bearing organ, at its apex, but in some primitive plants, such as *Magnolia*, the stamen may not be markedly differentiated.

The number and position of the stamens are significant in the classification of flowering plants. Generally the more advanced plant families have fewer stamens, but they are often positioned more effectively so that the likelihood of successful pollination is not reduced.

stand-alone computer self-contained computer, usually a microcomputer, that is not connected to a network of computers and can be used in isolation from any other device.

standard atmosphere alternative term for *atmosphere*, a unit of pressure.

standard deviation in statistics, a measure (symbol σ or s) of the spread of data. The deviation (difference) of each of the data items from the mean is found, and their values squared. The mean value of these squares is then calculated. The standard deviation is the square root of this mean.

If n is the number of items of data, x is the value of each item, and \bar{x} is the mean value, the standard deviation σ may be given by the formula

$$\sigma = \sqrt{[\sum(x - \bar{x})^2/n]}$$

where Σ indicates that the differences between the value of each item of data and the mean should be summed.

To simplify the calculations, the formula may be rearranged to $\sigma = \sqrt{[\sum x^2/n - \bar{x}^2]}$. As a result, it becomes necessary only to calculate $\sum x$ and $\sum x^2$.

For example, if the ages of a set of children were 4, 4.5, 5, 5.5, 6, 7, 9, and 11, $\sum x$ would be 52, \bar{x} would be $52/8 = 6.5$, and $\sum x^2$ would be 378.5 ($= 4^2 + 4.5^2 + 5^2 + 5.5^2 + 6^2 + 7^2 + 9^2 + 11^2$). Therefore, the standard deviation σ would be $\sqrt{[378.5/8 - (6.5)^2]} = \sqrt{5.0625} = 2.25$.

standard form or **scientific notation** method of writing numbers often used by scientists, particularly for very large or very small numbers. The numbers are written with one digit before the decimal point and multiplied by a power of 10. The number of digits

given after the decimal point depends on the accuracy required. For example, the speed of light is 2.9979×10^8 m/1.8628 $\times 10^5$ mi per second.

standard gravity acceleration due to gravity, generally taken as 9.81274 m/32.38204 ft per second per second. See also *g scale*.

standard illuminant any of three standard light intensities, A, B, and C, used for illumination when phenomena involving colour are measured. A is the light from a filament at 2,848K (2,575°C/4,667°F), B is noon sunlight, and C is normal daylight. B and C are defined with respect to A. Standardization is necessary because colours appear different when viewed in different lights.

standard model in physics, the modern theory of elementary particles and their interactions. According to the standard model, elementary particles are classified as leptons (light particles, such as electrons), hadrons (particles, such as neutrons and protons, that are formed from quarks), and gauge bosons. Leptons and hadrons interact by exchanging gauge bosons, each of which is responsible for a different fundamental force: photons mediate the electromagnetic force, which affects all charged particles; gluons mediate the strong nuclear force, which affects quarks; gravitons mediate the force of gravity; and the weakons (intermediate vector bosons) mediate the weak nuclear force. See also forces, fundamental, quantum electrodynamics, and quantum chromodynamics.

standards in computing, any agreed system or protocol that helps different pieces of software or different computers to work together.

In the fast-moving area of computer technology, standards have sometimes developed haphazardly: market forces brought about de facto standards such as the MS-DOS operating system for PCs, or the 3.5 in floppy disc. If computers are to communicate over a network, however, standards must be co-ordinated: the World Wide Web, for example, works because everybody who uses it agrees to follow the same conventions, such as using HTML to build Web documents. Other standards, like SMTP – the procedure for sending e-mail – exist to make cross-platform communication (for example between a UNIX machine and a Macintosh) possible. Bodies involved with this process include: the Internet Architecture Board, which lays down basic procedures by promulgating RFCs, the W3 Consortium, which looks after HTML, and the International Standards Organization.

standard temperature and pressure (STP) in chemistry, a standard set of conditions for experimental measurements, to enable comparisons to be made between sets of results. Standard temperature is 0°C/32°F (273K) and standard pressure 1 atmosphere (101,325 Pa).

standard volume in physics, the volume occupied by one kilogram molecule (the molecular mass in kilograms) of any gas at standard temperature and pressure. Its value is approximately 22.414 cubic metres.

standing wave in physics, a wave in which the positions of nodes (positions of zero vibration) and antinodes (positions of maximum vibration) do not move. Standing waves result when two similar waves travel in opposite directions through the same space.

For example, when a sound wave is reflected back along its own path, as when a stretched string is plucked, a standing wave is formed. In this case the antinode remains fixed at the centre and the nodes are at the two ends. Water and electromagnetic waves can form standing waves in the same way.

staphylococcus spherical bacterium that occurs in clusters. It is found on the skin and mucous membranes of humans and other animals. It can cause abscesses and systemic infections that may prove fatal.

Staphylococcus aureus is a very common bacterium, present in the nose in 30% of people. Normally it gives no trouble, but, largely due to over-prescribing of antibiotics, strains have arisen that are resistant to the drugs used to treat them, principally methicillin, a semisynthetic form of penicillin. Methicillin-resistant *S. aureus* (MRSA) strains represent a serious hazard to the critically ill or immunosuppressed.

MRSA normally responds to two antibiotics which are considered too toxic for use in any but life-threatening infections (vancomycin and teicoplanin) but still causes fatalities.

STARS AND CONSTELLATIONS

<http://www.astro.wisc.edu/~dolan/constellations/constellations.html>

Hugely informative site on stars and constellations. It includes star charts of all major stars and constellations, details of the origins of the various names, photographs of the galaxy and the Milky Way, and details on what stars can be seen at any given time.

star luminous globe of gas, mainly hydrogen and helium, which produces its own heat and light by nuclear reactions. Although stars shine for a very long time – many billions of years – they are not eternal, and have been found to change in appearance at different stages in their lives.

The smallest mass possible for a star is about 8% that of the Sun (80 times that of Jupiter), otherwise nuclear reactions do not occur. Objects with less than this critical mass shine only dimly, and are termed brown dwarfs.

I ask you to look both ways. For the road to a knowledge of the stars leads through the atom; and important knowledge of the atom has been reached through the stars.

ARTHUR STANLEY EDDINGTON British astronomer.

starburst galaxy in astronomy, a spiral galaxy that appears unusually bright in the infrared part of the spectrum due to a recent burst of star formation, possibly triggered by the gravitational influence of a nearby companion galaxy.

starch widely distributed, high-molecular-mass carbohydrate, produced by plants as a food store; main dietary sources are cereals, legumes, and tubers, including potatoes. It consists of varying proportions of two glucose polymers (polysaccharides): straight-chain (amylose) and branched (amylopectin) molecules.

Purified starch is a white powder used to stiffen textiles and paper and as a raw material for making various chemicals. It is used in the food industry as a thickening agent. Chemical treatment of starch gives rise to a range of 'modified starches' with varying properties. Hydrolysis (splitting) of starch by acid or enzymes generates a variety of 'glucose syrups' or 'liquid glucose' for use in the food industry. Complete hydrolysis of starch with acid generates the monosaccharide glucose only. Incomplete hydrolysis or enzymic hydrolysis yields a mixture of glucose, maltose, and non-hydrolysed fractions called dextrins.

star cluster group of related stars, usually held together by gravity. Members of a star cluster are thought to form together from one large cloud of gas in space. Open clusters such as the Pleiades contain from a dozen to many hundreds of young stars, loosely scattered over several light years. Globular clusters are larger and much more densely packed, containing perhaps 100,000 old stars.

The more conspicuous clusters were originally catalogued with the nebulae, and are usually known by their Messier or NGC numbers. A few clusters like the Pleiades, Hyades, and Praesepe are also known by their traditional names.

stardust US project to obtain a sample of dust and gas from the head of a comet. Due for launch in February 1999, the Stardust space probe will fly through the head Comet Wild 2 in January 2004, passing within 100 km/62 mi of the 4 km/2.5 mi nucleus. It will return to Earth with its samples in January 2006.

starfish or *sea star* any echinoderm of the subclass Asteroidea with arms radiating from a central body. Usually there are five arms, but some species have more. They are covered with spines and small pincerlike organs. There are also a number of small tubular processes on the skin surface that assist in locomotion and respiration. Starfish are predators, and vary in size from 1.2 cm/0.5 in to 90 cm/3 ft.

Some species use their suckered tube feet to pull open the shells of bivalve molluscs, then evert their stomach to surround and digest the animal inside. The poisonous and predatory crown-of-thorns of the Pacific is very destructive to coral and severely damaged Australia's Great Barrier Reef when it multiplied prolifically in the 1960s-70s. Although it had practically disappeared by 1990, in 1996 another outbreak along the Great Barrier Reef was officially declared.

Another destructive species, *Asteria amurensis*, spread round the coast of Tasmania in 1993, and could reach as far as Sydney. It is normally found only in the northern Pacific and was probably introduced into Tasmania in the ballast water of a ship travelling from Japan.

starfish The large starfish *Stichaster striatus* on the rocky Pacific coastline of Peru. Starfish live along shorelines and on seabeds, feeding mainly on molluscs and crustaceans. They have the ability to regenerate an arm if one is broken off. Premaphotos Wildlife

star fruit fruit of the carambola tree.

starling any member of a large widespread Old World family (Sturnidae) of chunky, dark, generally gregarious birds of the order Passeriformes. The European starling *Sturnus vulgaris*, common in N Eurasia, has been naturalized in North America from the late 19th century. The black, speckled plumage is glossed with green and purple. The feathers on the upper parts are tipped with buff, and the wings are greyish-black, with a reddish-brown fringe. The female is less glossy and lustrous than the male. Its own call is a bright whistle, but it is a mimic of the songs of other birds. It is about 20 cm/8 in long.

Strikingly gregarious in feeding, flight, and roosting, it often becomes a pest in large cities, where it becomes attached to certain buildings as 'dormitories', returning each night from omnivorous foraging in the countryside, feeding principally on worms, snails, and insects. Nests are made almost anywhere, and about five pale blue eggs are laid. If disturbed, starlings have been known to lay eggs in the nests of other birds before starting a new nest with their mate elsewhere.

start bit a bit used in asynchronous communications to indicate the beginning of a piece of data.

startup screen in computing, screen displayed by a PC while it loads its operating system and other resident software. Well-known startup screens include the Windows 95 'flying window' motif and the Macintosh 'smiling face'. It is also possible to create a custom start-up screen, perhaps incorporating a favourite image or corporate logo.

states of matter forms (solid, liquid, or gas) in which material can exist. Whether a material is solid, liquid, or gaseous depends on its temperature and the pressure on it. The transition between states takes place at definite temperatures, called melting point and boiling point.

Kinetic theory describes how the state of a material depends on the movement and arrangement of its atoms or molecules.

The atoms or molecules of gases move randomly in otherwise empty space, filling any size or shape of container. Gases can be liquefied by cooling as this lowers the speed of the molecules and enables attractive forces between them to bind them together.

A liquid forms a level surface and assumes the shape of its container; its atoms or molecules do not occupy fixed positions, nor do they have total freedom of movement.

Solids hold their own shape as their atoms or molecules are not free to move about but merely vibrate about fixed positions, such as those in crystal lattices. See illustration on page 716.

state symbol symbol used in chemical equations to indicate the physical state of the substances present. The symbols are: (s) for solid, (l) for liquid, (g) for gas, and (aq) for aqueous.

static electricity electric charge that is stationary, usually acquired by a body by means of electrostatic induction or friction. Rubbing different materials can produce static electricity, as seen in the sparks produced on combing one's hair or removing a nylon shirt. In some processes static electricity is useful, as in paint spraying where the parts to be sprayed are charged with electricity of opposite polarity to that on the paint droplets, and in xerography.

static IP address (abbreviation for *static Internet Protocol address*) in computing, an IP address which is permanently assigned to a particular user. Most Internet Service Providers (ISPs) use dynamic IP addressing for their customers. Static IP addressing, however, generally used by businesses or any organization running its own site and is also available for individuals from some ISPs, such as Demon Internet, allowing them to set up FTP or Web sites on their home computers. Static IP addressing also allows a higher degree of tracking an individual user's actions on the Internet.

statics branch of mechanics concerned with the behaviour of bodies at rest and forces in equilibrium, and distinguished from dynamics.

statistical mechanics branch of physics in which the properties of large collections of particles are predicted by considering the motions of the constituent particles. It is closely related to thermodynamics.

statistics branch of mathematics concerned with the collection and interpretation of data. For example, to determine the mean age of the children in a school, a statistically acceptable answer might be obtained by calculating an average based on the ages of a representative sample, consisting, for example, of a random tenth of the pupils from each class. Probability is the branch of statistics dealing with predictions of events.

mean, median, and mode The mean, median, and mode are different ways of finding a 'typical' or 'central' value of a set of data. The mean is obtained by adding up all the observed values and dividing by the number of values; it is the number which is commonly used as an average value. The median is the middle value, that is, the value which is exceeded by half the items in the sample. The mode is the value which occurs with greatest frequency the most common value. The mean is the most useful measure for the purposes of statistical theory. The idea of the median may be extended and a distribution can be divided into four quartiles. The first quartile is the value which is exceeded by three-quarters of

state of matter Matter changes state when heat energy is absorbed or released.

the items; the second quartile is the same as the median; the third quartile is the value that is exceeded by one-quarter of the items. **standard deviation and other measures of dispersion** The mean is a very incomplete summary of a group of observations; it is useful to know also how closely the individual members of a group approach the mean, and this is indicated by various measures of dispersion. The **range** is the difference between the maximum and minimum values of the group; it is not very satisfactory as a measure of dispersion. The **mean deviation** is the arithmetic mean of the differences between the mean and the individual values, the differences all being taken as positive. However, the mean deviation also does not convey much useful information about a group of observations. The most useful measure of dispersion is the **variance**, which is the arithmetic mean of the squares of the deviations from the mean. The positive square root of the variance is called the **standard deviation**, a measure (symbol σ or s) of the spread of data. The deviation (difference) of each of the data items from the mean is found, and their values squared. The mean value of these squares is then calculated. The standard deviation is the square root of this mean.

It is usual to standardize the measurements by working in units of the standard deviation measured from the mean of the distributions, enabling statistical theories to be generalized. A standardized distribution has a mean of zero and a standard deviation of unity. Another useful measure of dispersion is the semi-interquartile range, which is one-half of the distance between the first and third quartiles, and can be considered as the average distance of the quartiles from the median. In many typical distributions the semi-interquartile range is about two-thirds of the standard deviation and the mean deviation is about four-fifths of the standard deviation.

applications One of the most important uses of statistical theory is in testing whether experimental data support hypotheses or not. For example, an agricultural researcher arranges for different groups of cows to be fed different diets and records the milk yields. The milk-yield data are analysed and the means and standard deviations of yields for different groups vary. The researcher can use statistical tests to assess whether the variation is of an amount that should be expected because of the natural variation in cows or whether it is larger than normal and therefore likely to be influenced by the difference in diet.

correlation Correlation measures the degree to which two quantities are associated, in the sense that a variation in one quantity is accompanied by a predictable variation in the other. For example, if the pressure on a quantity of gas is increased then its volume decreases. If observations of pressure and volume are taken then statistical correlation analysis can be used to determine whether

the volume of a gas can be completely predicted from a knowledge of the pressure on it.

STD abbreviation for (sexually transmitted disease).

steady-state theory in astronomy, a rival theory to that of the Big Bang, which claims that the universe has no origin but is expanding because new matter is being created continuously throughout the universe. The theory was proposed in 1948 by Hermann Bondi, Thomas Gold (1920–), and Fred Hoyle, but was dealt a severe blow in 1965 by the discovery of cosmic background radiation (radiation left over from the formation of the universe) and is now largely rejected.

steam in chemistry, a dry, invisible gas formed by vaporizing water.

The visible cloud that normally forms in the air when water is vaporized is due to minute suspended water particles. Steam is widely used in chemical and other industrial processes and for the generation of power.

steam engine engine that uses the power of steam to produce useful work. It was the principal power source during the British Industrial Revolution in the 18th century. The first successful steam engine was built 1712 by English inventor Thomas Newcomen at Dudley, West Midlands; it was developed further by Scottish mining engineer James Watt from 1769 and by English mining engineer Richard Trevithick, whose high-pressure steam engine of 1802 led to the development of the steam locomotive.

In Newcomen's engine, steam was admitted to a cylinder as a piston moved up, and was then condensed by a spray of water, allowing air pressure to force the piston downwards. James Watt improved Newcomen's engine in 1769 by condensing the steam outside the cylinder (thus saving energy formerly used to reheat the cylinder) and by using steam to force the piston upwards. Watt also introduced the double-acting engine, in which steam is alter-

STEAM ENGINE

http://www.easystreet.com/pnwc/museum/Steam_Locomotive.html

Basic guide to the principles behind the steam engine. It includes a labelled diagram and explanatory text of the engine in its most well-known form – the steam locomotive.

nately sent to each side of the piston. The **compound engine** (1781) uses the exhaust from one cylinder to drive the piston of another. A later development was the steam turbine, still used today to power ships and generators in power stations. In other contexts, the steam engine was superseded by the internal-combustion engine.

stearic acid $\text{CH}_3(\text{CH}_2)_{16}\text{COOH}$ saturated long-chain fatty acid, soluble in alcohol and ether but not in water. It is found in many fats and oils, and is used to make soap and candles and as a lubricant. The salts of stearic acid are called **stearates**.

stearin mixture of stearic and palmitic acids, used to make soap.

steel alloy or mixture of iron and up to 1.7% carbon, sometimes with other elements, such as manganese, phosphorus, sulphur, and silicon. The USA, Russia, Ukraine, and Japan are the main steel producers. Steel has innumerable uses, including ship and car manufacture, skyscraper frames, and machinery of all kinds.

Steels with only small amounts of other metals are called **carbon steels**. These steels are far stronger than pure iron, with properties varying with the composition. Alloy steels contain greater amounts of other metals. Low-alloy steels have less than 5% of the alloying material; high-alloy steels have more. Low-alloy steels containing up to 5% silicon with relatively little carbon have a high electrical resistance and are used in power transformers and motor or generator cores, for example. **Stainless steel** is a high-alloy steel containing at least 11% chromium. Steels with up to 20% tungsten are very hard and are used in high-speed cutting tools. About 50% of the world's steel is now made as scrap.

Steel is produced by removing impurities, such as carbon, from raw or pig iron, produced by a blast furnace. The main industrial process is the basic-oxygen process, in which molten pig iron and scrap steel is placed in a container lined with heat-resistant, alkaline (basic) bricks. A pipe or lance is lowered near to the surface of the molten metal and pure oxygen blown through it at high pressure. The surface of the metal is disturbed by the blast and the impurities are oxidized (burned out). The open-hearth process is an older steelmaking method in which molten iron and limestone are placed in a shallow bowl or hearth (see open-hearth furnace). Burning oil or gas is blown over the surface of the metal, and the impurities are oxidized. High-quality steel is made in an electric furnace. A large electric current flows through electrodes in the furnace, melting a charge of scrap steel and iron. The quality of the steel produced can be controlled precisely because the temperature of the furnace can be maintained exactly and there are no combustion by-products to contaminate the steel. Electric furnaces are also used to refine steel, producing the extra-pure steels used, for example, in the petrochemical industry.

The steel produced is cast into ingots, which can be worked when hot by hammering (forging) or pressing between rollers to produce sheet steel. Alternatively, the **continuous-cast process**, in which the molten metal is fed into an open-ended mould cooled by water, produces an unbroken slab of steel.

Stefan-Boltzmann law in physics, a law that relates the energy, E , radiated away from a perfect emitter (a black body), to the temperature, T , of that body. It has the form $E = \sigma T^4$, where E is the energy radiated per unit area per second, T is the temperature, and σ is the **Stefan-Boltzmann constant**. Its value is $5.6705 \times 10^{-8} \text{ W m}^{-2} \text{ K}^{-4}$. The law was derived by Austrian physicists Joseph Stefan and Ludwig Boltzmann.

steganography in computing, camouflaging messages in large computer files, especially those carrying audio, video, or graphics, by appropriating a small percentage of their constituent data. For example, a graphics file measuring 500×500 pixels, using 32 bits to represent each pixel, contains 8 million bits. A single bit of each pixel (perhaps the 1st, the 15th or the 32nd) could be used to insert some 5,000 words of text, chopped into individual bits, without making any perceptible difference to the image. The text message itself can be encrypted using Pretty Good Privacy (PGP) for added security.

Stegosaurus genus of late Jurassic North American dinosaurs of the order Ornithischia. They were ungainly herbivores, with very

small heads, a double row of triangular plates along the back, and spikes on the tail.

steinbok or **steenbok** southern African antelope. It is reddish-brown and about 60 cm/23.5 in high at the shoulder.

classification The steinbok *Raphicerus campestris* is in family Bovidae, in order Artiodactyla.

stellar population in astronomy, a classification of stars according to their chemical composition as determined by spectroscopy.

Population I stars have a relatively high abundance of elements heavier than hydrogen and helium, and are confined to the spiral arms and disc of the Galaxy. They are believed to be young stars formed from material that has already been enriched with elements created by nuclear fusion in earlier generations of stars. Examples include open clusters and supergiants. **Population II** stars have a low abundance of heavy elements and are found throughout the Galaxy but especially in the central bulge and outer halo. They are among the oldest objects in the Galaxy, and include globular clusters. The Sun is a Population I star.

Steller's sea cow extinct member of the order Sirenia (today consisting of dugongs and manatees) discovered in 1741. They weighed approximately 10 tonnes, fed on kelp, and lived in shallow waters around the Bering Sea. Hunted relentlessly for their meat, they died out within 27 years of their discovery. The reduction in their kelp food supply may also have contributed to their extinction.

Stephenson, George (1781–1848)

English engineer. He built the first successful steam locomotive. He also invented a safety lamp independently of Humphrey Davy in 1815. He was appointed engineer of the Stockton and Darlington Railway, the world's first public railway, in 1821, and of the Liverpool and Manchester Railway in 1826. In 1829 he won a prize with his locomotive *Rocket*.

Experimenting with various gradients, Stephenson found that a slope of 1 in 200, common enough on roads, reduced the haulage power of a locomotive by 50% (on a completely even surface, a tractive force of less than 5 kg/11 lb would move a

tonne). Friction was virtually independent of speed. It followed that railway gradients should always be as low as possible, and cuttings, tunnels, and embankments were therefore necessary. He also advocated the use of malleable iron rails instead of cast iron. The gauge for the Stockton and Darlington railway was set by Stephenson at 1.4 m/4 ft 8 in, which became the standard gauge for railways in most of the world.

Mary Evans Picture Library

stem main supporting axis of a plant that bears the leaves, buds, and reproductive structures; it may be simple or branched. The plant stem usually grows above ground, although some grow underground, including rhizomes, corms, rootstocks, and tubers. Stems contain a continuous vascular system that conducts water and food to and from all parts of the plant.

The point on a stem from which a leaf or leaves arise is called a node, and the space between two successive nodes is the internode.

In some plants, the stem is highly modified; for example, it may form a leaf-like cladode or it may be twining (as in many climbing plants), or fleshy and swollen to store water (as in cacti and other succulents). In plants exhibiting secondary growth, the stem may become woody, forming a main trunk, as in trees, or a number of branches from ground level, as in shrubs.

steppe the temperate grasslands of Europe and Asia. Sometimes the term refers to other temperate grasslands and semi-arid desert edges.

stepper motor electric motor that can be precisely controlled by signals from a computer. The motor turns through a precise angle each time it receives a signal pulse from the computer. By varying the rate at which signal pulses are produced, the motor can be run at different speeds or turned through an exact angle and then stopped. Switching circuits can be constructed to allow the computer to reverse the direction of the motor.

By combining two or more motors, complex movement control becomes possible. For example, if stepper motors are used to power the wheels of a small vehicle, a computer can manoeuvre the vehicle in any direction.

Stepper motors are commonly used in small-scale applications where computer-controlled movement is required. In larger applications, where greater power is necessary, pneumatic or hydraulic systems are usually preferred.

step rocket another term for δ multistage rocket.

steradian SI unit (symbol sr) of measure of solid (three-dimensional) angles, the three-dimensional equivalent of the δ radian. One steradian is the angle at the centre of a sphere when an area on the surface of the sphere equal to the square of the sphere's radius is joined to the centre.

stereocilium sensory hair cell found on the cochlea in the inner ear. When the cochlear fluid vibrates in response to sound the hairs move together pushing on protein molecules on their surface. On each stereocilium the protein molecule triggers the opening of an ion gate that enables the flow of potassium ions through the hair. The ion flow causes an electrical signal to be transmitted to the brain as a nerve impulse, where it is interpreted as sound.

stereophonic sound system of sound reproduction using two complementary channels leading to two loudspeakers, which gives a more natural depth to the sound. Stereo recording began with the introduction of two-track magnetic tape in the 1950s. See ϕ hi-fi.

Stereo is more democratic, mono more totalitarian.

JEAN-LUC GODARD French filmmaker and writer.
Opening a cinema in Dolby stereo in Moscow, Feb 1992

sterilization the killing or removal of living organisms such as bacteria and fungi. A sterile environment is necessary in medicine, food processing, and some scientific experiments. Methods include heat treatment (such as boiling), the use of chemicals (such as disinfectants), irradiation with gamma rays, and filtration. See also ϕ asepsis.

sterilization in medicine, any surgical operation to terminate the possibility of reproduction. In women, this is normally achieved by sealing or tying off the ϕ Fallopian tubes (tubal ligation) so that fer-

tilization can no longer take place. In men, the transmission of sperm is blocked by ϕ vasectomy.

According to the results of a long-term US study released in 1996, the failure rate for female sterilization is 1 in 50, higher than previously believed, with some pregnancies occurring as long as 14 years after the operation.

Sterilization may be encouraged by governments to limit population growth or as part of a selective-breeding policy (see ϕ eugenics).

sterling silver alloy containing 925 parts of silver and 75 parts of copper. The copper hardens the silver, making it more useful.

sternum or *breastbone*, the large flat bone, 15–20 cm/5.9–7.8 in long in the adult, at the front of the chest, joined to the ribs. It gives protection to the heart and lungs. During open-heart surgery the sternum must be split to give access to the thorax.

steroid in biology, any of a group of cyclic, unsaturated alcohols (lipids without fatty acid components), which, like sterols, have a complex molecular structure consisting of four carbon rings. Steroids include the sex hormones, such as ϕ testosterone, the corticosteroid hormones produced by the ϕ adrenal gland, bile acids, and ϕ cholesterol.

The term is commonly used to refer to ϕ anabolic steroid. In medicine, synthetic steroids are used to treat a wide range of conditions.

Steroids are also found in plants. The most widespread are the brassinosteroids, necessary for normal plant growth.

sterol any of a group of solid, cyclic, unsaturated alcohols, with a complex structure that includes four carbon rings; cholesterol is an example. Steroids are derived from sterols.

stethoscope instrument used to ascertain the condition of the heart and lungs by listening to their action. It consists of two earpieces connected by flexible tubes to a small plate that is placed against the body. It was invented in 1819 in France by René Th  ophile Hyacinthe La  n  c.

stick insect insect of the order Phasmoda, closely resembling a stick or twig. The eggs mimic plant seeds. Many species are wingless. The longest reach a length of 30 cm/1 ft.

Fossilized eggs were identified in 1995, and are thought to be around 44 million years old.

stickleback any fish of the family Gasterosteidae, found in marine and fresh waters of the northern hemisphere. It has a long body that can grow to 18 cm/7 in. The spines along a stickleback's back take the place of the first dorsal fin, and can be raised to make the

stick insect The Brazilian *Phibalosoma phyllinum*, which is 30 cm/1 ft long, spends the day resting in cryptic pose in trees and bushes. Stick insects do not always rest among twigs. Many species from tropical rainforests rest on top of large leaves such as palms, where they resemble a fallen twig. Premaphotos Wildlife

STERILIZATION

In 1632, the weekly food ration for each child in a children's hospital in Norwich, England, included two gallons of beer. In the days before reliable water-purification systems, the potential bad effects of alcohol were far outweighed by its sterilizing properties.

fish difficult to eat for predators. After the eggs have been laid the female takes no part in rearing the young; the male builds a nest for the eggs, which he then guards and rears for the first two weeks.

The common three-spined stickleback *Gasterosteus aculeatus*, up to 10 cm/4 in, is found in freshwater habitats and also in brackish estuaries.

stigma in a flower, the surface at the tip of a carpel that receives the pollen. It often has short outgrowths, flaps, or hairs to trap pollen and may produce a sticky secretion to which the grains adhere.

stimulant any substance that acts on the brain to increase alertness and activity; for example, amphetamine. When given to children, stimulants may have a paradoxical, calming effect. Stimulants cause liver damage, are habit-forming, have limited therapeutic value, and are now prescribed only to treat narcolepsy and severe obesity.

stimulus any agency, such as noise, light, heat, or pressure, that can be detected by an organism's receptors.

stringray cartilaginous fish that is a species of ray.

stinkhorn any of a group of foul-smelling European fungi (see *fungus*), especially *P. impudicus*; they first appear on the surface as white balls. (Genus *Phallus*, order Phallales.)

The spores of the stinkhorn are dispersed by flies. The flies are attracted by the its corpse-like aroma and feed on the spore-containing slime at its tip. This gives them diarrhoea almost immediately, so the spores are spread but still likely to end up in suitable habitat.

stinkwood any of various trees with unpleasant-smelling wood. The S African tree *O. bullata* has offensive-smelling wood when newly felled, but fine, durable timber used for furniture. Another stinkwood is *G. augusta* from tropical America. (Genera *Ocotea*, family Lauraceae; *Gustavia*.)

stipule outgrowth arising from the base of a leaf or leaf stalk in certain plants. Stipules usually occur in pairs or fused into a single semicircular structure.

Stirling engine hot-air external combustion engine invented by Scottish priest Robert Stirling 1816. The engine operates by adapting to the fact that the air in its cylinders heats up when it is compressed and cools when it expands. The engine will operate on any fuel, is nonpolluting and relatively quiet. It was used fairly widely in the 19th century before the appearance of small, powerful, and reliable electric motors. Attempts have also been made in recent times to use Stirling's engine to power a variety of machines.

stoat carnivorous mammal *Mustela erminea* of the northern hemisphere, in the weasel family, about 37 cm/15 in long including the black-tipped tail. It has a long body and a flattened head. The upper parts and tail are red-brown, and the underparts are white. In the colder regions, the coat turns white (ermine) in winter. Its young are called kits.

The stoat is an efficient predator, killing its prey (typically rodents and rabbits) by biting the back of the neck. It needs to consume the equivalent of almost a third of its body weight each day. Females are about half the size of males, and males and females live in separate territories. Stoats live in Europe, Asia, and North America; they have been introduced to New Zealand.

stock in botany, any of a group of herbaceous plants commonly grown as garden ornamentals. Many cultivated varieties, including simple-stemmed, queen's, and ten-week stocks, have been derived from the wild stock (*M. incana*); night-scented (or evening) stock (*M. bicornis*) becomes aromatic at night. (Genus *Matthiola*, family Cruciferae.)

stokes c.g.s. unit (symbol St) of kinematic viscosity (a liquid's resistance to flow).

Liquids with higher kinematic viscosity have higher turbulence

stoma The stomata, tiny openings in the epidermis of a plant, are surrounded by pairs of crescent-shaped cells, called guard cells. The guard cells open and close the stoma by changing shape.

than those with low kinematic viscosity. It is found by dividing the dynamic viscosity in poise by the density of the liquid.

STOL (acronym for *short takeoff and landing*) aircraft fitted with special devices on the wings (such as sucking flaps) that increase aerodynamic lift at low speeds. Small passenger and freight STOL craft may become common with the demand for small airports, especially in difficult terrain.

stolon in botany, a type of runner.

stolport (acronym for *short take off and landing port*) airport that can be used by planes adapted to a shorter than normal runway. Such planes tend to have a restricted flying range. Stolport sites are found in built-up areas where ordinary planes would not be able to land safely.

stoma (plural *stomata*) in botany, a pore in the epidermis of a plant. Each stoma is surrounded by a pair of guard cells that are crescent-shaped when the stoma is open but can collapse to an oval shape, thus closing off the opening between them. Stomata allow the exchange of carbon dioxide and oxygen (needed for photosynthesis and respiration) between the internal tissues of the plant and the outside atmosphere. They are also the main route by which water is lost from the plant, and they can be closed to conserve water, the movements being controlled by changes in turgidity of the guard cells.

stomach the first cavity in the digestive system of animals. In mammals it is a bag of muscle situated just below the diaphragm. Food enters it from the oesophagus, is digested by the acid and enzymes secreted by the stomach lining, and then passes into the duodenum. Some plant-eating mammals have multichambered stomachs that harbour bacteria in one of the chambers to assist in the digestion of cellulose. See illustration on page 718.

The gizzard is part of the stomach in birds.

stone (plural *stones*) imperial unit (abbreviation st) of mass. One stone is 14 pounds (6.35 kg).

Stone Age the developmental stage of humans in prehistory before the use of metals, when tools and weapons were made chiefly of stone, especially flint. The Stone Age is subdivided into the Old or Palaeolithic, when flint implements were simply chipped

stomach The human stomach can hold about 1.5 l/2.6 pt of liquid. The digestive juices are acidic enough to dissolve metal. To avoid damage, the cells of the stomach lining are replaced quickly – 500,000 cells are replaced every minute, and the whole stomach lining every three days.

into shape; the Middle or Mesolithic; and the New or Neolithic, when implements were ground and polished. Palaeolithic people were hunters and gatherers; by the Neolithic period people were taking the first steps in agriculture, the domestication of animals, weaving, and pottery.

Recent research has been largely directed towards the relationship of the Palaeolithic period to $\delta^{13}C$ chronology (the measurement of geological time) and to the clarification of an absolute chronology based upon geology. The economic aspects of the Neolithic cultures have attracted as much attention as the typology of the implements and pottery, and the study of chambered tombs.

stonechat small insectivorous δ thrush *Saxicola torquata*, family Muscicapidae, order Passeriformes, frequently found in Eurasia and Africa on open land with bushes. The male has a black head and throat, tawny breast, and dark back; the female is browner. It is about 13 cm/5 in long.

stonecrop any of a group of plants belonging to the orpine family, succulent herbs with fleshy leaves and clusters of red, yellow, or white starlike flowers. Stonecrops are characteristic of dry, rocky places and some grow on walls. (Genus *Sedum*, family Crassulaceae.)

stonefish any of a family (Synanceiidae) of tropical marine bony fishes with venomous spines and bodies resembling encrusted rocks.

stonefly any insect of the order Plecoptera, with a long tail and antennae and two pairs of membranous wings. Stoneflies live near fresh water. There are over 1,300 species.

STONEFISH

Stonefish are the most poisonous of all fish. The needle-like spines along their backs contain sufficient venom to kill within six hours anyone unlucky enough to tread upon them.

Stonehenge Old English 'hanging stones' megalithic monument on Salisbury Plain, 3 km/1.9 mi W of Amesbury, Wiltshire, England. The site developed over various periods from a simple henge (earthwork circle and ditch), dating from about 3000 BC, to a complex stone structure, from about 2100 BC, which included a circle of 30 upright stones, their tops linked by lintel stones to form a continuous circle about 30 m/100 ft across.

Within this sarsen peristyle was a horseshoe arrangement of five sarsen trilithons (two uprights plus a lintel, set as five separate entities), and the so-called 'Altar Stone' – an upright pillar – on the axis of the horseshoe at the open, NE end, which faces in the direction of the rising sun. A further horseshoe and circle within the sarsen peristyle were constructed from bluestone relocated from previous outer circles.

It has been suggested that Stonehenge was constructed as an observatory.

stop bit δ bit used in δ asynchronous communications to indicate the end of a piece of data.

stopping distance the minimum distance in which a vehicle can be brought to rest in an emergency from the moment that the driver notices danger ahead. It is the sum of the thinking distance and the braking distance.

store-and-forward technology in computing, general term for systems like δ UUCP and e-mail, which work by storing data that has been received and then forwarding it on demand to the authorized recipient. Most of the Internet is based on store-and-forward technology.

stork any of the 17 species of the Ciconiidae, a family of long-legged, long-necked wading birds with long, powerful wings, and long conical bills used for spearing prey. Some species grow up to 1.5 m/5 ft tall.

species Species include the Eurasian white stork *Ciconia ciconia*, which is encouraged to build on rooftops as a luck and fertility symbol. It feeds on reptiles, small mammals, and insects. Its plumage is greyish white, its quills and long feathers on the wing coverts black, and the beak and legs red. It migrates to Africa in winter. The jabiru *Jabiru mycteria* of the Americas is up to 1.5 m/5 ft high, and is white plumaged, with a black and red head. In the black stork *C. nigra*, the upper surface is black and the lower parts are white. It is widely found in southern and central Europe, Asia, and parts of Africa. The adjutant bird, δ ibis, δ heron, and δ poonbill are related birds.

STORK

Dissatisfied white stork chicks sometimes switch nests. A wandering chick is initially greeted with aggression at its new home, but is soon accepted. The most attractive nests are those where the resident chicks are younger than the new arrival, who will therefore not have to battle for food with older siblings.

story board in film and television, technique for reviewing a particular story or scene before it is expensively filmed, animated, or scripted.

The scene is broken down into key frames or moments, and sketched in varying detail onto boards with accompanying text outlining the plot's progress.

STP abbreviation for standard temperature and pressure.

straight line a line that does not bend or curve. The graph of a linear relationship is a straight line and is often presented in the form $y = mx + c$, where m is the slope, or gradient, of the line and c is the y -intercept (the point at which the line cuts the y -axis).

strain in the science of materials, the extent to which a body is distorted when a deforming force (stress) is applied to it. It is a ratio of the extension or compression of that body (its length, area, or volume) to its original dimensions (see Hooke's law. For example, linear strain is the ratio of the change in length of a body to its original length.

stratigraphy branch of geology that deals with the sequence of formation of sedimentary rock layers and the conditions under which they were formed. Its basis was developed by William Smith, a British canal engineer. The basic principle of superimposition establishes that upper layers or deposits have accumulated later in time than the lower ones.

Stratigraphy involves both the investigation of sedimentary structures to determine past environments represented by rocks, and the study of fossils for identifying and dating particular beds of rock. A body of rock strata with a set of unifying characteristics indicative of an environment is called a facies.

Stratigraphic units can be grouped in terms of time or lithology (rock type). Strata that were deposited at the same time belong to a single chronostratigraphic unit but need not be the same lithology. Strata of a specific lithology can be grouped into a lithostratigraphic unit but are not necessarily the same age.

Stratigraphy in the interpretation of archaeological excavations provides a relative chronology for the levels and the artefacts within rock beds. It is the principal means by which the context of archaeological deposits is evaluated.

stratosphere that part of the atmosphere 10–40 km/6–25 mi from the Earth's surface, where the temperature slowly rises from a low of $-55^{\circ}\text{C}/-67^{\circ}\text{F}$ to around $0^{\circ}\text{C}/32^{\circ}\text{F}$. The air is rarefied and at around 25 km/15 mi much ozone is concentrated.

strawberry low-growing perennial plant widely cultivated for its red, fleshy fruits, which are rich in vitamin C. Commercial cultivated forms bear one crop of fruit in summer, with the berries resting on a bed of straw to protect them from the damp soil, and multiply by runners. The flowers are normally white, although pink-flowering varieties are cultivated as ornamentals. (Genus *Fragaria*, family Rosaceae.)

streaming in computing, sending data, for example video frames or radio broadcasts, in a steady flow over the Internet. Streaming requires data to pass through a special channel or dedicated connection; conventional packets, which travel by a multiplicity of routes, may arrive in the wrong order or be duplicated on the way. RealAudio and CU-SeeMe make use of streaming.

streamlining shaping a body so that it offers the least resistance when travelling through a medium such as air or water. Aircraft, for example, must be carefully streamlined to reduce air resistance, or drag.

High-speed aircraft must have swept-back wings, supersonic craft a sharp nose and narrow body.

strength of acids and bases in chemistry, the ability of acids and bases to dissociate in solution with water, and hence to produce a low or high pH, respectively.

A strong acid is fully dissociated in aqueous solution, whereas a weak acid is only partly dissociated. Since the dissociation of acids generates hydrogen ions, a solution of a strong acid will have a high concentration of hydrogen ions and therefore a low pH. A strong base will have a high pH, whereas a weaker base will not dissociate completely and will have a pH of nearer 7.

streptomycin antibiotic drug discovered in 1944, active against a wide range of bacterial infections.

Streptomycin is derived from a soil bacterium *Streptomyces griseus* or synthesized.

stress in psychology, any event or situation that makes heightened demands on a person's mental or emotional resources. Stress can be caused by overwork, anxiety about exams, money, job security, unemployment, bereavement, poor relationships, marriage breakdown, sexual difficulties, poor living or working conditions, and constant exposure to loud noise.

Many changes that are apparently 'for the better', such as being promoted at work, going to a new school, moving to a new house, and getting married, are also a source of stress. Stress can cause, or aggravate, physical illnesses, among them psoriasis, eczema, asthma, and stomach and mouth ulcers. Apart from removing the source of stress, acquiring some control over it and learning to relax when possible are the best responses.

stress and strain in the science of materials, measures of the deforming force applied to a body (stress) and of the resulting change in its shape (strain). For a perfectly elastic material, stress is proportional to strain (Hooke's law).

stress protein one of a group of proteins produced by a cell when it is under stress. Stress proteins are created in response to a wide variety of stresses including illness, high temperatures, alcohol, and poisons. They act as a buffer for the cell and repair damage.

stridulatory organs in insects, organs that produce sound when rubbed together. Crickets rub their wings together, but grasshoppers rub a hind leg against a wing. Stridulation is thought to be used for attracting mates, but may also serve to mark territory.

strike the compass direction of a horizontal line on a planar structural surface, such as a fault plane, bedding plane, or the trend of a structural feature, such as the axis of a fold. Strike is 90° from dip.

string in computing, a group of characters manipulated as a single object by the computer. In its simplest form a string may consist of a single letter or word – for example, the single word SMITH might be established as a string for processing by a computer. A string can also consist of a combination of words, spaces, and numbers – for example, 33 HIGH STREET ANYTOWN ALLSHIRE could be established as a single string.

Most high-level languages have a variety of string-handling functions. For example, functions may be provided to read a character from any given position in a string or to count automatically the number of characters in a string.

string theory mathematical theory developed in the 1980s to explain the behaviour of elementary particles; see superstring theory.

string, vibrations of the standing waves set up in a stretched string or wire when it is plucked, or stroked with a bow. They are formed by the reflection of progressive waves at the fixed ends of the string. Waves of many different frequencies can be established on a string at the same time. Those that match the natural frequencies of the string will, by a process called resonance, produce large-amplitude vibrations. The vibration of lowest frequency is called the fundamental vibration; vibrations of frequencies that are multiples of the fundamental frequency are called harmonics.

strip mining another term for open-pit mining.

strobilus in botany, a reproductive structure found in most gymnosperms and somepteridophytes, notably the club mosses. In confers the strobilus is commonly known as a cone.

stroboscope instrument for studying continuous periodic motion by using light flashing at the same frequency as that of the motion; for example, rotating machinery can be optically 'stopped' by illuminating it with a stroboscope flashing at the exact rate of rotation.

stroke or cerebrovascular accident or apoplexy interruption of the blood supply to part of the brain due to a sudden bleed in the brain (cerebral haemorrhage) or embolism or thrombosis. Strokes vary in severity from producing almost no symptoms to

proving rapidly fatal. In between are those (often recurring) that leave a wide range of impaired function, depending on the size and location of the event.

Strokes involving the right side of the brain, for example, produce weakness of the left side of the body. Some affect speech. Around 80% of strokes are ischaemic strokes, caused by a blood clot blocking an artery transporting blood to the brain. Transient ischaemic attacks, or 'mini-strokes', with effects lasting only briefly (less than 24 hours), require investigation to try to forestall the possibility of a subsequent full-blown stroke.

The disease of the arteries that predisposes to stroke is atherosclerosis. High blood pressure (hypertension) is also a precipitating factor – a worldwide study in 1995 estimated that high blood pressure before middle age gives a tenfold increase in the chance of having a stroke later in life.

Strokes can sometimes be prevented by surgery (as in the case of some aneurysms), or by use of anticoagulant drugs or vitamin E or daily aspirin to minimize the risk of stroke due to blood clots. According to the results of a US trial announced in December 1995, the clot-buster drug tPA, if administered within three hours of a stroke, can cut the number of stroke victims experiencing lasting disability by 50%.

stromatolite mound produced in shallow water by mats of algae that trap mud particles. Another mat grows on the trapped mud layer and this traps another layer of mud and so on. The stromatolite grows to heights of a metre or so. They are uncommon today but their fossils are among the earliest evidence for living things – over 2,000 million years old.

strong nuclear force one of the four fundamental forces of nature, the other three being the electromagnetic force, gravity, and the weak nuclear force. The strong nuclear force was first described by Japanese physicist Hideki Yukawa in 1935. It is the strongest of all the forces, acts only over very small distances (within the nucleus of the atom), and is responsible for binding together quarks to form hadrons, and for binding together protons and neutrons in the atomic nucleus. The particle that is the carrier of the strong nuclear force is the gluon, of which there are eight kinds, each with zero mass and zero charge.

strontium soft, ductile, pale-yellow, metallic element, symbol Sr, atomic number 38, relative atomic mass 87.62. It is one of the alkaline-earth metals, widely distributed in small quantities only as a sulphate or carbonate. Strontium salts burn with a red flame and are used in fireworks and signal flares.

The radioactive isotopes Sr-89 and Sr-90 (half-life 25 years) are some of the most dangerous products of the nuclear industry; they are fission products in nuclear explosions and in the reactors of nuclear power plants. Strontium is chemically similar to calcium and deposits in bones and other tissues, where the radioactivity is damaging. The element was named in 1808 by English chemist Humphry Davy, who isolated it by electrolysis, after Strontian, a mining location in Scotland where it was first found.

strophanthus any of a group of tropical plants belonging to the dogbane family, native to Africa and Asia. Seeds of the handsome climber *S. gratus* yield a poison, strophanthin, which is used on arrowheads in hunting, and in medicine as a heart stimulant. (Genus *Strophanthus*, family Apocynaceae.)

structured programming in computing, the process of writing a program in small, independent parts. This makes it easier to control a program's development and to design and test its individual component parts. Structured programs are built up from units called modules, which normally correspond to single procedures or functions. Some programming languages, such as PASCAL and Modula-2, are better suited to structured programming than others.

strychnine $C_{21}H_{33}N_2O_2$ bitter-tasting, poisonous alkaloid. It is a poison that causes violent muscular spasms, and is usually obtained by powdering the seeds of plants of the genus *Strychnos* (for example *S. nux vomica*). Curare is a related drug.

sturgeon any of a family of large, primitive, bony fishes with five rows of bony plates, small sucking mouths, and chin barbels used

for exploring the bottom of the water for prey.

Sturgeons take 6–25 years to reach sexual maturity. The population in the Caspian Sea is threatened by pollution and intensive fishing for caviar; there was a 75% decline in the catch 1984–94. It has been estimated that sturgeon will vanish from the Caspian Sea by 2007 as a result of poaching and smuggling of the fish. Rising pollution levels and the damming of rivers also mean that fewer sturgeon are returning to rivers to spawn. A million sturgeon used to go to the Ural river to spawn, but now there are only 200,000. Some 90% of the caviar taken from the Caspian Sea is smuggled, and poachers often catch the females before they are mature enough to produce eggs, thus further decimating the stocks. In an effort to preserve Acipenseridae, all sturgeon species valued for their caviar were added in 1997 to the Convention on International Trade in Endangered Species (CITES) Appendix 2 (classed as vulnerable).

Sturt's desert pea scarlet pea-shaped flower with prominent black 'eye' *Clinanthus formosus*. It is the floral emblem of South Australia.

style in flowers, the part of the carpel bearing the stigma at its tip. In some flowers it is very short or completely lacking, while in others it may be long and slender, positioning the stigma in the most effective place to receive the pollen.

Style, Old and New forms of dating, see calendar.

style sheet in computing, pre-set group of formats used in word processing, presentation graphics and page layout programs. Style sheets impose margins, fonts, point sizes, alignments, and other criteria to give text a uniform appearance. In a page layout program, designers might use different style sheets for headings, picture captions, and main text.

subatomic particle in physics, a particle that is smaller than an atom. Such particles may be indivisible elementary particles, such as the electron and quark, or they may be composites, such as the proton, neutron, and alpha particle. See also particle physics.

subduction zone region where two plates of the Earth's rigid lithosphere collide, and one plate descends below the other into the weaker asthenosphere. Subduction occurs along ocean trenches, most of which encircle the Pacific Ocean; portions of the ocean plate slide beneath other plates carrying continents.

Ocean trenches are usually associated with volcanic island arcs and deep-focus earthquakes (more than 300 km/185 mi below the surface), both the result of disturbances caused by the plate subduction. The Aleutian Trench bordering Alaska is an example of an active subduction zone, which has produced the Aleutian Island arc.

subject drift in computing, tendency for postings in Usenet, and sometimes entire newsgroups, to wander away from their original subject matter. As threads accumulate in response to a posting, the subject heading is retained, but the discussions can rapidly go off at a tangent. Thus a thread headed 'Re: Ice cream – favourite flavours' might actually be a long-running discussion about Napoleon.

sublimation in chemistry, the conversion of a solid to vapour without passing through the liquid phase.

Sublimation depends on the fact that the boiling-point of the solid substance is lower than its melting-point at atmospheric pressure. Thus by increasing pressure, a substance which sublimates can be made to go through a liquid stage before passing into the vapour state.

Some substances that do not sublime at atmospheric pressure can be made to do so at low pressures. This is the principle of freeze-drying, during which ice sublimates at low pressure.

submarine underwater warship. The first underwater boat was constructed in 1620 for James I of England by the Dutch scientist Cornelius van Drebbel (1572–1633). A naval submarine, or submersible torpedo boat, the *Gymnote*, was launched by France in 1888. The conventional submarine of World War I was driven by

diesel engine on the surface and by battery-powered electric motors underwater.

The diesel engine also drove a generator that produced electricity to charge the batteries.

history In the 1760s, the American David Bushnell (1742–1824) designed a submarine called *Turtle* for attacking British ships, and in 1800 Robert Fulton designed a submarine called *Nautilus* for Napoleon for the same purpose. John P. Holland, an Irish emigrant to the USA, designed a submarine about 1875, which was used by both the US and the British navies at the turn of the century. Submarine warfare was really established as a distinct form of naval tactics during World War I and submarines, from the ocean-going vessels to the midge type, played a vital role in both world wars. In particular, German U-boats caused great difficulty to Allied merchant shipping, until the radio codes were broken in 1942.

nuclear submarines In 1954 the USA launched the first nuclear-powered submarine, the *Nautilus*. The US nuclear submarine *Ohio*, in service from 1981, is 170 m/560 ft long and carries 24 Trident missiles, each with 12 independently targetable nuclear warheads. The nuclear warheads on US submarines have a range that is being extended to 11,000 km/6,750 mi. Three Vanguard-class Trident missile-carrying submarines, which when armed will each yield more firepower than was used in the whole of World War II, are being built in the 1990s in the UK. Operating depth is usually up to 300 m/1,000 ft, and nuclear-powered speeds of 30 knots (55 kph/34 mph) are reached. As in all nuclear submarines, propulsion is by steam turbine driving a propeller. The steam is raised using the heat given off by the nuclear reactor (see nuclear energy). In oceanography, salvage, and pipe-laying, smaller submarines called submersibles are used. They are also being developed for tourism.

submersible vessel designed to operate under water, especially a small submarine used by engineers and research scientists as a ferry craft to support diving operations. The most advanced submersibles are the so-called lock-out type, which have two compartments: one for the pilot, the other to carry divers. The diving compartment is pressurized and provides access to the sea.

subnotebook in computing, a portable computer, usually a PC-compatible, that is smaller than a notebook computer but larger than a handheld computer. Subnotebooks often leave out features such as floppy disc and CD-ROM drives. One example is the Toshiba Libretto.

subroutine in computing, a small section of a program that is executed ('called') from another part of the program. Subroutines provide a method of performing the same task at more than one point in the program, and also of separating the details of a program from its main logic. In some computer languages, subroutines are similar to functions or procedures.

substitute in mathematics, to put values in the place of variables in an algebraic expression or formula. An algebraic expansion or simplification can be checked by substituting simple values for each variable. For example, to check that $x^3 + y^3 = (x + y)(x^2 + y^2 - xy)$ the value $x = 1$ and $y = 2$ might be substituted in both sides of the expression, giving left-hand side: $1^3 + 2^3 = 1 + 8 = 9$ right-hand side: $(1 + 2)(1^2 + 2^2 - 2) = 3 \times 3 = 9$.

The two sides are the same, so the expansion of $x^3 + y^3$ is correct.

substitution reaction in chemistry, the replacement of one atom or functional group in an organic molecule by another.

substrate in biochemistry, a compound or mixture of compounds acted on by an enzyme. The term also refers to a substance such as agar that provides the nutrients for the metabolism of microorganisms. Since the enzyme systems of microorganisms regulate their metabolism, the essential meaning is the same.

substring in computing, a portion of a string. In searching a text database, for example, specifying that a sequence of letters is a substring will widen the search from just matching words to other words in which that sequence of letters appears. For example, searching a database on the string 'computer' will not

retrieve entries which use 'computing' or 'compute'. Searching on the substring 'comput' however, will retrieve all three. The technique adds flexibility when the exact syntax of the search term is unknown.

subsystem in computing, hardware and/or software that performs a specific function within a larger system. Silicon Graphics, for example, uses subsystems to perform the many calculations needed for computer animation.

subtraction taking one number or quantity away from another, or finding the difference between two quantities; it is one of the four basic operations of arithmetic. Subtraction is neither commutative: $a - b \neq b - a$ nor associative: $a - (b - c) \neq (a - b) - c$. For example, $8 - 5 \neq 5 - 8$ $7 - (4 - 3) \neq (7 - 4) - 3$.

subway North American term for underground railway.

succession in ecology, a series of changes that occur in the structure and composition of the vegetation in a given area from the time it is first colonized by plants (primary succession), or after it has been disturbed by fire, flood, or clearing (secondary succession).

If allowed to proceed undisturbed, succession leads naturally to a stable climax community (for example, oak and hickory forest or savannah grassland) that is determined by the climate and soil characteristics of the area.

succession The succession of plant types along a lake. As the lake gradually fills in, a mature climax community of trees forms inland from the shore. Extending out from the shore, a series of plant communities can be discerned with small, rapidly growing species closest to the shore.

succulent plant thick, fleshy plant that stores water in its tissues; for example, cacti and stonecrops *Sedum*. Succulents live either in areas where water is very scarce, such as deserts, or in places where it is not easily obtainable because of the high concentrations of salts in the soil, as in salt marshes. Many desert plants are xerophytes.

sucker fish another name for dremora.

suckering in plants, reproduction by new shoots (suckers) arising from an existing root system rather than from seed. Plants that produce suckers include elm, dandelion, and members of the rose family.

SUCCULENT PLANT

The flowers of the stapeliads of Africa and southern Asia look very like dung or decaying meat. This is because they rely on carrion-feeding beetles to pollinate them. So convincing are the flowers that they are often covered with maggots that have hatched from eggs mistakenly laid on them.

sucrase enzyme capable of digesting sucrose into its constituent molecules of glucose and fructose.

In mammals this action takes place within the wall of the intestine, the products of the reaction being liberated into the lumen. This is an example of intracellular digestion.

sucrose or *cane sugar* or *beet sugar* $C_{12}H_{22}O_{11}$ a sugar found in the pith of sugar cane and in sugar beets. It is popularly known as *çugar*.

Sucrose is a disaccharide sugar, each of its molecules being made up of two simple sugar (monosaccharide) units: glucose and fructose.

sudden infant death syndrome (SIDS) in medicine, the technical term for *çot* death.

sugar or *sucrose* sweet, soluble, crystalline carbohydrate found in the pith of sugar cane and in sugar beet. It is a **disaccharide** sugar, each of its molecules being made up of two simple-sugar (monosaccharide) units: glucose and fructose. Sugar is easily digested and forms a major source of energy in humans, being used in cooking and in the food industry as a sweetener and, in high concentrations, as a preservative. A high consumption is associated with obesity and tooth decay. In the UK, sucrose may not be used in baby foods.

The main sources of sucrose sugar are tropical sugar cane *Saccharum officinarum*, which accounts for two-thirds of production, and temperate sugar beet *Beta vulgaris*. Minor quantities are produced from the sap of maple trees, and from sorghum and date palms. Raw sugar crystals obtained by heating the juice of sugar canes are processed to form brown sugars, such as Muscovado and Demerara, or refined and sifted to produce white sugars, such as granulated, caster, and icing sugar. The syrup that is drained away from the raw sugar is molasses; it may be processed to form golden syrup or treacle, or fermented to form rum. Molasses obtained from sugar beet juice is too bitter for human consumption. The fibrous residue of sugar cane, called bagasse, is used in the manufacture of paper, cattle feed, and fuel; and new types of cane are being bred for low sugar and high fuel production.

Approximately 9 million hectares/22.25 million acres of beet, mostly in Europe, Russia, Ukraine, Georgia, Belarus, and Armenia, and 13 million hectares/32 million acres of cane, grown in tropical and subtropical countries, together produce 100 million tonnes of raw sugar each year. Cane usually yields over 20 tonnes of sugar per hectare/9 tons per acre per year; sugar beet rarely exceeds 7 tonnes per hectare/3 tons per acre per year.

Of the 100 sugar cane-producing countries, India and Brazil are the largest, with 3 million and 2.5 million hectares/7.5 million acres and 6 million acres respectively. In many smaller countries, such as Barbados and Mauritius, sugar production is a vital component of the national economy. However, subsidies given to European beet-sugar producers by the European Union have affected world markets and the export earnings of many Third World sugar-producing countries.

sugar maple E North American *çmaple* tree.

sulphate SO_4^{2-} salt or ester derived from sulphuric acid. Most sulphates are water soluble (the exceptions are lead, calcium, strontium, and barium sulphates), and require a very high temperature to decompose them.

The commonest sulphates seen in the laboratory are copper(II) sulphate ($CuSO_4$), iron(II) sulphate ($FeSO_4$), and aluminium

sulphate ($Al_2(SO_4)_3$). The ion is detected in solution by using barium chloride or barium nitrate to precipitate the insoluble sulphate.

sulphide compound of sulphur and another element in which sulphur is the more *ç*electronegative element (see electronegativity). Sulphides occur in a number of minerals. Some of the more volatile sulphides have extremely unpleasant odours (hydrogen sulphide smells of bad eggs).

sulphite SO_3^{2-} salt or ester derived from sulphurous acid.

sulphonamide any of a group of compounds containing the chemical group sulphonamide (SO_2NH_2) or its derivatives, which were, and still are in some cases, used to treat bacterial diseases. Sulphadiazine ($C_{10}H_{10}N_4O_2S$) is an example.

Sulphonamide was the first commercially available antibacterial drug, the forerunner of a range of similar drugs. Toxicity and increasing resistance have limited their use chiefly to the treatment of urinary-tract infection.

sulphur brittle, pale-yellow, nonmetallic element, symbol S, atomic number 16, relative atomic mass 32.064. It occurs in three allotropic forms: two crystalline (called rhombic and monoclinic, following the arrangements of the atoms within the crystals) and one amorphous. It burns in air with a blue flame and a stifling odour. Insoluble in water but soluble in carbon disulphide, it is a good electrical insulator. Sulphur is widely used in the manufacture of sulphuric acid (used to treat phosphate rock to make fertilizers) and in making paper, matches, gunpowder and fireworks, in vulcanizing rubber, and in medicines and insecticides.

It is found abundantly in nature in volcanic regions combined with both metals and nonmetals, and also in its elemental form as a crystalline solid. It is a constituent of proteins, and has been known since ancient times.

sulphur dioxide SO_2 pungent gas produced by burning sulphur in air or oxygen. It is widely used for disinfecting food vessels and equipment, and as a preservative in some food products. It occurs in industrial flue gases and is a major cause of *çad* rain.

sulphuric acid or *oil of vitriol* H_2SO_4 a dense, viscous, colourless liquid that is extremely corrosive. It gives out heat when added to water and can cause severe burns. Sulphuric acid is used extensively in the chemical industry, in the refining of petrol, and in the manufacture of fertilizers, detergents, explosives, and dyes. It forms the acid component of car batteries.

sulphurous acid H_2SO_3 solution of sulphur dioxide (SO_2) in water. It is a weak acid.

sulphur trioxide SO_3 colourless solid prepared by reacting sulphur dioxide and oxygen in the presence of a vanadium(V) oxide catalyst in the *ç*contact process. It reacts violently with water to give sulphuric acid.

The violence of its reaction with water makes it extremely dangerous. In the contact process, it is dissolved in concentrated sulphuric acid to give oleum ($H_2S_2O_7$).

sumac any bush or tree of the genus *Rhus* of the cashew family, having pinnate compound leaves and clusters of small reddish fruits. Staghorn sumac *Rhus typhina*, growing to 36 ft/11 m tall, is common in North America. Included too are several poisonous plants (sometimes referred to collectively as the genus *Toxicodendron*), such as poison *çivy*, poison sumac, and certain Japanese sumacs.

summer time practice introduced in the UK in 1916 whereby legal time from spring to autumn is an hour in advance of Greenwich mean time.

Continental Europe 'puts the clock back' a month earlier than the UK in autumn. British summer time was permanently in force February 1940–October 1945 and February 1968–October 1971. Double summer time (2 hours in advance) was in force during the summers of 1941–45 and 1947.

In North America the practice is known as *daylight saving time*.

... in my studies of astronomy and philosophy I hold this opinion about the universe, that the Sun remains fixed in the centre of the circle of heavenly bodies, without changing its place: and the Earth, turning upon itself moves round the Sun.

GALILEO Italian physicist.
Letter to Cristina di Lorena 1615

Sun the δ star at the centre of the Solar System. Its diameter is 1,392,000 km/865,000 mi; its temperature at the surface is about 5,800K (5,500°C/9,900°F), and at the centre 15,000,000K (about 15,000,000°C/27,000,000°F). It is composed of about 70% hydrogen and 30% helium, with other elements making up less than 1%. The Sun's energy is generated by nuclear fusion reactions that turn hydrogen into helium at its centre. The gas core is far denser than mercury or lead on Earth. The Sun is about 4.7 billion years old, with a predicted lifetime of 10 billion years.

SUN

<http://www.hawastsoc.org/solar/eng/sun.htm>

All you every wanted to know about our closest star, including cross sections, photographs, a history of exploration, animations of eclipses, and much more. You can also take a multimedia tour of the Sun or find out what today's weather is like on the Sun.

sun-and-planet gear another term for δ epicyclic gear.

sundew any of a group of insectivorous plants found growing in bogs; sticky hairs on the leaves catch and digest insects that land on them. (Genus *Drosera*, family *Droseraceae*.)

sundial instrument measuring time by means of a shadow cast by the Sun. Almost completely superseded by the proliferation of clocks, it survives ornamentally in gardens. The dial is marked with the hours at graduated distances, and a style or gnomon (parallel to Earth's axis and pointing to the north) casts the shadow.

sunfish marine fish *Mola mola* with disc-shaped body 3 m/10 ft long found in all temperate and tropical oceans. The term also applies to fish of the North American freshwater Centrarchidae family, which have compressed, almost circular bodies, up to 80 cm/30 in long, and are nestbuilders and avid predators.

sunflower tall, thick-stemmed plant with a large, single, yellow-petalled flower, belonging to the daisy family. The common or giant sunflower (*H. annuus*), probably native to Mexico, can grow up to 4.5 m/15 ft high. It is commercially cultivated in central Europe, the USA, Russia, Ukraine, and Australia for the oil-bearing seeds that ripen in the central disc of the flower head; sunflower oil is widely used as a cooking oil and in margarine. (Genus *Helianthus*, family Compositae.)

Sun Microsystems (named after the *Stanford University Network*) US-based computer manufacturer founded in 1982 with the motto 'the network is the computer'. Sun specializes in office networks, workstations, and servers running Solaris, a version of the UNIX operating system. Sun pioneered the concept of open systems – technology that is available to other manufacturers – and in 1995 released Java, a platform-independent programming language.

sunspot dark patch on the surface of the Sun, actually an area of cooler gas, thought to be caused by strong magnetic fields that block the outward flow of heat to the Sun's surface. Sunspots consist of a dark central *umbra*, about 4,000K (3,700°C/6,700°F), and a lighter surrounding *penumbra*, about 5,500K (5,200°C/9,400°F). They last from several days to over a month, ranging in size from 2,000 km/1,250 mi to groups stretching for over 100,000 km/62,000 mi.

Sun The structure of the Sun. Nuclear reactions at the core releases vast amounts of energy in the form of light and heat that radiate out to the photosphere and corona. Surges of glowing gas rise as prominences from the surface of the Sun and cooler areas, known as sunspots appear as dark patches on the giant stars surface.

SUNSPOTS

<http://athena.wednet.edu/curric/space/sun/sunspot.html>

Well-written and easily understandable explanation of sunspots.

There is a high-resolution image of a group of sunspots and a link for further sunspot pictures. There is information on how to observe sunspots and the Sun's cycle of magnetic activity. For more detailed information, there are links to solar observatories.

Sunspots are more common during active periods in the Sun's magnetic cycle, when they are sometimes accompanied by nearby flares. The number of sunspots visible at a given time varies from none to over 100, in a cycle averaging 11 years. There was a full in sunspot activity, known as the Maunder minimum, 1645-1715, that coincided with a cold spell in Europe.

Sunyaev-Zel'dovich effect slight dip in the γ -cosmic background radiation when observed through the gas that surrounds clusters of galaxies.

First mapped in 1993 by British astronomers around the Abell 2218 galaxy cluster. The size of the Sunyaev-Zel'dovich effect is a measure of the gas thickness the cosmic background radiation passes through.

superactinide any of a theoretical series of superheavy, radioactive elements, starting with atomic number 113, that extend beyond the transactinide series in the periodic table. They do not occur in nature and none has yet been synthesized.

It is postulated that this series has a group of elements that have half-lives longer than those of the transactinide series.

This group, centred on element 114, is referred to as the 'island of stability', based on the nucleon arrangement. The longer half-lives will, it is hoped, allow enough time for their chemical and physical properties to be studied when they have been synthesized.

supercluster in astronomy, a grouping of several clusters of galaxies to form a structure about 100-300 million light years across. Our own Galaxy and its neighbours lie on the edge of the local supercluster of which the γ Virgo cluster is the dominant member.

supercomputer the fastest, most powerful type of computer, capable of performing its basic operations in picoseconds (thousand-billionths of a second), rather than nanoseconds (billionths of a second), like most other computers.

To achieve these extraordinary speeds, supercomputers use several processors working together and techniques such as cooling processors down to nearly absolute zero temperature, so that their components conduct electricity many times faster than normal. Supercomputers are used in weather forecasting, fluid dynamics, and aerodynamics. Manufacturers include Cray Research, Fujitsu, and NEC.

Of the world's 500 most powerful supercomputers 232 are in the USA, 109 in Japan, and 140 in Europe, with 23 in the UK. In 1992 Fujitsu announced the launch of the first computer capable of performing 300 billion calculations a second. In 1996 University of Tokyo researchers completed a computer able to perform 1.08 trillion floating-point operations per second.

superconductivity in physics, increase in electrical conductivity at low temperatures. The resistance of some metals and metallic compounds decreases uniformly with decreasing temperature until at a critical temperature (the superconducting point), within a few degrees of absolute zero (0K/-273.15°C/-459.67°F), the resistance suddenly falls to zero. The phenomenon was discovered by Dutch scientist Heike Kamerlingh Onnes in 1911.

Some metals, such as platinum and copper, do not become superconductive; as the temperature decreases, their resistance decreases to a certain point but then rises again. Superconductivity can be nullified by the application of a large magnetic field.

In the superconducting state, an electric current will continue

indefinitely once started, provided that the material remains below the superconducting point. In 1986 IBM researchers achieved superconductivity with some ceramics at -243°C/-405°F, opening up the possibility of 'high-temperature' superconductivity: Paul Chu at the University of Houston, Texas, achieved superconductivity at -179°C/-290°F, a temperature that can be sustained using liquid nitrogen.

In 1993 Swiss researchers produced an alloy of mercury, barium, and copper which becomes superconducting at 133 K (-140°C/-220°F). A high-temperature semiconductor material, called bismuth ceramic, which is superconducting at 100 K, became commercially available in 1997.

supercooling the cooling of a liquid below its freezing point without freezing taking place; or the cooling of a saturated solution without crystallization taking place, to form a supersaturated solution. In both cases supercooling is possible because of the lack of solid particles around which crystals can form. Crystallization rapidly follows the introduction of a small crystal (seed) or agitation of the supercooled solution.

supercritical fluid fluid that combines the properties of a gas and a liquid, see γ fluid, supercritical.

superego in Freudian psychology, the element of the human mind concerned with the ideal, responsible for ethics and self-imposed standards of behaviour. It is characterized as a form of conscience, restraining the γ ego, and responsible for feelings of guilt when the moral code is broken.

superfluid fluid that flows without viscosity or friction and has a very high thermal conductivity. Liquid helium at temperatures below 2K (-271°C/-456°F) is a superfluid: it shows unexpected behaviour; for instance, it flows uphill in apparent defiance of gravity and, if placed in a container, will flow up the sides and escape.

super giant the largest and most luminous type of star known, with a diameter of up to 1,000 times that of the Sun and absolute magnitudes of between -5 and -9. Supergiants are likely to become γ supernovae.

superheterodyne receiver the most widely used type of radio receiver, in which the incoming signal is mixed with a signal of fixed frequency generated within the receiver circuits. The resulting signal, called the intermediate-frequency (i.f.) signal, has a frequency between that of the incoming signal and the internal signal. The intermediate frequency is near the optimum frequency of the amplifier to which the i.f. signal is passed.

This arrangement ensures greater gain and selectivity. The superheterodyne system is also used in basic television receivers.

superior planet planet that is farther away from the Sun than the Earth is: that is, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto.

supernova the explosive death of a star, which temporarily attains a brightness of 100 million Suns or more, so that it can shine as brilliantly as a small galaxy for a few days or weeks. Very approximately, it is thought that a supernova explodes in a large galaxy about once every 100 years. Many supernovae - astronomers estimate some 50% - remain undetected because of obscuring by interstellar dust.

The name 'supernova' was coined by US astronomers Fritz Zwicky and Walter Baade in 1934. Zwicky was also responsible for the division into types I and II. Type I supernovae are thought to occur in binary star systems, in which gas from one star falls on to a γ white dwarf, causing it to explode. Type II supernovae occur in stars ten or more times as massive as the Sun, which suffer runaway internal nuclear reactions at the ends of their lives, leading to explosions. These are thought to leave behind γ neutron stars and γ black holes. Gas ejected by such an explosion causes an expanding radio source, such as the γ Crab nebula. Supernovae are thought to be the main source of elements heavier than hydrogen and helium.

superphosphate phosphate fertilizer made by treating apatite (calcium phosphate mineral) with sulphuric or phosphoric acid.

The commercial mixture contains largely monocalcium phosphate. Single-superphosphate obtained from apatite and sulphuric acid contains 16–20% available phosphorus, as P_2O_5 ; triple-superphosphate, which contains 45–50% phosphorus, is made by treating apatite with phosphoric acid.

supersaturation in chemistry, the state of a solution that has a higher concentration of solute than would normally be obtained in a saturated solution.

Many solutes have a higher solubility at high temperatures. If a hot saturated solution is cooled slowly, sometimes the excess solute does not come out of solution. This is an unstable situation and the introduction of a small solid particle will encourage the release of excess solute.

supersonic speed speed greater than that at which sound travels, measured in Mach numbers. In dry air at $0^\circ\text{C}/32^\circ\text{F}$, sound travels at about 1,170 kph/727 mph, but decreases its speed with altitude until, at 12,000 m/39,000 ft, it is only 1,060 kph/658 mph.

When an aircraft passes the sound barrier, shock waves are built up that give rise to sonic boom, often heard at ground level. US pilot Captain Charles Yeager was the first to achieve supersonic flight, in a Bell V-S-1 rocket plane on 14 October 1947.

superstring theory in physics, a mathematical theory developed in the 1980s to explain the properties of elementary particles and the forces between them (in particular, gravity and the nuclear forces) in a way that combines relativity and quantum theory.

In string theory, the fundamental objects in the universe are not pointlike particles but extremely small stringlike objects. These objects exist in a universe of ten dimensions, although, for reasons not yet understood, only three space dimensions and one dimension of time are discernible.

There are many unresolved difficulties with superstring theory, but some physicists think it may be the ultimate 'theory of everything' that explains all aspects of the universe within one framework.

supersymmetry in physics, a theory that relates the two classes of elementary particle, the fermions and the bosons. According to supersymmetry, each fermion particle has a boson partner particle, and vice versa. It has not been possible to marry up all the known fermions with the known bosons, and so the theory postulates the existence of other, as yet undiscovered fermions, such as the photinos (partners of the photons), gluinos (partners of the gluons), and gravitinos (partners of the gravitons). Using these ideas, it has become possible to develop a theory of gravity – called supergravity – that extends Einstein's work and considers the gravitational, nuclear, and electromagnetic forces to be manifestations of an underlying superforce. Supersymmetry has been incorporated into the superstring theory, and appears to be a crucial ingredient in the 'theory of everything' sought by scientists.

support in computing, a particular type of hardware or software that is compatible with a relevant standard or another type of hardware or software. A given printer might, for example, support 600 dpi (dots per inch) resolution, or a particular computer system might support SVG graphics.

support environment in computing, a collection of programs (software) used to help people design and write other programs. At its simplest, this includes a text editor (word-processing software) and a compiler for translating programs into executable form; but it can also include interactive debuggers for helping to locate faults, data dictionaries for keeping track of the data used, and rapid prototyping tools for producing quick, experimental mock-ups of programs.

suprachiasmatic nucleus one of two small regions in the hypothalamus that play a part in controlling circadian rhythm.

suprarenal gland alternative name for the adrenal gland.

surd expression containing the root of an irrational number that can never be exactly expressed – for example, $\sqrt{3} = 1.732050808\dots$

surface area the area of the outside surface of a solid. See illustration on page 728.

surface-area-to-volume ratio the ratio of an animal's surface area (the area covered by its skin) to its total volume. This is high for small animals, but low for large animals such as elephants.

The ratio is important for endothermic (warm-blooded) animals because the amount of heat lost by the body is proportional to its surface area, whereas the amount generated is proportional to its volume. Very small birds and mammals, such as hummingbirds and shrews, lose a lot of heat and need a high intake of food to maintain their body temperature. Elephants, on the other hand, are in danger of overheating, which is why they have no fur.

surface tension in physics, the property that causes the surface of a liquid to behave as if it were covered with a weak elastic skin; this is why a needle can float on water. It is caused by the exposed surface's tendency to contract to the smallest possible area because of cohesive forces between molecules at the surface. Allied phenomena include the formation of droplets, the concave profile of a meniscus, and the capillary action by which water soaks into a sponge.

surfactant (contraction of *surface-active agent*) substance added to a liquid in order to increase its wetting or spreading properties. Detergents are examples.

surfing in computing, exploring the Internet. The term is derived from 'channel surfing', or flicking rapidly through the dozens of channels typically available on cable TV networks.

surgeon fish any fish of the tropical marine family Acanthuridae. It has a flat body up to 50 cm/20 in long, is brightly coloured, and has a movable spine on each side of the tail that can be used as a weapon.

SURGERY

An English surgeon received £3,000 and a knighthood for removing a bladder stone from Leopold I, uncle to Queen Victoria. The surgeon, Henry Thompson, removed the stone using a lithotrite – an instrument inserted into the bladder through the penis, which crushes the stone so that it can be expelled naturally.

surgery branch of medicine concerned with the treatment of disease, abnormality, or injury by operation. Traditionally it has been performed by means of cutting instruments, but today a number of technologies are used to treat or remove lesions, including ultrasonic waves and laser surgery.

Surgery is carried out under sterile conditions using an anaesthetic. There are many specialized fields, including cardiac (heart), orthopaedic (bones and joints), ophthalmic (eye), neuro (brain and nerves), thoracic (chest), and renal (kidney) surgery; other specialties include plastic and reconstructive surgery, and transplant surgery.

Historically, surgery for abscesses, amputation, dental problems, trepanning, and childbirth was practised by the ancient civilizations of both the Old World and the New World.

During the Middle Ages, Arabic surgeons passed their techniques on to Europe, where, during the Renaissance, anatomy and physiology were pursued. By the 19th century, anaesthetics and Joseph Lister's discovery of antiseptics became the basis for successful surgical practices. The 20th century's use of antibiotics and blood transfusions has made surgery safer and more effective.

Some early operations, such as thoracoplasty (causing partial collapse of a lung) for tuberculosis, have been replaced by other treatments. Also, the need for exploratory surgery has been reduced by the introduction of noninvasive imaging techniques,

surface area of common three-dimensional shapes

surface area of a **cube**
(faces are identical)
= $6 \times$ area of each surface
= $6l^2$

surface area of a **cuboid**
(opposite faces are identical)
= area of two end faces + area of two sides
+ area of top and base
= $2lh + 2hb + 2lb$
= $2(lh + hb + lb)$

surface area of a **cylinder**
= area of a curved surface + area of top
and base
= $2\pi \times$ (radius of cross-section \times height)
+ 2π (radius of cross-section) 2
= $2\pi rh + 2\pi r^2$
= $2\pi r(h + r)$

surface area of a **cone**
= area of a curved surface + area base
= $\pi \times$ (radius of cross-section \times slant height)
+ π (radius of cross-section) 2
= $\pi rl + \pi r^2$
= $\pi r(l + r)$

surface area of a **sphere**
= $4\pi \times$ radius 2
= $4\pi r^2$

surface area Surface areas of common three-dimensional shapes.

such as ultrasound and CAT scans. The practice of endoscopy (examination of the interior of the body by direct viewing) has enabled the development of minimally invasive keyhole surgery.

Sine experientia nihil sufficienter sciri potest.
Without experience nothing can be known sufficiently.

ROGER BACON English philosopher and scientist.
Opus Majus, 1267–68

surgical spirit Methanol to which has been added a small amount of ethanol to render it unfit to drink. It is used to sterilize surfaces and to cleanse skin abrasions and sores.

surrogacy practice whereby a woman is sought, and usually paid, to bear a child for an infertile couple or a single parent.

survey in statistics, a method of collecting data in which people are asked to answer a number of questions (usually in the form of a questionnaire). An opinion poll is a survey. The reliability of a survey's results depends on whether the sample from which the information has been collected is free from bias and sufficiently large.

surveying the accurate measuring of the Earth's crust, or of land features or buildings. It is used to establish boundaries, and to evaluate the topography for engineering work. The measurements used are both linear and angular, and geometry and trigonometry are applied in the calculations.

susceptibility in physics, ratio of the intensity of magnetization produced in a material to the intensity of the magnetic field to which the material is exposed. It measures the extent to which a material is magnetized by an applied magnetic field. ϕ Diamagnetic materials have small negative susceptibilities; ϕ paramagnetic materials have small positive susceptibilities; ϕ ferromagnetic materials have large positive susceptibilities. See also ϕ magnetism.

suslik small Eurasian ground ϕ squirrel *Citellus citellus*.

suspension mixture consisting of small solid particles dispersed in a liquid or gas, which will settle on standing. An example is milk of magnesia, which is a suspension of magnesium hydroxide in water.

suspension bridge ϕ bridge in which the spanning roadway or railway is supported by a system of steel ropes suspended from two or more tall towers.

suspensory ligament in the ϕ eye, a ring of fibre supporting the lens. The ligaments attach to the ciliary muscles, the circle of muscle mainly responsible for changing the shape of the lens during ϕ accommodation. If the ligaments are put under tension, the lens becomes flatter, and therefore able to focus on objects in the far distance.

Sussex spaniel breed of small Gundog, originating at Rosehill Park, Sussex, England. Weighing only about 23 kg/50 lb and standing 40 cm/15 in tall, it is characterized by its golden liver-coloured coat.

sustainable capable of being continued indefinitely. For example, the sustainable yield of a forest is equivalent to the amount that grows back. Environmentalists made the term a catchword, in advocating the sustainable use of resources.

SUSTAINABLE DEVELOPMENT

<http://iisd1.iisd.ca/>

Tackles a complex issue from many different points of view. There are sections on trade and key topics such as forests and oceans. The site also reports on global initiatives to encourage sustainability.

One of the major advantages of this site, though, is that it makes this issue easy to understand for beginners through its 'contents and principles' section.

sustained-yield cropping in ecology, the removal of surplus individuals from a ϕ population of organisms so that the population maintains a constant size. This usually requires selective removal of animals of all ages and both sexes to ensure a balanced ϕ population structure. Taking too many individuals can result in a population decline, as in overfishing.

Excessive cropping of young females may lead to fewer births in following years, and a fall in population size. Appropriate cropping frequencies can be determined from an analysis of a ϕ life table.

SUSY in physics, an abbreviation for ϕ supersymmetry.

SVGA (abbreviation for *super video graphics array*) in computing, a graphic display standard providing higher resolution than ϕ VGA. SVGA screens have resolutions of either 800 \times 600 or 1,024 \times 768.

swallow any bird of the family Hirundinidae of small, insect-eating birds in the order Passeriformes, with long, narrow wings, and deeply forked tails. Swallows feed while flying, capturing winged

insects in the mouth, which is lined with bristles made viscid (sticky) by a salivary secretion.

SWALLOW

Most birds have fleas; there are 17 species of flea found only on swallows and martins.

swamp region of low-lying land that is permanently saturated with water and usually overgrown with vegetation; for example, the everglades of Florida, USA. A swamp often occurs where a lake has filled up with sediment and plant material. The flat surface so formed means that runoff is slow, and the water table is always close to the surface. The high humus content of swamp soil means that good agricultural soil can be obtained by draining.

swamp cypress or *bald cypress* deciduous tree belonging to the redwood family, found growing in or near water in the southeastern USA and Mexico; it is a valuable timber tree. (*Taxodium distichum*, family Taxodiaceae.)

swan large water bird, with a long slender neck and webbed feet, closely related to ducks and geese. The four species of swan found in the northern hemisphere are white; the three species found in the southern hemisphere are all or partly black. The male (cob) and female (pen) are similar in appearance, and they usually pair for life. They nest on or near water in every continent, except Africa and Antarctica. Swans produce a clutch of 4-6 greenish coloured eggs and their young are known as cygnets. Cygnets are covered with a grey down and only become fully feathered and able to fly after 14-16 weeks.

Swans feed mainly on aquatic plants. They are among the largest and heaviest birds that can fly and because of this require large areas of water to take off. They fly with a slow, graceful wing beat and when migrating, fly in a distinctive V-shaped flock.

The mute swan is the most common species. It is native to northern Europe and Asia, but has been introduced and is now widespread in North America. The mute swan has white feathers, black legs and a bright orange flattened bill with a black knob on the upper bill, near the eyes. It may be as long as 150 cm/5 ft in length and weigh as much as 14 kg/30 lb. It hisses loudly when angry.

classification Swans belong to animal phylum Chordata, class Aves (birds), order Anseriformes, family Anatidae. They belong to the genus *Cygnus*. There are seven species: the mute swan (*Cygnus olor*), the whooper swan (*C. cygnus*), Bewick's swan (*C. bewicki*), the tundra (whistling) swan (*C. columbianus*), the North American trumpeter swan (*C. buccinator*), the black swan of Australia (*C. atratus*), and the South American black-necked swan (*C. melanocoryphus*). The North American trumpeter swan is the largest, with a wingspan of 2.4 m/8 ft.

swap in computing, to move segments of data in and out of memory. For fast operation as much data as possible is required in main memory, but it is generally not possible to include all data at the same time. Swapping is the operation of writing and reading from the backup store, often a special space on the disc.

S-wave (abbreviation of *secondary wave*) in seismology, a class of seismic wave that passes through the Earth in the form of transverse shear waves. S-waves from an earthquake travel at roughly half the speed of P-waves and arrive later at monitoring stations (hence secondary waves) though with greater amplitude. They can travel through solid rock but not through the liquid outer core of the Earth.

sweat gland ϕ gland within the skin of mammals that produces surface perspiration. In primates, sweat glands are distributed over the whole body, but in most other mammals they are more localized; for example, in cats and dogs they are restricted to the feet and around the face.

swede annual or biennial plant widely cultivated for its edible root, which is purple, white, or yellow. It is similar in taste to the

turnip but is of greater food value, firmer fleshed, and can be stored for a longer time. (*Brassica napus*, family Cruciferae.)

sweet cicely plant belonging to the carrot family, native to S Europe; the root is eaten as a vegetable, and the aniseed-flavoured leaves are used in salads. (*Myrrhis odorata*, family Umbelliferae.)

sweetener any chemical that gives sweetness to food. Caloric sweeteners are various forms of δ sugar; noncaloric, or artificial, sweeteners are used by dieters and diabetics and provide neither energy nor bulk. Questions have been raised about the long-term health effects from several artificial sweeteners.

Sweeteners are used to make highly processed foods attractive, whether sweet or savoury. Most of the noncaloric sweeteners do not have E numbers. Some are banned for baby foods and for young children: thaumatin, aspartame, acesulfame-K, sorbitol, and mannitol. Cyclamate is banned in the UK and the USA; acesulfame-K is banned in the USA.

In 1997, Japanese geneticists engineered a strain of yeast that produces a protein, called monellin, which is 3,000 times as sweet as sugar and 15 times sweeter than aspartame. Monellin occurs naturally in the berries of a West African plant, *Dioscoreophyllum cumminisii* and, as a protein, it contains only 4 kilocalories per gram.

sweet pea plant belonging to the δ pea family.

sweet potato tropical American plant belonging to the morning-glory family; the white-orange tuberous root is used as a source of starch and alcohol and eaten as a vegetable. (*Ipomoea batatas*, family Convolvulaceae.)

sweet william biennial to perennial plant belonging to the pink family, native to S Europe. It is grown for its fragrant red, white, and pink flowers. (*Dianthus barbatus*, family Caryophyllaceae.)

swift fast-flying, short-legged bird of the family Apodidae, order Apodiformes, of which there are about 75 species, found largely in the tropics. They are 9–23 cm/4–11 in long, with brown or grey plumage, long, pointed wings, and usually a forked tail. They are capable of flying at 110 kph/70 mph.

The nests of the **grey-rumped swiftlet** *Collocalia francica* of Borneo consist almost entirely of solidified saliva, and are harvested for bird's-nest soup. The increasing removal of nests for commercial purposes is endangering the birds.

swim bladder thin-walled, air-filled sac found between the gut and the spine in bony fishes. Air enters the bladder from the gut or from surrounding capillaries (see δ capillary), and changes of air pressure within the bladder maintain buoyancy whatever the water depth.

In evolutionary terms, the swim bladder of higher fishes is a derivative of the lungs present in all primitive fishes (not just lungfishes).

swing wing correctly **variable-geometry wing** aircraft wing that can be moved during flight to provide a suitable configuration for either low-speed or high-speed flight. The British engineer Barnes Wallis developed the idea of the swing wing, first used on the US-built Northrop X-4, and since used in several aircraft, including the US F-111, F-114, and the B-1, the European Tornado, and several Soviet-built aircraft.

These craft have their wings projecting nearly at right angles for takeoff and landing and low-speed flight, and swung back for high-speed flight.

Swiss cheese plant common name for δ monstera, a plant belonging to the arum family.

swordfish marine bony fish *Xiphias gladius*, the only member of its family (Xiphiidae), characterized by a long swordlike beak protruding from the upper jaw. It may reach 4.5 m/15 ft in length and weigh 450 kg/1,000 lb.

sycamore deciduous tree native to Europe. The leaves are five-lobed, and the hanging clusters of flowers are followed by winged

swing wing A British Aerospace Tornado F2 swing-wing (variable-geometry) fighter-bomber. It is flying at a relatively low speed and the wings are fully extended. British Aerospace

fruits. The timber is used for furniture making. (*Acer pseudoplatanus*.)

syenite grey, crystalline, plutonic (intrusive) δ igneous rock, consisting of feldspar and hornblende; other minerals may also be present, including small amounts of quartz.

symbiosis any close relationship between two organisms of different species, and one where both partners benefit from the association. A well-known example is the pollination relationship between insects and flowers, where the insects feed on nectar and carry pollen from one flower to another. This is sometimes known as δ mutualism.

symbol in chemistry, letter or letters used to represent a chemical element, usually derived from the beginning of its English or Latin name. Symbols derived from English include B, boron; C, carbon; Ba, barium; and Ca, calcium. Those derived from Latin include Na, sodium (Latin *natrium*); Pb, lead (Latin *plumbum*); and Au, gold (Latin *aurum*).

symbolic address in computing, a symbol used in δ assembly language programming to represent the binary δ address of a memory location.

symbolic processor computer purpose-built to run so-called symbol-manipulation programs rather than programs involving a great deal of numerical computation. They exist principally for the δ artificial intelligence language δ LISP, although some have also been built to run δ PROLOG.

symmetry exact likeness in shape about a given line (axis), point, or plane. A figure has symmetry if one half can be rotated and/or reflected onto the other. (Symmetry preserves length, angle, but not necessarily orientation.) In a wider sense, symmetry exists if a change in the system leaves the essential features of the system unchanged; for example, reversing the sign of electric charges does not change the electrical behaviour of an arrangement of charges.

plane symmetry

cuboid has three planes of symmetry

square-based pyramid has four planes of symmetry

sphere has infinite number of planes of symmetry

axes of symmetry

symmetry The planes of symmetry of some common three-dimensional shapes and the axes of symmetry of some common two-dimensional ones.

There will come a time, when the world will be filled with one science, one truth, one industry, one brotherhood, one friendship with nature ... this is my belief, it progresses, it grows stronger, this is worth living for, this is worth waiting for.

DMITRI IVANOVICH MENDELEYEV Russian chemist.
In Y A Urmanets *The Symmetry of Nature
and the Nature of Symmetry* 1974

symptom any change or manifestation in the body suggestive of disease as perceived by the sufferer. Symptoms are subjective phenomena. In strict usage, symptoms are events or changes reported by the patient; signs are noted by the doctor during the patient's examination.

synapse junction between two nerve cells, or between a nerve cell and a muscle (a neuromuscular junction), across which a nerve impulse is transmitted. The two cells are separated by a narrow gap called the synaptic cleft. The gap is bridged by a chemical neurotransmitter, released by the nerve impulse.

The threadlike extension, or axon, of the transmitting nerve cell has a slightly swollen terminal point, the synaptic knob. This forms one half of the synaptic junction and houses membrane-bound vesicles, which contain a chemical neurotransmitter. When nerve impulses reach the knob, the vesicles release the transmitter and this flows across the gap and binds itself to special receptors on the receiving cell's membrane. If the receiving cell is a nerve cell, the other half of the synaptic junction will be one or more extensions called dendrites; these will be stimulated by the neurotransmitter to set up an impulse, which will then be conducted along the length of the nerve cell and on to its own axons. If the receiving cell is a muscle cell, it will be stimulated by the neurotransmitter to contract.

Synapsida group of mammal-like reptiles living 315–195 million years ago, whose fossil record is largely complete, and who were for a while the dominant land animals, before being replaced by the dinosaurs. The true mammals are their descendants.

synchronous regular. Most communication within a computer system is synchronous, controlled by the computer's own internal clock, while communication between computers is usually asynchronous. Synchronous telecommunications are, however, becoming more widely used.

synchronous orbit another term for geostationary orbit.

synchronous rotation in astronomy, another name for captured rotation.

synchrotron particle accelerator in which particles move, at increasing speed, around a hollow ring. The particles are guided around the ring by electromagnets, and accelerated by electric fields at points around the ring. Synchrotrons come in a wide range of sizes, the smallest being about a metre across while the largest is 27 km across. The Tevatron synchrotron at Fermilab is some 6 km in circumference and accelerates protons and antiprotons to 1 TeV.

The European Synchrotron Radiation Facility (ESRF) opened in Grenoble, France, in September 1994, funded by £400 million from 12 European countries.

syndine geological term for a fold in the rocks of the Earth's crust in which the layers or beds dip inwards, thus forming a trough-like structure with a sag in the middle. The opposite structure, with the beds arching upwards, is an anticline.

syndrome in medicine, a set of signs and symptoms that always occur together, thus characterizing a particular condition or disorder.

synergy in medicine, the 'cooperative' action of two or more drugs, muscles, or organs; applied especially to drugs whose combined action is more powerful than their simple effects added together.

synodic period the time taken for a planet or moon to return to the same position in its orbit as seen from the Earth; that is, from one opposition to the next. It differs from the sidereal period because the Earth is moving in orbit around the Sun.

synovial fluid viscous colourless fluid that bathes movable joints between the bones of vertebrates. It nourishes and lubricates the cartilage at the end of each bone.

Synovial fluid is secreted by a membrane, the synovium, that links movably jointed bones. The same kind of fluid is found in bursae, the membranous sacs that buffer some joints, such as in the shoulder and hip region.

synthesis in chemistry, the formation of a substance or compound from more elementary compounds. The synthesis of a drug can involve several stages from the initial material to the final product; the complexity of these stages is a major factor in the cost of production.

synthetic any material made from chemicals. Since the 1900s, more and more of the materials used in everyday life are synthetic, including plastics (polythene, polystyrene), synthetic fibres (nylon, acrylics, polyesters), synthetic resins, and synthetic rubber. Most naturally occurring organic substances are now made synthetically, especially pharmaceuticals.

synthetic fibre fibre made by chemical processes, unknown in nature. There are two kinds. One is made from natural materials that have been chemically processed in some way; rayon, for example, is made by processing the cellulose in wood pulp. The other type is the true synthetic fibre, made entirely from chemicals. Nylon was the original synthetic fibre, made from chemicals obtained from petroleum (crude oil).

Fibres are drawn out into long threads or filaments, usually by so-called spinning methods, melting or dissolving the parent material and then forcing it through the holes of a perforated plate, or spinneret.

syphilis sexually transmitted disease caused by the spiral-shaped bacterium (spirochete) *Treponema pallidum*. Untreated, it runs its course in three stages over many years, often starting with a painless hard sore, or chancre, developing within a month on the area of infection (usually the genitals). The second stage, months later, is a rash with arthritis, hepatitis, and/or meningitis. The third stage, years later, leads eventually to paralysis, blindness, insanity, and death. The Wassermann test is a diagnostic blood test for syphilis.

With widespread availability of antibiotics, syphilis is now increasingly treatable in the industrialized world, at least to the extent that the final stage of the disease is rare. The risk remains that the disease may go undiagnosed or that it may be transmitted by a pregnant woman to her fetus.

SYPHILIS

Undergarments with a mercury coating to protect the wearer against syphilis were sometimes worn as a precautionary measure in 17th-century Italy.

Syquest manufacturer of removable hard disc drives and high-capacity floppy disc drives, which may be used to transport large files from one location to another.

syringa common, but incorrect, name for the mock orange. The genus *Syringa* includes lilacs, and is not related to the mock orange.

syrinx the voice-producing organ of a bird. It is situated where the trachea divides in two and consists of vibrating membranes, a reverberating capsule, and numerous controlling muscles.

sysop (contraction of *system operator*) in computing, the operator of a bulletin board system (BBS).

system administrator (or *sysadmin*) in computing, person who runs and maintains a computer system, especially a local area network (LAN). The responsibilities of a systems administrator typically include installing hardware and software, supervising system security, fixing faults, and organizing training.

systematics science of naming and identifying species, and determining their degree of relatedness. It plays an important role in preserving biodiversity; only a small fraction of existing species have been named and described. See also classification.

Systeme International d'Unités official French name for SI units.

system flow chart type of flow chart used to describe the flow of data through a particular computer system.

systemic in medicine, relating to or affecting the body as a whole. A systemic disease is one where the effects are present throughout the body, as opposed to local disease, such as conjunctivitis, which is confined to one part.

system implementation in computing, the process of installing a new computer system.

To ensure that a system's implementation takes place as efficiently and with as little disruption as possible, a number of tasks are necessary. These include ordering and installing new equipment, ordering new stationery and storage media, training personnel, converting data files into new formats, drawing up an overall implementation plan, and preparing for a period of either parallel running or pilot running.

SYSTEM.INI (abbreviation for *System Initialization*) in computing, file used by Microsoft Windows to store information about which parts of Windows to load and how to set itself up on the PC on which it is running, for example SYSTEM.INI specifies drivers for the keyboard, graphics card, and sound card, if any.

system requirements in computing, minimum specification necessary in order to use a particular piece of hardware or software.

systems analysis in computing, the investigation of a business activity or clerical procedure, with a view to deciding if and how it can be computerized. The analyst discusses the existing procedures with the people involved, observes the flow of data through

the business, and draws up an outline specification of the required computer system. The next step is systems design.

Systems in use in the 1990s include Yourdon, SSADM (Structured Systems Analysis and Design Methodology), and Soft Systems Methodology.

Systems Application Architecture (SAA) in computing, IBM model for client-server computing, introduced in 1987. SAA was a grandiose attempt to reduce the incompatibilities between IBM's many ranges of hardware, including mainframes, minicomputers, and PCs. It uses CUA (common user access) standards to ensure that commands and keystrokes are used consistently in different applications.

systems design in computing, the detailed design of an applications package. The designer breaks the system down into component programs, and designs the required input forms, screen layouts, and printouts. Systems design forms a link between systems analysis and programming.

Systems Network Architecture (SNA) a set of communication protocols developed by IBM and incorporated in hardware and software implementations. See also TCP/IP and Open Systems Interconnection (OSI).

systems program in computing, a program that performs a task related to the operation and performance of the computer system itself. For example, a systems program might control the operation of the display screen, or control and organize backing storage. In contrast, an applications program is designed to carry out tasks for the benefit of the computer user.

System X in communications, a modular, computer-controlled, digital switching system used in telephone exchanges.

ystole in biology, the contraction of the heart. It alternates with diastole, the resting phase of the heart beat.

syzygy in astronomy, the alignment of three celestial bodies, usually the Sun, Earth, and Moon or the Sun, Earth, and another planet. A syzygy involving the Sun, Earth, and Moon usually occurs during solar and lunar eclipses.

The term also refers to the Moon or another planet when it is in conjunction or opposition.

t symbol for tonne, ton.

T1 link digital telephone line which can transfer data at 1.544 megabits per second. T1 lines are a type of Integrated Services Digital Network (ISDN) communication.

T3 digital telephone standard that transmits data at 44.736 megabits per second, widely used for Integrated Services Digital Network (ISDN) lines.

tabby cat breed of short- or long-haired domestic cat. The distinctive patterning of the coat is inherited from the cat's pre-domesticated ancestors. It is believed that all colour variations of short-haired cats have been bred from the tabby. The coat's ground colour is either grey or golden-brown overlaid with stripes ('mackerel'), blotches ('classic'), or (less frequently) spots. There are many varieties.

The name is derived from the striped watered silk, known in Britain as tabby silk, produced by the weavers of the Attariya district of Baghdad.

tachograph combined speedometer and clock that records a vehicle's speed (on a small card disc, magnetic disc, or tape) and the length of time the vehicle is moving or stationary. It is used to monitor a lorry driver's working hours.

taiga or **boreal forest** Russian name for the forest zone south of the tundra, found across the northern hemisphere. Here, dense forests of conifers (spruces and hemlocks), birches, and poplars occupy glaciated regions punctuated with cold lakes, streams, bogs, and marshes. Winters are prolonged and very cold, but the summer is warm enough to promote dense growth.

The varied fauna and flora are in delicate balance because the conditions of life are so precarious. This ecology is threatened by mining, forestry, and pipeline construction.

taipan species of small-headed cobra *Oxyuranus scutellatus*, found in NE Australia and New Guinea. It is about 3 m/10 ft long, and has a brown back and yellow belly. Its venom is fatal within minutes.

takahe flightless bird *Porphyrio mantelli* of the rail family, order Gruiformes, native to New Zealand. It is about 60 cm/2 ft tall and weighs just over 2 kg/4.4 lb, with blue and green plumage and a red bill. The takahe was thought to have become extinct at the end of the 19th century, but in 1948 small numbers were rediscovered in the tussock grass of a mountain valley on South Island.

talc $Mg_3Si_2O_{10}(OH)_2$, mineral, hydrous magnesium silicate. It occurs in tabular crystals, but the massive impure form, known as steatite or soapstone, is more common. It is formed by the alteration of magnesium compounds and is usually found in metamorphic rocks. Talc is very soft, ranked 1 on the Mohs' scale of hardness. It is used in powdered form in cosmetics, lubricants, and as an additive in paper manufacture.

French chalk and potstone are varieties of talc. Soapstone has a greasy feel to it, and is used for carvings such as Inuit sculptures.

Talgai skull cranium of a pre-adult male, dating from 10,000–20,000 years ago, found at Talgai station, S Queensland, Australia. It was one of the earliest human archaeological finds in Australia, having been made in 1886. Its significance was not realized, however, until the work of Edgeworth David and others after

1914. The skull is large with heavy eyebrow ridges and cheekbones.

tallowwood large tree *Eucalyptus microcorys*, family Myrtaceae, of New South Wales and Queensland, Australia, growing in coastal forests and yielding a strong timber. Its nectar is much prized by apiarists.

tamandua tree-living toothless anteater *Tamandua tetradactyla* found in tropical forests and tree savanna from S Mexico to Brazil. About 56 cm/1.8 ft long with a prehensile tail of equal length, it has strong foreclaws with which it can break into nests of tree ants and termites, which it licks up with its narrow tongue.

tamarack coniferous tree native to boggy soils in North America, where it is used for timber. It is a type of larch. (*Larix laricina*, family Pinaceae.)

tamarind evergreen tropical tree native to the Old World, with pinnate leaves (leaflets either side of the stem) and reddish-yellow flowers, followed by pods. The pulp surrounding the seeds is used in medicine and as a flavouring. (*Tamarindus indica*, family Leguminosae.)

tamarisk any of a group of small trees or shrubs that flourish in warm, salty, desert regions of Europe and Asia where no other vegetation is found. The common tamarisk *T. gallica*, which grows in European coastal areas, has small, scalelike leaves on feathery branches and produces spikes of small pink flowers. (Genus *Tamarix*, family Tamaricaceae.)

tanager New World bird of the family Emberizidae, order Passeriformes. There are about 230 species in forests of Central and South America, all brilliantly coloured. They are 10–20 cm/4–8 in long, with plump bodies and conical beaks. The tanagers of North America all belong to the genus *Piranga*.

Species include the **paradise tanager** *Tangara chilensis*. Its plumage has a metallic lustre; the head is sea-green in colour, the breast is violet, and there is a flame-coloured patch on the lower part of the back. It feeds on fruit and insects. The **scarlet tanager** *Piranga olivacea* is about 18 cm/7 in long, and has brilliant scarlet plumage in the male with black wings and tail. In autumn its plumage changes to a dull green, like that of the female.

Tanegashima Space Centre Japanese rocket-launching site on a small island off S Kyushu.

Tanegashima is run by the National Space Development Agency (NASDA), responsible for the practical applications of Japan's space programme (research falls under a separate organization based at Kagoshima Space Centre). NASDA, founded in 1969, has headquarters in Tokyo; a tracking and testing station, the Tsukuba Space Centre, in E central Honshu; and an Earth observation centre near Tsukuba.

tangent in geometry, a straight line that touches a curve and gives the gradient of the curve at the point of contact. At a maximum, minimum, or point of inflection, the tangent to a curve has zero gradient. Also, in trigonometry, a function of an acute angle in a right-angled triangle, defined as the ratio of the length of the side opposite the angle to the length of the side adjacent to it; a way of expressing the gradient of a line.

tangerine small type of orange.

tangram puzzle made by cutting up a square into seven pieces.

tannic acid or **tannin** $C_{14}H_{10}O_9$ yellow astringent substance, composed of several phenolic rings, occurring in the bark, wood, roots, fruits, and galls (growths) of certain trees, such as the oak. It precipitates gelatin to give an insoluble compound used in the manufacture of leather from hides (tanning).

tanning treating animal skins to preserve them and make them into leather. In vegetable tanning, the prepared skins are soaked in tannic acid. Chrome tanning, which is much quicker, uses solutions of chromium salts.

tansy perennial herb belonging to the daisy family, native to Europe. The yellow flower heads grow in clusters on stalks up to

tangent The tangent of an angle is a mathematical function used in the study of right-angled triangles. If the tangent of an angle B is known, then the length of the opposite side can be found given the length of the adjacent side, or vice versa.

120 cm/4 ft tall, and the aromatic leaves are used in cookery. (*Tanacetum vulgare*, family Compositae.)

tantalum hard, ductile, lustrous, grey-white, metallic element, symbol Ta, atomic number 73, relative atomic mass 180.948. It occurs with niobium in tantalite and other minerals. It can be drawn into wire with a very high melting point and great tenacity, useful for lamp filaments subject to vibration. It is also used in alloys, for corrosion-resistant laboratory apparatus and chemical equipment, as a catalyst in manufacturing synthetic rubber, in tools and instruments, and in rectifiers and capacitors.

It was discovered and named in 1802 by Swedish chemist Anders Ekeberg (1767–1813) after the mythological Greek character Tantalus.

tape recording, magnetic method of recording electric signals on a layer of iron oxide, or other magnetic material, coating a thin plastic tape. The electrical signals from the microphone are fed to

the electromagnetic recording head, which magnetizes the tape in accordance with the frequency and amplitude of the original signal. The impulses may be audio (for sound recording), video (for television), or data (for computer). For playback, the tape is passed over the same, or another, head to convert magnetic into electrical signals, which are then amplified for reproduction. Tapes are easily demagnetized (erased) for reuse, and come in cassette, cartridge, or reel form.

tape streamer in computing, a backing storage device consisting of a continuous loop of magnetic tape. Tape streamers are largely used to store dumps (rapid backup copies) of important data files (see Ⓓdata security).

tapeworm any of various parasitic flatworms of the class Cestoda. They lack digestive and sense organs, can reach 15 m/50 ft in length, and attach themselves to the host's intestines by means of hooks and suckers. Tapeworms are made up of hundreds of individual segments, each of which develops into a functional hermaphroditic reproductive unit capable of producing numerous eggs. The larvae of tapeworms usually reach humans in imperfectly cooked meat or fish, causing anaemia and intestinal disorders.

TAPI (abbreviation for Telephony Application Programming Interface) in computing, program included in ⓂWindows 95 to enable applications to use the telephone. The TAPI standard was developed by Microsoft and Intel in 1993.

tapir any of the odd-toed hoofed mammals (perissodactyls) of the single genus *Tapirus*, now constituting the family Tapiridae. There are four species living in the American and Malaysian tropics. They reach 1 m/3 ft at the shoulder and weigh up to 350 kg/770 lb. Their survival is in danger because of destruction of the forests.

Tapirs have thick, hairy, black skin, short tails, and short trunks. They are vegetarian, harmless, and shy. They are related to the rhinoceros, and slightly more distantly to the horse.

The Malaysian tapir *T. indicus* is black with a large white patch on the back and hindquarters. The three South American species are dark to reddish brown; the Brazilian tapir *T. terrestris* is the most widespread. Baird's tapir *T. bairdii* is rare and found only in Central America.

The mountain tapir *T. pinchaque* is the rarest tapir (less than 2,500 remaining), and is found only in the northern Andes. It weighs 150–200 kg/330–440 lb and is about 80 cm/32 in tall. It is mainly solitary except when breeding. The gestation period is 13 months and the single young remains with the mother for 18 months. Mountain tapirs are strong swimmers.

taproot in botany, a single, robust, main root that is derived from the embryonic root, or Ⓐradicle, and grows vertically downwards, often to considerable depth. Taproots are often modified for food storage and are common in biennial plants such as the carrot *Daucus carota*, where they act as Ⓐperennating organs.

tar dark brown or black viscous liquid obtained by the destructive distillation of coal, shale, and wood. Tars consist of a mixture of hydrocarbons, acids, and bases. ⒶCreosote and Ⓐparaffin are produced from wood tar. See also Ⓐcoal tar.

TAR in computing, UNIX-based compression routine in common use on the Internet.

tarantula wolf spider *Lycosa tarantula* (family Lycosidae) with a 2.5 cm/1 in body. It spins no web, relying on its speed in hunting to

AMERICAN TARANTULA SOCIETY

<http://www.concentric.net/~Dmartin/ats/about.html>

Information on tarantulas, other spiders, and scorpions from the world's largest arachnid society. There are articles on buying, feeding, looking after, and breeding tarantulas. Tarantula owners exchange experiences and there is a listing of other arachnid sites.

tarantula The mygalomorph bird-eating spider *Stichoplostus incei* and related species are generally described as tarantulas. Native to tropical America, they are largely nocturnal and feed mainly on insects, but will also attack larger prey such as mice and birds. Their bite is painful but not fatal. Premaphotos Wildlife

catch its prey. The name 'tarantula' is also used for any of the numerous large, hairy spiders of the family Theraphosidae, with large poison fangs, native to the SW USA and tropical America.

The theraphosid *Aphonopelma* has a body length of 5 cm/2 in and a leg span of 12.5 cm/5 in. They are no more poisonous than other spiders of similar size. They burrow in the ground and catch their prey by pouncing on it and not by means of a web.

In the Middle Ages, the wolf spider's bite was thought to cause hysterical ailments or **tarantism** for which dancing was the cure, hence the name 'tarantula' and its popular association with the dance 'tarantella'.

tare common name for any of the plants known as ÷vetches.

taro or **eddo** plant belonging to the arum family, native to tropical Asia; the tubers (underground stems) are edible and are the source of Polynesian poi (a fermented food). (*Colocasia esculenta*, family Araceae.)

tarpon large silver-sided fish *Tarpon atlanticus* of the family Megalopidae. It reaches 2 m/6 ft and may weigh 135 kg/300 lb. It lives in warm W Atlantic waters.

tarragon perennial bushy herb belonging to the daisy family, native to the Old World. It grows up to 1.5 m/5 ft tall and has narrow leaves and small green-white flower heads arranged in groups. Tarragon contains an aromatic oil; its leaves are used to flavour salads, pickles, and tartar sauce. It is closely related to wormwood. (*Artemisia dracunculus*, family Compositae.)

tarsier any of three species of the prosimian primates, genus *Tarsius*, of the East Indies and the Philippines. These survivors of early primates are about the size of a rat with thick, light-brown fur, very large eyes, and long feet and hands. They are nocturnal, arboreal, and eat insects and lizards.

tartaric acid $\text{HOOC}(\text{CHOH})_2\text{COOH}$ organic acid present in vegetable tissues and fruit juices in the form of salts of potassium, calcium, and magnesium. It is used in carbonated drinks and baking powders.

tartrazine (E102) yellow food colouring produced synthetically from petroleum. Many people are allergic to foods containing it. Typical effects are skin disorders and respiratory problems. It has been shown to have an adverse effect on hyperactive children.

taskbar in computing, strip at the bottom of a ÷Windows 95 or NT 4 screen containing icons ('task buttons') of all programs launched

in the current session. The taskbar makes it possible to switch between applications simply by clicking the mouse on a task button.

Tasmanian devil carnivorous marsupial *Sarcophilus harrisii*, in the same family (Dasyuridae) as native 'cats'. It is about 65 cm/2.1 ft long with a 25 cm/10 in bushy tail. It has a large head, strong teeth, and is blackish with white patches on the chest and hind parts. It is nocturnal, carnivorous, and can be ferocious when cornered. It has recently become extinct in Australia and survives only in remote parts of Tasmania.

TASMANIAN DEVIL

<http://www.cyberdata.com.au/currumbin/page29.html>

Profile of the largest of Australia's surviving marsupial carnivores. There is a picture of a devil, details of its appearance and behaviour, and explanation of how it became extinct on the Australian mainland. There is an accompanying note about the demise of the Tasmanian tiger.

Tasmanian wolf or **thylacine** carnivorous marsupial *Thylacinus cynocephalus*, in the family Dasyuridae. It is doglike in appearance with a long tail, characteristic dark stripes on back and hindquarters, and measures nearly 2 m/6 ft from nose to tail tip. It was hunted to probable extinction in the 1930s, but there are still occasional unconfirmed reports of sightings, both on the Australian mainland and in the Tasmanian mountains, its last known habitat.

taste sense that detects some of the chemical constituents of food. The human tongue can distinguish only four basic tastes (sweet, sour, bitter, and salty) but it is supplemented by the sense of smell. What we refer to as taste is really a composite sense made up of both taste and smell.

tau elementary particle with the same electric charge as the electron but a mass nearly double that of a proton. It has a lifetime of around 3×10^{-13} seconds and belongs to the ÷lepton family of particles – those that interact via the electromagnetic, weak nuclear, and gravitational forces, but not the strong nuclear force.

Taube German military aircraft of World War I. At the outbreak of war it was the principal aircraft of the German Army and performed useful service as a scout, notably in the detection of Russian movements which resulted in Hindenburg's victory at the Battle of Tannenberg in 1914.

Tau Ceti one of the nearest stars visible to the naked eye, 11.9 light years from Earth in the constellation Cetus. It has a diameter slightly less than that of the Sun, and an actual luminosity of about 45% of the Sun's. Its similarity to the Sun is sufficient to suggest that Tau Ceti may possess a planetary system, although observations have yet to reveal evidence of this.

Taurus conspicuous zodiacal constellation in the northern hemisphere near ÷Orion, represented as a bull. The Sun passes through Taurus from mid-May to late June. In astrology, the dates for Taurus are between about 20 April and 20 May (see ÷precession).

The V-shaped ÷Hyades open ÷star cluster forms the bull's head, with ÷Aldebaran as the red eye. The ÷Pleiades open cluster is in the shoulder. Taurus also contains the ÷Crab nebula, the remnants of the supernova of AD 1054, which is a strong radio and X-ray source and the location of one of the first ÷pulsars to be discovered.

tautomerism form of isomerism in which two interconvertible isomers are in equilibrium. It is often specifically applied to an equilibrium between the keto ($-\text{CH}_2-\text{C}=\text{O}$) and enol ($-\text{CH}=\text{C}(\text{OH})-$) forms of carbonyl compounds.

taxis (plural taxes) or **tactic movement** in botany, the movement of a single cell, such as a bacterium, protozoan, single-celled alga, or gamete, in response to an external stimulus. A movement

directed towards the stimulus is described as positive taxis, and away from it as negative taxis. The alga *Chlamydomonas*, for example, demonstrates positive phototaxis by swimming towards a light source to increase the rate of photosynthesis.

Chemotaxis is a response to a chemical stimulus, as seen in many bacteria that move towards higher concentrations of nutrients.

taxonomy another name for the classification of living organisms.

Tay-Sachs disease inherited disorder, due to a defective gene, causing an enzyme deficiency that leads to blindness, retardation, and death in infancy. It is most common in people of E European Jewish descent.

TB abbreviation for the infectious disease tuberculosis.

TB RESOURCES: ABOUT TUBERCULOSIS

<http://www.cpmc.columbia.edu/tbcpp/abouttb.html>

Basic and useful information about tuberculosis. The fact sheet includes presentations on the signs and tests for TB, an explanation of TB infection and the ways TB is spread, and an assessment of the importance of drugs for the cure of the disease.

TBT (abbreviation for *tributyl tin*) chemical used in antifouling paints that has become an environmental pollutant.

T cell or **T lymphocyte** immune cell (see immunity and lymphocyte) that plays several roles in the body's defences. T cells are so called because they mature in the thymus.

There are three main types of T cells: T helper cells (Th cells), which allow other immune cells to go into action; T suppressor cells (Ts cells), which stop specific immune reactions from occurring; and T cytotoxic cells (Tc cells), which kill cells that are cancerous or infected with viruses. Like B cells, to which they are related, T cells have surface receptors that make them specific for particular antigens.

TCP/IP (abbreviation for *transport control protocol/Internet protocol*) set of network protocols, developed principally by the US Department of Defense. TCP/IP is widely used, particularly in UNIX and on the Internet and it is now incorporated into operating systems, such as Microsoft Windows 95.

tea evergreen shrub or small tree whose fermented, dried leaves are soaked in hot water to make a refreshing drink, also called tea. Known in China as early as 2737 BC, tea was first brought to Europe AD 1610 and rapidly became a popular drink. In 1823 the shrub was found growing wild in N India, and plantations were later established in Assam and Sri Lanka; producers today include Africa, South America, Georgia, Azerbaijan, Indonesia, and Iran. (*Camellia sinensis*, family Theaceae.)

the tea plant In the wild the tea plant can grow as tall as 12 m/40 ft, but in cultivation it is kept down to a bush 1.5 m/5 ft high. The young shoots and leaves are picked every five days.

processing Once plucked, the young leaves are spread out on shelves in withering lofts and allowed to wither (dry and shrivel up) in a current of air for 4–18 hours. Black teas (from Sri Lanka and India) are macerated (soaked and softened) in rolling machines to release the essential oils, allowed to ferment, and then dried and graded. The fermentation gives them a blackish-brown colour. Green teas (from China, Taiwan, and Japan) are steamed or heated and then rolled, dried, and finally graded. They are green or partly green in colour.

Some teas are scented with plant oils: Earl Grey, for example, is flavoured with oil of bergamot.

grading Grading is carried out according to the size of leaf. For example, some Sri Lankan (Ceylon) tea grades are orange pekoe,

flowery pekoe, broken orange pekoe, broken pekoe, and fannings. The latter grades are mostly the black teas sold in tea bags. Black teas make up 75% of the world's trade in tea.

tea customs Methods of drinking tea vary in different countries: in Japan special tea-houses and an elaborate tea ceremony have evolved, and in Tibet, hard slabs of compressed tea are used as money before being finally brewed.

teak tropical Asian timber tree with yellowish wood used in furniture and shipbuilding. (*Tectona grandis*, family Verbenaceae.)

teal any of various small, short-necked dabbling ducks of the genus *Anas*, order Anseriformes, but particularly *A. crecca*. The male is dusky grey; its tail feathers ash grey; the crown of its head deep cinnamon or chestnut; its eye is surrounded by a black band, glossed with green or purple, which unites on the nape; its wing markings are black and white; and its bill is black and resembles that of the widgeon. The female is mottled brown. The total length is about 35 cm/14 in.

The blue-winged teal *A. discors* is a brilliantly coloured bird 35–42 cm/14–17 in long, with bright blue wing coverts. It is a native of North America, and migrates in winter to South America.

tear gas any of various volatile gases that produce irritation and watering of the eyes, used by police against crowds and used in chemical warfare. The gas is delivered in pressurized, liquid-filled canisters or grenades, thrown by hand or launched from a specially adapted rifle. Gases (such as Mace) cause violent coughing and blinding tears, which pass when the victim breathes fresh air, but there are no lasting effects.

tears salty fluid exuded by lacrimal glands in the eyes. The fluid contains proteins that are antibacterial, and also absorbs oils and mucus. Apart from cleaning and disinfecting the surface of the eye, the fluid supplies nutrients to the cornea, which does not have a blood supply.

If insufficient fluid is produced, as sometimes happens in older people, the painful condition of 'dry-eye' results and the eye may be damaged.

teasel upright prickly biennial herb, native to Europe and Asia. It grows up to 1.5 m/5 ft, has prickly stems and leaves, and a large prickly head of purple flowers. The dry, spiny seed heads were once used industrially to tease or fluff up the surface fibres of cloth. (*Dipsacus fullonum*, family Dipsacaceae.)

tea tree shrub or small tree native to Australia and New Zealand. It is thought that some species of tea tree were used by the explorer Captain Cook to brew tea; it was used in the first years of settlement for this purpose. (Genus *Leptospermum*, family Myrtaceae.)

technetium Greek *technetos* 'artificial' silver-grey, radioactive, metallic element, symbol Tc, atomic number 43, relative atomic mass 98.906. It occurs in nature only in extremely minute amounts, produced as a fission product from uranium in pitchblende and other uranium ores. Its longest-lived isotope, Tc-99, has a half-life of 216,000 years. It is a superconductor and is used as a hardener in steel alloys and as a medical tracer.

It was synthesized in 1937 (named in 1947) by Italian physicists Carlo Perrier and Emilio Segrè, who bombarded molybdenum with deuterons, looking to fill a missing spot in the periodic table of the elements (at that time it was considered not to occur in nature). It was later isolated in large amounts from the fission product debris of uranium fuel in nuclear reactors.

technology the use of tools, power, and materials, generally for the purposes of production. Almost every human process for getting food and shelter depends on complex technological systems, which have been developed over a 3-million-year period. Significant milestones include the advent of the steam engine in 1712, the introduction of electricity and the internal combustion engine in the mid-1870s, and recent developments in communications, electronics, and the nuclear and space industries. The advanced technology (highly automated and specialized) on which modern industrialized society depends is frequently contrasted

Communications

BY PETER LAFFERTY

Introduction

Early 1998 saw a remarkable demonstration of the power of modern communications technology. Signals were received from the most distant spaceprobe, *Voyager 1*, launched by the US in 1977. In February 1998, *Voyager 1* was over 10.5 billion km/6.5 billion mi from the Earth, a distance so great that data from the probe took almost 9 h to reach the Earth, travelling at the speed of light. This was the longest distance over which a radio message has been received.

Of course, radio astronomers might argue that they routinely receive data from far greater distances, from stellar objects at the edge of the universe. They are correct, which again illustrates the wonderful sensitivity of modern radio receivers. The World's largest radio telescope is at Arecibo in Puerto Rico. Its dish is 305 m/1,000 ft across, wider than three football fields. It can pick up signals as weak as one ten-thousandth of a millionth of a millionth of the power of a household light bulb.

Worldwide mobile phones

On Earth, a new generation of communications network based on low-orbit satellites is being put in place. Because the new satellites are much nearer the Earth than current communications satellites, it will not be necessary to own a huge receiver dish to collect the signal. A hand-held mobile phone will communicate directly with an overhead satellite and route the call through other satellites, to the receiver. The first such system, called Iridium, got under way with the launch of five satellites in May 1997; seven more satellites were launched in June 1997. The Iridium system will eventually consist of 66 satellites which will fly in 11 polar orbits, 675 km/420 mi high. The satellites will blanket the globe – there will be a satellite overhead at all times wherever you are. You will be able to phone anyone, anywhere on the planet, even if they are in the middle of the Sahara Desert. Initially, the Iridium handsets are expected to be expensive, although the price should come down once several similar systems are competing for the market. A rival operator, Teledesic, plans to launch 288 satellites which will provide a worldwide high-speed data and phone service.

Fibre optics

Conventional Earth-bound telephony has also progressed. A plan to build a worldwide optical fibre network took a step forward in 1997 when the Fibreoptic Link Around the Globe (FLAG) was completed. It links Britain and the Far East, a distance of 27,000 km/17,000 mi. However, with FLAG barely completed, an even more ambitious enterprise got underway.

In 1998 more than 300 international telecommunications companies signed up for a scheme called Project Oxygen. This project will involve laying 320,000 km/200,000 mi of optical fibre to link 171 countries, with the first cables being in place by the year 2000 and the rest completed by 2003. The cable would be able to carry 320 billion bits of information each second – existing submarine cables carry less than 10 billion bits per second. Cables that do not require optical amplifiers would be able to carry 1 trillion bits per second.

The enormous capacity of fibre optic cable links arises because the cable can carry more than one signal at once. The cables can carry signals at different wavelengths (or colour) without interference. In the past year, telephone companies have started to install cables that can carry four separate signals at different wavelengths. The cable planned for Project Oxygen will carry eight signals at the same time. But this is not the limit to this technology: research at Lucent Technology, New Jersey and NTT in Japan, indicates that up to 100 signals could be transmitted.

'Beam me up, Scottie'

Telephones as small as buttons – reminiscent of James Kirk's communicator in 'Star Trek' – are promised by the Dutch

electronics firm Philips. Philips have developed a method of miniaturizing radio receivers. The secret is to fix the miniature radio components to an insulating base. If a silicon base is used – the usual process in modern electronics – the components interfere with each other via electronic conduction in the base. With an insulator there is no interference, and the power needed to work the device is 10 times less.

Internet radio and telephones

A wide variety of material is now being transmitted over the Internet, including images and audio and video files. One of the interesting new media services on the Internet is digitized audio. Audio-digitizing chips and add-in boards are available for most computer systems. The most popular products for PCs are Soundblaster boards, and many computers have sound equipment as a standard feature.

Audio files have been transmitted over the Internet for some time, but now we have Internet telephony and Internet radio. Internet telephony uses the Internet to send audio between two or more computer users in real time, so the users can converse. Vocaltec introduced the first internet telephony software in 1995. Running a multimedia PC, the Vocaltec Internet Phone lets users speak into their microphones and listen via their speakers. Internet radio transmits audio and music programs produced for traditional radio broadcasts over the Internet for playing through the user's computer speakers.

The problem with Internet telephony and radio is that transfer of audio files can be rather slow. The result is that, even with a fast modem, audio files will be transferred at a rate slightly greater than real time – a 5-min audio file will take over 5 min to transfer. Moreover, if someone else is also using the Internet link, or a slow modem is being used, the problem is even worse. The delay experienced in Internet telephony is typically 10 times that on the public telephone networks. Web radio concentrates at present on spoken programmes, rather than music. Programmes broadcast by the Canadian Broadcasting Commission include a science magazine show, a variety show and documentaries. The audio quality is far from that achieved by compact discs, but is equivalent or better than a standard telephone service. Moreover, for this type programme, the quality is usually acceptable.

Internet music broadcasters use a technology called streaming. This technique transmits music in 2-s blocks, with one block being downloaded while the preceding block is being played. In this way, it is not necessary to download an entire song before playing it.

Digital television

Digital television will be launched late in 1998 in Europe and the USA. In digital television, information is broadcast as a complex series of on/off signals, known as a digital signal. Existing television programmes are transmitted as continuous signals, known as analogue signals. The analogue signals build up a television picture made up of 625 lines. Digital television will double that, providing pictures of much better quality. Viewers will also be able to control the picture on the screen by cropping it, zooming in on a detail, or choosing which viewing angle they want at a sports event, for example. However, the biggest effect of digital television will be to greatly increase the number of channels available. Digital signals are much more compressed than analogue signals, so more channels can be transmitted.

A question waiting for an answer is whether television broadcasters will choose to use their digital frequencies for a single high-definition channel or will transmit up to five standard definition programmes (this is called multi-casting). Cable TV operators are faced with a similar dilemma. The debate between high-definition and multi-casting is the most important single issue facing the television industry in 1998.

In the USA, the largest cable television operator, TCI, started testing its digital service in 1997. The service delivers more

channels (over 150 channels of audio and video), and provides a high-quality picture. This may be part of an attempt by the cable industry to force broadcasters to devote their entire frequency spectrum to high-definition broadcasts rather than providing a multi-channel service which would compete with cable operators.

Interactive television

Interactive television is another road forward for television. This system allows the viewer to access services such as home banking and shopping through their television sets. It can also give viewers access to movies, games, children's TV and local information. In the UK, Sky TV has an interactive channel called Intertext, and British Telecom has tested an interactive channel. Similar trials in the USA cast doubt over the future of interactive TV, as there seemed to be

no real demand for such services, causing Bell Atlantic and TCI/Microsoft to scale back their trials. Time Warner has announced that it is shutting down its interactive service in Orlando, Florida. The service, which began with much hype, has been plagued by technical difficulties.

Pay-per-view TV

Pay-per-view TV is a system by which viewers pay an additional fee, usually by credit card, to watch specific programmes. This has proved successful in the USA, particularly for films and sporting events. In the UK, BSkyB has experimented with the idea and is set to screen more programmes in this way. With the introduction of digital TV, the main terrestrial television stations are expected to introduce pay-per-view.

with the low technology (labour-intensive and unspecialized) that characterizes some developing countries. Intermediate technology is an attempt to adapt scientifically advanced inventions to less developed areas by using local materials and methods of manufacture. Appropriate technology refers to simple and small-scale tools and machinery of use to developing countries.

power In human prehistory, the only power available was muscle power, augmented by primitive tools, such as the wedge or lever.

The domestication of animals about 8500 BC and invention of the wheel about 2000 BC paved the way for the water mill (1st century BC) and later the windmill (12th century AD). Not until 1712 did an alternative source of power appear in the form of the first working steam engine, constructed by English inventor Thomas Newcomen; subsequent modifications improved its design. English chemist and physicist Michael Faraday's demonstration of the dynamo in 1831 revealed the potential of the electrical motor, and in 1876 the German scientist Nikolaus Otto introduced the four-stroke cycle used in the modern internal combustion engine. The 1940s saw the explosion of the first atomic bomb and the subsequent development of the nuclear power industry. Latterly concern over the use of nonrenewable power sources and the pollution caused by the burning of fossil fuels has caused technologists to turn increasingly to exploring renewable sources of energy, in particular solar energy, wind energy, and wave power.

materials The earliest materials used by humans were wood, bone, horn, shell, and stone. Metals were rare and/or difficult to obtain, although forms of bronze and iron were in use from 6000 BC and 1000 BC respectively. The introduction of the blast furnace in the 15th century enabled cast iron to be extracted, but this process remained expensive until English ironmaker Abraham Darby substituted coke for charcoal in 1709, thus ensuring a plentiful supply of cheap iron at the start of the Industrial Revolution. Rubber, glass, leather, paper, bricks, and porcelain underwent similar processes of trial and error before becoming readily available. From the mid-1800s, entirely new materials, synthetics, appeared. First dyes, then plastic and the more versatile celluloid, and later drugs were synthesized, a process continuing into the 1980s with the growth of genetic engineering, which enabled the production of synthetic insulin and growth hormones.

production The utilization of power sources and materials for production frequently lagged behind their initial discovery. The plow, known in antiquity in the form of a pole powered by a foot treadle, was not fully developed until the 18th century when it was used to produce objects of great precision, ranging from astronomical instruments to mass-produced screws. The realization that gears, cranks, cams, and wheels could operate in harmony to perform complex motion made mechanization possible. Early attempts at automation include Scottish engineer James Watt's introduction of the fly-ball governor into the steam engine in 1769 to regulate the machine's steam supply automatically, and French textile maker Joseph Marie Jacquard's demonstration in 1804 of how looms could be controlled automatically by punched cards. The first moving assembly line appeared in 1870 in meat-packing factories in Chicago, USA, transferring to the motor industry in 1913. With the perfection of the programmable

electronic computer in the 1960s, the way lay open for fully automatic plants. The 1960s-90s saw extensive developments in the electronic and microelectronic industries (initially in the West, later joined by Japan and the Pacific region) and in the field of communications.

Any sufficiently advanced technology is indistinguishable from magic.

ARTHUR C CLARKE English science and science-fiction writer.
The Lost Worlds of 2001

technology education training for the practical application of science in industry and commerce. Britain's Industrial Revolution preceded that of the rest of Europe by half a century and its prosperity stimulated other countries to encourage technological education.

tectonics in geology, the study of the movements of rocks on the Earth's surface. On a small scale tectonics involves the formation of folds and faults, but on a large scale plate tectonics deals with the movement of the Earth's surface as a whole.

Teflon trade name for polytetrafluoroethene (PTFE), a tough, waxlike, heat-resistant plastic used for coating nonstick cookware and in gaskets and bearings.

tektite Greek *tekton* 'molten' small, rounded glassy stone, found in certain regions of the Earth, such as Australasia. Tektites are probably the scattered drops of molten rock thrown out by the impact of a large meteorite.

telco in computing slang, contraction of *telecommunications company*.

TeleAdapt company that specializes in supplying worldwide telephone and power adaptor plugs for portable computer users.

telecommunications communications over a distance, generally by electronic means. Long-distance voice communication was pioneered in 1876 by Scottish scientist Alexander Graham Bell when he invented the telephone. Today it is possible to communicate internationally by telephone cable or by satellite or microwave link, with over 100,000 simultaneous conversations and several television channels being carried by the latest satellites.

history The first mechanical telecommunications systems were semaphore and the heliograph (using flashes of sunlight), invented in the mid-19th century, but the forerunner of the present telecommunications age was the electric telegraph. The earliest practicable telegraph instrument was invented by William Cooke and Charles Wheatstone in Britain in 1837 and used by railway companies. In the USA, Samuel Morse invented a signalling code, Morse code, which is still used, and a recording telegraph, first used commercially between England and France in 1851.

Following German physicist Heinrich Hertz's discovery of elec-

Telecommunications: chronology

| | | | |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1794 | Claude Chappe in France built a long-distance signalling system using semaphore. | 1977 | The first optical fibre cable was installed in California. |
| 1839 | Charles Wheatstone and William Cooke devised an electric telegraph in England. | 1984 | First commercial cellphone service started in Chicago, USA. |
| 1843 | Samuel Morse transmitted the first message along a telegraph line in the USA, using his Morse code of signals – short (dots) and long (dashes). | 1988 | International Services Digital Network (ISDN), an international system for sending signals in digital format along optical fibres and coaxial cable, launched in Japan. |
| 1858 | The first transatlantic telegraph cable was laid. | 1989 | The first transoceanic optical fibre cable, capable of carrying 40,000 simultaneous telephone conversations, was laid between Europe and the USA. |
| 1876 | Alexander Graham Bell invented the telephone. | 1991 | ISDN introduced in the UK. |
| 1877 | Thomas Edison invented the carbon transmitter for the telephone. | 1992 | Videophones, made possible by advances in image compression and the development of ISDN, introduced in the UK. |
| 1878 | The first telephone exchange was opened at New Haven, Connecticut. | 1993 | Electronic version of the <i>Guardian</i> newspaper, for those with impaired vision, launched in the UK. The newspaper is transmitted to the user's home and printed out in braille or spoken by a speech synthesizer. |
| 1884 | The first long-distance telephone line was installed, between Boston and New York. | 1995 | The USA's main carrier of long-distance telecommunications, AT&T, processed 160 million calls daily, an increase of 50% since 1990. |
| 1891 | A telephone cable was laid between England and France. | 1996 | Researchers in Tokyo and California used lasers to communicate with an orbiting satellite, the first time lasers have been used to provide two-way communications with space. |
| 1892 | The first automatic telephone exchange was opened, at La Porte, Indiana. | 1996 | Work began on laying the world's longest fibreoptic cable, which will follow a 17,000-mi/27,300-km route around the globe from Europe, through the Suez Canal, across the Indian Ocean, and around the Pacific. |
| 1894 | Guglielmo Marconi pioneered wireless telegraphy in Italy, later moving to England. | 1996 | Computer scientists in Japan and the USA transmitted information along optical fibre at a rate of one trillion bits. At this rate, 300 years' worth of a daily newspaper could be transmitted in one second. |
| 1900 | Reginald Fessenden in the USA first broadcast voice by radio. | 1997 | There were 300 active artificial satellites in orbit around Earth, the majority of which were used for communications purposes. |
| 1901 | Marconi transmitted the first radio signals across the Atlantic. | 1998 | US vice president Al Gore announced plans for Internet2, a high-speed data communications network that would serve the main US research universities, and bypass the congestion on the Internet. |
| 1904 | John Ambrose Fleming invented the thermionic valve. | | |
| 1907 | Charles Krumm introduced the forerunner of the teleprinter. | | |
| 1920 | Stations in Detroit and Pittsburgh began regular radio broadcasts. | | |
| 1922 | The BBC began its first radio transmissions, for the London station 2LO. | | |
| 1932 | The Telex was introduced in the UK. | | |
| 1956 | The first transatlantic telephone cable was laid. | | |
| 1962 | Telstar pioneered transatlantic satellite communications, transmitting live TV pictures. | | |
| 1966 | Charles Kao in England advanced the idea of using optical fibres for telecommunications transmissions. | | |
| 1969 | Live TV pictures were sent from astronauts on the Moon back to Earth. | | |
| 1975 | Prestel, the world's first viewdata system, using the telephone lines to link a computer data bank with the TV screen, was introduced in the UK. | | |

telecommunications The international telecommunications system relies on microwave and satellite links for long-distance international calls. Cable links are increasingly made of optical fibres. The capacity of these links is enormous. The TDRS-C (tracking data and relay satellite communications) satellite, the world's largest and most complex satellite, can transmit in a single second the contents of a 20-volume encyclopedia, with each volume containing 1,200 pages of 2,000 words. A bundle of optical fibres, no thicker than a finger, can carry 10,000 phone calls – more than a copper wire as thick as an arm.

tromagnetic waves, Italian inventor Guglielmo (Marconi pioneered a 'wireless' telegraph, ancestor of the radio. He established wireless communication between England and France in 1899 and across the Atlantic in 1901.

The modern telegraph uses teleprinters to send coded messages along telecommunications lines. Telegraphs are keyboard-operated machines that transmit a five-unit Baudot code (see (baud)). The receiving teleprinter automatically prints the received message. The modern version of the telegraph is (electronic mail) in which text messages are sent electronically from computer to computer via network connections such as the (Internet).

communications satellites The chief method of relaying long-distance calls on land is microwave radio transmission. The drawback to long-distance voice communication via microwave radio transmission is that the transmissions follow a straight line from tower to tower, so that over the sea the system becomes impracticable. A solution was put forward 1945 by the science-fiction writer Arthur C Clarke, when he proposed a system of communications satellites in an orbit 35,900 km/22,300 mi above the Equator, where they would circle the Earth in exactly 24 hours, and thus appear fixed in the sky. Such a system is now in operation internationally, by (Intelsat). The satellites are called geostationary satellites (syncoms). The first to be successfully launched, by Delta rocket from Cape Canaveral, was *Syncom 2* in July 1963. Many such satellites are now in use, concentrated over heavy traffic areas such as the Atlantic, Indian, and Pacific oceans. Telegraphy, telephony, and television transmissions are carried simultaneously by high-frequency radio waves. They are beamed to the satellites from large dish antennae or Earth stations, which connect with international networks.

(Integrated Services Digital Network (ISDN) makes videophones and high-quality fax possible; the world's first large-scale centre of ISDN began operating in Japan in 1988. ISDN is a system that transmits voice and image data on a single transmission line by changing them into digital signals.

Fibre-optic cables consisting of fine glass fibres present an alternative to the usual copper cables for telephone lines. The telecommunications signals are transmitted along the fibres in digital form as pulses of laser light.

telecommuting working from home using a telephone, fax, and (modem) to keep in touch with the office of the employing company. In the mid 1990s, it was estimated that 5% of US workers and 2.3% (600,000) of the British workforce were telecommuters.

Most telecommuters are self-employed, or sales people spending much of their time on the road. However, the number of part-time telecommuters, for example working one day per week at home, is growing.

Telecom Tower formerly *Post Office Tower* building in London, 189 m/620 ft high. Completed in 1966, it is a microwave relay tower capable of handling up to 150,000 simultaneous telephone conversations and over 40 television channels.

telegraphy transmission of messages along wires by means of electrical signals. The first modern form of telecommunication, it now uses printers for the transmission and receipt of messages. Telex is an international telegraphy network.

Overland cables were developed in the 1830s, but early attempts at underwater telegraphy were largely unsuccessful until the discovery of the insulating gum gutta-percha in 1843 enabled a cable to be laid across the English Channel in 1851. Duplex telegraph was invented in the 1870s, enabling messages to be sent in both directions simultaneously. Early telegraphs were mainly owned by the UK: 72% of all submarine cables were British-owned in 1900.

telemedicine in computing, the use of computer communications to improve medical practice and training.

TELEMEDICINE: A GUIDE TO ASSESSING TELECOMMUNICATIONS FOR HEALTH CARE

[http://www.nap.edu/readingroom/
books/telemed/summary.html](http://www.nap.edu/readingroom/books/telemed/summary.html)

Overview of the development of telemedicine and summary of a US report into its future direction. The difficulties of evaluating telemedicine are set out.

telemetry measurement at a distance, in particular the systems by which information is obtained and sent back by instruments on board a spacecraft. See (remote sensing).

telepathy form of (extrasensory perception) defined as 'the communication of impressions of any kind from one mind to another, independently of the recognized channels of sense', by the English essayist F W H Myers (1843-1901), cofounder in 1882 of the Psychical Research Society, who coined the term.

telephone instrument for communicating by voice along wires, developed by Scottish inventor Alexander Graham (Bell) in 1876. The transmitter (mouthpiece) consists of a carbon microphone, with a diaphragm that vibrates when a person speaks into it. The

telephone In the telephone, sound vibrations are converted to an electric signal and back again. The mouthpiece contains a carbon microphone that produces an electrical signal which varies in step with the spoken sounds. The signal is routed to the receiver via local or national exchanges. The earpiece contains an electromagnetic loudspeaker which reproduces the sounds by vibrating a diaphragm.

diaphragm vibrations compress grains of carbon to a greater or lesser extent, altering their resistance to an electric current passing through them. This sets up variable electrical signals, which travel along the telephone lines to the receiver of the person being called. There they cause the magnetism of an electromagnet to vary, making a diaphragm above the electromagnet vibrate and give out sound waves, which mirror those that entered the mouthpiece originally.

The standard instrument has a handset, which houses the transmitter (mouthpiece), and receiver (earpiece), resting on a base, which has a dial or push-button mechanism for dialling a telephone number. Some telephones combine a push-button mechanism and mouthpiece and earpiece in one unit. A cordless telephone is of this kind, connected to a base unit not by wires but by radio. It can be used at distances up to about 100 m/330 ft from the base unit. In 1988 Japan and in 1991 Britain introduced an Integrated Services Digital Network (see telecommunications), providing fast transfer of computerized information.

The art of dialling has replaced the art of dialogue.

GITA MEHTA Indian writer.
Karma Cola VIII 2

telephone tapping or **telephone bugging** listening in on a telephone conversation, without the knowledge of the participants; in the UK and the USA this is a criminal offence if done without a warrant or the consent of the person concerned.

Telephony Application Programming Interface in computing, Windows 95 program, commonly abbreviated to TAPI.

teletypewriter or **teletypewriter** transmitting and receiving device used in telecommunications to handle coded messages. Teletypewriters are automatic typewriters keyed telegraphically to convert typed words into electrical signals (using a five-unit Baudot code, see baud) at the transmitting end, and signals into typed words at the receiving end.

telescope optical instrument that magnifies images of faint and distant objects; any device for collecting and focusing light and other forms of electromagnetic radiation. It is a major research tool in astronomy and is used to sight over land and sea; small telescopes can be attached to cameras and rifles. A telescope with a large aperture, or opening, can distinguish finer detail and fainter objects than one with a small aperture. The refracting telescope uses lenses, and the reflecting telescope uses mirrors. A third type, the **catadioptric telescope**, is a combination of lenses and mirrors. See also **radio telescope**.

refractor In a refractor, light is collected by a lens called the **object glass** or **objective**, which focuses light down a tube, forming an image magnified by an eyepiece. Invention of the refractor is attributed to a Dutch optician, Hans Lippershey, in 1608. Hearing of the invention in 1609, Galileo quickly constructed one for himself and went on to produce a succession of such instruments which he used from 1610 onwards for astronomical observations. The largest refracting telescope in the world, at Yerkes Observatory, Wisconsin, USA, has an aperture of 102 cm/40 in.

reflector In a reflector, light is collected and focused by a concave mirror. The first reflector was built about 1670 by Isaac Newton. Large mirrors are cheaper to make and easier to mount than large lenses, so all the largest telescopes are reflectors. The largest reflector with a single mirror, 6 m/236 in, is at Zelenchukskaya, Russia. Telescopes with larger apertures composed of numerous smaller segments have been built, such as the Keck Telescope on Mauna Kea. A multiple-mirror telescope was installed on Mount Hopkins, Arizona, USA, in 1979. It consists of six mirrors of 1.8 m/72 in aperture, which perform like a single 4.5-m/176-in mirror. Schmidt telescopes are used for taking wide-field photographs of the sky. They have a main mirror plus a thin lens at the front of the tube to increase the field of view.

The liquid-mirror telescope is a reflecting telescope constructed with a rotating mercury mirror. In 1995 NASA completed a

telescope Three kinds of telescope. The refracting telescope uses a large objective lens to gather light and form an image which the smaller eyepiece lens magnifies. A reflecting telescope uses a mirror to gather light. The Schmidt telescope uses a corrective lens to achieve a wide field of view. It is one of the most widely used tools of astronomy.

3-m/9.8-ft liquid mirror telescope at its Orbital Debris Observatory in New Mexico, USA.

telescopes in space Large telescopes can now be placed in orbit above the distorting effects of the Earth's atmosphere. Telescopes in space have been used to study infrared, ultraviolet, and X-ray radiation that does not penetrate the atmosphere but carries much information about the births, lives, and deaths of stars and galaxies. The 2.4-m/94-in Hubble Space Telescope, launched in 1990, can see the sky more clearly than can any telescope on Earth.

In 1996 an X-ray telescope was under development by UK, US, and Australian astronomers, based on the structure of a lobster's eye, which has thousands of square tubes reflecting light onto the retina. The £4 million Lobster Eye telescope will contain millions of tubes 10–20 micrometres across and is intended for use on a satellite.

teletext broadcast system of displaying information on a television screen. The information – typically about news items, entertainment, sport, and finance – is constantly updated. Teletext is a form of videotext, pioneered in Britain by the British Broadcasting Corporation (BBC) with Ceefax and by Independent Television with Teletext.

television (TV) reproduction of visual images at a distance using radio waves. For transmission, a television camera converts the pattern of light it takes in into a pattern of electrical charges. This is scanned line by line by a beam of electrons from an electron gun, resulting in variable electrical signals that represent the picture. These signals are combined with a radio carrier wave and broadcast as electromagnetic waves. The TV aerial picks up the wave and feeds it to the receiver (TV set). This separates out the vision signals, which pass to a cathode-ray tube where a beam of electrons is made to scan across the screen line by line, mirroring the action of the electron gun in the TV camera. The result is a recreation of the pattern of light that entered the camera. Twenty-five pictures are built up each second with interlaced scanning in Europe (30 in North America), with a total of 625 lines (525 lines in North America and Japan).

receiving aerials Because the wavelength of any television signal is short a resonant aerial becomes possible, and this usually con-

television Simplified block diagram of a complete colour television system – transmitting and receiving. The camera separates the picture into three colours – red, blue, green – by using filters and different camera tubes for each colour. The audio signal is produced separately from the video signal. Both signals are transmitted from the same aerial using a special coupling device called a diplexer. There are four sections in the receiver: the aerial, the tuners, the decoders, and the display. As in the transmitter, the audio and video signals are processed

sists of a half-wave aerial made of light alloy or steel tube, fed at the centre with low-impedance coaxial or balanced cable. Greater gain is obtained if a reflector element is added, and quite complicated arrays are used in areas of weak signal strength.

These aerials are mounted either vertically or horizontally to conform with the polarization of the transmitting aerials. Tubing is used for the elements, since an aerial made of wire would be too sharply resonant, with resulting loss of bandwidth, and therefore poor picture definition.

television channels In addition to transmissions received by all viewers, the 1970s and 1980s saw the growth of pay-television cable networks, which are received only by subscribers, and of devices, such as those used in the Qube system (USA), which allow the viewers' opinions to be transmitted instantaneously to the studio via a response button, so that, for example, a home viewing audience can vote in a talent competition. The number of programme channels continues to increase, following the introduction of satellite-beamed TV signals.

Further use of TV sets has been brought about by videotext and the use of video recorders to tape programmes for playback later or to play pre-recorded video cassettes, and by their use as computer screens and for security systems. Extended-definition television gives a clear enlargement from a microscopic camera and was first used in 1989 in neurosurgery to enable medical students to watch brain operations.

history In 1873 it was realized that, since the electrical properties of the nonmetallic chemical element selenium vary according to the amount of light to which it is exposed, light could be converted into electrical impulses, making it possible to transmit such impulses

over a distance and then reconvert them into light. The chief difficulty was seen to be the 'splitting of the picture' so that the infinite variety of light and shade values might be transmitted and reproduced. In 1908 it was found that cathode-ray tubes would best effect transmission and reception. Mechanical devices were used at the first practical demonstration of television, given by Scottish electrical engineer John Logie Baird in London on 27 January 1926, and cathode-ray tubes were used experimentally in the UK from 1934.

The world's first public television service was started from the BBC station at Alexandra Palace in N London, on 2 November 1936. In the USA, TV technology was pioneered by David Sarnoff and Philo Taylor Farnsworth (1906–1971) and sets became available in the 1930s, but few performances were televised until the late 1940s, when local and network shows were scheduled in major cities and, by coaxial cable, across the nation. Live performances gave way to videotaped shows by the late 1950s, and colour sets became popular from the 1960s.

colour television Baird was an early pioneer in this area, and one of the first techniques developed employed a system whereby the normal frame frequency was increased by a factor of three, each successive frame containing the material for one primary colour. The receiver used revolving colour discs in front of the viewing screen, synchronized with the correct frame colours at the camera. A similar system replaced the colour discs by three superimposed projected pictures corresponding to the three primary colours. Baird demonstrated colour TV in London in 1928, but it was not until December 1953 that the first successful system was adopted for broadcasting, in the USA. This was called the NTSC system,

Digital Television

BY BARRY FOX

An analogue television station needs up to 8 MHz of frequency space. Two terrestrial transmitters cannot use the same frequency within several hundred kilometres of each other because even weak signals from one will interfere with strong signals from the other. Therefore, each country can only have a few television channels.

A satellite can transmit more channels, but its transmitters cover a wide geographical area. So the satellite usually delivers a handful of channels in different languages to several adjacent countries.

Converting a transmission system from analogue to digital multiplies the number of programme channels it can deliver, by up to ten. The bitstream can be used to carry a few programmes with better-than-analogue picture quality or many programmes with compromised clarity.

Digital television needs only one-hundredth the transmission power of analogue television. As a result, the digital signals can slot between the analogue frequencies, in the so-called 'taboo' channels which cannot be used for analogue broadcasting because of interference risks. Because the digital terrestrial frequencies are similar to existing analogue frequencies, existing aerials should be able to receive new digital broadcasts.

Once digital television is ubiquitous, broadcasters can plan the end of analogue broadcasting. This will release more frequencies either for digital broadcasting or mobile radio.

Initially, viewers will use a set-top box which converts the digital signals into analogue television, which an existing television set displays. New television sets will incorporate the digital circuitry. They will also have a wide format screen, with 16:9 aspect ratio to do justice to movies and widescreen sports broadcasts. Conventional television sets, with 4:3 screens, will show a slight letterboxing effect with black borders at the top and bottom of the picture.

National broadcasters will usually 'simulcast' existing 4:3 analogue programmes in digital widescreen, 'free to air'. Extra programmes will be encrypted, and available only if the viewer pays a fee, either by subscription or special event payment. Pay viewing will be controlled by a smart card, a credit card with a microchip that slots into the receiver to authorize decoding.

The digital television system for Europe was developed in the 1990s by an independent voluntary industry group, the Digital

Video Broadcasting Group (DVB). The DVB's standards were then simply rubber-stamped by Europe's governments and official bodies. Some services will start before the year 2000.

The impetus for DVB came from the commercial failure of the high-definition television system developed in the 1980s as an official European research project, Eureka 95. High Definition Multiplexed Analogue Components (HD-MAC) was a hybrid system; the transmitted pictures were analogue but they travelled with digitally coded 'helper' signals which a suitable television set could use to make the images much wider and clearer than for conventional television. Although HD-MAC worked, high-definition receivers were prohibitively expensive.

There are three main DVB standards, for cable, satellite and terrestrial broadcasting. All are based on MPEG-2 coding, the digital compression standard set by the Motion Picture Experts Group of the International Electrotechnical Commission (IEC) and the International Standards Organisation (ISO). The main differences are in the way the compressed signal is packaged for transmission.

Terrestrial digital television uses a system similar to that developed for digital radio. Instead of transmitting one wide channel, the broadcaster transmits several thousand narrow sub-channels, packed tightly together. The digital code is split into a similar number of streams, so each channel carries fewer bits of code each second, and the bits in each channel are widely spaced apart in time. Unwanted reflections arrive in the gaps and the receiver rejects them.

The USA already has a commercial digital satellite service, called DSS, and existing networks will broadcast terrestrial digital television. The European DVB and North American systems are not compatible. The main difference is that the American system was designed to bridge the gap between televisions and computers, with emphasis on high-definition viewing, whereas the European system is aimed primarily at squeezing more programme channels into available frequency space.

Some observers fear that although the basic systems follow agreed standards, there is room for individual broadcasters to use their own proprietary systems to control pay viewing. This could block the design of a single receiver that works with rival satellite or terrestrial services.

since it was developed by the National Television System Committee, and variations of it have been developed in Europe; for example, SECAM (sequential and memory) in France and Eastern Europe, and PAL (phase alternation by line) in most of Western Europe. The three differ only in the way colour signals are prepared for transmission, the scanning rate, and the number of lines used. When there was no agreement on a universal European system in 1964, in 1967 the UK, West Germany, the Netherlands, and Switzerland adopted PAL while France and the USSR adopted SECAM. In 1989 the European Community (now the European Union) agreed to harmonize TV channels from 1991, allowing any station to show programmes anywhere in the EC.

The method of colour reproduction is related to that used in colour photography and printing. It uses the principle that any colours can be made by mixing the primary colours red, green, and blue in appropriate proportions. (This is different from the mixing of paints, where the primary colours are red, yellow, and blue.) In colour television the receiver reproduces only three basic colours: red, green, and blue. The effect of yellow, for example, is reproduced by combining equal amounts of red and green light, while white is formed by a mixture of all three basic colours.

Signals indicate the amounts of red, green, and blue light to be generated at the receiver. To transmit each of these three signals in the same way as the single brightness signal in black and white

television would need three times the normal band width and reduce the number of possible stations and programmes to one-third of that possible with monochrome television. The three signals are therefore coded into one complex signal, which is transmitted as a more or less normal black and white signal and produces a satisfactory – or compatible – picture on black and white receivers. A fraction of each primary red, green, and blue signal is added together to produce the normal brightness, or luminance, signal. The minimum of extra colouring information is then sent by a special subcarrier signal, which is superimposed on the brightness signal. This extra colouring information corresponds to the hue and saturation of the transmitted colour, but without any of the fine detail of the picture. The impression of sharpness is conveyed only by the brightness signal, the colouring being added as a broad colour wash. The various colour systems differ only in the way in which the colouring information is sent on the subcarrier signal. The colour receiver has to amplify the complex signal and decode it back to the basic red, green, and blue signals; these primary signals are then applied to a colour cathode-ray tube.

The colour display tube is the heart of any colour receiver. Many designs of colour picture tubes have been invented; the most successful of these is known as the 'shadow mask tube'. It operates on similar electronic principles to the black and white television picture tube, but the screen is composed of a fine mosaic of over 1 mil-

Television: chronology

| | | | |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1878 | William Crookes in England invented the Crookes tube, which produced cathode rays. | 1956 | The first videotape recorder was produced in California by the Ampex Corporation. |
| 1884 | Paul Nipkow in Germany built a mechanical scanning device, the Nipkow disc, a rotating disc with a spiral pattern of holes in it. | 1962 | TV signals were transmitted across the Atlantic via the Telstar satellite. |
| 1897 | Karl Ferdinand Braun, also in Germany, modified the Crookes tube to produce the ancestor of the TV receiver picture tube. | 1970 | The first videodisc system was announced by Decca in Britain and AEG-Telefunken in Germany, but it was not perfected until the 1980s, when laser scanning was used for playback. |
| 1906 | Boris Rosing in Russia began experimenting with the Nipkow disc and cathode-ray tube, eventually succeeding in transmitting some crude TV pictures. | 1973 | The BBC and Independent Television in the UK introduced the world's first teletext systems, Ceefax and Oracle, respectively. |
| 1923 | Vladimir Zworykin in the USA invented the first electronic camera tube, the iconoscope. | 1975 | Sony introduced their videocassette tape-recorder system, Betamax, for domestic viewers, six years after their professional U-Matic system. The UK Post Office (now British Telecom) announced their Prestel viewdata system. |
| 1926 | John Logie Baird demonstrated a workable TV system, using mechanical scanning by Nipkow disc. | 1979 | Matsushita in Japan developed a pocket-sized, flat-screen TV set, using a liquid-crystal display. |
| 1928 | Baird demonstrated colour TV. | 1986 | Data broadcasting using digital techniques was developed, an enhancement of teletext was produced. |
| 1929 | The BBC began broadcasting experimental TV programmes, using Baird's system. | 1989 | The Japanese began broadcasting high-definition television; satellite television was introduced in the UK. |
| 1931 | US physicist Allen Balcum Du Mont perfected the first practical, low-cost cathode ray tube. | 1990 | The BBC introduced a digital stereo sound system (NICAM); MAC, a European system allowing greater picture definition, more data, and sound tracks, was introduced. |
| 1936 | The BBC began regular broadcasting from Alexandra Palace, London, using a high-definition all-electronic system developed by EMI. This marked the end of the BBC's usage of Baird's system. | 1992 | All-digital high-definition television demonstrated in the USA. |
| 1938 | Allen Balcum Du Mont manufactured the first all-electronic receiver to be marketed in the USA. It used a huge 35 cm/14 in cathode ray tube. | 1993 | A worldwide standard for digital television agreed at meeting of manufacturers and broadcasters in Sydney, Australia. The Japanese electronics company NEC announced the development of a flat thin screen that produces full-colour high resolution pictures, without a cathode ray tube. Television in the form of wraparound 'Sport' television glasses went on sale in the USA, enabling the wearer to watch television whilst walking. |
| 1939 | The NBC (National Broadcasting Company) began the first regular television broadcasting service in the USA. | | US House of Representatives voted in favour of including a chip in all TV sets that will allow parents to censor and block out certain categories of programmes that they consider unsuitable for their children's viewing. |
| 1940 | Experimental colour TV transmission began in the USA, as CBS in New York City made colour broadcasts using a semi-mechanical method called the 'field sequential system'. | | |
| 1953 | Successful colour TV transmissions began in the USA, using the NTSC (National Television Systems Committee) system. This system is used today throughout the American continents and Japan. | | |

lion dots arranged in an orderly fashion. One-third of the dots glow red when bombarded by electrons, one-third glow green, and one-third blue. There are three sources of electrons, respectively modulated by the red, green, and blue signals. The tube is arranged so that the shadow mask allows only the red signals to hit red dots, the green signals to hit green dots, and the blue signals to hit blue dots. The glowing dots are so small that from a normal viewing distance the colours merge into one another and a picture with a full range of colours is seen.

teleworking or telecommuting working from home rather than in an office, typically using a telephone and a personal computer connected to the office via a modem. The term was introduced in the 1980s.

Convenient for employers as it reduces overheads, it also facilitates working part-time for those with such commitments as young children. However, it has proved more costly to administer than many advocates had anticipated in the 1980s. Teleworking is most successful when combined with some attendance at the workplace. In 1991 an estimated 500,000 people in Britain were employed full time in this way, with a further 1.5 million part-time. According to a 1997 estimate, about 2% of the US population were teleworking on any one day.

telex (acronym for *teletypewriter exchange*) international telecommunications network that handles teletype messages in the form of coded signals. It uses teletypewriters for transmitting and receiving, and makes use of land lines (cables) and radio and satellite links to make connections between subscribers.

tellurium Latin *Tellus* 'Earth' silver-white, semi-metallic (metalloid) element, symbol Te, atomic number 52, relative atomic mass 127.60. Chemically it is similar to sulphur and selenium,

and it is considered one of the sulphur group. It occurs naturally in telluride minerals, and is used in colouring glass blue-brown, in the electrolytic refining of zinc, in electronics, and as a catalyst in refining petroleum.

It was discovered in 1782 by Austrian mineralogist Franz Müller (1740–1825), and named in 1798 by German chemist Martin Klaproth.

Teller, Edward (1908–)

Hungarian-born US physicist known as the father of the hydrogen bomb. He worked on the fission bomb – the first atomic bomb – 1942–46 (the Manhattan Project) and on the fusion bomb, or H-bomb, 1946–52. In the 1980s he was one of the leading supporters of the Star Wars programme (Strategic Defense Initiative).

He was a key witness against his colleague Robert Oppenheimer at the security hearings in 1954. Teller was widely believed to be the model for the leading character in Stanley Kubrick's 1964 film *Dr Strangelove*. It was also Teller who convinced President Reagan of the feasibility of the Star Wars project for militarizing space with fission-bomb-powered X-ray lasers. Millions of dollars were spent before the project was discredited. Teller then suggested 'brilliant pebbles' – thousands of missile-interceptors based in space – and the use of nuclear explosions to prevent asteroids hitting the Earth. He opposed all test-ban treaties.

EDWARD TELLER PROFILE

<http://www.achievement.org/autodoc/page/telpro-1>

Description of the life and work of the 'father of the hydrogen bomb', physicist Edward Teller. The Web site contains not only a profile and biographical information, but also holds a lengthy interview with Teller from 1990 accompanied by a large number of photographs, video sequences, and audio clips.

Telnet In computing, Internet utility that enables a user to work on a remote computer as if directly connected. Telnet connections to a remote computer system are typically much cheaper than long-distance telephone calls; the user makes a local call to an Internet access provider and the rest of the connection is handled via the Internet at no additional cost. ¶Bulletin board systems usually work via Telnet.

telomere Greek *telos* 'end'; *meros* 'part' chromosome tip. Telomeres prevent chromosomes sticking together. Like DNA they are made up of nucleotides, usually rich in thymine and guanine. Every time a cell divides, the telomeres shorten. They trigger the cell's senescence (inability to reproduce) when they reach a threshold length. This process is prevented from happening during the replication of cancer cells by the presence of the enzyme telomerase. Telomerase replaces the segments of the telomeres, maintaining their length so that cell replication is no longer controlled.

Telstar US communications satellite, launched on 10 July 1962, which relayed the first live television transmissions between the USA and Europe. *Telstar* orbited the Earth in 158 minutes, and so had to be tracked by ground stations, unlike the geostationary satellites of today.

temperature degree or intensity of heat of an object and the condition that determines whether it will transfer heat to another object or receive heat from it, according to the laws of thermodynamics. The temperature of an object is a measure of the average kinetic energy possessed by the atoms or molecules of which it is composed. The SI unit of temperature is the kelvin (symbol K) used with the Kelvin scale. Other measures of temperature in common use are the Celsius scale and the Fahrenheit scale.

The normal temperature of the human body is about 36.9°C/98.4°F. Variation by more than a degree or so indicates ill health, a rise signifying excessive activity (usually due to infection), and a decrease signifying deficient heat production (usually due to lessened vitality).

TO UNDERSTAND TEMPERATURE ON THE CELSIUS SCALE FOR THOSE USED TO FAHRENHEIT TEMPERATURES:

30 IS HOT; 20 IS NICE; 10 IS COLD; 0 IS ICE

temperature regulation the ability of an organism to control its internal body temperature; in warm-blooded animals this is known as homeothermy.

Although some plants have evolved ways of resisting extremes of temperature, sophisticated mechanisms for maintaining the correct temperature are found in multicellular animals. Such mechanisms may be behavioural, as when a lizard moves into the shade in order to cool down, or internal, as in mammals and birds, where temperature is regulated by the medulla.

tempering heat treatment for improving the properties of metals, often used for steel alloys. The metal is heated to a certain temperature and then cooled suddenly in a water or oil bath.

template in computing, file that lays down a document's format.

Templates are used in word processing, spreadsheet, and other programs to specify all the styles used in a document, such as fonts, margins, macros, formulas and so on. They are widely used to automate the production of documents such as memos, mailings and reports, making sure that they have a uniform appearance.

temporary hardness hardness of water that is removed by boiling (see hard water).

tench European freshwater bony fish *Tinca tinca*, a member of the carp family, now established in North America. It is about 45 cm/18 in long, weighs 2 kg/4.5 lb, and is coloured olive-green above and grey beneath. The scales are small and there is a barbel at each side of the mouth.

tendon or *sineu* in vertebrates, a cord of very strong, fibrous connective tissue that joins muscle to bone. Tendons are largely composed of bundles of fibres made of the protein collagen, and because of their inelasticity are very efficient at transforming muscle power into movement.

tendrils in botany, a slender, threadlike structure that supports a climbing plant by coiling around suitable supports, such as the stems and branches of other plants. It may be a modified stem, leaf, leaflet, flower, leaf stalk, or stipule (a small appendage on either side of the leaf stalk), and may be simple or branched. The tendrils of Virginia creeper *Parthenocissus quinquefolia* are modified flower heads with suckerlike pads at the end that stick to walls, while those of the grapevine *Vitis* grow away from the light and thus enter dark crevices where they expand to anchor the plant firmly.

tendrils Tendrils are specially modified leaves, shoots, or stems. They support the plant by twining around the stems of other plants nearby, as in the pea, or they may attach themselves to suitable surfaces by means of suckers, as in the Virginia creeper.

tension in physics, the stress (force) set up in a stretched material. In a stretched string or wire it exerts a pull that is equal in magnitude but opposite in direction to the stress being applied at the string ends. Tension is measured in newtons.

terabyte in computing, 1,024 gigabytes, or 1,099,511,627,776 bytes.

teratogen any substance or agent that can induce deformities in the fetus if absorbed by the mother during pregnancy. Teratogens include some drugs (notably alcohol and thalidomide), other chemicals, certain disease organisms, and radioactivity.

terbium soft, silver-grey, metallic element of the lanthanide series, symbol Tb, atomic number 65, relative atomic mass 158.925. It occurs in gadolinite and other ores, with yttrium and ytterbium, and is used in lasers, semiconductors, and television tubes. It was named in 1843 by Swedish chemist Carl Mosander (1797-1858) for the town of Ytterby, Sweden, where it was first found.

terminal in computing, a device consisting of a keyboard and display screen (VDU) to enable the operator to communicate with the computer. The terminal may be physically attached to the computer or linked to it by a telephone line (remote terminal). A 'dumb' terminal has no processor of its own, whereas an 'intelligent' terminal has its own processor and takes some of the processing load away from the main computer.

terminal emulation in computing, communications program such as *QTelnet* that allows a computer to emulate a terminal or workstation of a remote host. The host accepts instructions from the remote computer as if it were one of its own workstations.

terminal moraine linear, slightly curved ridge of rocky debris deposited at the front end, or snout, of a glacier. It represents the furthest point of advance of a glacier, being formed when deposited material (till), which was pushed ahead of the snout as it advanced, became left behind as the glacier retreated.

terminal velocity or **terminal speed** the maximum velocity that can be reached by a given object moving through a fluid (gas or liquid) under the action of an applied force. As the speed of the object increases so does the total magnitude of the forces resisting its motion. Terminal velocity is reached when the resistive forces exactly balance the applied force that has caused the object to accelerate; because there is now no resultant force, there can be no further acceleration.

For example, an object falling through air will reach a terminal velocity and cease to accelerate under the influence of gravity when the air resistance equals the object's weight.

Parachutes are designed to increase air resistance so that the acceleration of a falling person or package ceases more rapidly, thereby limiting terminal velocity to a safe level.

terminal voltage the potential difference (pd) or voltage across the terminals of a power supply, such as a battery of cells. When the supply is not connected in circuit its terminal voltage is the same as its electromotive force (emf); however, as soon as it begins to supply current to a circuit its terminal voltage falls because some electric potential energy is lost in driving current against the supply's own internal resistance. As the current flowing in the circuit is increased the terminal voltage of the supply falls.

terminate and stay resident (TSR) term given to an MS-DOS program that remains in the memory - for example, a clock, calculator, or thesaurus. The program is installed by the use of a batch file.

terminating decimal decimal fraction with a finite number of digits (a recurring decimal, by contrast, has an infinite number of digits). Only those fractions with denominators that are powers of two and five can be converted into terminating decimals.

termite any member of the insect order Isoptera. Termites are soft-bodied social insects living in large colonies which include one

TERMITE

Termite nests may house 2 million termites and reach heights of up to 6 m/6.6 yd. A skyscraper built to the same scale would be 8 km/5 mi high.

or more queens (of relatively enormous size and producing an egg every two seconds), much smaller kings, and still smaller soldiers, workers, and immature forms. Termites build galleried nests of soil particles that may be 6 m/20 ft high.

One group, the Macrotermitinae, constructs fungus gardens from its own faeces by infecting them with a special fungus that digests the faeces and renders them edible. Termites may dispose of a quarter of the vegetation litter of an area, and their fondness for wood (as in houses and other buildings) brings them into conflict with humans. The wood is broken down in their stomachs by numerous microorganisms living in symbiosis with their hosts. Some species construct adjustable air vents in their nests, and one species moistens the inside of the nest with water to keep it cool. Fossilized termite nests found in Arizona, USA, have been estimated to be about 220 million years old.

tern any of various lightly built seabirds in the gull family Laridae, order Charadriiformes, with pointed wings and bill, and usually a forked tail. Terns plunge-dive after aquatic prey. They are 20-50 cm/8-20 in long, and usually coloured in combinations of white and black. They are extensively distributed, especially in temperate climates.

species The common tern *Sterna hirundo* has white underparts, grey upper wings, and a black crown on its head. The Arctic tern *Sterna paradisaea* migrates from northern parts of Greenland, North America, and Europe to the Antarctic, thereby ensuring most of its life is spent in daylight. The Antarctic tern *Sterna vittata* has a striking blood-red beak; it does not migrate.

terrapin member of some species of the order Chelonina (turtles and tortoises). Terrapins are small to medium-sized, aquatic or semi-aquatic, and are found widely in temperate zones. They are omnivorous, but generally eat aquatic animals. Some species are in danger of extinction owing to collection for the pet trade; most of the animals collected die in transit.

Species include the diamondback terrapin *Malaclemys terrapin* of the eastern USA, the yellow-bellied terrapin, and the red-eared terrapin *Pseudemys scripta elegans*.

terrestrial planet in astronomy, any of the four small, rocky inner planets of the Solar System: Mercury, Venus, Earth, and Mars. The Moon is sometimes also included, although it is a satellite of the Earth and not strictly a planet.

terrier any of various breeds of highly intelligent, active dogs. They are usually small. Types include the bull, cairn, fox, Irish, Scottish, Sealyham, Skye, and Yorkshire terriers. They were originally bred for hunting rabbits and following quarry such as foxes down into burrows.

The small Parson Jack Russell terrier was recognized by the Kennel Club in 1990 as a variant of the fox terrier.

territorial behaviour in biology, any behaviour that serves to exclude other members of the same species from a fixed area or territory. It may involve aggressively driving out intruders, marking the boundary (with dung piles or secretions from special scent glands), conspicuous visual displays, characteristic songs, or loud calls.

territory in animal behaviour, a fixed area from which an animal or group of animals excludes other members of the same species. Animals may hold territories for many different reasons; for example, to provide a constant food supply, to monopolize potential mates, or to ensure access to refuges or nest sites.

The size of a territory depends in part on its function: some nesting and mating territories may be only a few square metres, whereas feeding territories may be as large as hundreds of square kilometres.

terror bird or *phorusrhacoid* member of an extinct group of flightless, carnivorous birds that lived 62–2.5 million years ago in South America. During this time they were the dominant predators. From fossils, 25 species of terror bird have been recognized, ranging in height from 1–3 m/3.3–9.8 ft. Their closest living relative is the *öseriema*.

Tertiary period of geological time 65–1.64 million years ago, divided into five epochs: Palaeocene, Eocene, Oligocene, Miocene, and Pliocene. During the Tertiary period, mammals took over all the ecological niches left vacant by the extinction of the dinosaurs, and became the prevalent land animals. The continents took on their present positions, and climatic and vegetation zones as we know them became established. Within the geological time column the Tertiary follows the Cretaceous period and is succeeded by the Quaternary period.

Terylene trade name for a synthetic polyester fibre produced by the chemicals company ICI. It is made by polymerizing ethylene glycol and terephthalic acid. Cloth made from Terylene keeps its shape after washing and is hard-wearing.

Terylene was the first wholly synthetic fibre invented in Britain. It was created by the chemist I.R. Whinfield of Accrington in 1941. In 1942 the rights were sold to ICI (Du Pont in the USA) and bulk production began in 1955. Since 1970 it has been the most widely produced synthetic fibre, often under the generic name polyester. In 1989 8.4 million tonnes were produced, constituting over 50% of world synthetic fibre output.

tesla SI unit (symbol T) of magnetic flux density. One tesla represents a flux density of one weber per square metre, or 10^4 gauss. It is named after the Croatian-born US engineer Nikola Tesla.

Tesla, Nikola (1856–1943)

Croatian-born US physicist and electrical engineer who invented fluorescent lighting, the Tesla induction motor (1882–87), and the Tesla coil, and developed the alternating current (AC) electrical supply system.

The Tesla coil is an air core transformer with the primary and secondary windings tuned in resonance to produce high-frequency, high-voltage electricity. Using this device, Tesla produced an electric spark 40m/135 ft long in 1899. He also lit more than 200 lamps over a distance of 40 km/25 mi without the use of intervening wires. Gas-filled tubes are readily energized by high-frequency currents and so lights of this type were easily operated within the field of a large Tesla coil. Tesla soon developed all manner of coils which have since found numerous applications in electrical and electronic devices.

Mary Evans Picture Library

TESLA, NIKOLA

<http://www.neuronet.pitt.edu/~bogdan/tesla/>

Short biography of the electrical inventor plus quotations by and about Tesla, anecdotes, a photo gallery, and links to other sites of interest.

testa the outer coat of a seed, formed after fertilization of the ovule. It has a protective function and is usually hard and dry. In some cases the coat is adapted to aid dispersal, for example by being hairy. Humans have found uses for many types of testa, including the fibre of the cotton seed.

test cross in genetics, a breeding experiment used to discover the genotype of an individual organism. By crossing with a double recessive of the same species, the offspring will indicate whether the test individual is homozygous or heterozygous for the characteristic in question. In peas, a tall plant under investigation would be crossed with a double recessive short plant with known genotype *tt*. The results of the cross will be all tall plants if the test plant is *TT*. If the individual is in fact *Tt* then there will be some short plants (genotype *tt*) among the offspring.

test data data designed to test whether a new computer program is functioning correctly. The test data are carefully chosen to ensure that all possible branches of the program are tested. The expected results of running the data are written down and are then compared with the actual results obtained using the program.

testis (*plural testes*) the organ that produces ϕ sperm in male (and hermaphrodite) animals. In vertebrates it is one of a pair of oval structures that are usually internal, but in mammals (other than elephants and marine mammals), the paired testes (or testicles) descend from the body cavity during development, to hang outside the abdomen in a scrotal sac. The testes also secrete the male sex hormone ϕ androgen.

test message in computing, a message in ϕ USENET that is posted simply to make sure that one's software or network connections are working properly.

testosterone in vertebrates, hormone secreted chiefly by the testes, but also by the ovaries and the cortex of the adrenal glands. It promotes the development of secondary sexual characteristics in males. In animals with a breeding season, the onset of breeding behaviour is accompanied by a rise in the level of testosterone in the blood.

Synthetic or animal testosterone is used to treat inadequate development of male characteristics or (illegally) to aid athletes' muscular development. Like other sex hormones, testosterone is a ϕ steroid.

tetanus or *lockjaw* acute disease caused by the toxin of the bacillus *Clostridium tetani*, which usually enters the body through a wound. The bacterium is chiefly found in richly manured soil. Untreated, in seven to ten days tetanus produces muscular spasm and rigidity of the jaw spreading to other parts of the body, convulsions, and death. There is a vaccine, and the disease may be treatable with tetanus antitoxin and antibiotics.

CHILDHOOD INFECTIONS – TETANUS

<http://kidshealth.org/parent/common/tetanus.html>

Important information on the signs and symptoms of tetanus, the incubation, duration, and treatment of the illness. Specific reference is made to neonatal tetanus that affects new born infants as a result of inefficient surgical techniques during delivery.

Tethys Sea sea that once separated ϕ Laurasia from Gondwanaland. It has now closed up to become the Mediterranean, the Black, the Caspian, and the Aral seas.

tetra any of various brightly coloured tropical freshwater bony fishes of the family Characidae, formerly placed in the genus *Tetragonopterus*. Tetras are found mainly in tropical South America, and also in Africa.

tetrachloromethane CCl_4 or carbon tetrachloride chlorinated organic compound that is a very efficient solvent for fats and

greases, and was at one time the main constituent of household dry-cleaning fluids and of fire extinguishers used with electrical and petrol fires. Its use became restricted after it was discovered to be carcinogenic and it has now been largely removed from educational and industrial laboratories.

tetracycline one of a group of antibiotic compounds having in common the four-ring structure of chlortetracycline, the first member of the group to be isolated. They are prepared synthetically or obtained from certain bacteria of the genus *Streptomyces*. They are broad-spectrum antibiotics, effective against a wide range of disease-causing bacteria.

tetraethyl lead $Pb(C_2H_5)_4$ compound added to leaded petrol as a component of antiknock to increase the efficiency of combustion in car engines. It is a colourless liquid that is insoluble in water but soluble in organic solvents such as benzene, ethanol, and petrol.

tetrahedron (plural *tetrahedra*) in geometry, a solid figure (polyhedron) with four triangular faces; that is, a pyramid on a triangular base. A regular tetrahedron has equilateral triangles as its faces.

In chemistry and crystallography, tetrahedra describe the shapes of some molecules and crystals; for example, the carbon atoms in a crystal of diamond are arranged in space as a set of interconnected regular tetrahedra.

tetrahedron A regular tetrahedron is a pyramid on a triangular base with all its sides equal in length.

tetrapod Greek 'four-legged' type of vertebrate. The group includes mammals, birds, reptiles, and amphibians. Birds are included because they evolved from four-legged ancestors, the forelimbs having become modified to form wings. Even snakes are tetrapods, because they are descended from four-legged reptiles.

T_EX (pronounced 'tek') public domain text formatting and typesetting system, developed by Donald Knuth and widely used for producing mathematical and technical documents. Unlike desktop publishing applications, T_EX is not WYSIWYG, although in some implementations a screen preview of pages is possible.

text editor in computing, a program that allows the user to edit text on the screen and to store it in a file. Text editors are similar to word processors, except that they lack the ability to format text into paragraphs and pages and to apply different typefaces and styles.

textured vegetable protein manufactured meat substitute; see TVP.

TFT display another name for active matrix LCD.

TGV (abbreviation for *train à grande vitesse*) (French 'high-speed train') French electrically powered train that provides the

world's fastest rail service. Since it began operating in 1981, it has carried more than 100 million passengers between Paris and Lyon, at average speeds of 214 kph/133 mph. In 1990, a TGV broke the world speed record, reaching a speed of 515.3 kph/320.2 mph (about half that of a passenger jet aircraft) on a stretch of line near Tours.

In 1990 a second service, the Atlantique, was launched, running from Paris to Le Mans and Tours. A third linking Paris with the Channel Tunnel, Brussels, and Cologne opened in 1993. The TGV network now extends to the Mediterranean, Switzerland, and Brittany. A new route is planned eastwards to Strasbourg, opening in 2006.

thalassaemia or *Cooley's anaemia* any of a group of chronic hereditary blood disorders that are widespread in the Mediterranean countries, Africa, the Far East, and the Middle East. They are characterized by an abnormality of the red blood cells and bone marrow, with enlargement of the spleen. The genes responsible are carried by about 100 million people worldwide. The diseases can be diagnosed prenatally.

thallium Greek *thallos* 'young green shoot' soft, bluish-white, malleable, metallic element, symbol Tl, atomic number 81, relative atomic mass 204.38. It is a poor conductor of electricity. Its compounds are poisonous and are used as insecticides and rodent poisons; some are used in the optical-glass and infrared-glass industries and in photocells.

Discovered spectroscopically by its green line, thallium was isolated and named by William Crookes in 1861.

thallus any plant body that is not divided into true leaves, stems, and roots. It is often thin and flattened, as in the body of a seaweed, lichen, or liverwort, and the gametophyte generation (prothallus) of a fern.

Some flowering plants (angiosperms) that are adapted to an aquatic way of life may have a very simple plant body which is described as a thallus (for example, duckweed *Lemna*).

Thames barrier movable barrier built across the river Thames at Woolwich, London, UK, as part of the city's flood defences. Completed in 1982, the barrier comprises curved flood gates which are rotated 90° into position from beneath the water to form a barrier when exceptionally high tides are expected.

THAMES BARRIER

<http://www.environment-agency.gov.uk/info/barrier.html>

Interesting and comprehensive description from Britain's environment ministry of the functions of the world's largest movable flood barrier and how it saves London from flooding. There is a comprehensive history of the Barrier, description of how surge tides are generated, and information for visitors.

thaumatin naturally occurring, non-carbohydrate sweetener derived from the bacterium *Thaumatococcus daniellii*. Its sweetness is not sensed as quickly as that of other sweeteners, and it is not as widely used in the food industry.

thebaine $C_{19}H_{21}NO_3$ highly poisonous extract of opium.

theodolite instrument for the measurement of horizontal and vertical angles, used in surveying. It consists of a small telescope mounted so as to move on two graduated circles, one horizontal and the other vertical, while its axes pass through the centre of the circles. See also triangulation.

theorem mathematical proposition that can be deduced by logic from a set of axioms (basic facts that are taken to be true without proof). Advanced mathematics consists almost entirely of theorems and proofs, but even at a simple level theorems are important.

It is also a good rule not to put too much confidence in experimental results until they have been confirmed by theory.

ARTHUR STANLEY EDDINGTON British astrophysicist.
Quoted in R. L. Weber *More Random Walks in Science*

theory in science, a set of ideas, concepts, principles, or methods used to explain a wide set of observed facts. Among the major theories are ϕ relativity, quantum theory, evolution, and ϕ plate tectonics.

Theory of Everything (ToE) another name for ϕ grand unified theory.

therm unit of energy defined as 10^5 British thermal units; equivalent to 1.055×10^5 J. It is no longer in scientific use.

thermal capacity another name for ϕ heat capacity

thermal conductivity in physics, the ability of a substance to conduct heat. Good thermal conductors, like good electrical conductors, are generally materials with many free electrons (such as metals).

Thermal conductivity is expressed in units of joules per second per metre per kelvin ($\text{J s}^{-1} \text{m}^{-1} \text{K}^{-1}$). For a block of material of cross-sectional area a and length l , with temperatures T_1 and T_2 at its end faces, the thermal conductivity λ equals $lH/at(T_2 - T_1)$, where H is the amount of heat transferred in time t .

thermal dissociation reversible breakdown of a compound into simpler substances by heating it (see ϕ dissociation). The splitting of ammonium chloride into ammonia and hydrogen chloride is an example. On cooling, they recombine to form the salt.

thermal expansion in physics, expansion that is due to a rise in temperature. It can be expressed in terms of linear, area, or volume expansion.

The coefficient of linear expansion α is the fractional increase in length per degree temperature rise; area, or superficial, expansion β is the fractional increase in area per degree; and volume, or cubic, expansion γ is the fractional increase in volume per degree. To a close approximation, $\beta = 2\alpha$ and $\gamma = 3\alpha$.

thermal prospecting an expensive remote-sensing method used in aerial reconnaissance, based on weak variations in temperature which can be found above buried structures whose thermal properties are different from those of their surroundings.

thermal reactor nuclear reactor in which the neutrons released by fission of uranium-235 nuclei are slowed down in order to increase their chances of being captured by other uranium-235 nuclei, and so induce further fission. The material (commonly graphite or heavy water) responsible for doing so is called a **moderator**. When the fast newly-emitted neutrons collide with the nuclei of the moderator's atoms, some of their kinetic energy is lost and their speed is reduced. Those that have been slowed down to a speed that matches the thermal (heat) energy of the surrounding material are called **thermal neutrons**, and it is these that are most likely to induce fission and ensure the continuation of the chain reaction. See ϕ nuclear reactor and ϕ nuclear energy.

thermic lance cutting tool consisting of a tube of mild steel, enclosing tightly packed small steel rods and fed with oxygen. On ignition, temperatures above $3,000^\circ\text{C}/5,400^\circ\text{F}$ are produced and the thermic lance becomes its own sustaining fuel. It rapidly penetrates walls and a 23-cm/9-in steel door can be cut through in less than 30 seconds.

thermionics branch of electronics dealing with the emission of electrons from matter under the influence of heat.

thermistor semiconductor device whose electrical ϕ resistance falls as temperature rises. The current passing through a thermistor increases rapidly as its temperature rises, and so they are used in electrical thermometers.

thermite process method used in incendiary devices and welding operations. It uses a powdered mixture of aluminium and (usually) iron oxide, which, when ignited, gives out enormous heat. The oxide is reduced to iron, which is molten at the high temperatures produced. This can be used to make a weld. The process was discovered in 1895 by German chemist Hans Goldschmidt (1861–1923).

thermocouple electric temperature measuring device consisting of a circuit having two wires made of different metals welded together at their ends. A current flows in the circuit when the two junctions are maintained at different temperatures (ϕ Seebeck effect). The electromotive force generated – measured by a millivoltmeter – is proportional to the temperature difference.

thermodynamics branch of physics dealing with the transformation of heat into and from other forms of energy. It is the basis of the study of the efficient working of engines, such as the steam and internal combustion engines. The three laws of thermodynamics are: (1) energy can be neither created nor destroyed, heat and mechanical work being mutually convertible; (2) it is impossible for an unaided self-acting machine to convey heat from one body to another at a higher temperature; and (3) it is impossible by any procedure, no matter how idealized, to reduce any system to the ϕ absolute zero of temperature ($0\text{K}/-273^\circ\text{C}/-459^\circ\text{F}$) in a finite number of operations. Put into mathematical form, these laws have widespread applications in physics and chemistry.

If someone points out to you that your pet theory of the universe is in disagreement with Maxwell's equations – then so much the worse for Maxwell's equations. If it is found to be contradicted by observation – well, these experimentalists do bungle things sometimes. But if your theory is found to be against the second law of thermodynamics I can give you no hope; there is nothing for it but to collapse in deepest humiliation.

ARTHUR STANLEY EDDINGTON British astronomer.

thermography photographic recording of heat patterns. It is used medically as an imaging technique to identify 'hot spots' in the body – for example, tumours, where cells are more active than usual. Thermography was developed in the 1970s and 1980s by the military to assist night vision by detecting the body heat of an enemy or the hot engine of a tank. It uses a photographic method (using infrared radiation) employing infrared-sensitive films.

thermoluminescence (TL) release, in the form of a light pulse, of stored nuclear energy (electrons) in a mineral substance when heated to 500°C by ϕ irradiation. The energy results from the radioactive decay of uranium and thorium, which is absorbed by crystalline inclusions within the mineral matrix, such as quartz and feldspar. The release of TL from these crystalline substances is used in archaeology to date pottery, and by geologists in studying terrestrial rocks and meteorites.

thermoluminescent dating Crystalline substances find their way into the clay fabric of ancient pottery as additives designed to strengthen the material and allow it to breathe during kiln-firing at 600°C and above. Firing erases the huge level of TL energy accrued in geological times and sets a 'time-zero' for fresh energy accumulation over archaeological times, the TL intensity measured today being proportional to the pottery's age. TL can date inorganic materials, including stone tools left as burnt flint, older than about 50,000–80,000 years, although it is regarded as less precise in its accuracy than radiocarbon dating.

thermometer instrument for measuring temperature. There are many types, designed to measure different temperature ranges to varying degrees of accuracy. Each makes use of a different physical effect of temperature. Expansion of a liquid is employed in common liquid-in-glass thermometers, such as those containing mercury or alcohol. The more accurate gas thermometer uses the effect of temperature on the pressure of a gas held at constant

thermometer Maximum and minimum thermometers are universally used in weather-reporting stations. The maximum thermometer, shown here, includes a magnet that fits tightly inside a capillary tube and is moved up it by the rising mercury. When the temperature falls, the magnet remains in position, thus enabling the maximum temperature to be recorded.

volume. A resistance thermometer takes advantage of the change in resistance of a conductor (such as a platinum wire) with variation in temperature. Another electrical thermometer is the \varnothing thermocouple. Mechanically, temperature change can be indicated by the change in curvature of a bimetallic strip (as commonly used in a \varnothing thermostat).

thermopile instrument for measuring radiant heat, consisting of a number of \varnothing thermocouples connected in series with alternate junctions exposed to the radiation. The current generated (measured by an \varnothing ammeter) is proportional to the radiation falling on the device.

thermoplastic or thermosoftening plastic type of plastic that always softens on repeated heating. Thermoplastics include polyethylene (polyethene), polystyrene, nylon, and polyester.

Thermos trade name for a type of \varnothing vacuum flask.

thermoset type of plastic that remains rigid when set, and does not soften with heating. Thermosets have this property because the long-chain polymer molecules cross-link with each other to give a rigid structure. Examples include Bakelite, resins, melamine, and urea-formaldehyde resins.

thermosphere layer in the Earth's \varnothing atmosphere above the mesosphere and below the exosphere. Its lower level is about 80 km/

50 mi above the ground, but its upper level is undefined. The ionosphere is located in the thermosphere. In the thermosphere the temperature rises with increasing height to several thousand degrees Celsius. However, because of the thinness of the air, very little heat is actually present.

thermostat temperature-controlling device that makes use of feedback. It employs a temperature sensor (often a bimetallic strip) to operate a switch or valve to control electricity or fuel supply. Thermostats are used in central heating, ovens, and car engines.

At the required preset temperature (for example of a room or gas oven), the movement of the sensor switches off the supply of electricity to the room heater or gas to the oven. As the room or oven cools down, the sensor turns back on the supply of electricity or gas.

thiamine or **vitamin B₁** a water-soluble vitamin of the B complex. It is found in seeds and grain. Its absence from the diet causes the disease \varnothing beriberi.

1394 in computing, high speed external serial \varnothing bus system designed to connect computers and consumer electronics devices such as camcorders, digital television sets, DVD players, scanners, and colour printers. One 1394 port can connect up to 63 devices.

1394 is being specified as a standard by an Institute of Electronic and Electrical Engineers committee, IEEE.1394. The system started life at Apple Computer as FireWire, and is called i.Link by Sony Corporation. 1394 was designed in part to replace the \varnothing SCSI bus.

35 mm width of photographic film, the most popular format for the camera today. The 35-mm camera falls into two categories, the \varnothing SLR and the \varnothing rangefinder.

32-bit in computing, term describing the ability to process 32 \varnothing bits at a time. The Intel 386 and 486 series of microprocessors are examples of 32-bit processors.

The term is also used to specify the quality of sound produced by \varnothing sound cards, where increased speed indicates the ability to produce more fully detailed (and therefore more realistic) sound. Windows NT, OS/2, and Windows 95 are all examples of 32-bit operating systems.

thistle any of a group of prickly plants with spiny stems, soft cottony purple flower heads, and deeply indented leaves with prickly edges. The thistle is the national emblem of Scotland. (Genera include *Carduus*, *Carlina*, *Onopordum*, and *Cirsium*; family Compositae.)

thorax in four-limbed vertebrates, the part of the body containing the heart and lungs, and protected by the ribcage; in arthropods, the middle part of the body, between the head and abdomen.

In mammals the thorax is separated from the abdomen by the muscular diaphragm. In insects the thorax bears the legs and wings. The thorax of spiders and crustaceans, such as lobsters, is fused with the head, to form the cephalothorax.

thorium dark-grey, radioactive, metallic element of the \varnothing actinide series, symbol Th, atomic number 90, relative atomic mass 232.038. It occurs throughout the world in small quantities in minerals such as thorite and is widely distributed in monazite beach sands. It is one of three fissile elements (the others are uranium and plutonium), and its longest-lived isotope has a half-life of 1.39×10^{10} years. Thorium is used to strengthen alloys. It was discovered by Jöns Berzelius in 1828 and was named by him after the Norse god Thor.

| Monomer I | Monomer II | Polymer name | Uses |
|-------------------------|------------|-----------------------|--------------------------------------------|
| formaldehyde (methanal) | phenol | PF resins (Bakelites) | electrical fittings, radio cabinets |
| formaldehyde | urea | UF resins | electrical fittings, insulation, adhesives |
| formaldehyde | melamine | melamines | laminates for furniture |

thermoset Unlike thermoplastics, thermosets remain rigid when set and do not soften when heated.

| Monomer | Polymer | Name | Uses |
|---------------------------------------------------------------------|------------------------------------------------------------|---------------------------------------------|--------------------------------------------------------------------------------|
| $\text{CH}_2=\text{CH}_2$ ethene | $[\text{CH}_2-\text{CH}_2]_n$ | poly(ethene), polythene | bottles, packaging, insulation, pipes |
| $\text{CH}_2=\text{CH}-\text{CH}_3$ propene | $[\text{CH}_2-\text{CH}]_n$ CH_3 | poly(propene), polypropylene | mouldings, film, fibres |
| $\text{CH}_2=\text{CH}-\text{Cl}$ chloroethene (vinyl chloride) | $[\text{CH}_2-\text{CH}]_n$ Cl | polyvinylchloride (PVC), poly(chloroethene) | insulation, flooring, household fabric |
| $\text{CH}_2=\text{CH}-\text{C}_6\text{H}_5$ phenylethene (styrene) | $[\text{CH}_2-\text{CH}]_n$ C_6H_5 | polystyrene, poly(phenylethene) | insulation, packaging |
| $\text{CF}_2=\text{CF}_2$ tetrafluoroethene | $[\text{CF}_2-\text{CF}_2]_n$ | poly(tetrafluoroethene) (PTFE) | high resistance to chemical and electrical reaction, low-friction applications |
| $(n = 1000+)$ | | | |

thermoplastic Examples of thermosoftening plastics, their basic monomer origins, polymer trade names, and everyday uses.

thorn apple or *Jimson weed* annual plant belonging to the nightshade family, native to America and naturalized worldwide. It grows to 2 m/6 ft in northern temperate and subtropical areas and has white or violet trumpet-shaped flowers followed by capsulike fruits that split to release black seeds. All parts of the plant are poisonous. (*Datura stramonium*, family Solanaceae.)

thread in computing, subject line of electronic messages within an online topic or conference. Most online conferencing systems use some kind of threading; one advantage is that it makes it easy for readers of a particular conference or forum to skip over sections that do not interest them. Threading is an important feature of off-line readers, as otherwise it is difficult to tell how individual messages relate to one another.

threadworm kind of nematode.

3-D graphics in computing, graphics defined by width, height, and depth (in mathematical terms, x , y , and z axes). In business applications such as spreadsheets, 3-D graphics allow users to display complex relationships between several different types of data. In computer animation, 3-D graphics allow animators to create characters which look rounded and real enough to interact with humans, such as the cartoon characters in the film *Who Framed Roger Rabbit?* in 1988 or the liquid-metal man in *Terminator 2* in 1991.

thrift or *sea pink* any of several perennial low-growing coastal plants. The common sea pink *A. maritima* occurs in clumps on seashores and cliffs throughout Europe. The leaves are small and linear and the dense round heads of pink flowers rise on straight stems. (Genus *Armeria*, family Plumbaginaceae.)

thrips any of a number of tiny insects of the order Thysanoptera, usually with feathery wings. Many of the 3,000 species live in flowers and suck their juices, causing damage and spreading disease. Others eat fungi, decaying matter, or smaller insects.

throat in human anatomy, the passage that leads from the back of the nose and mouth to the trachea and oesophagus. It includes the pharynx and the larynx, the latter being at the top of the trachea. The word 'throat' is also used to mean the front part of the neck, both in humans and other vertebrates; for example, in describing the plumage of birds. In engineering, it is any narrowing entry, such as the throat of a carburettor.

thrombosis condition in which a blood clot forms in a vein or artery, causing loss of circulation to the area served by the vessel. If it breaks away, it often travels to the lungs, causing pulmonary embolism.

Thrombosis in veins of the legs is often seen in association with phlebitis, and in arteries with atheroma. Thrombosis increases the risk of heart attack and stroke. It is treated by surgery and/or anticoagulant drugs.

thrush any bird of the large family Turdidae, order Passeriformes, found worldwide and known for their song. Thrushes are usually brown with speckles of other colours. They are 12–30 cm/5–12 in long.

thrush infection usually of the mouth (particularly in infants), but also sometimes of the vagina, caused by a yeastlike fungus (*Candida*). It is seen as white patches on the mucous membranes.

Thrush, also known as candidiasis, may be caused by antibiotics removing natural antifungal agents from the body. It is treated with a further antibiotic.

Thrust 2 jet-propelled car in which British driver Richard Noble set a world land speed record in the Black Rock desert of Nevada, USA, on 4 October 1983. The record speed was 1,019.4 kph/633.468 mph. In 1996 Noble attempted to break the sound barrier in Thrust SCC. Thrust SCC has two Rolls-Royce Spey engines (the same kind used in RAF Phantom jets) that provide 110,000 horsepower; it weighs 6,350 kg/13,970 lb, and is 16.5 m/54 ft in length. It was driven by RAF fighter pilot Andy Green to break the sound barrier in September 1997, setting a speed of 1,149.272 kph/714.144 mph.

thulium soft, silver-white, malleable and ductile, metallic element of the lanthanide series, symbol Tm, atomic number 69, relative atomic mass 168.94. It is the least abundant of the rare earth metals, and was first found in gadolinite and various other minerals. It is used in arc lighting.

The X-ray-emitting isotope Tm-170 is used in portable X-ray units. Thulium was named by French chemist Paul Lecoq de Boisbaudran in 1886 after the northland, Thule.

thumbnail in computing, a small version of a larger image used for reference. A PhotoCD or clip art collection might initially present images as thumbnails, while publishing programs include the facility for designers to produce thumbnail page layouts.

Thrust: Breaking the Land Speed Record

BY CHARLES ARTHUR

The attempt to break the sound barrier in a car, and in doing so establish a new land speed record, began in 1991. The idea was sparked off in the mind of Richard Noble, the UK driver who had established a new record of 960.9 kph/600.6 mph, when Craig Breedlove – the US rival whose record Noble had just broken – announced that he intended to break the sound barrier. Noble recalled later: 'From that moment, I knew we had to mount a challenge. I could not let Breedlove beat me to what is the last great challenge to man.'

The History Behind Land Speed Record Attempts

The history of the land speed record began on 18 December 1898, when Gaston Chasseloup-Laubat of France, driving an electric vehicle at Achères, achieved 62.792 kph/39.245 mph. Since 15 September 1924, it has been held either by a Briton or an American – increasing 32 times from its value then of 234 kph/146 mph.

How the Speed Is Measured

The measurement process has become increasingly precise: it now uses laser interferometry for timing and distance. Today, a valid attempt must be made twice over a measured mile. The two runs, one in each direction, must be completed within one hour; the final speed is the average of the two runs. For a jet-fuelled car such as Noble's, or Craig Breedlove's *Spirit of America*, that 'turnaround' time represented a considerable challenge, even though covering the distance itself takes only a few seconds.

Work Begins on Thrust

In June 1994 work started on Thrust SSC ('SuperSonic Car'). By the time Noble had succeeded in his mission, it had cost £5 million. In many ways it was a revolutionary design, but the black Thrust SSC could hardly be called pretty. The Rolls-Royce jet engines, with their long tubular intakes and afterburners mounted either side of the needle-shaped body, came from a Phantom jet fighter. The steering was done by the rear wheels – a bit like a supermarket shopping trolley or forklift truck – the feasibility of which was first tested on a Mini. The car was driven by Andy Green, normally a Tornado jet pilot with the UK Royal Air Force.

The Team Heads for Nevada

After testing during June 1997 in the Jordanian desert, the Thrust SSC team left for Black Rock, Nevada, in September. They were short of cash – a call for £200,000 was made as the team left – but determined to break the record. Also heading there was Craig Breedlove, with the *Spirit of America II*. He too intended to break the record and go supersonic. The thin air of Black Rock's high-altitude setting, and its flat, dry desert provides the ideal location for speed attempts, even though the teams had to drive more than 160 km/100 mi every day from their lodgings to the site.

Craig Breedlove's Many Attempts and Successes at Breaking the Record

Breedlove has a long history of setting the land speed record: he broke the 640 kph/400 mph, 800 kph/500 mph, and 960 kph/600 mph barriers. In October 1996 his car was hurtling across the Black Rock desert at 1,080 kph/675 mph, within seconds of

setting a new record, when it crashed. Breedlove survived. The car didn't.

Craig Breedlove's 1997 version was powered by a single 48,000 horsepower fighter jet engine. In early testing he managed 549 kph/343 mph. But there was intense speculation among observers and engineers about whether Breedlove's car was stable enough. He admitted that if he was not confident enough to ride in it, he would try to pilot the car by a remote control link at up to 1,120 kph/700 mph – an idea that Noble insisted was dangerous.

Testing, Checking, and Repairing

Because the tiniest fault could be deadly at high speeds, the teams spent long hours checking and repairing any problems that turned up in low-speed testing. Such is the sophistication of modern cars that some of the 'repairs' involved computer code – controlling the suspension and engines – rather than anything physical. But after nearly a month, the Thrust SSC, driven by Green, was ready to make a serious attempt.

Thrust Goes Supersonic

The attempt to break the record succeeded on 25 September when the car broke Noble's 1993 record of 1,013 kph/633 mph by the remarkable margin of 130 kph/81 mph, as Green drove the car at 1,120/700 mph on the first run and 1,165 kph/728 mph on the second for a 1,142 kph/714 mph average. The Queen sent her congratulations from Buckingham Palace. But the team had greater aims. The car had only been using 70 % of its power: they were convinced it could go supersonic.

The media were interested in what the experience was like. Green replied: 'The world looks the same at that speed. The mountains are still in the distance, the ground just moves past you a little faster.'

The training runs went on. Then on Monday 13 October the car broke the speed of sound on each run – but a parachute failure meant the car rolled more than a mile past its intended stopping place. It took 61 minutes to complete the second run – rendering it invalid as a record by 60 seconds, according to the international rules. The speeds were 1,222.669 kph/764.168 mph – or 1.007 % above the speed of sound – and 1,216.245 kph/760.153 mph.

But on Wednesday 15 October, during the first run at 9.07 a.m. local time, the car hit 1,214.932 kph/759.333 mph. The return speed of 1,225.774 kph/766.109 mph, completed in the time limit, set the new record at 1,220.354 kph/762.721 mph.

Congratulations for the Team

Among the first to congratulate the team was the UK Prime Minister Tony Blair, who sent a message calling it 'a triumph in which the nation can share and take pride. This success is an excellent example of Britain at its best'.

Noble flew back to the UK, and welcomed the team when they returned with the car on 30 October. 'I think we were all actually quite pleased that it went so smoothly,' he said. And did he have any more plans – for 800 mph and upwards, perhaps? He refused to be drawn. 'We have got something planned but there's a lot of research to do first,' he replied.

thunderstorm severe storm of very heavy rain, thunder, and lightning. Thunderstorms are usually caused by the intense heating of the ground surface during summer. The warm air rises rapidly to form tall cumulonimbus clouds with a characteristic anvil-shaped top. Electrical charges accumulate in the clouds and are discharged to the ground as flashes of lightning. Air in the path of lightning becomes heated and expands rapidly, creating shock waves that are heard as a crash or rumble of thunder.

The rough distance between an observer and a lightning flash

can be calculated by timing the number of seconds between the flash and the thunder. A gap of three seconds represents about a kilometre; five seconds represents about a mile.

thylacine another name for the Tasmanian wolf.

thyme any of several herbs belonging to the mint family. Garden thyme *T. vulgaris*, native to the Mediterranean, grows to 30 cm/1 ft high and has small leaves and pinkish flowers. Its aromatic leaves are used for seasoning in cookery. (Genus *Thymus*, family Labiatae.)

thymus organ in vertebrates, situated in the upper chest cavity in humans. The thymus processes lymphocyte cells to produce T-lymphocytes (T denotes 'thymus-derived'), which are responsible for binding to specific invading organisms and killing them or rendering them harmless.

The thymus reaches full size at puberty, and shrinks thereafter; the stock of T-lymphocytes is built up early in life, so this function diminishes in adults, but the thymus continues to function as an endocrine gland, producing the hormone thymosin, which stimulates the activity of the T-lymphocytes.

thyristor type of rectifier, an electronic device that conducts electricity in one direction only. The thyristor is composed of layers of semiconductor material sandwiched between two electrodes called the anode and cathode. The current can be switched on by using a third electrode called the gate.

Thyristors are used to control mains-driven motors and in light-dimmer controls.

thyroid endocrine gland of vertebrates, situated in the neck in front of the trachea. It secretes several hormones, principally thyroxine, an iodine-containing hormone that stimulates growth, metabolism, and other functions of the body. The thyroid gland may be thought of as the regulator gland of the body's metabolic rate. If it is overactive, as in hyperthyroidism, the sufferer feels hot and sweaty, has an increased heart rate, diarrhoea, and weight loss. Conversely, an underactive thyroid leads to myxoedema, a condition characterized by sensitivity to the cold, constipation, and weight gain. In infants, an underactive thyroid leads to cretinism, a form of mental retardation.

thyrotoxicosis synonym for hyperthyroidism.

thyroxine in medicine, a hormone containing iodine that is produced by the thyroid gland. It is used to treat conditions that are due to deficiencies in thyroid function, such as myxoedema.

Tibetan mastiff large breed of dog regarded as the ancestor of many present breeds. It is a very powerful animal with a long black or black and tan coat. It is about 71 cm/28 in in height and 60 kg/132 lb in weight.

Tibetan mastiffs were used in Tibet as watchdogs and are mentioned in old Chinese literature and by Marco Polo.

Tibetan spaniel breed of miniature dog from the valleys of Tibet. Standing up to 28 cm/11 in tall, it has a fine, silky coat in a range of solid or broken colours. Its tail curves over its back.

Tibetan terrier breed of small herding dog used by the nomads of Tibet to gather and guard their flocks. It has a long, wavy coat that may be black, white, grey, beige, or any range of colours in between. Its tail curves over its back. It reaches a height of about 43 cm/17 in.

The name 'Tibetan terrier' is misleading as it has nothing in common with the terrier group of dogs and resembles a small Old English sheepdog.

tibia the anterior of the pair of bones in the leg between the ankle and the knee. In humans, the tibia is the shinbone. It articulates with the femur above to form the knee joint, the fibula externally at its upper and lower ends, and with the talus below, forming the ankle joint.

tick any of the arachnid family Ixodidae, order Acarina, of large bloodsucking mites. They have flat bodies protected by horny shields. Many carry and transmit diseases to mammals (including humans) and birds.

life cycle During part of their existence they parasitize animals and birds, for which they have developed a rostrum or beak composed of two barbed harpoons above and a dart below. Their eggs are laid on rough herbage and hatch into white six-legged larvae, which climb up the legs of passing animals and in some species complete their life history on the animal's skin, but in others return to the grass for a period, dropping from the host when engorged with blood.

Ticks cause irritation and anaemia, and can also transmit *Cytoph*, Lyme disease, rickettsia, and relapsing fever.

tidal energy energy derived from the tides. The tides mainly gain their potential energy from the gravitational forces acting between the Earth and the Moon. If water is trapped at a high level during high tide, perhaps by means of a barrage across an estuary, it may then be gradually released and its associated gravitational potential energy exploited to drive turbines and generate electricity. Several schemes have been proposed for the Bristol Channel, in SW England, but environmental concerns as well as construction costs have so far prevented any decision from being taken.

tidal heating in astrophysics, a process in which one body is heated internally by tidal stresses set up by the gravitational pull of another body. Tidal heating is common among the moons of the giant planets, and is the heat source for volcanic activity on *I*o, one of the moons of *J*upiter.

tidal power station hydroelectric power plant that uses the 'head' of water created by the rise and fall of the ocean tides to spin the water turbines. The world's only large tidal power station is located on the estuary of the river Rance in the Gulf of St Malo, Brittany, France, and has been in use since 1966. It produces 240 megawatts and can generate electricity on both the ebb and flow of the tide.

tidal wave common name for a tsunami.

Tidbinbilla space tracking station and nature reserve in Australia, just S of Canberra. It provides tracking facilities and command transmissions in support of NASA manned and unmanned spacecraft including the *Voyager* probes.

tide the rhythmic rise and fall of the sea level in the Earth's oceans and their inlets and estuaries due to the gravitational attraction of the Moon and, to a lesser extent, the Sun, affecting regions of the Earth unequally as it rotates. Water on the side of the Earth nearest the Moon feels the Moon's pull and accumulates directly below it producing high tide.

High tide occurs at intervals of 12 hr 24 min 30 sec. The maxi-

tide The gravitational pull of the Moon is the main cause of the tides. Water on the side of the Earth nearest the Moon feels the Moon's pull and accumulates directly under the Moon. When the Sun and the Moon are in line, at new and full moon, the gravitational pull of Sun and Moon are in line and produce a high spring tide. When the Sun and Moon are at right angles, lower neap tides occur.

mum high tides, or spring tides, occur at or near new and full Moon when the Moon and Sun are in line and exert the greatest combined gravitational pull. Lower high tides, or neap tides, occur when the Moon is in its first or third quarter and the Moon and Sun are at right angles to each other.

TIFF (acronym for *tagged image file format*) a graphics file format.

tiger largest of the great cats, *Panthera tigris* (family Felidae, order Carnivora), formerly found in much of central and S Asia, from Siberia south to Sumatra, but nearing extinction (5,000 in 1997) because of hunting and the high prices paid for the pelt, as well as the destruction of its natural habitat.

The male tiger can grow to 3.6 m/12 ft long, while the female averages about 2.6 m/8.5 ft. It weighs up to 300 kg/660 lbs, and has a yellow-orange coat with black stripes. Tigers are solitary, and largely nocturnal. They will eat carrion, but generally kill for themselves. Their food consists mainly of deer, antelopes, and smaller animals, but they sometimes kill wild boar. Human-eating tigers are rare and are the result of weakened powers or shortage of game.

TIGER

http://www.fws.gov/~r9extaff/biologues/bio_tige.html

Important addition to the ecological sites on the Web: this page offers descriptions of several types of tigers with details of their anatomy, hunting methods, habitats, the pressures they are under, and the measures taken to protect them. services and legal assistance.

tiger beetle brightly coloured beetle with long legs and antennae. The most striking feature is their large eyes. Most adult tiger beetles are in shades of blue, bronze, or green, with yellow or white markings. They are typically found on sand or dry soils. Some 2,000 species have been recorded, mostly in the tropics.

The adults move rapidly and fly readily. The larvae live in burrows in the soil, where they lie in wait with their powerful mandibles, or jaws, ready to grab any insect that passes by. **classification** Tiger beetles are members of the family Cicindelidae, order Coleoptera, class Insecta, phylum Arthropoda. The main genus is *Cicindela*.

tiling in computing, arrangement of windows in a graphical user interface system so that they do not overlap.

till or **boulder clay** deposit of clay, mud, gravel, and boulders left by a glacier. It is unsorted, with all sizes of fragments mixed up together, and shows no stratification; that is, it does not form clear layers or beds.

tilt-rotor aircraft type of vertical takeoff aircraft, also called a **convertiplane**.

timber wood used in construction, furniture, and paper pulp. **Hardwoods** include tropical mahogany, teak, ebony, rosewood, temperate oak, elm, beech, and eucalyptus. All except eucalyptus are slow-growing, and wood supplies are almost exhausted. **Softwoods** comprise the conifers (pine, fir, spruce, and larch), which are quick to grow and easy to work but inferior in quality of grain. **White woods** include ash, birch, and sycamore; all have light-coloured timber, are fast-growing, and can be used as veneers on cheaper timber.

time continuous passage of existence, recorded by division into hours, minutes, and seconds. Formerly the measurement of time was based on the Earth's rotation on its axis, but this was found to be irregular. Therefore the second, the standard SI unit of time, was redefined in 1956 in terms of the Earth's annual orbit of the Sun, and in 1967 in terms of a radiation pattern of the element caesium.

time out in computing, pre-set period of time during which a computer waits for a response from a device or another computer. For example, when sending a fax, a computer will time out the telephone call if the receiving fax machine fails to answer.

Times Beach town in Missouri, USA, that accidentally became contaminated with dioxin, and was bought by the Environmental Protection Agency in 1983 for cleansing.

time-sharing in computing, a way of enabling several users to access the same computer at the same time. The computer rapidly switches between user terminals and programs, allowing each user to work as if he or she had sole use of the system.

Time-sharing was common in the 1960s and 1970s before the spread of cheaper computers, and might make a comeback in the late 1990s, with the advent of network computing.

timestamp in computing, digital signature that 'fixes' a document in time, so that any later alterations can be readily detected.

tin soft, silver-white, malleable and somewhat ductile, metallic element, symbol Sn (from Latin *stannum*), atomic number 50, relative atomic mass 118.69. Tin exhibits allotropy, having three forms: the familiar lustrous metallic form above 13.2°C/55.8°F; a brittle form above 161°C/321.8°F; and a grey powder form below 13.2°C/55.8°F (commonly called tin pest or tin disease). The metal is quite soft (slightly harder than lead) and can be rolled, pressed, or hammered into extremely thin sheets; it has a low melting point. In nature it occurs rarely as a free metal. It resists corrosion and is therefore used for coating and plating other metals.

Tin and copper smelted together form the oldest desired alloy, bronze; since the Bronze Age (3500 BC) that alloy has been the basis of both useful and decorative materials. Tin is also alloyed with metals other than copper to make solder and pewter. It was recognized as an element by Antoine Lavoisier, but the name is very old and comes from the Germanic form *zinn*. The mines of Cornwall were the principal western source of tin until the 19th century, when rich deposits were found in South America, Africa, SE Asia, and Australia. Tin production is concentrated in Malaysia, Indonesia, Brazil, and Bolivia.

tinamou fowl-like bird of the family Tinamidae, in the South American order Tinamiformes, of which there are some 45 species. They are up to 40 cm/16 in long, and their drab colour provides good camouflage. They are excellent runners but poor flyers and are thought to be related to the cratites (flightless birds). Tinamous are mainly vegetarian, but sometimes eat insects. They escape predators by remaining still or by burrowing through dense cover.

Several females lay eggs in one nest; one hen may also lay eggs in nests guarded by different males. The males build the nests and incubate the eggs.

tininitis in medicine, constant buzzing or ringing in the ears. The phenomenon may originate from prolonged exposure to noisy conditions (drilling, machinery, or loud music) or from damage to or disease of the middle or inner ear. The victim may become overwhelmed by the relentless noise in the head.

In some cases there is a hum at a frequency of about 40 Hz, which resembles that heard by people troubled by environmental hum but may include whistles and other noises resembling a machine workshop. Being in a place where external noises drown the internal ones gives some relief, and devices may be worn that create pleasant, soothing sounds to override them.

Objective tininitis is a very rare form in which other people can also hear the noises. This may be caused by muscle spasms in the inner ear or throat, or abnormal resonance of the eardrum and ossicles.

tin ore mineral from which tin is extracted, principally cassiterite, SnO₂. The world's chief producers are Malaysia, Thailand, and Bolivia.

tinplate milled steel coated with tin, the metal used for most 'tin' cans. The steel provides the strength, and the tin provides the corrosion resistance, ensuring that the food inside is not contaminated. Tinplate may be made by electroplating or by dipping in a bath of molten tin.

TinyMUD in computing, one of the oldest and most popular ϕ MUDs, named for the efficiency of its program code.

TinySex in computing, cybersex on ϕ TinyMUD.

TIR abbreviation for *Transports Internationaux Routiers* (French 'International Road Transport').

tire US spelling of ϕ tyre.

tissue in biology, any kind of cellular fabric that occurs in an organism's body. Several kinds of tissue can usually be distinguished, each consisting of cells of a particular kind bound together by cell walls (in plants) or extracellular matrix (in animals). Thus, nerve and muscle are different kinds of tissue in animals, as are ϕ parenchyma and ϕ scierenchyma in plants.

tissue culture process by which cells from a plant or animal are removed from the organism and grown under controlled conditions in a sterile medium containing all the necessary nutrients. Tissue culture can provide information on cell growth and differentiation, and is also used in plant propagation and drug production.

tissue plasminogen activator (tPA) naturally occurring substance in the body tissues that activates the enzyme plasmin that is able to dissolve blood clots. Human tPA, produced in bacteria by genetic engineering, has, like streptokinase, been used to dissolve blood clots in the coronary arteries of heart attack victims. It has been shown to be more effective than streptokinase when used in conjunction with heparin, but it is much more expensive.

tit or **titmouse** any of 65 species of insectivorous, acrobatic bird of the family Paridae, order Passeriformes. Tits are 8-20 cm/3-8 in long and have grey or black plumage, often with blue or yellow markings. They are found in Eurasia and Africa, and also in North America, where they are called chickadees.

TIT

Birds are not the only inhabitants of bird nests. A Finnish study of 56 bird species found that their nests harboured 529 different kinds of invertebrates (including 228 species of mite). One great tit's nest was home to 3,469 arthropods.

Titan in astronomy, largest moon of the planet Saturn, with a diameter of 5,150 km/3,200 mi and a mean distance from Saturn of 1,222,000 km/759,000 mi. It was discovered in 1655 by Dutch mathematician and astronomer Christiaan ϕ Huygens, and is the second largest moon in the Solar System (Ganymede, of Jupiter, is larger).

Titan is the only moon in the Solar System with a substantial atmosphere (mostly nitrogen), topped with smoggy orange clouds that obscure the surface, which may be covered with liquid ethane lakes. Its surface atmospheric pressure is greater than Earth's. Radar signals suggest that Titan has dry land as well as oceans (among the planets, only Earth has both in the Solar System).

titanium strong, lightweight, silver-grey, metallic element, symbol Ti, atomic number 22, relative atomic mass 47.90. The ninth-most abundant element in the Earth's crust, its compounds occur in practically all igneous rocks and their sedimentary deposits. It is very strong and resistant to corrosion, so it is used in building high-speed aircraft and spacecraft; it is also widely used in making alloys, as it unites with almost every metal except copper and aluminium. Titanium oxide is used in high-grade white pigments.

Titanium bonds with bone in a process called *osseointegration*. As the body does not react to the titanium it is valuable for permanent implants such as prostheses.

The element was discovered in 1791 by English mineralogist William Gregor (1761-1817) and was named by German chemist Martin Klaproth in 1796 after the Titans, the giants of Greek mythology. It was not obtained in pure form until 1925.

titanium ore any mineral from which titanium is extracted, principally ilmenite (FeTiO_3) and rutile (TiO_2). Brazil, India, and Canada are major producers. Both these ore minerals are found either in rock formations or concentrated in heavy mineral sands.

Titan rocket family of US space rockets, developed from the Titan intercontinental missile. Two-stage Titan rockets launched the ϕ Gemini crewed missions. More powerful Titans, with additional stages and strap-on boosters, were used to launch spy satellites and space probes, including the ϕ Viking and ϕ Voyager probes and *Mars Observer*.

titration in analytical chemistry, a technique to find the concentration of one compound in a solution by determining how much of it will react with a known amount of another compound in solution.

One of the solutions is measured by ϕ pipette into the reaction vessel. The other is added a little at a time from a ϕ burette. The end-point of the reaction is determined with an ϕ indicator or an electrochemical device.

titration A method used to find the concentration of an acid or an alkali. Typically a burette is filled with an acid of unknown concentration which is slowly (drop by drop) added to an alkali of a known concentration, mixed with an indicator (such as phenolphthalein). The volume of acid needed to neutralize the alkali in the flask can be used to calculate the concentration of the acid.

TLA (abbreviation for *three letter acronym*) hackers' self-fulfilling reference to the apparent ubiquity of three-letter abbreviations (all popularly and wrongly referred to as acronyms) in the computing world. Anyone who has used a DOS-based CPU and a VGA or LCD ϕ VDU (or, indeed, an IBM ϕ MPC) to create ϕ GIFs, WAVs or ϕ PDF files, or who has hooked up to an ISP (ϕ Internet Service Provider) to access IRC, WWW, a BBS or a ϕ MUD, or to get an ϕ FAQ by ϕ FTP, will be familiar with this syndrome.

Some hackers are so addicted to using TLAs that a four-letter acronym is known mockingly as an 'ETLA' - Extended Three-Letter Acronym.

TN3270 in computing, variation of ϕ Telnet used to connect to IBM mainframes.

TNT (abbreviation for *trinitrotoluene*) $\text{CH}_3\text{C}_6\text{H}_2(\text{NO}_2)_3$, a powerful high explosive. It is a yellow solid, prepared in several isomeric forms from ϕ toluene by using sulphuric and nitric acids.

toad any of the more terrestrial warty-skinned members of the tailless amphibians (order Anura). The name commonly refers to members of the genus *Bufo*, family Bufonidae, which are found worldwide, except for Australia (where the marine or cane toad *B. marinus* has been introduced), Madagascar, and Antarctica. They differ from frogs chiefly by the total absence of teeth, and in certain other anatomical features.

toadflax any of a group of small plants belonging to the snapdragon family, native to W Europe and Asia. Toadflaxes have spurred, two-lipped flowers, commonly purple or yellow, and grow 20–80 cm/8–32 in tall. (Genus *Linaria*, family Scrophulariaceae.)

toadstool common name for many umbrella-shaped fruiting bodies of fungi (see *fungus*). The term is normally applied to those that are inedible or poisonous.

tobacco any of a group of large-leaved plants belonging to the nightshade family, native to tropical parts of the Americas. The species *N. tabacum* is widely cultivated in warm, dry climates for use in cigars and cigarettes, and in powdered form as snuff. (Genus *Nicotiana*, family Solanaceae.)

The leaves are cured, or dried, and matured in storage for two to three years before use. Introduced to Europe as a medicine in the 16th century, tobacco has been recognized from the 1950s as a major health hazard; see *cancer*. The leaves also yield nicotine, a colourless oil, one of the most powerful poisons known, and addictive in humans. It is used in insecticides.

Worldwide, the tobacco conglomerations make a net profit of \$6 billion each year. A US Supreme Court decision in 1992 ruled that tobacco companies can be held legally responsible for the dangerous effects of smoking on health; conglomerations spend \$50 million a year on legal advice to avoid paying out compensation to victims. However, in March 1996 the Liggett Group became the first tobacco company to agree to settle smoking-related claims.

In early 1998 a court case in Minnesota, USA, revealed that the tobacco industry was aware of the carcinogenic effects of smoking cigarettes in 1958 when British scientists informed manufacturers (British American Tobacco) of the link between smoking and lung cancer. By the end of the 1970s tobacco companies were considering producing nicotine-containing merchandise other than cigarettes, should they become socially unacceptable. The research involved identifying a pattern of repeat consumption; a product that involved repeated handling; nicotine (or a 'direct' substitute) as the main constituent; the product being non-ignitable. At that time, tobacco manufacturers were aware that nicotine was the addictive, though not the most harmful, element in cigarettes.

When I was young, I kissed my first woman, and smoked my first cigarette on the same day. Believe me, never since have I wasted any more time on tobacco.

ARTURO TOSCANINI Italian conductor.

Attributed remark 1957

tocopherol or **vitamin E** fat-soluble chemical found in vegetable oils. Deficiency of tocopherol leads to multiple adverse effects on health. In rats, vitamin E deficiency has been shown to cause sterility.

tog unit of measure of thermal insulation used in the textile trade; a light summer suit provides 1.0 tog.

The tog value of an object is equal to ten times the temperature difference (in °C) between its two surfaces when the flow of heat is equal to one watt per square metre; one tog equals 0.645 *clco*.

toggle in computing, to switch between two settings. In software a toggle is usually triggered by the same code, so it is important that this code only has two meanings. An example is the use of the same character in a text file to indicate both opening and closing quotation marks; if the same character is also used to mean an apostrophe, then conversion, via a toggle switch, for a desktop publishing system that uses different opening and closing quotation marks, will not be carried out correctly.

toilet place where waste products from the body are excreted. Simple latrines, with sewers to carry away waste, have been found in the Indus Valley and ancient Babylon; the medieval garderobe is essentially the same, even though flushing lavatories had been known to Roman civilizations.

tokamak Russian acronym for toroidal magnetic chamber, an experimental machine conceived by Soviet physicist Andrei Sakharov and developed in the Soviet Union to investigate controlled nuclear fusion. It consists of a doughnut-shaped chamber surrounded by electromagnets capable of exerting very powerful magnetic fields. The fields are generated to confine a very hot (millions of degrees) plasma of ions and electrons, keeping it away from the chamber walls. See also *JET*.

Token Ring protocol for local area networks, developed by IBM in 1985.

toluene or **methyl benzene** $C_6H_5CH_3$, colourless, inflammable liquid, insoluble in water, derived from petroleum. It is used as a solvent, in aircraft fuels, in preparing phenol (carboic acid, used in making resins for adhesives, pharmaceuticals, and as a disinfectant), and the powerful high explosive TNT.

tomato annual plant belonging to the nightshade family, native to South America. It is widely cultivated for its shiny, round, red fruit containing many seeds (technically a berry), which is widely used in salads and cooking. (*Lycopersicon esculentum*, family Solanaceae.)

A genetically engineered tomato, the first genetically engineered food for sale, appeared in shops in California and Chicago in May 1994.

tomography the technique of using X-rays or ultrasound waves to procure images of structures deep within the body for diagnostic purposes. In modern medical imaging there are several techniques, such as the CAT scan (computerized axial tomography).

ton imperial unit of mass. The long ton, used in the UK, is 1,016 kg/2,240 lb; the short ton, used in the USA, is 907 kg/2,000 lb. The metric ton or tonne is 1,000 kg/2,205 lb.

ton in shipping, unit of volume equal to 2.83 cubic metres/100 cubic feet. Gross tonnage is the total internal volume of a ship in tons; net register tonnage is the volume used for carrying cargo or passengers. Displacement tonnage is the weight of the vessel, in terms of the number of imperial tons of seawater displaced when the ship is loaded to its load line; it is used to describe warships.

tongue in tetrapod vertebrates, a muscular organ usually attached to the floor of the mouth. It has a thick root attached to a U-shaped bone (hyoid), and is covered with a mucous membrane containing nerves and taste buds. It is the main organ of taste. The tongue directs food to the teeth and into the throat for chewing and swallowing. In humans, it is crucial for speech; in other animals, for lapping up water and for grooming, among other functions. In some animals, such as frogs, it can be flipped forwards to catch insects; in others, such as anteaters, it serves to reach for food found in deep holes.

tonka South American tree *Dipteryx odorata*, family Leguminosae. The fruit, a dry fibrous pod, encloses a black aromatic bean used in flavouring, perfumery, and the manufacture of snuff and tobacco.

tonne the metric ton of 1,000 kg/2,204.6 lb; equivalent to 0.9842 of an imperial *cton*.

tonsillitis inflammation of the *tonsils*.

tonsils in higher vertebrates, masses of lymphoid tissue situated at the back of the mouth and throat (palatine tonsils), and on the rear surface of the tongue (lingual tonsils). The tonsils contain many lymphocytes and are part of the body's defence system against infection.

The *adenoids* are sometimes called pharyngeal tonsils.

tooth Adults have 32 teeth: two incisors, one canine, two premolars, and three molars on each side of each jaw. Each tooth has three parts: crown, neck, and root. The crown consists of a dense layer of mineral, the enamel, surrounding hard dentine with a soft centre, the pulp.

toolbar in computing, area at the top or side of a screen with push-buttons and other features to perform frequently-used tasks. For example, the toolbar of a paint program might offer quick access to different brushes, spraycans, erasers, and other useful tools.

ToolBook in computing, multimedia authoring tool created by the US company Asymetrix for Microsoft Windows.

tooth in vertebrates, one of a set of hard, bonelike structures in the mouth, used for biting and chewing food, and in defence and aggression. In humans, the first set (20 milk teeth) appear from age six months to two and a half years. The permanent dentition replaces these from the sixth year onwards, the wisdom teeth (third molars) sometimes not appearing until the age of 25 or 30. Adults have 32 teeth: two incisors, one canine (eye tooth), two premolars, and three molars on each side of each jaw. Each tooth consists of an enamel coat (hardened calcium deposits), dentine (a thick, bonelike layer), and an inner pulp cavity, housing nerves and blood vessels. Mammalian teeth have roots surrounded by cementum, which fuses them into their sockets in the jawbones.

The neck of the tooth is covered by the gum, while the enamel-covered crown protrudes above the gum line.

The chief diseases of teeth are misplacements resulting from defect or disturbance of the tooth-germs before birth, eruption out of their proper places, and caries (decay).

A genetically engineered protein able to stimulate the recovery of tooth tissue in decayed teeth was undergoing trials in 1993.

TOOTH

About one in every 2,000 babies is born with a tooth. Louis XIV of France was born with two teeth, which may explain why he had had eight wet-nurses by the time he moved on to solid foods.

topaz mineral, aluminium fluorosilicate, $Al_2(F_2SiO_4)$. It is usually yellow, but pink if it has been heated, and is used as a gemstone when transparent. It ranks 8 on the Mohs' scale of hardness.

tope slender shark *Galeorhinus galeus* ranging through temperate and tropical seas. Dark grey above and white beneath, it reaches 2 m/6 ft in length. The young are born well-formed, sometimes 40 at a time.

topi or korrugum antelope *Damaliscus korrigum* of equatorial Africa, head and body about 1.7 m/5.5 ft long, 1.1 m/3.5 ft high at the shoulder, with a chocolate-brown coat.

topography the surface shape and composition of the landscape, comprising both natural and artificial features, and its study. Topographical features include the relief and contours of the land: the distribution of mountains, valleys, and human settlements; and the patterns of rivers, roads, and railways.

topology in computing, the arrangement of devices in a network. Common topologies include **star networks**, where a central computer manages network access, and **ring networks**, where users can establish direct connections with other workstations.

topology branch of geometry that deals with those properties of a figure that remain unchanged even when the figure is trans-

this figure is topologically equivalent to this one

topology A topological oddity, the Klein bottle is a bottle in name only because it has only one surface and no outside or inside.

formed (bent, stretched) – for example, when a square painted on a rubber sheet is deformed by distorting the sheet.

Topology has scientific applications, as in the study of turbulence in flowing fluids.

The topological theory, proposed 1880, that only four colours are required in order to produce a map in which no two adjoining countries have the same colour, inspired extensive research, and was proved in 1972 by Kenneth Appel and Wolfgang Haken.

topsoil the upper, cultivated layer of soil, which may vary in depth from 8 to 45 cm/3 to 18 in. It contains organic matter – the decayed remains of vegetation, which plants need for active growth – along with a variety of soil organisms, including earthworms.

tornado extremely violent revolving storm with swirling, funnel-shaped clouds, caused by a rising column of warm air propelled by strong wind. A tornado can rise to a great height, but with a diameter of only a few hundred metres or less. Tornadoes move with wind speeds of 160–480 kph/100–300 mph, destroying everything in their path. They are common in central USA and Australia.

TORNADO PROJECT ONLINE

<http://www.tornadopproject.com/>

All about tornadoes – including myths and oddities, personal experiences, tornado chasing, tornado safety, and tornadoes past and present.

torpedo or **electric ray** any species of the order Torpediniformes of mainly tropical rays (cartilaginous fishes), whose electric organs between the pectoral fin and the head can give a powerful shock. They can grow to 180 cm/6 ft in length.

The electric ray *Torpedo nobiliana* is found on both sides of the Atlantic.

torque the turning effect of force on an object. A turbine produces a torque that turns an electricity generator in a power station. Torque is measured by multiplying the force by its perpendicular distance from the turning point.

torque converter device similar to a turbine, filled with oil, used in automatic transmission systems in motor vehicles and locomotives to transmit power (torque) from the engine to the gears.

torr unit of pressure equal to 1/760 of an atmosphere, used mainly in high-vacuum technology.

One torr is equivalent to 133.322 pascals, and for practical purposes is the same as the millimetre of mercury. It is named after the Italian physicist Evangelista Torricelli.

torsion in physics, the state of strain set up in a twisted material; for example, when a thread, wire, or rod is twisted, the torsion set up in the material tends to return the material to its original state. The torsion balance, a sensitive device for measuring small gravitational or magnetic forces, or electric charges, balances these against the restoring force set up by them in a torsion suspension.

tortoise reptile of the order Chelonina, family Testudinidae, with the body enclosed in a hard shell. Tortoises are related to the chelonians and turtles, and range in length from 10 cm/4 in to 150 cm/5 ft. The shell consists of a curved upper carapace and flattened lower plastron joined at the sides. The head and limbs is withdrawn into it when the tortoise is in danger. Most land tortoises are herbivorous, feeding on plant material, and have no teeth. The

mouth forms a sharp-edged beak. Tortoises have been known to live for 150 years.

The sex of a tortoise is difficult to determine, except when the female is on heat. Mating can last up to five hours. Eggs are laid in warm earth in great numbers, and are not incubated by the mother.

Best known in the pet trade is the small spur-thighed tortoise *Testudo graeca*, found in Asia Minor, the Balkans, and N Africa. It was extensively exported, often in appalling conditions, until the 1980s, when strict regulations were introduced to prevent its probable extinction. The giant tortoises of the Galápagos in the Pacific and the Seychelles in the Indian Ocean may reach a length of 150 cm/5 ft and weigh over 225 kg/500 lbs, and can yield about 90 kg/200 lbs of meat; hence its almost complete extermination by sailors in passing ships.

Tortoiseshell is the semi-transparent shell of the hawksbill turtle.

TORTOISE GUIDE

<http://easyweb.easynet.co.uk/~slowcoach/slow/slocoach.html>

Essential site for tortoise enthusiasts and owners. It contains a history of tortoises in the UK, a comprehensive selection of 'care sheets' covering different areas of keeping and caring for tortoises, and tips for the less experienced tortoise owner. There's also a picture gallery of the many varieties that can be found throughout the world and a summary of the Convention on International Trade in Endangered Species which governs trade in tortoises. You can also keep up to date with tortoise-related events via the 'what's on' page.

tortoise beetle leaf-feeding beetle usually found in the tropics. The outer margins of its wing covers and the prothorax (shield) are drawn out to form a convex shield a bit like the outline of a tortoise. They are often brilliantly coloured with a metallic sheen.

The larvae generally have spiky outgrowths, and they cover themselves with excrement or cast skins as methods of camouflage. **classification** Tortoise beetles comprise the subfamily Cassidinae, family Chrysomelidae, order Coleoptera, class Insecta, phylum Arthropoda.

torus ring with a D-shaped cross-section used to contain plasma in nuclear fusion reactors such as the Joint European Torus (JET) reactor.

tosa breed of dog specially bred in Japan during the 19th century for fighting. It is powerfully built, with the males standing at least 60 cm/24 in at the shoulder. The short, coarse coat is generally either red or red-flecked on white.

total internal reflection the complete reflection of a beam of light that occurs from the surface of an optically 'less dense' material. For example, a beam from an underwater light source can be reflected from the surface of the water, rather than escaping through the surface. Total internal reflection can only happen if a light beam hits a surface at an angle greater than the critical angle for that particular pair of materials.

Total internal reflection is used as a means of reflecting light inside optical fibres. Light is contained inside an optical fibre not by the cladding around it, but by the ability of the internal surface of the glass-fibre core to reflect 100% of the light, thereby keeping it trapped inside the fibre.

toucan any South and Central American forest-dwelling bird of the genus *Ramphastos*, family Ramphastidae, order Piciformes. Toucans have very large, brilliantly coloured beaks and often handsome plumage. They live in small flocks and eat fruits, seeds, and insects. They nest in holes in trees, where the female lays 2–4 eggs; both parents care for the eggs and young. There are 37 species, ranging from 30 cm/1 ft to 60 cm/2 ft in size.

In the true toucans the ground colour of the plumage is generally

TORTOISE

Aeschylus, the founder of Classical Greek tragedy, is said to have died when an eagle passing overhead dropped a tortoise on his head.

black; the throat, breast and rump are adorned with yellow, red and white; the body is short and thick; the tail is rounded or even and can be turned up over the back when the bird goes to roost. The largest are about 60 cm/24 in long.

touch sensation produced by specialized nerve endings in the skin. Some respond to light pressure, others to heavy pressure. Temperature detection may also contribute to the overall sensation of touch. Many animals, such as nocturnal ones, rely on touch more than humans do. Some have specialized organs of touch that project from the body, such as whiskers or antennae.

touch screen in computing, an input device allowing the user to communicate with the computer by touching a display screen with a finger. In this way, the user can point to a required menu option or item of data. Touch screens are used less widely than other pointing devices such as the mouse or joystick.

Typically, the screen is able to detect the touch either because the finger presses against a sensitive membrane or because it interrupts a grid of light beams crossing the screen surface.

touch sensor in a computer-controlled robot, a device used to give the robot a sense of touch, allowing it to manipulate delicate objects or move automatically about a room. Touch sensors provide the feedback necessary for the robot to adjust the force of its movements and the pressure of its grip. The main types include the strain gauge and the microswitch.

touraco or turaco any fruit-eating African bird of the family Musophagidae, order Cuculiformes. They have a small high bill, notched and serrated mandibles, a long tail, erectile crest, and short, rounded wings. The largest are 70 cm/28 in long.

Many of them are brilliantly coloured with glossy blue, red, violet and green plumage. There are about 18 species including the violet plantain-eater *Muscophaga violacea* and the white-cheeked touraco *Touraco leucotis*, which resembles a multi-coloured magpie.

tourmaline hard, brittle mineral, a complex silicate of various metals, but mainly sodium aluminium borosilicate.

Small tourmalines are found in granites and gneisses. The common varieties range from black (schorl) to pink, and the transparent gemstones may be colourless (achromatic), rose pink (rubellite), green (Brazilian emerald), blue (indicolite, verdelite, Brazilian sapphire), or brown (dravite).

toxaemia another term for blood poisoning; toxaemia of pregnancy is another term for pre-eclampsia.

toxicity tests tests carried out on new drugs, cosmetics, food additives, pesticides, and other synthetic chemicals to see whether they are safe for humans to use. They aim to identify potential toxins, carcinogens, teratogens, and mutagens.

Traditionally such tests use live animals such as rats, rabbits, and mice. Animal tests have become a target for criticism by antivivisection groups, and alternatives have been sought. These include tests on human cells cultured in a test tube and on bacteria.

In Europe in 1990, 4,365 animals were used for testing cosmetic products, out of a total of 276,674 animals used to test products other than pharmaceuticals. Including pharmaceuticals, a total of around 3.2 million animals were used in experimentation. The US Office of Technology Assessment estimates that around 1.6 million animals are used annually in government research laboratories, of which 90% are rats or mice.

toxic shock syndrome rare condition marked by rapid onset of fever, vomiting, and low blood pressure, sometimes leading to death. It is caused by a toxin of the bacterium *Staphylococcus aureus*, normally harmlessly present in the body. It is seen most often in young women using tampons during menstruation.

toxic syndrome fatal disease for which the causes are not confirmed. In an outbreak in Spain in the early 1980s, more than 20,000 people became ill and 600–700 died.

One theory held that the toxic syndrome was caused by adulterated industrial oil, illegally imported from France into Spain, re-refined, and sold for human consumption from 1981. However,

other studies pointed more convincingly to the use of a 'plaguicide' product, Nema-cur (produced by Bayer), which contains organophosphates, and can be dangerous if fruit and vegetables are eaten too soon after its application. Animal tests have shown symptoms similar to toxic syndrome, with damage to the nervous system, after ingesting organophosphates.

toxic waste dumped hazardous waste.

toxin any poison produced by another living organism (usually a bacterium) that can damage the living body. In vertebrates, toxins are broken down by enzyme action, mainly in the liver.

TOXIN

The purple cone shell's venom acts extremely fast. It can paralyse a fish within less than two seconds. The venom is administered by a spearlike hollow tooth

toxoplasmosis disease transmitted to humans by animals, often in pigeon or cat excrement, or in undercooked meat. It causes flu-like symptoms and damages the central nervous system, eyes, and visceral organs. It is caused by a protozoan, *Toxoplasma gondii*. Congenital toxoplasmosis, transmitted from an infected mother to her unborn child, can lead to blindness and retardation.

trace in computing, a method of checking that a computer program is functioning correctly by causing the changing values of all the variables involved to be displayed while the program is running. In this way it becomes possible to narrow down the search for a bug, or error, in the program to the exact instruction that causes the variables to take unexpected values.

trace element chemical element necessary in minute quantities for the health of a plant or animal. For example, magnesium, which occurs in chlorophyll, is essential to photosynthesis, and iodine is needed by the thyroid gland of mammals for making hormones that control growth and body chemistry.

tracer a small quantity of a radioactive isotope (form of an element) used to follow the path of a chemical reaction or a physical or biological process. The location (and possibly concentration) of the tracer is usually detected by using a Geiger-Müller counter.

For example, the activity of the thyroid gland can be monitored by giving the patient an injection containing a small dose of a radioactive isotope of iodine, which is selectively absorbed from the bloodstream by the gland.

traceroute in computing, network utility program which allows the user to find out the path taken by packets of data sent across the Internet. Traceroute can help to debug a network, or check how it works.

trachea tube that forms an airway in air-breathing animals. In land-living vertebrates, including humans, it is also known as the windpipe and runs from the larynx to the upper part of the chest. Its diameter is about 1.5 cm/0.6 in and its length 10 cm/4 in. It is strong and flexible, and reinforced by rings of cartilage. In the upper chest, the trachea branches into two tubes: the left and right bronchi, which enter the lungs. Insects have a branching network of tubes called tracheae, which conduct air from holes (spiracles) in the body surface to all the body tissues. The finest branches of the tracheae are called tracheoles.

Some spiders also have tracheae but, unlike insects, they possess gill-like lungs (book lungs) and rely on their circulatory system to transport gases throughout the body.

tracheid cell found in the water-conducting tissue (xylem) of many plants, including gymnosperms (conifers) and pteridophytes (ferns). It is long and thin with pointed ends.

The cell walls are thickened by lignin, except for numerous small rounded areas, or pits, through which water and dissolved

trachea The human trachea, or windpipe. The larynx, or voice box, lies at the entrance to the trachea. The two vocal cords are membranes that normally remain open and still. When they are drawn together, the passage of air makes them vibrate and produce sounds.

minerals pass from one cell to another. Once mature, the cell itself dies and only its walls remain.

tracheotomy or **tracheostomy** surgical opening in the windpipe (trachea), usually created for the insertion of a tube to enable the patient to breathe. It is done either to bypass an airway impaired by disease or injury, or to safeguard it during surgery or a prolonged period of mechanical ventilation.

trachoma chronic eye infection, resembling severe conjunctivitis. The conjunctiva becomes inflamed, with scarring and formation of pus, and there may be damage to the cornea. It is caused by a viruslike organism (*Chlamydia*), and is a disease of dry tropical regions. Although it responds well to antibiotics, numerically it remains the biggest single cause of blindness worldwide. There were 700 million people suffering from trachoma in Africa and the Middle East in 1996.

track in computing, part of the magnetic structure created on a disc surface during disc formatting so that data can be stored on it. The disc is first divided into circular tracks and then each circular track is divided into a number of sectors.

trackball input device that carries out the same function as a mouse, but remains stationary. In a trackball the ball controlling the cursor position is operated directly with the fingers.

tracking in computing, amount of space between text characters. Many word processing and page layout programs allow users to adjust tracking for a wide-spaced or slightly condensed appearance.

tracking agent chemical compound (most usually NPPD, nitrophenyl pentadiene) used in espionage. It is applied to people, clothes, and cars to trace their movements and contacts.

tradescantia any of a group of plants native to North and Central America, with variegated or striped leaves. The spiderwort *T. virginiana* is a cultivated garden plant; the wandering jew *T. albiflora*

is a common house plant, with green oval leaves tinged with pink or purple or silver-striped. They are named after English botanist John Tradescant the Younger. (Genus *Tradescantia*, family Commelinaceae.)

trade wind prevailing wind that blows towards the Equator from the northeast and southeast. Trade winds are caused by hot air rising at the Equator and the consequent movement of air from north and south to take its place. The winds are deflected towards the west because of the Earth's west-to-east rotation.

The unpredictable calms known as the doldrums lie at their convergence.

The trade-wind belts move north and south about 5° with the seasons. The name is derived from the obsolete expression 'blow trade' meaning to blow regularly, which indicates the trade winds' importance to navigation in the days of cargo-carrying sailing ships.

traffic in computing, messages sent over a network such as the Internet.

traffic vehicles using public roads. Traffic moves more slowly in London, New York, Tokyo and other cities around the world than it did when horses were used. Britons spend the equivalent of five-and-a-half days a year in traffic jams, while congestion costs the USA \$40 billion a year in lost production.

tragopan any of several species of bird of the genus *Tragopan*, a short-tailed pheasant living in wet forests along the S Himalayas. Tragopans are brilliantly coloured with arrays of spots, long crown feathers and two blue erectile crests. All have been reduced in numbers by destruction of their habitat. The western tragopan is the rarest, as a result of extensive deforestation.

Males inflate coloured wattles and throat pouches in their spring courtship displays.

tramway transport system for use in cities, where wheeled vehicles run along parallel rails. Trams are powered either by electric conductor rails below ground or by conductor arms connected to overhead wires. Greater manoeuvrability is achieved with the trolley bus, similarly powered by conductor arms overhead but without tracks.

trance mental state in which the subject loses the ordinary perceptions of time and space, and even of his or her own body.

In this highly aroused state, often induced by rhythmic music, 'speaking in tongues' (glossolalia) may occur; this usually consists of the rhythmic repetition of apparently meaningless syllables, with a euphoric return to normal consciousness. It is also practised by Native American and Australian Aboriginal healers, Afro-Brazilian spirit mediums, and in shamanism.

tranquillizer common name for any drug for reducing anxiety or tension (anxiolytic), such as benzodiazepines, barbiturates, antidepressants, and beta-blockers. The use of drugs to control anxiety is becoming much less popular, because most of the drugs available are capable of inducing dependence.

transactinide element any of a series of eight radioactive, metallic elements with atomic numbers that extend beyond the actinide series, those from 104 (rutherfordium) to 111 (ununilium). They are grouped because of their expected chemical similarities (they are all bivalent), the properties differing only slightly with atomic number. All have half-lives that measure less than two minutes.

transaction file in computing, a file that contains all the additions, deletions, and amendments required during file updating to produce a new version of a master file.

Trans-Alaskan Pipeline one of the world's greatest civil engineering projects, the construction of a pipeline to carry petroleum (crude oil) 1,285 km/800 mi from N Alaska to the ice-free port of Valdez. It was completed in 1977 after three years' work and much criticism by ecologists. In 1997 the Pipeline delivered more than 20% of US oil production.

The engineers had to elevate nearly half the pipeline on supports above ground level to avoid thawing the permafrost (permanently frozen ground), which would have caused much environmental damage. They also had to cross 600 rivers and streams and two mountain ranges, and allow for earthquakes.

transcription in living cells, the process by which the information for the synthesis of a protein is transferred from the ϕ DNA strand on which it is carried to the messenger ϕ RNA strand involved in the actual synthesis.

It occurs by the formation of ϕ base pairs when a single strand of unwound DNA serves as a template for assembling the complementary nucleotides that make up the new RNA strand.

transducer device that converts one form of energy into another. For example, a thermistor is a transducer that converts heat into an electrical voltage, and an electric motor is a transducer that converts an electrical voltage into mechanical energy. Transducers are important components in many types of ϕ sensors, converting the physical quantity to be measured into a proportional voltage signal.

transduction the transfer of genetic material between cells by an infectious mobile genetic element such as a virus. Transduction is used in ϕ genetic engineering to produce new varieties of bacteria.

transfermium element or **superheavy element** chemical element with an atomic number greater than 100 (the atomic number of fermium). Transfermium elements are all highly unstable and have existed only briefly, and because of this there is a continuing controversy over who should be credited with their discoveries. See also ϕ transuranic element.

transfer orbit elliptical path followed by a spacecraft moving from one orbit to another, designed to save fuel although at the expense of a longer journey time.

Space probes travel to the planets on transfer orbits. A probe aimed at Venus has to be 'slowed down' relative to the Earth, so that it enters an elliptical transfer orbit with its perigee (point of closest approach to the Sun) at the same distance as the orbit of Venus; towards Mars, the vehicle has to be 'speeded up' relative to the Earth, so that it reaches its apogee (furthest point from the Sun) at the same distance as the orbit of Mars. **Geostationary transfer orbit** is the highly elliptical path followed by satellites to be placed in ϕ geostationary orbit around the Earth (an orbit coincident with Earth's rotation). A small rocket is fired at the transfer orbit's apogee to place the satellite in geostationary orbit.

transfer orbit The transfer orbit used by a spacecraft when travelling from Earth to Mars. The orbit is chosen to minimize the fuel needed by the spacecraft; the craft is in free fall for most of the journey.

transformation in mathematics, a mapping or ϕ function, especially one which causes a change of shape or position in a geomet-

ric figure. ϕ Reflection, rotation, enlargement, and translation are the main geometrical transformations.

transformer device in which, by electromagnetic induction, an alternating current (AC) of one voltage is transformed to another voltage, without change of frequency. Transformers are widely used in electrical apparatus of all kinds, and in particular in power transmission where high voltages and low currents are utilized.

A transformer has two coils, a primary for the input and a secondary for the output, wound on a common iron core. The ratio of the primary to the secondary voltages (and currents) is directly (and inversely) proportional to the number of turns in the primary and secondary coils.

transfusion intravenous delivery of blood or blood products (plasma, red cells) into a patient's circulation to make up for deficiencies due to disease, injury, or surgical intervention.

Cross-matching is carried out to ensure the patient receives the right blood group. Because of worries about blood-borne disease, there is a growing interest in autologous transfusion with units of the patient's own blood 'donated' over the weeks before an operation.

Blood is rarely transfused whole. Blood cells and platelets are separated and resuspended in solution. Plasma can be frozen and is used to treat clotting deficiencies.

Blood transfusion, first successfully pioneered in humans in 1818, remained highly risky until the discovery of blood groups, by Austrian-born immunologist Karl Landsteiner in 1900, which indicated the need for compatibility of donated blood.

transgenic organism plant, animal, bacterium, or other living organism which has had a foreign gene added to it by means of ϕ genetic engineering.

transistor solid-state electronic component, made of ϕ semiconductor material, with three or more electrodes, that can regulate a current passing through it. A transistor can act as an amplifier, ϕ oscillator, photocell, or switch, and (unlike earlier thermionic valves) usually operates on a very small amount of power. Transistors commonly consist of a tiny sandwich of ϕ germanium or ϕ silicon, alternate layers having different electrical properties because they are impregnated with minute amounts of different impurities.

A crystal of pure germanium or silicon would act as an insulator (nonconductor). By introducing impurities in the form of atoms of other materials (for example, boron, arsenic, or indium) in minute amounts, the layers may be made either n-type, having an excess of electrons, or p-type, having a deficiency of electrons. This enables electrons to flow from one layer to another in one direction only.

Transistors have had a great impact on the electronics industry, and thousands of millions are now made each year. They perform many of the functions of the thermionic valve, but have the advantages of greater reliability, long life, compactness, and instantaneous action, no warming-up period being necessary. They are widely used in most electronic equipment, including portable radios and televisions, computers, and satellites, and are the basis of the ϕ integrated circuit (silicon chip). They were invented at Bell Telephone Laboratories in the USA in 1948 by John Bardeen and Walter Brattain, developing the work of William Shockley.

transistor-transistor logic (TTL) in computing, the type of integrated circuit most commonly used in building electronic products. In TTL chips the bipolar transistors are directly connected (usually collector to base). In mass-produced items, large numbers of TTL chips are commonly replaced by a small number of ϕ uncommitted logic arrays (ULAs), or logic gate arrays.

transit in astronomy, the passage of a smaller object across the visible disc of a larger one. Transits of the inferior planets occur when they pass directly between the Earth and the Sun, and are seen as tiny dark spots against the Sun's disc.

Other forms of transit include the passage of a satellite or its shadow across the disc of Jupiter and the passage of planetary surface features across the central meridian of that planet as seen from Earth. The passage of an object in the sky across the observer's meridian is also known as a transit.

transition in computing, way in which one image changes to another in a (slide show, animation or multimedia presentation.

Different transitions have a different effect on the viewer: slow mixes (fades) are gentler on the eye than sudden blackouts, and wipes – in which one scene replaces the next like a blind being pulled across the screen – are an especially dynamic type of transition.

transition metal any of a group of metallic elements that have incomplete inner electron shells and exhibit variable valency – for example, cobalt, copper, iron, and molybdenum. They are excellent conductors of electricity, and generally form highly coloured compounds.

translation in living cells, the process by which proteins are synthesized. During translation, the information coded as a sequence of nucleotides in messenger (mRNA) is transformed into a sequence of amino acids in a peptide chain. The process involves the 'translation' of the (genetic code. See also (transcription.

translation program in computing, a program that translates another program written in a high-level language or assembly language into the machine-code instructions that a computer can obey. See (assembler, compiler, and interpreter.

translocation in genetics, the exchange of genetic material between chromosomes. It is responsible for congenital abnormalities, such as Down's syndrome.

transmission electron microscope (TEM) the most powerful type of (electron microscope, with a resolving power ten times better than that of a (scanning electron microscope and a thousand times better than that of an optical microscope. A fine electron beam passes through the specimen, which must therefore be sliced extremely thinly – typically to about one-thousandth of the thickness of a sheet of paper (100 nanometres). The TEM can resolve objects 0.001 micrometres (0.04 millionth of an inch) apart, a gap that is 100,000 times smaller than the unaided eye can see.

A TEM consists of a tall evacuated column at the top of which is a heated filament that emits electrons. The electrons are accelerated down the column by a high voltage (around 100,000 volts) and pass through the slice of specimen at a point roughly half-way down. Because the density of the specimen varies, the 'shadow' of the beam falls on a fluorescent screen near the bottom of the column and forms an image. A camera is mounted beneath the screen to record the image.

The electron beam is controlled by magnetic fields produced by electric coils, called electron lenses. One electron lens, called the condenser, controls the beam size and brightness before it strikes the specimen. Another electron lens, called the objective, focuses the beam on the specimen and magnifies the image about 50 times. Other electron lenses below the specimen then further magnify the image.

The **high voltage transmission electron microscope (HVEM)** uses voltages of up to 3 million volts to accelerate the electron beam. The largest of these instruments is as tall as a three-storey building.

The first experimental TEM was built in 1931 by German scientists Max Knoll and Ernest Ruska of the Technische Hochschule, Berlin, Germany. They produced a picture of a platinum grid magnified 117 times. The first commercial electron microscope was built in England in 1936.

transparency in photography, a picture on slide film. This captures the original in a positive image (direct reversal) and can be used for projection or printing on positive-to-positive print material, for example by the Cibachrome or Kodak R-type process.

Slide film is usually colour but can be obtained in black and white.

transpiration the loss of water from a plant by evaporation. Most water is lost from the leaves through pores known as (stomata, whose primary function is to allow (gas exchange between the plant's internal tissues and the atmosphere. Transpiration from the leaf surfaces causes a continuous upward flow of water from the roots via the (xylem, which is known as the transpiration stream.

transpiration The loss of water from a plant by evaporation is known as transpiration. Most of the water is lost through the surface openings, or stomata, on the leaves. The evaporation produces what is known as the transpiration stream, a tension that draws water up from the roots through the xylem, water-carrying vessels in the stem.

transplant in medicine, the transfer of a tissue or organ from one human being to another or from one part of the body to another (skin grafting). In most organ transplants, the operation is for life-saving purposes, although the immune system tends to reject foreign tissue. Careful matching and immunosuppressive drugs must be used, but these are not always successful.

Corneal grafting, which may restore sight to a diseased or damaged eye, was pioneered in 1905, and is the oldest successful human transplant procedure. Of the internal organs, kidneys were first transplanted successfully in the early 1950s and remain most in demand. Modern transplantation also encompasses the heart, lungs, liver, pancreatic tissue, bone, and bone-marrow. In the USA 19,017 people received organ transplants in 1994.

Most transplant material is taken from cadaver donors, usually those suffering death of the (brainstem, or from frozen tissue

TRANSPLANTATION AND DONATION

<http://monroe.mcit.med.umich.edu/trans/transweb/>

This site includes organ and tissue transplantation and donation, the latest research developments, answers to commonly asked questions, and information about donation. It is supported by articles and reports from medical professionals.

Transplant: chronology

| | | | |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1682 | A Russian doctor used bone from a dog to repair the skull of an injured nobleman. The graft was reportedly successful, though it angered the Russian Orthodox church. | 1986 | British surgeons John Wallwork and Roy Calne perform the first triple transplant – heart, lung, and liver – at Papworth Hospital, Cambridge, England. |
| 1771 | Scottish surgeon John Hunter describes his experiments in the transplantation of tissues, including a human tooth into a cock's comb in <i>Treatise on the Natural History of Human Teeth</i> . | 1987 | The world's longest-surviving heart-transplant patient died in France, 18 years after his operation. A three-year-old girl in the USA receives a new liver, pancreas, small intestine, and parts of the stomach and colon; the first successful five-organ transplant. |
| 1905 | Corneal grafting, which may restore sight to a diseased or damaged eye, was pioneered. | 1989 | Grafts of fetal brain tissue were first used to treat Parkinson's disease. |
| 1950s | The kidneys were first transplanted successfully; kidney transplants were pioneered by British surgeon Roy Calne. Peter Medawar conducted vital research into the body's tolerance of transplanted organs and skin grafts. | 1990 | Nobel Prize for Medicine or Physiology was awarded to two US surgeons, Donall Thomas and Joseph Murray, for their pioneering work on organ and tissue transplantation. |
| 1964 | Chimpanzee kidneys were transplanted into humans in the USA, but with little success; in the UK a pig's heart valve was transplanted successfully and the operation became routine. | 1995 | The first experiments to use genetically altered animal organs in humans were given US government approval July – genetically altered pig livers were attached to the circulatory systems of patients whose livers had failed. An AIDS patient received a bone marrow transplant from a baboon but the graft failed to take. |
| 1967 | South African surgeon Christiaan Barnard performed the first human heart transplant. The 54-year-old patient lived for 18 days. | 1997 | Fetal nerve cells from pigs were injected into the brains of Parkinson's patients. In one case the cells survived for seven months. |
| 1969 | The world's first heart and lung transplant is performed at the Stanford Medical Centre, California, USA. | 1998 | (23 June) Cultured human neural cells were injected into the brain of a stroke victim. This was the first transplant of brain tissue used in stroke treatment and the first use of cultured cells rather than fetal tissue. |
| 1970 | The first successful nerve transplant is achieved in West Germany. | | |
| 1978 | Cyclosporin, an immunosuppressive drug derived from a fungus revolutionized transplant surgery by reducing the incidence and severity of rejection of donor organs. | | |
| 1982 | Janvik 7, an artificial heart made of plastic and aluminium was transplanted; the recipient lived another 112 days. | | |

banks. In rare cases, kidneys, corneas, and part of the liver may be obtained from living donors. Besides the shortage of donated material, the main problem facing transplant surgeons is rejection of the donated organ by the recipient's body. The 1990 Nobel Prize for Medicine or Physiology was awarded to two US surgeons, Donall Thomas and Joseph Murray, for their pioneering work on organ and tissue transplantation.

The first experiments to use genetically altered animal organs in humans were given US government approval in July 1995 – genetically altered pig livers were attached to the circulatory systems of patients who were near death or whose livers had failed. Need for the tests had arisen due to a shortage of human organs available for transplant.

It is infinitely better to transplant a heart than to bury it to be eaten by worms.

CHRISTIAAN BARNARD South African surgeon.
Time 31 October 1969

transposon or **jumping gene** segment of DNA able to move within or between chromosomes. Transposons trigger changes in gene expression by shutting off genes or causing insertion mutations.

The origins of transposons are obscure, but geneticists believe some may be the remnants of viruses that have permanently integrated their genes with those of their hosts. They were first identified by US geneticist Barbara McClintock in 1947.

transputer in computing, a member of a family of microprocessors designed for parallel processing, developed in the UK by Inmos. In the circuits of a standard computer the processing of data takes place in sequence; in a transputer's circuits processing takes place in parallel, greatly reducing computing time for those programs that have been specifically written for it.

The transputer implements a special programming language called OCCAM, which Inmos based on CSP (communicating sequential processes), developed by C A R Hoare of Oxford University Computing Laboratory.

Though backed by the British government, Inmos was not commercially successful. It was taken over by UK company Thorn-EMI

in 1984 and traded to the French-Italian electronics company SGS-Thomson in 1989.

transsexual person who identifies himself or herself completely with the opposite sex, believing that the wrong sex was assigned at birth. Unlike transvestites, who desire to dress in clothes traditionally worn by the opposite sex; transsexuals think and feel emotionally in a way typically considered appropriate to members of the opposite sex, and may undergo surgery to modify external sexual characteristics.

In 1995 Dutch researchers identified a structural difference between the brains of transsexual men and other men. Within the brain a small cluster of cells, the bed nucleus of the stria terminalis (BST), is smaller in women than men. Transsexual males in the study were found to have a female-sized BST. Research is continuing into the significance of this finding.

Trans-Siberian Railway the world's longest single-service railway, connecting the cities of European Russia with Omsk, Novosibirsk, Irkutsk, and Khabarovsk, and terminating at Nakhodka on the Pacific coast east of Vladivostok. The line was built between 1891 and 1915, and has a total length of 9,289 km/5,772 mi, from Moscow to Vladivostok.

The greater part of the Trans-Siberian Railway was completed in record time in the period 1891–99. The line opened up the regions of Siberia and the Far East to extensive Russian colonization. It also enabled large-scale geological prospecting of the Kuznetsk, Karaganda, Ekibastuz and Cherekhovo coal basins and of the Amur and Kolyma gold deposits to be carried out, which laid the basis for the economic development of Siberia. The Trans-Mongolian Railway branches off at Lake Baikal and travels via the Mongolian capital Ulan-Bator to Beijing. At Tarskaya, almost 3,000 km west of Vladivostok, the Trans-Siberian meets the Trans-Manchurian Railway, which reaches Beijing via Harbin. A new northern rail route across Siberia, the Baikal-Amur Mainline (BAM), stretching 3,102 km/1,928 mi from Ust-Kut to the Pacific, was officially opened in 1991 after seventeen years' work.

transuranic element or **transuranium element** chemical element with an atomic number of 93 or more – that is, with a greater number of protons in the nucleus than has uranium. All transuranic elements are radioactive. Neptunium and plutonium are found in nature; the others are synthesized in nuclear reactions.

First Organ Transplants

BY PAULETTE PRATT

Although transplantation may sound wholly contemporary, it is not really all that new. The term 'transplant', for instance, is thought to have been coined by the renowned 18th-century Scottish surgeon John Hunter (1728-93) in describing animal experiments. The oldest transplant procedure is corneal grafting, pioneered by an eye surgeon called Eduard Zirm in the small town of Olmutz in Moravia in 1905.

Throughout the early years of this century experimentation continued in animals. An early pioneer was the French-American surgeon Alexis Carrel, working at the Rockefeller Institute in New York. Besides switching around dogs' hearts, he developed the techniques of surgical anastomosis - reconnecting severed blood vessels - which would be essential to major surgery in general and certainly to transplant operations.

Carrel received the Nobel prize for this work in 1912 and, two years later, informed the International Surgical Association: 'The surgical side of transplantation of organs is completed as we are now able to perform transplantation of organs with perfect ease... All our efforts must now be directed toward the biological methods which will prevent the reaction of the organism against foreign tissue.'

However, almost two decades were to pass before anyone tried transplanting organs in human beings. Between 1933 and 1939 the Russian surgeon Voronoy, working in the Ukraine, made six attempts to graft cadaver kidneys into very sick patients, all of which failed. Next, in 1946, US surgeons used a cadaver graft in a bid to save a patient who was in acute kidney failure due to septicaemia. This worked only in that the patient's own kidneys resumed their function within two days.

The major problem was that of rejection, the body's destructive response to 'foreign' tissue. Although the phenomenon was widely recognized by the mid 20th century, no one understood how it came about. So, in 1953, when surgeons in Paris made the first attempt at grafting a kidney from a living donor - mother to son - the organ functioned well for three weeks, until rejection set in.

Finally, the world's first truly successful organ transplant took place in December 1954, when surgeons at the Peter Bent Brigham Hospital in Boston opted for the only formula where rejection does not occur: a transplant between identical twins. They removed one of Robert Herrick's kidneys and grafted it into his brother, Richard, who was dying of kidney failure. Robert made an uneventful recovery and lived quite normally with a single kidney; Richard lived for a further eight years.

This historic operation established the procedure still in use today, whereby in most cases the non-functioning kidneys are left in place and the donor kidney is inserted in the recipient's lower abdomen, usually on the right-hand side; it is connected via the ureter to the bladder. Once the blood vessels are anastomosed (connected together) and circulation is established, the grafted kidney may begin producing urine before the surgeons have had time to close (though some may not function for several weeks).

However, following the success in Boston, further attempts at kidney grafting ended in failure, except in the case of identical twins. The survival rate hardly improved even when patients were

exposed to total body irradiation to knock out the immune system and given anti-cancer drugs against rejection. Now, with their own body defences obliterated, most kidney recipients died from infection.

A number of developments in the early 1960s however, began to transform renal grafting from an experimental procedure into a viable option for end-stage kidney disease. First came the introduction of tissue typing - matching donor and recipient for compatibility in order to minimize the strength of the immune response. Then, in 1962, came the major breakthrough: the appearance of azathioprine, the first effective anti-rejection drug. The following year a steroid drug, prednisone, was added and the two-drug combination formed the basis of immunosuppressive treatment for many years.

Meanwhile, pioneering attempts to transplant other organs proved considerably more problematic. The first human being to undergo liver transplantation, a three-year-old boy with biliary atresia, died on the operating table in Denver, Colorado, in 1963. Few patients undergoing this formidable procedure - one of the most challenging in the entire surgical repertoire - survived in the early years.

In 1967, researchers at Stanford University in California, who had been experimenting with cardiac transplantation for years, were pipped at the post when the South African surgeon Christiaan Barnard performed the world's first human heart transplant. The patient, 54-year-old Louis Washkansky, seemed to spend most of the remaining 18 days of his life in front of television cameras before finally dying from pneumonia. Further attempts were made at various centres but the results were so disastrous that heart transplantation had to virtually be abandoned for more than a decade.

Still the twin spectres haunting the transplant scene were infection and rejection. It was very hard to get the formula right. Except in the case of kidney grafting, where there was the fall-back of dialysis, if organ recipients received insufficient immunosuppression they died of rejection; or, if the immune system was knocked out completely, they succumbed to infection. It was mainly the arrival of the powerful new anti-rejection drug cyclosporin - available from 1980 onwards - that transformed the picture.

Today there is a whole range of life-saving transplants available - kidney, liver, heart, lung(s), pancreas and small bowel. Except for kidney transplants, none of these procedures would be possible without the life-support technology developed over the last few decades. Ventilators, for instance, are used to maintain the brainstem-dead donors who are the main source of organs for grafting; the ventilator, too, sustains the recipient's breathing during and immediately after surgery. The heart-lung machine, introduced in 1953, is essential in major transplants where the recipient's own circulation has to be interrupted.

With all this high-profile activity, too often overlooked are the more humdrum grafts - of tissues such as skin, bone, joints, nerves and corneas - which can restore mobility, sensation or sight or prevent loss of a limb. Other than blood, bone is now the most frequently grafted tissue worldwide.

transverse wave A wave in which the displacement of the medium's particles is at right-angles to the direction of travel of the wave motion.

transverse wave The diagram illustrates the motion of a transverse wave. Light waves are examples of transverse waves: they undulate at right angles to the direction of travel and are characterized by alternating crests and troughs. Simple water waves, such as the ripples produced when a stone is dropped into a pond, are also examples of transverse waves.

trapezium A trapezium is a four-sided plane figure with two of its sides parallel.

trapezium (US *trapezoid*) in geometry, a four-sided plane figure (quadrilateral) with two of its sides parallel. If the parallel sides have lengths a and b and the perpendicular distance between them is h (the height of the trapezium), its area $A = \frac{1}{2}h(a+b)$.

An isosceles trapezium has its sloping sides equal, and is symmetrical about a line drawn through the midpoints of its parallel sides.

travel graph type of distance-time graph which shows the stages of a journey. Stops on the journey are shown as horizontal lines. Travel graphs can be used to find out where vehicles will overtake each other or meet if travelling in opposite directions.

travel sickness nausea and vomiting caused by the motion of cars, boats, or other forms of transport. Constant vibration and movement may stimulate changes in the fluid of the semicircular canals (responsible for balance) of the inner ear, to which the individual fails to adapt, and to which are added visual and psychological factors. Some proprietary remedies contain antihistamine drugs.

Space sickness is a special case: in weightless conditions normal body movements result in unexpected and unfamiliar signals to the brain. Astronauts achieve some control of symptoms by wedging themselves in their bunks.

tree perennial plant with a woody stem, usually a single stem (trunk), made up of wood and protected by an outer layer of bark. It absorbs water through a root system. There is no clear dividing line between shrubs and trees, but sometimes a minimum achievable height of 6 m/20 ft is used to define a tree.

angiosperms A tree-like form has evolved independently many times in different groups of plants. Among the angiosperms, or flowering plants, most trees are dicotyledons. This group includes trees such as oak, beech, ash, chestnut, lime, and maple, and they are often referred to as broad-leaved trees because their leaves are broader than those of conifers, such as pine and spruce. In temperate regions angiosperm trees are mostly deciduous (that is, they lose their leaves in winter), but in the tropics most angiosperm trees are evergreen. There are fewer trees among the gymnocotyledons, but the palms and bamboos (some of which are tree-like) belong to this group.

gymnosperms The gymnosperms include many trees and they are classified into four orders: Cycadales (including cycads and sago palms), Coniferales (the conifers), Ginkgoales (including only one living species, the ginkgo, or maidenhair tree), and Taxales (including yews). Apart from the ginkgo and the larches (conifers), most gymnosperm trees are evergreen.

tree ferns There are also a few living trees in the opteridophyte group, known as tree ferns. In the swamp forests of the Carboniferous era, 300 million years ago, there were giant tree-like horsetails and club mosses in addition to the tree ferns.

oldest trees The world's oldest living trees are found in the Pacific forest of North America, some more than 2,000 years old.

tree-and-branch filing system in computing, a filing system where all files are stored within directories, like folders in a filing

tree-and-branch filing system The directory filing structure used by computers. The structure can be likened to an upside-down tree, with the root at the top, branching downwards and outwards into sub-directories.

cabinet. These directories may in turn be stored within further directories. The root directory contains all the other directories and may be thought of as equivalent to the filing cabinet. Another way of picturing the system is as a tree with branches from which grow smaller branches, ending in leaves (individual files).

tree creeper small, short-legged bird of the family Certhiidae, which spirals with a mouselike movement up tree trunks searching for food with its thin down-curved beak.

The common tree creeper *Certhia familiaris* is 12 cm/5 in long, brown above, white below, and is found across Europe, N Asia, and North America.

tree diagram in probability theory, a branching diagram consisting only of arcs and nodes (but not loops curving back on themselves), which is used to establish probabilities.

tree rings rings visible in the wood of a cut tree; see *annual rings*.

trefoil any of several clover plants of a group belonging to the pea family, the leaves of which are divided into three leaflets. The name is also used for other plants with leaves divided into three lobes. (Genus *Trifolium*, family Leguminosae.)

Bird's-foot trefoil *Lotus corniculatus*, also belonging to the pea family, is a low-growing perennial found in grassy places throughout Europe, N Asia, parts of Africa, and Australia. It has five leaflets to each leaf, but the first two are bent back so it appears to have only three. The yellow flowers, often tinged orange or red, are borne in heads with only a few blooms. Hop trefoil *T. campestre* has leaves with only three leaflets and tight-packed round heads of yellow flowers about 1.5 cm/0.6 in across. It also grows in grassy places throughout Europe, W Asia, N Africa, and North America. In Australia, Austral trefoil *Lotus australis* is a widespread native with pink or white flowers. It is suspected of being poisonous.

trematode parasitic flatworm with an oval non-segmented body, of the class Trematoda, including the fluke.

tremor minor earthquake.

trepan sea cucumbers used as food.

triangle in geometry, a three-sided plane figure, the sum of whose interior angles is 180°. Triangles can be classified by the relative lengths of their sides. A scalene triangle has three sides of unequal length; an isosceles triangle has at least two equal sides; an equilateral triangle has three equal sides (and three equal angles of 60°).

triangle of forces method of calculating the force (the resultant) produced by two other forces. It is based on the fact that if three forces acting at a point can be represented by the sides of a triangle, the forces are in equilibrium. See *parallelogram of forces*.

triangulation technique used in surveying and navigation to determine distances, using the properties of the triangle. To begin, surveyors measure a certain length exactly to provide a base line. From each end of this line they then measure the angle to a distant point, using a theodolite. They now have a triangle in which they know the length of one side and the two adjacent angles. By simple trigonometry they can work out the lengths of the other two sides.

To make a complete survey of the region, they repeat the process, building on the first triangle.

Triassic period of geological time 245–208 million years ago, the first period of the Mesozoic era. The continents were fused together to form the world continent Pangea. Triassic sediments contain remains of early dinosaurs and other reptiles now extinct. By late Triassic times, the first mammals had evolved.

tribology the science of friction, lubrication, and lubricants. It studies the origin of frictional forces, the wearing of interacting surfaces, and the problems of efficient lubrication.

tributyl tin (TBT) chemical used in antifouling paints on ships' hulls and other submarine structures to deter the growth of barnacles. The tin dissolves in sea water and enters the food chain. It can cause reproductive abnormalities – exposed female whelks develop penises; the use of TBT has therefore been banned in many countries, including the UK.

triceratops any of a genus *Triceratops* of massive, horned dinosaurs of the order Ornithischia. They had three horns and a neck frill and were up to 8 m/25 ft long; they lived in the Cretaceous period.

trichloromethane technical name for chloroform.

triconodonta one of the oldest orders of fossil mammals. Triconodonts lived in Jurassic times and were small in size. They had a characteristic dentition, with each tooth bearing three conical cusps.

tricuspid valve flap of tissue situated on the right side of the heart between the atrium and the ventricle. It prevents blood flowing backwards when the ventricle contracts.

As in all valves, its movements are caused by pressure changes during the beat rather than by any intrinsic muscular activity. As the valve snaps shut, a vibration passes through the chest cavity and is detectable as the first sound of the heartbeat.

triggerfish any marine bony fish of the family Balistidae, with a laterally compressed body, up to 60 cm/2 ft long, and a deep belly. They have small mouths but strong jaws and teeth. The first spine on the dorsal fin locks into an erect position, allowing them to fasten themselves securely in crevices for protection; it can only be moved by depressing the smaller third ('trigger') spine.

There are many species, found mainly in warm waters, and some are very colourful.

trigger plant any of a group of grasslike plants, with most species occurring in Australia. Flowers of the trigger plant are fertilized by insects trapped by a touch-sensitive column within the flower. In struggling to free themselves, the insects become covered in pollen, which they then spread to other flowers after escaping (Genus *Stylidium*, family Stylidiaceae.)

Equilateral triangle: all the sides are the same length; all the angles are equal to 60°

Isosceles triangle: two sides and two angles are the same

Scalene triangle: all the sides and angles are different

Acute-angle triangle: each angle is acute (less than 90°)

Obtuse-angle triangle: one angle is obtuse (more than 90°)

Right-angle triangle: one angle is 90° ; the *hypotenuse* is the side opposite the right angle

Triangles are congruent if

Similar triangles have

triglyceride chemical name for $\dot{\text{O}}$ fat comprising three fatty acids reacted with a glycerol.

trigonometry branch of mathematics that solves problems relating to plane and spherical triangles. Its principles are based on the fixed proportions of sides for a particular angle in a right-angled triangle, the simplest of which are known as the $\dot{\text{O}}$ sine, $\dot{\text{O}}$ cosine, and $\dot{\text{O}}$ tangent (so-called trigonometrical ratios). Trigonometry is of practical importance in navigation, surveying, and simple harmonic motion in physics.

Using trigonometry, it is possible to calculate the lengths of the sides and the sizes of the angles of a right-angled triangle as long as one angle and the length of one side are known, or the lengths of two sides. The longest side, which is always opposite to the right angle, is called the **hypotenuse**. The other sides are named depending their position relating to the angle that is to be found or used: the side opposite this angle is always termed **opposite** and that adjacent is the **adjacent**. So the following trigonometrical ratios are used:

$$\text{sine} = \frac{\text{opposite}}{\text{hypotenuse}}$$

$$\text{cosine} = \frac{\text{adjacent}}{\text{hypotenuse}}$$

$$\text{tangent} = \frac{\text{opposite}}{\text{adjacent}}$$

for any right-angled triangle with angle θ as shown the trigonometrical ratios are

$$\sin(\theta) = \frac{BC}{AB} = \frac{\text{opposite}}{\text{hypotenuse}}$$

$$\cos \theta = \frac{AC}{AB} = \frac{\text{adjacent}}{\text{hypotenuse}}$$

$$\tan \theta = \frac{BC}{AC} = \frac{\text{opposite}}{\text{adjacent}}$$

trigonometry At its simplest level, trigonometry deals with the relationships between the sides and angles of triangles. Unknown angles or lengths are calculated by using trigonometrical ratios such as sine, cosine, and tangent. The earliest applications of trigonometry were in the fields of navigation, surveying, and astronomy, and usually involved working out an inaccessible distance such as the distance of the Earth from the Moon.

large variations in the current. The triode was commonly used in amplifiers but has now been almost entirely superseded by the $\dot{\text{O}}$ transistor.

triple bond three covalent bonds between adjacent atoms, as in the $\dot{\text{O}}$ alkynes ($\text{C}\equiv\text{C}$).

triple nose-leaf bat one of many threatened bats in Africa, *Trinaeops persicus* is found scattered along much of the coastal regions of E Africa and faces threats from disturbance of the caves in which it breeds. Tourism development, resulting in disturbance to coral caves which the bats inhabit, is a particular problem.

triploblastic in biology, having a body wall composed of three layers. The outer layer is the **ectoderm**, the middle layer the **mesoderm**, and the inner layer the **endoderm**. This pattern of development is shown by most multicellular animals (including humans).

triticale cereal crop of recent origin that is a cross between wheat *Triticum* and rye *Secale*. It can produce heavy yields of high-protein grain, principally for use as animal feed.

tritium radioactive isotope of hydrogen, three times as heavy as ordinary hydrogen, consisting of one proton and two neutrons. It has a half-life of 12.5 years.

Triton in astronomy, the largest of Neptune's moons. It has a diameter of 2,700 km/1,680 mi, and orbits Neptune every 5.88 days in a retrograde (east to west) direction. It takes the same time to rotate about its own axis as it does to make one revolution of Neptune.

It is slightly larger than the planet Pluto, which it is thought to resemble in composition and appearance. Probably Triton was formerly a separate body like Pluto but was captured by Neptune. Triton was discovered in 1846 by British astronomer William Lassell (1799–1880) only weeks after the discovery of Neptune. Triton's surface, as revealed by the *Voyager 2* space probe, has a

TRIGONOMETRIC FUNCTIONS

http://www-history.mcs.st-and.ac.uk/~history/HistTopics/Trigonometric_functions.html

History of the development of the trigonometric functions in mathematics. The site also explains the basic principles of the use of these functions and details the role they have played in the advancement of other branches of mathematics. Biographical details of the mathematicians chiefly responsible for the discovery of trigonometry are also available here.

triiodomethane technical name for $\dot{\text{O}}$ iodoform.

trillium any of a group of perennial herbaceous woodland plants belonging to the lily family, native to Asia and North America. They have a circle, or whorl, of three leaves around the stem, at the end of which the single flower has three green $\dot{\text{O}}$ sepals and three usually maroon or white petals. The nodding trillium *T. cernuum* ranges across most of the eastern half of North America. (Genus *Trillium*, family Liliaceae.)

trilobite any of a large class (Trilobita) of extinct, marine, invertebrate arthropods of the Palaeozoic era, with a flattened, oval body, 1–65 cm/0.4–26 in long. The hard-shelled body was divided by two deep furrows into three lobes. There existed more than 1,500 genera of trilobites.

Some were burrowers, others were swimming and floating forms. Their worldwide distribution, many species, and the immense quantities of their remains make them useful in geological dating.

Triton in computing, $\dot{\text{O}}$ monitor based on a $\dot{\text{O}}$ cathode-ray tube developed by $\dot{\text{O}}$ Sony, designed to give a sharper image and more uniform brightness than conventional monitors.

triode three-electrode thermionic $\dot{\text{O}}$ valve containing an anode and a cathode (as does a $\dot{\text{O}}$ diode) with an additional negatively biased control grid. Small variations in voltage on the grid bias result in

temperature of 38K (-235°C/-391°F), making it the coldest known place in the solar system. It is covered with frozen nitrogen and methane, some of which evaporates to form a tenuous atmosphere with a pressure only 0.00001 that of the Earth at sea level. Triton has a pink south polar cap, probably coloured by the effects of solar radiation on methane ice. Dark streaks on Triton are thought to be formed by geysers of liquid nitrogen. The surface has few impact craters (the largest is the Mazomba, with a diameter of 27 km/17 mi), indicating that many of the earlier craters have been erased by the erupting and freezing of water (cryovolcanism).

trogon Greek *trogein* 'to gnaw' any species of the family Trogonidae, order Trogoniformes, of tropical birds, up to 50 cm/1.7 ft long, with resplendent plumage, living in the Americas, Africa, and Asia. They are primarily birds of forest or woodland, living in trees. Their diet consists mainly of insects and other arthropods, and sometimes berries and other fruit. Most striking is the quetzal.

troilite FeS, probable mineral of the Earth's core, abundant in meteorites.

Trojan in computing, a program that looks as though it will do something entertaining or useful but actually does something else, such as reformatting the user's hard disc. Trojans are named after the Trojan horse in Greek mythology. A virus is not a Trojan, but inserting a virus into another program – such as virus checker – would make that program a Trojan.

trolling in computing, mischievously posting a deliberately erroneous or obtuse message to a newsgroup in order to tempt others to reply – usually in a way that makes them appear gullible, intemperate or foolish.

tropical cyclone another term for hurricane.

tropical disease any illness found mainly in hot climates. The most important tropical diseases worldwide are malaria, leishmaniasis, sleeping sickness, lymphatic filariasis, and schistosomiasis. Other major scourges are Chagas's disease, leprosy, and river blindness. Malaria kills about 1.5 million people each year, and produces chronic anaemia and tiredness in 100 times as many, while schistosomiasis is responsible for 1 million deaths a year. All the main tropical diseases are potentially curable, but the facilities for diagnosis and treatment are rarely adequate in the countries where they occur.

tropics the area between the tropics of Cancer and Capricorn, defined by the parallels of latitude approximately 23°30' N and S of the Equator. They are the limits of the area of Earth's surface in which the Sun can be directly overhead. The mean monthly temperature is over 20°C/68°F.

Climates within the tropics lie in parallel bands. Along the Equator is the intertropical convergence zone, characterized by high temperatures and year-round heavy rainfall. Tropical rainforests are found here. Along the tropics themselves lie the tropical high-pressure zones, characterized by descending dry air and desert conditions. Between these, the conditions vary seasonally between wet and dry, producing the tropical grasslands.

tropine C₈H₁₁NO poisonous crystalline solid formed by the hydrolysis of the alkaloid atropine.

tropism or **tropic movement** the directional growth of a plant, or part of a plant, in response to an external stimulus such as gravity or light. If the movement is directed towards the stimulus it is described as positive; if away from it, it is negative. **Geotropism** for example, the response of plants to gravity, causes the root (positively geotropic) to grow downwards, and the stem (negatively geotropic) to grow upwards.

Phototropism occurs in response to light, **hydrotropism** to water, **chemotropism** to a chemical stimulus, and **thigmotropism**, or **haptotropism**, to physical contact, as in the tendrils of climbing plants when they touch a support and then grow around it.

Tropic movements are the result of greater rate of growth on one side of the plant organ than the other. Tropism differs from a nastic movement in being influenced by the direction of the stimulus.

troposphere lower part of the Earth's atmosphere extending about 10.5 km/6.5 mi from the Earth's surface, in which temperature decreases with height to about -60°C/-76°F except in local layers of temperature inversion. The **tropopause** is the upper boundary of the troposphere, above which the temperature increases slowly with height within the atmosphere. All of the Earth's weather takes place within the troposphere.

trout any of various bony fishes in the salmon family, popular for sport and food, usually speckled and found mainly in fresh water. They are native to the northern hemisphere. Trout have thick bodies and blunt heads, and vary in colour. The common trout *Salmo trutta* is widely distributed in Europe, occurring in British fresh and coastal waters. Sea trout are generally silvery and river trout olive-brown, both with spotted fins and sides.

In the USA, the name 'trout' is given to various species, notably to the rainbow trout *S. gairdneri*, which has been naturalized in many other countries.

Troy (Latin *Ilium*) ancient city (now Hissarlik or Hisarlik in Turkey) of Asia Minor, just S of the Dardanelles, besieged in the legendary ten-year Trojan War (mid-13th century BC), as described in Homer's *Iliad*. According to the legend, the city fell to the Greeks, who first used the stratagem of leaving behind, in a feigned retreat, a large wooden horse containing armed infiltrators to open the city's gates. Believing it to be a religious offering, the Trojans took it within the walls.

Nine cities found one beneath another were originally excavated by Heinrich Schliemann 1874-90. Recent research suggests that the seventh, sacked and burned about 1250 BC, is probably the Homeric Troy, which was succeeded by a shanty town which was sacked after 800 BC. The later city of Ilium was built on the same site in the 7th century BC, and survived to the Roman period. It has been suggested that Homer's tale of war might have a basis in fact, for example, a conflict arising from trade rivalry (Troy was on a tin trade route), which might have been triggered by such an incident as Paris running off with Helen. The wooden horse may have been a votive offering for Poseidon (whose emblem was a horse) left behind by the Greeks after an earthquake had opened breaches in the city walls.

troy system system of units used for precious metals and gems. The pound troy (0.37 kg) consists of 12 ounces (each of 120 carats) or 5,760 grains (each equal to 65 mg).

TrueType scalable font system, jointly developed by Apple and Microsoft. It allows scalable fonts to be used by non-PostScript printers. Such printers are usually cheaper.

truffle any of a group of underground fungi (see fungus), certain of which are highly valued as edible delicacies; in particular, the species *Tuber melanosporum*, generally found growing under oak trees. It is native to the Périgord region of France but is cultivated in other areas as well. It is rounded, blackish-brown, externally covered with warts, and has blackish flesh. (Order Tuberales.)

Dogs and pigs are traditionally used to sniff out truffles, but in 1990 an artificial 'nose' developed at the University of Manchester Institute of Science and Technology, England, proved more effective in tests in Bordeaux.

Trumpet in computing, popular shareware TCP/IP program for Windows or MS-DOS.

trumpeter any South American bird of the genus *Psophia*, family Psophiidae, order Gruiformes, up to 50 cm/20 in tall, related to the cranes. Trumpeters have long legs, a short bill, and dark plumage. The trumpeter swan is unrelated.

P. crepitans is a bird of lustrous and brilliantly-coloured plumage and is often domesticated. There are three species; very little is known about any of them in the wild.

Tropical Diseases (and How to Avoid Them)

BY KEITH WALLBANKS

The concept of 'tropical disease' first arose when Victorian Europeans explored the tropics and encountered diseases, in areas such as the 'white man's grave' in West Africa, with which they were unfamiliar. However, it now usually encompasses all the diseases of the tropics, including those, such as tuberculosis, which are also common in temperate regions.

It is difficult for most of us to grasp the impact of tropical diseases on the human race because the numbers are so large. Of the 52 million deaths in 1996, for example, 40 million occurred in the developing world and 17 million of these (nearly three times the number killed by cancers worldwide) were caused by infectious or parasitic disease. Such disease accounts for 45% of all deaths in developing countries, compared with just over 1% in the rest of the world.

Disease in the tropics may be caused by poor nutrition, environmental factors and/or by living organisms such as fungi (ringworm, athlete's foot), viruses (polio, hepatitis A and B, yellow fever, some forms of meningitis), bacteria (travellers' diarrhoea, typhoid, cholera, tetanus, tuberculosis, leprosy, legionnaires' disease, other forms of meningitis), the single-celled organisms known as protozoa (malaria, sleeping sickness, amoebic dysentery, Chagas's disease, leishmaniasis) and the worms known as nematodes (elephantiasis, river blindness, Guinea worm, hookworm, *Strongyloides*), trematodes (bilharzia) and cestodes (tapeworms, hydatid disease). Each of the living organisms has to get below the surface of the skin to survive. Some of the fungi live in the keratin just below the surface but the other pathogens need to get deeper, often into the bloodstream or gut. Several of them (the bacteria causing typhoid, cholera, other causes of diarrhoea, the amoebae causing dysentery, the *Ascaris* roundworm, Guinea worm, hepatitis A virus and tapeworms) rely on us to swallow them in food or water or to ingest them accidentally as we touch our mouths with unclean hands. Other pathogens (some hepatitis B and human immunodeficiency viruses (HIV)) rely on openings in the skin, caused by accident or injection, to gain access to the bloodstream, although HIV, hepatitis B and gonorrhoea are mainly spread by sexual contact between men and women. As 30% of the populations of some towns in the tropics now carry HIV, sex (particularly unprotected sex) with a new partner is a life-threatening gamble. The bacteria causing tuberculosis are drawn into our lungs from the air and those causing leprosy are mostly passed on in sneezes. A few parasites have stages in their life cycles which simply burrow into our skin, either from the soil (hookworm, *Strongyloides*) or water (bilharzia). Some of the most successful parasites of humans (those causing malaria, sleeping sickness, river blindness, elephantiasis, yellow fever and leishmaniasis) spend part of their life cycle in insects (called the vectors of the pathogens) which distribute the parasites and later transmit them to humans as the insects feed. The parasites causing malaria and elephantiasis use mosquitoes in this way, the nematodes of river blindness use blackflies (which breed in rivers, hence the name) and the trypanosomes of sleeping sickness and Chagas's disease use tsetse flies and bugs, respectively. Clean insects acquire the parasites when they feed on an infected individual. Most of the parasites do not simply use the vectors for distribution but also multiply and develop within them, the vectors acting as intermediate hosts of the parasites and humans as the definitive hosts. Freshwater snails act as the intermediate hosts of the schistosomes causing bilharzia, and pork and beef tapeworms use pigs and cattle, respectively, in a similar way.

Malaria remains one of the most important human parasitic diseases. More than two-fifths of the world's population live in the 100 countries where transmission of malaria occurs and there are about 400 million clinical cases of malaria each year (1.5–2.7 million of them fatal). Human malaria may be caused by any of four species: *Plasmodium falciparum*, *Plasmodium vivax* and the

rarer *Plasmodium ovale* and *Plasmodium malariae*. Although only one of these species (*P. falciparum*) causes fatal infections, it is this species which is the most common and widespread, being present in 92 of the 100 countries where malaria transmission occurs. In fact, *P. falciparum* may cause more illness and deaths in humans than any other pathogen on Earth.

The malarial parasite injected by a feeding mosquito passes to the liver and multiplies there for a week or two. It then emerges, invades the red blood cells and multiplies again until the blood cells rupture and the released parasites invade more cells. It is the rupture of the infected red cells, which occurs more or less at the same time (every 2–3 days), that causes the first symptom of malaria: intermittent fever. After a while, some of the parasites breaking out of the blood cells develop into the sexual forms which are capable of infecting mosquitoes. Liver and kidney failure, severe anaemia, convulsions, coma and/or death may develop in falciparum malaria. As malarial parasites in the liver are not affected by the majority of anti-malarial drugs in the bloodstream, any traveller who is infected in the last few days of their trip returns home with viable parasites. All travellers at risk of malaria must therefore continue to take anti-malarials for 4 weeks after leaving a malarious area, so that parasites emerging from the liver to infect the blood cells are killed. Two species causing human malaria (*P. vivax* and *P. ovale*) have special stages, called hypnozoites, which can lie dormant in the liver for months and sometimes years, and cause attacks of malaria when they eventually become active.

The relationship between an individual's natural resistance to disease (their level of immunity) and the severity of their suffering is an important one. Those who live in countries where tropical diseases are common are often exposed to the diseases many times and those that survive may have high levels of immunity to them. One individual infected with *P. falciparum* may stay healthy whereas another, infected in exactly the same way but without any immunity to the infection, may die within 24 h. This is why a traveller to such countries may suffer when all around appear healthy.

The recent increase in the numbers of visitors to the tropics has meant that more of those from the developed world are putting themselves at risk of acquiring a tropical disease and of taking it home. Although there is usually little risk of the returned traveller passing on their disease, there is a major risk that it will not be diagnosed or treated correctly, simply because local physicians are unfamiliar with its signs and symptoms or fail to consider it. The symptoms and signs of malaria are so non-specific that local physicians often take them to indicate influenza or gastritis unless the sick traveller mentions that they have visited a malarious area in the last year or more. Of those returning to the UK or USA and eventually dying of falciparum malaria, for example, almost 50% are misdiagnosed as cases of influenza or of another viral infection when first examined by their physicians. Fatal infectious or parasitic disease is fortunately rare in travellers to the tropics and accounts for only a small proportion of deaths in this group (most of the deaths are caused by accidents, especially road traffic accidents, while the travellers are drunk or by cardiovascular disease in the older traveller). The commonest afflictions the traveller to a developing country is likely to suffer are, in descending frequency, sunburn, diarrhoea and vomiting (usually caused by *Escherichia coli* and of a few days' duration), malaria, acute infection of the respiratory tract (with fever) and hepatitis A. The chances of acquiring some of the perhaps better known diseases, such as leprosy, are virtually nil.

Anyone from a temperate country planning to visit a tropical country can take many steps to reduce their chances of developing a health problem as a result (prevention is always better than cure, particularly when the disease involved may be rapidly fatal and

difficult to treat). It is important to be aware of the risks and how to avoid or minimize them. People should educate themselves by contacting local travel health clinics, reading recent guides or exploring the World Wide Web; one of the best Web sites on travel health is run by the 'Centers for Disease Control' in the USA (<http://www.cdc.gov>). Just in case a severe problem arises, travel insurance should be enough to cover the expenses of repatriation. Travellers must take appropriate advice on what drugs and other measures they should take to protect themselves against malaria. As the malarial parasites continue to develop resistance to the drugs used against them, it is important to seek up-to-date information on the best drug or drugs to use in any particular area. Use of a bednet (preferably one impregnated with insecticide), keeping the skin covered and using an insect repellent (preferably one containing DEET) and insecticides (in mosquito coils or from electronic vaporizers) not only reduces the risk of being bitten by mosquitoes carrying malarial parasites but also limits the nuisance and loss of sleep caused by other biting insects. It is possible to be vaccinated against several tropical diseases (hepatitis A and B, yellow fever, polio, typhoid) before travel. Every traveller should be immunized

against tetanus but the most common cholera vaccine is no longer generally recommended as it is not very effective (a new, more effective one is now on the market). As vaccination may take several weeks it is important to seek health advice early. Once in the tropics, personal hygiene is important and care should be taken with any food or drink. Any food should be cooked adequately and preferably eaten immediately after cooking (shellfish, ice cream and any raw foods, including salads and unpasteurized milk, are particularly hazardous). Any water to be drunk, if from a local source, is best boiled or sterilized chemically. Skin contact with fresh water should be avoided as much as possible as the water may contain the schistosome stages (cercariae) which can burrow into skin and lying directly on sand or walking barefoot should also be avoided. Most bouts of diarrhoea only last a few days even if untreated, but plenty of safe fluids should be drunk (and the use of oral rehydration salts which can be bought and taken with the traveller should also be considered) to prevent dehydration. Ice cubes (which may be made with contaminated water) are best avoided.

truncation error in computing, an error that occurs when a decimal result is cut off (truncated) after the maximum number of places allowed by the computer's level of accuracy.

truth table in electronics, a diagram showing the effect of a particular logic gate on every combination of inputs.

Every possible combination of inputs and outputs for a particular gate or combination of gates is described, thereby defining their action in full. When logic value 1 is written in the table, it indicates a 'high' (or 'yes') input of perhaps 5 volts; logic value 0 indicates a 'low' (or 'no') input of 0 volts.

trypanosomiasis any of several debilitating long-term diseases caused by a trypanosome (protozoan of the genus *Trypanosoma*). They include sleeping sickness in Africa, transmitted by the bites of tsetse flies, and Chagas's disease in Central and South America, spread by assassin bugs.

Trypanosomes can live in the bloodstream of humans and other vertebrates. Millions of people are affected in warmer regions of the world; the diseases also affect cattle, horses, and wild animals, which form a reservoir of infection.

trypsin an enzyme in the vertebrate gut responsible for the digestion of protein molecules. It is secreted by the pancreas but in an inactive form known as trypsinogen. Activation into working trypsin occurs only in the small intestine, owing to the action of another enzyme enterokinase, secreted by the wall of the duodenum. Unlike the digestive enzyme pepsin, found in the stomach, trypsin does not require an acid environment.

tsetse fly any of a number of blood-feeding African flies of the genus *Glossina*, some of which transmit the disease nagana to cattle and sleeping sickness to human beings. Tsetse flies may grow up to 1.5 cm/0.6 in long.

There are 22 species of tsetse fly in sub-Saharan Africa.

TSR abbreviation for terminate and stay resident.

tsunami (Japanese 'harbour wave') ocean wave generated by vertical movements of the sea floor resulting from earthquakes or volcanic activity. Unlike waves generated by surface winds, the entire depth of water is involved in the wave motion. In the open ocean the tsunami takes the form of several successive waves, rarely in excess of 1 m/3 ft in height but travelling at speeds of 650–800 kph/400–500 mph. In the coastal shallows tsunamis slow down and build up producing huge swells over 15 m/45 ft high in some cases and over 30 m/90 ft in rare instances. The waves sweep inland causing great loss of life and property. On 26 May 1983, an earthquake in the Pacific Ocean caused tsunamis up to 14 m/42 ft high, which killed 104 people along the western coast of Japan near Minehama, Honshu.

Before each wave there may be a sudden withdrawal of water from the beach. Used synonymously with tsunami, the popular term 'tidal wave' is misleading: tsunamis are not caused by the gravitational forces that affect tides.

TSUNAMI!

<http://www.geophys.washington.edu/tsunami/intro.html>

Description of many aspects of tsunamis. Included are details on how a tsunami is generated and how it propagates, how they have affected humans, and how people in coastal areas are warned about them. The site also discusses if and how you may protect yourself from a tsunami and provides 'near real-time' tsunami information bulletins.

TTL abbreviation for transistor-transistor logic, a family of integrated circuits.

TTY in computing, contraction of teletype.

tuatara lizardlike reptile of the genus *Sphenodon*. It grows up to 70 cm/2.3 ft long, is greenish black, and has a spiny crest down its back. On the top of its head is the pineal body, or so-called 'third eye', linked to the brain, which probably acts as a kind of light meter. It is the sole survivor of the reptilian order Rhynchocephalia. It lays eggs in burrows that it shares with seabirds, and has the longest incubation period of all reptiles (up to 15 months).

S. punctatus is found on about 30 small islands off New Zealand, whereas *S. guntheri* has survived on one island only, and numbers around 300 individuals. In an attempt to found a second colony of *S. guntheri*, 50 4–6 year olds, reared in semi-natural captivity, along with 20 adults from the existing population, were released on to a new island November 1995.

tuber swollen region of an underground stem or root, usually modified for storing food. The potato is a stem tuber, as shown by the presence of terminal and lateral buds, the 'eyes' of the potato. Root tubers, for example dahlias, developed from adventitious roots (growing from the stem, not from other roots) lack these. Both types of tuber can give rise to new individuals and so provide a means of vegetative reproduction.

Unlike a bulb, a tuber persists for one season only; new tubers developing on a plant in the following year are formed in different places. See also rhizome.

tuber Tubers are produced underground from stems, as in the potato, or from roots, as in the dahlia. Tubers can grow into new plants.

tuberculosis (TB) formerly known as *consumption* or *phthisis* infectious disease caused by the bacillus *Mycobacterium tuberculosis*. It takes several forms, of which pulmonary tuberculosis is by far the most common. A vaccine, BCG, was developed around 1920 and the first antituberculosis drug, streptomycin, in 1944. The bacterium is mostly kept in check by the body's immune system; about 5% of those infected develop the disease. Treatment of patients with a combination of anti-TB medicines for 6–8 months produces a cure rate of 80%.

In pulmonary TB, a patch of inflammation develops in the lung, with formation of an abscess. Often, this heals spontaneously, leaving only scar tissue. The dangers are of rapid spread through both lungs (what used to be called 'galloping consumption') or the development of miliary tuberculosis (spreading in the bloodstream to other sites) or tuberculous meningitis.

Over the last 15 years there has been a sharp resurgence in countries where the disease was in decline. The increase has been most marked in deprived inner city areas, particularly in the USA, and here there is a clear link between TB and HIV, the virus which causes AIDS. TB is the main cause of death in HIV positive individuals.

According to a World Health Organization (WHO) report in 1995, TB is responsible for more than a quarter of all adult deaths in developing countries; worldwide there are 20 million with the disease and approximately 1.9 billion infected with the TB bacterium but not displaying symptoms. TB caused around 3.1 million deaths during 1995.

The last decade has seen the spread of drug-resistant strains of the TB bacterium. Many strains are now resistant to the two front-line drugs, isoniazid and rifampicin, and some are multi-drug resistant (MDR). Rare until its recent appearance in the USA, MDR TB is now spreading through a number of developing countries. It is untreatable and many of its victims have died. According to a 1996 WHO estimate there may be as many as 50 million people worldwide with the drug-resistant form of TB (Britain had its first case in 1995).

tuberose Mexican flowering plant belonging to the agave family, grown as a sweet-smelling greenhouse plant. It has spikes of scented white flowers like lilies. (*Polyanthes tuberosa*, family Agavaceae.)

Tucana constellation of the southern hemisphere, represented as a toucan. It contains the second most prominent globular cluster in the sky, 47 Tucanae, and the Small (Magellanic Cloud.

Tucana is one of the 11 constellations named by Johann Bayer early in the 17th century to complement the 65 constellations delineated in ancient times.

tucu-tuco any member of the genus *Ctenomys*, a burrowing South American rodent about 20 cm/8 in long with a 7 cm/3 in tail. It has a large head, sensitive ears, and enormous incisor teeth.

Tucu-tucos spend most of their time below ground in a burrow system, generally one animal to a burrow. The name tucu-tuco is an attempt to imitate the bubbling call.

tufa or **travertine** soft, porous, limestone rock, white in colour, deposited from solution from carbonate-saturated ground water around hot springs and in caves.

Undersea tufa columns, such as those in the Ikka Fjord in SW Greenland, that form over alkaline springs, can reach 20 m/65 ft in height and grow at about 50 cm/20 in per year. They provide a habitat for a wide variety of marine life.

tulip any of a group of spring-flowering bulbous plants belonging to the lily family, usually with single goblet-shaped flowers on the end of an upright stem and narrow oval leaves with pointed ends. Tulips come in a large range of shapes, sizes, and colours and are widely cultivated as a garden flower. (Genus *Tulipa*, family Liliaceae.)

T. gesneriana, from which most of the garden cultivars have been derived, probably originated in Asia Minor. It was quickly adopted in Europe from Turkey during the 16th century, and tulip collecting became a craze in 17th-century Holland – it was the subject of a novel, *The Black Tulip*, by Alexandre Dumas (père) in 1850. Today tulips are commercially cultivated on a large scale in the Netherlands and East Anglia, England.

The **tulip tree** (*Liriodendron tulipifera*) of the eastern USA is a member of the magnolia family, with large, tulip-shaped blooms.

TULIP BOOK

<http://www.bib.wau.nl/tulips/>

Online version of P Cos's manuscript catalogue of tulips, published in 1637.

tumour overproduction of cells in a specific area of the body, often leading to a swelling or lump. Tumours are classified as **benign** or **malignant** (see cancer). Benign tumours grow more slowly, do not invade surrounding tissues, do not spread to other parts of the body, and do not usually recur after removal. However, benign tumours can be dangerous in areas such as the brain. The most familiar types of benign tumour are warts on the skin. In some cases, there is no sharp dividing line between benign and malignant tumours.

US doctors managed to halt tumour growth in mice by firing gold beads coated with DNA from a gene gun in 1995.

tuna any of various large marine bony fishes of the mackerel family, especially the genus *Thunnus*, popular as food and game. Albacore *T. alalunga*, bluefin tuna *T. thynnus*, and yellowfin tuna *T. albacares* are commercially important.

Tuna fish gather in shoals and migrate inshore to breed, where they are caught in large numbers. The increasing use by Pacific tuna fishers of enormous driftnets, which kill dolphins, turtles, and other marine creatures as well as catching the fish, has caused protests by environmentalists; tins labelled 'dolphin-friendly' contain tuna not caught by driftnets. Thailand is a major tuna-importing and canning country.

Overfishing is causing a reduction in tuna stocks around the world. In spite of the introduction of quotas in Australia in the 1980s, the country's catch of southern bluefin tuna in 1990–91 was

5,000 tonnes – the lowest since 1962, and the species could be in danger of extinction. Tuna stocks in the Atlantic declined by almost 90% during 1970–92.

tundra region of high latitude almost devoid of trees, resulting from the presence of permafrost. The vegetation consists mostly of grasses, sedges, heather, mosses, and lichens. Tundra stretches in a continuous belt across N North America and Eurasia. Tundra is also used to describe similar conditions at high altitudes.

tung oil oil used in paints and varnishes, obtained from tung trees native to China. (Genus *Aleurites*, family Euphorbiaceae.)

tungsten Swedish *tung sten* 'heavy stone' hard, heavy, grey-white, metallic element, symbol W (from German *Wolfram*), atomic number 74, relative atomic mass 183.85. It occurs in the minerals wolframite, scheelite, and hubertite. It has the highest melting point of any metal (3,410°C/6,170°F) and is added to steel to make it harder, stronger, and more elastic; its other uses include high-speed cutting tools, electrical elements, and thermionic couplings. Its salts are used in the paint and tanning industries.

Tungsten was first recognized in 1781 by Swedish chemist Karl Scheele in the ore scheelite. It was isolated in 1783 by Spanish chemists Fausto D'Elhuyar (1755–1833) and his brother Juan José (1754–1796).

tungsten ore either of the two main minerals, wolframite (FeMn)WO₄ and scheelite, CaWO₄, from which tungsten is extracted. Most of the world's tungsten reserves are in China, but the main suppliers are Bolivia, Australia, Canada, and the USA.

Tunguska Event explosion at Tunguska, central Siberia, Russia, in June 1908, which devastated around 6,500 sq km/2,500 sq mi of forest. It is thought to have been caused by either a cometary nucleus or a fragment of Çencke's comet about 200 m/220 yards across, or possibly an asteroid. The magnitude of the explosion was equivalent to an atom bomb (10–20 megatons) and produced a colossal shock wave; a bright falling object was seen 600 km/375 mi away and was heard up to 1,000 km/625 mi away.

tunicate any marine Çchordate of the subphylum Tunicata (Urochordata), for example the Çsea squirt. Tunicates have transparent or translucent tunics made of cellulose. They vary in size from a few millimetres to 30 cm/1 ft in length, and are cylindrical, circular, or irregular in shape. There are more than 1,000 species.

We live today in a world in which poets and historians and men of affairs are proud that they wouldn't even begin to consider thinking about learning anything of science, regarding it as the far end of a tunnel too long for any wise man to put his head into.

J ROBERT OPPENHEIMER US physicist.
The Open Mind 1955

tunnel passageway through a mountain, under a body of water, or underground. Tunnelling is a significant branch of civil engineering in both mining and transport. The difficulties naturally increase with the size, length, and depth of tunnel, but with the mechanical appliances now available no serious limitations are imposed. Granite or other hard rock presents little difficulty to modern power drills. In recent years there have been notable developments in linings (for example, concrete segments and steel liner plates), and in the use of rotary diggers and cutters and explosives.

tunny another name for Çtuna.

turbine engine in which steam, water, gas, or air (see Çwindmill) is made to spin a rotating shaft by pushing on angled blades, like a fan. Turbines are among the most powerful machines. Steam turbines are used to drive generators in power stations and ships' propellers; water turbines spin the generators in hydroelectric power

plants; and gas turbines (as jet engines; see Çjet propulsion) power most aircraft and drive machines in industry.

The high-temperature, high-pressure steam for steam turbines is raised in boilers heated by furnaces burning coal, oil, or gas, or by nuclear energy. A steam turbine consists of a shaft, or rotor, which rotates inside a fixed casing (stator). The rotor carries 'wheels' consisting of blades, or vanes. The stator has vanes set between the vanes of the rotor, which direct the steam through the rotor vanes at the optimum angle. When steam expands through the turbine, it spins the rotor by reaction. The steam engine of Hero of Alexandria (130 BC), called the *aeolipile*, was the prototype of this type of turbine, called a reaction turbine. Modern development of the reaction turbine is largely due to English engineer Charles Parsons. Less widely used is the impulse turbine, patented in 1882 by Carl Gustaf Patrick de Laval (1845–1913). It works by directing a jet of steam at blades on a rotor. Similarly there are reaction and impulse water turbines: impulse turbines work on the same principle as the water wheel and consist of sets of buckets arranged around the edge of a wheel; reaction turbines look much like propellers and are fully immersed in the water.

In a gas turbine a compressed mixture of air and gas, or vaporized fuel, is ignited, and the hot gases produced expand through the turbine blades, spinning the rotor. In the industrial gas turbine, the rotor shaft drives machines. In the jet engine, the turbine drives the compressor, which supplies the compressed air to the engine, but most of the power developed comes from the jet exhaust in the form of propulsive thrust.

turbocharger turbine-driven device fitted to engines to force more air into the cylinders, producing extra power. The turbocharger consists of a 'blower', or Çcompressor, driven by a turbine, which in most units is driven by the exhaust gases leaving the engine.

turbopan jet engine of the type used by most airliners, so called because of its huge front fan. The fan sends air not only into the engine for combustion but also around the engine for additional thrust. This results in a faster and more fuel-efficient propulsive jet (see Çjet propulsion).

turbojet jet engine that derives its thrust from a jet of hot exhaust gases. Pure turbojets can be very powerful but use a lot of fuel.

A single-shaft turbojet consists of a shaft (rotor) rotating in a casing. At the front is a multiblade Çcompressor, which takes in and compresses air and delivers it to one or more combustion chambers. Fuel (kerosene) is then sprayed in and ignited. The hot gases expand through a nozzle at the rear of the engine after spinning a turbine. The Çturbine drives the compressor. Reaction to the backward stream of gases produces a forward propulsive thrust.

turboprop jet engine that derives its thrust partly from a jet of exhaust gases, but mainly from a propeller powered by a turbine in the jet exhaust. Turboprops are more economical than turbojets but can be used only at relatively low speeds.

A turboprop typically has a twin-shaft rotor. One shaft carries the compressor and is spun by one turbine, while the other shaft carries a propeller and is spun by a second turbine.

turbot any of various flatfishes of the flounder group prized as food, especially *Scophthalmus maximus* found in European waters. It grows up to 1 m/3 ft long and weighs up to 14 kg/30 lb. It is brownish above and whitish underneath.

turbulence irregular fluid (gas or liquid) flow, in which vortices and unpredictable fluctuations and motions occur. ÇStreamlining reduces the turbulence of flow around an object, such as an aircraft, and reduces drag. Turbulent flow of a fluid occurs when the ÇReynolds number is high.

turgor the rigid condition of a plant caused by the fluid contents of a plant cell exerting a mechanical pressure against the cell wall. Turgor supports plants that do not have woody stems.

Turing machine abstract model of an automatic problem-solving machine, formulated by Alan Turing in 1937. It provides the theoretical basis of modern digital computing.

Turing, Alan Mathison (1912–1954)

English mathematician and logician. In 1936 he described a 'universal computing machine' that could theoretically be programmed to solve any problem capable of solution by a specially designed machine. This concept, now called the Turing machine, foreshadowed the digital computer.

Turing is believed to have been the first to suggest (in 1950) the possibility of machine learning and artificial intelligence. His test for distinguishing between real (human) and simulated (computer) thought is known as the Turing test: with a person in one room and the machine in another, an interrogator in a third room asks questions of both to try to identify them. When the interrogator cannot distinguish between them by questioning, the machine will have reached a state of humanlike intelligence.

ALAN TURING HOME PAGE

<http://www.turing.org.uk/turing/>

Authoritative illustrated biography of the computer pioneer, plus links to related sites. This site contains information on his origins and his code-breaking work during World War II, as well as several works written by Turing himself.

turkey any of several large game birds of the pheasant family, Meleagrididae, order Galliformes, native to the Americas. The wild turkey *Meleagris gallopavo* reaches a length of 1.3 m/4.3 ft, and is native to North and Central American woodlands. The domesticated turkey derives from the wild species. The ocellated turkey *Agriocharis ocellata* is found in Central America; it has eyespots on the tail.

The domesticated turkey was introduced to Europe in the 16th century. Since World War II, it has been intensively bred, in the same way as the chicken. It is gregarious, except at breeding time.

turmeric perennial plant belonging to the ginger family, native to India and the East Indies; also the ground powder from its tuberous rhizomes (underground stems), used in curries to give a yellow colour and as a dyestuff. (*Curcuma longa*, family Zingiberaceae.)

In India it is traditionally applied in the form of a paste of powder to aid healing of cuts and grazes.

turnip biennial plant widely cultivated in temperate regions for its edible white- or yellow-fleshed root and young leaves, which are used as a green vegetable. Closely allied to it is the swede (*B. napus*). (*Brassica rapa*, family Cruciferae.)

turnkey system in computing, a system that the user has only to switch on to have direct access to application software that is usually specific to a particular application area. Turnkey systems often use menus. The user is expected to follow instructions on the screen and to have no knowledge of how the system operates.

turnpike road road with a gate or barrier preventing access until a toll had been paid, common from the mid-16th–19th centuries. In 1991, a plan for the first turnpike road to be built in the UK since the 18th century was announced: the privately funded Birmingham northern relief road, 50 km/31 mi long.

turnstone any small wading shorebirds of the genus *Arenaria*, order Charadriiformes, especially the ruddy turnstone *A. interpres*, which breeds in the Arctic and migrates to the southern hemisphere. It is seen on rocky beaches, turning over stones for small crustaceans and insects. It is about 23 cm/9 in long and has a

summer plumage of black and chestnut above, white below; it is duller in winter.

turpentine solution of resins distilled from the sap of conifers, used in varnish and as a paint solvent but now largely replaced by white spirit.

turquoise mineral, hydrous basic copper aluminium phosphate, $\text{CuAl}_6(\text{PO}_4)_4(\text{OH})_5\text{H}_2\text{O}$. Blue-green, blue, or green, it is a gemstone. Turquoise is found in Australia, Egypt, Ethiopia, France, Germany, Iran, Turkestan, Mexico, and southwestern USA. It was originally introduced into Europe through Turkey, from which its name is derived.

turtle small computer-controlled wheeled robot. The turtle's movements are determined by programs written by a computer user, typically using the high-level programming language ϕ LOGO.

turtle freshwater or marine reptile whose body is protected by a shell. Turtles are related to tortoises, and some species can grow to a length of up to 2.5 m/8 ft. Turtles often travel long distances to lay their eggs on the beaches where they were born. Many species have suffered through destruction of their breeding sites as well as being hunted for food and their shells. Unlike tortoises, turtles cannot retract their heads into their shells.

Marine turtles are generally herbivores, feeding mainly on sea grasses. Freshwater turtles eat a range of animals including worms, frogs, and fish. They are excellent swimmers, having legs that are modified to oarlike flippers but which make them awkward on land. The shell is more streamlined and lighter than that of the tortoise.

Species include the green turtle *Chelonia mydas*, the loggerhead *Caretta caretta*; the giant leatherhead or leatherback turtle *Dermochelys coriacea*, which can weigh half a tonne; and the hawksbill *Eretmochelys imbricata*, which is hunted for its shell which provides tortoiseshell, used in jewellery and ornaments, and is now endangered. Other turtles suffer because their eggs are taken by collectors and their breeding sites are regularly destroyed, often for tourist developments.

The use of radiotransmitters has shown that migrating leatherback turtles navigate by following the contours of the Earth's crust along existing pathways. The identification and protection of these pathways could substantially reduce the number of leatherback turtles drowned in driftnets or caught on fishing lines.

TURTLES

<http://www.turtles.org>

Site full of information about turtles. There are pictures, information on current research programmes, a kids corner, and stills from an underwater video camera.

tussock moth type of moth. Several species are major forest pests, both in Europe and in North America, for example, the gypsy moth *Lymantria dispar*, the nun moth *L. monacha*, and the browntail moth *Nygmia paeorrhoea*. The caterpillars have tufts (tussocks) of long hairs.

In some species, such as the white-marked tussock moth *Hemerocampa leucostigma*, the females are wingless.

classification Tussock moths are in the family Lymantriidae, order Lepidoptera, class Insecta, phylum Arthropoda.

TVP (abbreviation for *texturized vegetable protein*) meat substitute usually made from soy beans. In manufacture, the soybean solids (what remains after oil has been removed) are ground finely and mixed with a binder to form a sticky mixture. This is forced through a spinneret and extruded into fibres, which are treated with salts and flavourings, wound into hanks, and then chopped up to resemble meat chunks.

TWAIN (acronym for *technology without an interesting name*) in computing, software standard allowing images to be taken directly from a scanner or digital camera into any image processing application. Before TWAIN, users were restricted to the scanners explicitly supported by their software; now, the only necessity is that both items follow the TWAIN standard.

24-bit colour in computing, term specifying that a video adapter is able to display more than 16 million colours simultaneously. The human eye processes 16 million colours with every blink, and a computer needs the same number of colours to be able to display pictures of a photographic quality. Powerful microprocessors, large amounts of RAM, and mass storage media are needed to handle the large computer files involved in holding such complex data.

twin one of two young produced from a single pregnancy. Human twins may be genetically identical (monozygotic), having been formed from a single fertilized egg that splits into two cells, both of which became implanted. Nonidentical (fraternal or dizygotic) twins are formed when two eggs are fertilized at the same time.

twitch another common name for couch grass.

2-D graphics in computing, graphics defined only by width and height (in mathematical terms, x and y axes). Examples of 2-D graphics are the graphics generated by spreadsheets or animated characters with no shading.

256-colour in computing, term specifying the number of colours that an 8-bit video adapter or VGA screen is able to display simultaneously. The earliest VGA screens could handle only 16 colours. By 1996 most new computer systems came equipped with a video adapter and display that could handle 256 colours, allowing the use of more detailed and complex graphics. The extra depth is useful for applications such as games and multimedia encyclopedias.

two's complement number system number system, based on the binary number system, that allows both positive and negative numbers to be conveniently represented for manipulation by computer.

In the two's complement system the most significant column heading (the furthest to the left) is always taken to represent a negative number.

For example, the four-column two's complement number 1101 stands for -3, since: $-8 + 4 + 1 = -3$.

two-stroke cycle operating cycle for internal combustion piston engines. The engine cycle is completed after just two strokes (up or down) of the piston, which distinguishes it from the more common four-stroke cycle. Power mowers and lightweight motorcycles use two-stroke petrol engines, which are cheaper and simpler than four-strokes.

Most marine diesel engines are also two-stroke. In a typical two-stroke motorcycle engine, fuel mixture is drawn into the crankcase as the piston moves up on its first stroke to compress the mixture above it. Then the compressed mixture is ignited, and hot gases are produced, which drive the piston down on its second stroke. As it moves down, it uncovers an opening (port) that allows the fresh fuel mixture in the crankcase to flow into the combustion space above the piston. At the same time, the exhaust gases leave through another port.

type metal alloy of tin, lead, and antimony, for making the metal type used by printers.

typesetting means by which text, or copy, is prepared for printing, now usually carried out by computer.

Text is keyed on a typesetting machine in a similar way to typing. Laser or light impulses are projected on to light-sensitive film that, when developed, can be used to make plates for printing.

typewriter keyboard machine that produces characters on paper. The earliest known typewriter design was patented by Henry Mills in England in 1714. However, the first practical typewriter was built in 1867 in Milwaukee, Wisconsin, USA, by Christopher Sholes, Carlos Glidden, and Samuel Soule. By 1873

Remington and Sons, US gunmakers, had produced under contract the first typing machines for sale and in 1878 they patented the first with lower-case as well as upper-case (capital) letters.

The first typewriter patented by Sholes included an alphabetical layout of keys, but Remington's first commercial typewriter had the QWERTY keyboard, designed by Sholes to slow down typists who were too fast for their mechanical keyboards.

Other layouts include the Dvorak keyboard developed by John Dvorak in 1932, in which the most commonly used letters are evenly distributed between left and right, and are positioned under the strongest fingers. Later developments included tabulators from about 1898, portable machines about 1907, the gradual introduction of electrical operation (allowing increased speed, since the keys are touched, not depressed), proportional spacing in 1940, and the rotating typehead with stationary plates in 1962. More recent typewriters work electronically, are equipped with a memory, and can be given an interface that enables them to be connected to a computer. The wordprocessor has largely replaced the typewriter for typing letters and text.

If my doctor told me I only had six months to live, I wouldn't brood. I'd type a little faster.

ISAAC ASIMOV Russian-born US writer.
Life

typhoid fever acute infectious disease of the digestive tract, caused by the bacterium *Salmonella typhi*, and usually contracted through a contaminated water supply. It is characterized by bowel haemorrhage and damage to the spleen. Treatment is with antibiotics.

The symptoms begin 10-14 days after ingestion and include fever, headache, cough, constipation, and rash. The combined TAB vaccine protects both against typhoid and the milder, related condition known as paratyphoid fever.

typhoon violent revolving storm, a hurricane in the W Pacific Ocean.

typhus any one of a group of infectious diseases caused by bacteria transmitted by lice, fleas, mites, and ticks. Symptoms include fever, headache, and rash. The most serious form is epidemic typhus, which also affects the brain, heart, lungs, and kidneys and is associated with insanitary overcrowded conditions. Treatment is by antibiotics.

The small bacteria responsible are of the genus *Rickettsia*, especially *R. prowazekii*. A preventive vaccine exists.

TYPHUS

Typhus claimed fewer victims in World War II than fighting. This was the first war in which this was the case since the first documented typhus epidemic in 1489.

tyrannosaurus any of a genus *Tyrannosaurus* of gigantic flesh-eating dinosaurs, order Saurischia, that lived in North America and Asia about 70 million years ago. They had two feet, were up to 15 m/50 ft long, 6.5 m/20 ft tall, weighed 10 tonnes, and had teeth 15 cm/6 in long.

Only a few whole skeletons are known; the most complete was discovered in 1989 in Hell Creek, Montana, and preserved in the Museum of the Rockies, Bozeman, Montana, USA.

US archaeologists proved in February 1997 that tyrannosaurus had a biting force of 1,400 kg/3,000 lb, by analysing bite marks in the fossil skeleton of a triceratops and using these to create replica teeth. They then measured the force necessary to reproduce the marks in a cow skeleton using the replica teeth.

tyre (US *tire*) inflatable rubber hoop fitted round the rims of bicycle, car, and other road-vehicle wheels. The first pneumatic rubber tyre was patented in 1845 by the Scottish engineer Robert William Thomson (1822–73), but it was Scottish inventor John Boyd Dunlop

of Belfast who independently reinvented pneumatic tyres for use with bicycles in 1888–89. The rubber for car tyres is hardened by *vulcanization*.

Tyuratam site of the *ç*Baikonur Cosmodrome in Kazakhstan.

U

uakari any of several rare South American monkeys of the genus *Cacajao*. There are three species, all with bald faces and long fur. About 55 cm/1.8 ft long in head and body, and with a comparatively short 15 cm/6 in tail, they rarely leap, but are good climbers, remaining in the tops of the trees in swampy forests and feeding largely on fruit. The black uakari is in danger of extinction because it is found in such small numbers already, and the forests where it lives are fast being destroyed.

UART (abbreviation for **universal synchronous receiver-transmitter**) in computing, integrated circuit that converts computer data into asynchronous signals suitable for transmission via a telephone line, and vice versa. UARTs combine a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter) to provide a 'bridge' between the parallel signals used by the computer and the serial signals used by communications networks.

UHF (abbreviation for **ultra high frequency**) referring to radio waves of very short wavelength, used, for example, for television broadcasting.

UHT abbreviation for **ultra-heat treated** or **ultra-heat treatment**.

UKAEA abbreviation for **United Kingdom Atomic Energy Authority**.

ULA abbreviation for **uncommitted logic array**, a type of integrated circuit.

ulcer any persistent breach in a body surface (skin or mucous membrane). It may be caused by infection, irritation, or tumour and is often inflamed. Common ulcers include aphthous (mouth), gastric (stomach), duodenal, decubitus ulcers (pressure sores), and those complicating varicose veins.

Treatment of ulcers depends on the site. Drugs are the first line of attack against peptic ulcers (those in the digestive tract), though surgery may become necessary. Bleeding stomach ulcers can be repaired without an operation by the use of endoscopy: a flexible fibre-optic tube is passed into the stomach and under direct vision fine instruments are used to repair the tissues.

ULCER

Headless bedbugs were applied to ulcers in the 16th century, and crushed bedbugs were still believed to be effective in treating ulcers in 18th-century China. It was not until this century that positive evidence was found of the antibacterial properties of insect haemolymph.

ulna one of the two bones found in the lower limb of the tetrapod (four-limbed) vertebrate. It articulates with the shorter radius and humerus (upper arm bone) at one end and with the radius and wrist bones at the other.

ultrafiltration process by which substances in solution are separated on the basis of their molecular size. A solution is forced

through a membrane with pores large enough to permit the passage of small solute molecules but not large ones.

Ultrafiltration is a vital mechanism in the vertebrate kidney: the cell membranes lining the Bowman's capsule act as semipermeable membranes, allowing water and substances of low molecular weight such as urea and salts to pass through into the urinary tubules but preventing the larger proteins from being lost from the blood.

ultra-heat treatment (UHT) preservation of milk by raising its temperature to 132°C/269°F or more. It uses higher temperatures than pasteurization, and kills all bacteria present, giving the milk a long shelf life but altering the flavour.

ultrasonics branch of physics dealing with the theory and application of ultrasound: sound waves occurring at frequencies too high to be heard by the human ear (that is, above about 20 kHz).

The earliest practical application of ultrasonics was the detection of submarines during World War I by reflecting pulses of sound from them (see *vsonar*). Similar principles are now used in industry for nondestructive testing of materials and in medicine to produce images of internal organs and developing fetuses (ultrasound scanning). High-power ultrasound can be used for cleaning, welding plastics, and destroying kidney stones without surgery.

ultrasound scanning or **ultrasonography** in medicine, the use of ultrasonic pressure waves to create a diagnostic image. It is a safe, noninvasive technique that often eliminates the need for exploratory surgery.

The sound waves transmitted through the body are absorbed and reflected to different degrees by different body tissues.

ultraviolet astronomy study of cosmic ultraviolet emissions using artificial satellites. The USA launched a series of satellites for this purpose, receiving the first useful data in 1968. Only a tiny percentage of solar ultraviolet radiation penetrates the atmosphere, this being the less dangerous longer-wavelength ultraviolet. The dangerous shorter-wavelength radiation is absorbed by gases in the ozone layer high in the Earth's upper atmosphere.

The US Orbiting Astronomical Observatory (OAO) satellites provided scientists with a great deal of information regarding cosmic ultraviolet emissions. *OAO-1*, launched in 1966, failed after only three days, although *OAO-2*, put into orbit in 1968, operated for four years instead of the intended one year, and carried out the first ultraviolet observations of a supernova and also of Uranus. *OAO-3* (*Copernicus*), launched in 1972, continued transmissions into the 1980s and discovered many new ultraviolet sources. The *International Ultraviolet Explorer* (*IUE*), which was launched in January 1978 and ceased operation in September 1996, observed all the main objects in the Solar System (including Halley's comet), stars, galaxies, and the interstellar medium.

ultraviolet radiation electromagnetic radiation invisible to the human eye, of wavelengths from about 400 to 4 nm (where the X-ray range begins). Physiologically, ultraviolet radiation is extremely powerful, producing sunburn and causing the formation of vitamin D in the skin.

Levels of ultraviolet radiation have risen an average of 6.8% a decade in the northern hemisphere and 9.9% in the southern hemisphere 1972–96, according to data gathered by the Total Ozone Mapping Spectrometer on the *Nimbus 7* satellite.

Ultraviolet rays are strongly germicidal and may be produced artificially by mercury vapour and arc lamps for therapeutic use. The radiation may be detected with ordinary photographic plates or films. It can also be studied by its fluorescent effect on certain materials. The desert iguana *Disposaurus dorsalis* uses it to locate the boundaries of its territory and to find food.

Ulysses space probe to study the Sun's poles, launched in 1990 by a US space shuttle. It is a joint project by NASA and the European Space Agency. In February 1992, the gravity of Jupiter swung *Ulysses* on to a path that looped it first under the Sun's south pole in 1994 and then over its north pole in 1995 to study the Sun and solar wind at latitudes not observable from the Earth.

umbilical cord connection between the embryo and the placenta of placental mammals. It has one vein and two arteries, transporting oxygen and nutrients to the developing young, and removing waste products. At birth, the connection between the young and the placenta is no longer necessary. The umbilical cord drops off or is severed, leaving a scar called the navel.

umbra central region of a shadow that is totally dark because no light reaches it, and from which no part of the light source can be seen (compare penumbra). In astronomy, it is a region of the Earth from which a complete eclipse of the Sun or Moon can be seen.

umbrella bird any of three species of bird of tropical South and Central America, family Cotingidae, order Passeriformes, about 45 cm/18 in long. The Amazonian species *Cephalopterus ornatus*, the ornate umbrella bird, has an inflatable wattle at the neck to amplify its humming call, and in display elevates a long crest (12 cm/4 in) lying above the bill so that it rises umbrella-like above the head. These features are less noticeable in the female, which is brownish, while the male is blue-black.

In the long-wattled umbrella bird *C. penduliger*, the wattle is covered with black feathers and may reach a length of 28 cm/11 in. The wattle of *C. glabricollis* is short, bare, and red.

umbrella tree tree native to Queensland and the Northern Territory, Australia, with large shiny leaves each made up of leaflets arranged like an open hand, and small raspberry-like clusters of red flowers at the ends of branches. It is common as an indoor plant in many countries. (*Schefflera actinophylla*.)

unbundling in computing, marketing or selling products, usually hardware and software, separately rather than as a single package.

uncertainty principle or **indeterminacy principle** in quantum mechanics, the principle that it is impossible to know with unlimited accuracy the position and momentum of a particle. The principle arises because in order to locate a particle exactly, an observer must bounce light (in the form of a photon) off the particle, which must alter its position in an unpredictable way.

It was established by German physicist Werner Heisenberg, and gave a theoretical limit to the precision with which a particle's momentum and position can be measured simultaneously: the more accurately the one is determined, the more uncertainty there is in the other.

uncommitted logic array (ULA) or **gate array** in computing, a type of semicustomized integrated circuit in which the logic gates are laid down to a general-purpose design but are not connected to each other. The interconnections can then be set in place according to the requirements of individual manufacturers. Producing ULAs may be cheaper than using a large number of TTL (transistor-transistor logic) chips or commissioning a fully customized chip.

unconformity surface of erosion or nondeposition eventually overlain by younger sedimentary rock strata and preserved in the geologic record. A surface where the beds above and below lie at different angles is called an **angular unconformity**. The boundary between older igneous or metamorphic rocks that are truncated by erosion and later covered by younger sedimentary rocks is called a **nonconformity**.

unconscious in psychoanalysis, a part of the personality of which the individual is unaware, and which contains impulses or urges that are held back, or repressed, from conscious awareness.

undelete in computing, a command that allows a user to reinstate deleted text or files. See also **delete**.

underflow error in computing, an error that occurs if a number is outside the computer's range and is too small to deal with.

underground (US *subway*) rail service that runs underground. The first underground line in the world was in London, opened in 1863; it was essentially a roofed-in trench. The London Underground is still the longest, with over 400 km/250 mi of routes. Many large cities throughout the world have similar systems, and Moscow's underground, the Metro, handles up to 6.5 million passengers a day.

undernourishment condition that results from consuming too little food over a period of time. Like **malnutrition** – the result of a diet that is lacking in certain nutrients (such as protein or vitamins) – undernourishment is common in poor countries. Both lead to a reduction in mental and physical efficiency, a lowering of resistance to disease in general, and often to deficiency diseases such as beriberi or anaemia. In the Third World, lack of adequate food is a common cause of death.

In 1996, an estimated 195 million children under the age of five were undernourished in the world. Undernourishment is not just a problem of the developing world: there were an estimated 12 million children eating inadequately in the USA in 1992. According to UN figures there were 200 million Africans suffering from undernourishment in 1996.

ungulate general name for any hoofed mammal. Included are the odd-toed ungulates (perissodactyls) and the even-toed ungulates (artiodactyls), along with subungulates such as elephants.

In 1996 the fossil jaws and teeth of an early ungulate were discovered in Russia. The fossils are believed to be 85 million years old, indicating that ungulates were in existence 20 million years before the extinction of the dinosaurs.

UNGULATE

The aardvark, the hyrax, and the elephant look completely unlike, but in fact are more closely related to each other than to any other mammal. They are all primitive ungulates (hoofed grazing mammals).

unicellular organism animal or plant consisting of a single cell. Most are invisible without a microscope but a few, such as the giant amoeba, may be visible to the naked eye. The main groups of unicellular organisms are bacteria, protozoa, unicellular algae, and unicellular fungi or yeasts. Some become disease-causing agents, **opathogens**.

Unicode 16-bit character encoding system, intended to cover all characters in all languages (including Chinese and similar languages) and to be backwards compatible with ASCII.

Unlike ASCII, which is 8-bit and can therefore represent only 256 characters – insufficient for many diacritics outside the English language – Unicode can represent 65,536 characters, big enough to handle almost all written languages, including Japanese, Tibetan, and the International Phonetic Alphabet (IPA). It was created in the 1980s by Apple and Xerox in the US.

unidentified flying object or **UFO** any light or object seen in the sky whose immediate identity is not apparent. Despite unsubstantiated claims, there is no evidence that UFOs are alien spacecraft. On investigation, the vast majority of sightings turn out to have been of natural or identifiable objects, notably bright stars and planets, meteors, aircraft, and satellites, or to have been perpetrated by pranksters. The term **flying saucer** was coined in 1947.

My unconscious knows more about the consciousness of the psychologist than his consciousness knows about my unconscious.

KARL KRAUS Austrian dramatist and critic.
Die Fackel 18 January 1917

unified field theory in physics, the theory that attempts to explain the four fundamental forces (strong nuclear, weak nuclear, electromagnetic, and gravity) in terms of a single unified force (see ϕ particle physics).

Research was begun by Albert Einstein, and by 1971 a theory developed by US physicists Steven Weinberg and Sheldon Glashow, Pakistani physicist Abdus Salam, and others, had demonstrated the link between the weak and electromagnetic forces. The next stage is to develop a theory (called the ϕ grand unified theory) that combines the strong nuclear force with the electroweak force. The final stage will be to incorporate gravity into the scheme. Work on the ϕ superstring theory indicates that this may be the ultimate 'theory of everything'.

What God hath put asunder, no man shall ever join.

WOLFGANG PAULI Austrian-born Swiss physicist.
On Einstein's attempts at a unified field theory.
quoted in J P S Uberti *Culture and Science*

uniformitarianism in geology, the principle that processes that can be seen to occur on the Earth's surface today are the same as those that have occurred throughout geological time. For example, desert sandstones containing sand-dune structures must have been formed under conditions similar to those present in deserts today. The principle was formulated by James ϕ Hutton and expounded by Charles ϕ Lyell.

uninterruptible power supply (UPS) power supply that includes a battery, so that in the event of a power failure, it is possible to continue operations. UPSs are normally used to provide time either for a system to be shut down in the usual way (so that files are not corrupted) or for an alternative power supply to be connected. For large systems these operations are usually carried out automatically.

unit standard quantity in relation to which other quantities are measured. There have been many systems of units. Some ancient units, such as the day, the foot, and the pound, are still in use. ϕ SI units, the latest version of the metric system, are widely used in science.

United Kingdom Atomic Energy Authority (UKAEA) UK national authority, established in 1954 to be responsible for research and development of all nonmilitary aspects of nuclear energy. The authority also provided private industry with contract research and development, and specialized technical and advanced engineering services. The research function was split off into a new company, AEA Technology, which was put up for sale in September 1996 as part of the government's privatization programme. UKAEA now manages its nuclear installations and is responsible for decommissioning and maximizing the return on property.

The main areas of research are: thermal reactors, fast reactors, fusion, decommissioning of plants and radioactive waste management, nuclear fuels, and environmental and energy technology. The principal establishments are at the Atomic Energy Research Establishment, Harwell, Oxfordshire; the Culham Laboratory, Oxfordshire; Dounreay, Scotland; Risley, Cheshire; and Winfrith, Dorset.

United Kingdom Infrared Telescope (UKIRT) 3.8-m/150-in reflecting telescope for observing at infrared wavelengths, opened in 1978 on ϕ Mauna Kea and operated by the Royal Observatory, Edinburgh.

universal indicator in chemistry, a mixture of ϕ pH indicators, used to gauge the acidity or alkalinity of a solution. Each component changes colour at a different pH value, and so the indicator is capable of displaying a range of colours, according to the pH of the test solution, from red (at pH 1) to purple (at pH 13).

universal joint flexible coupling used to join rotating shafts; for example, the drive shaft in a car. In a typical universal joint the ends of the shafts to be joined end in U-shaped yokes. They dovetail into each other and pivot flexibly about an X-shaped spider. This construction allows side-to-side and up-and-down movement, while still transmitting rotary motion.

Universal Serial Bus (USB) in computing, a royalty-free connector intended to replace the out-of-date COM and parallel printer ports that have been used in PCs since 1981. The USB allows up to 127 peripherals – including joysticks, scanners, printers, and keyboards – to be daisy-chained from a single socket, offering higher speeds and improved plug-and-play facilities.

The USB includes hardware and software specifications controlled by the multivendor USB-IF (Universal Serial Bus Implementers Forum) formed in March 1995. Some PC motherboards have included USB connectors since October 1996, and Release 2 of Windows 95 supports USB as long as peripherals come with their own drivers. Microsoft provided full software support for USB in Windows 98.

universal time (UT) another name for ϕ Greenwich Mean Time. It is based on the rotation of the Earth, which is not quite constant. Since 1972, UT has been replaced by coordinated universal time (UTC), which is based on uniform atomic time; see ϕ time.

I have no doubt that in reality the future will be vastly more surprising than anything I can imagine. Now my own suspicion is that the universe is not only queerer than we suppose, but queerer than we can suppose.

J B S HALDANE British physiologist.
Possible Worlds and Other Papers 1927
Attributed remark

universe all of space and its contents, the study of which is called cosmology. The universe is thought to be between 10 billion and 20 billion years old, and is mostly empty space, dotted with ϕ galaxies for as far as telescopes can see. The most distant detected galaxies and quasars lie 10 billion light years or more from Earth, and are moving farther apart as the universe expands. Several theories attempt to explain how the universe came into being and evolved; for example, the ϕ Big Bang theory of an expanding universe originating in a single explosive event, and the contradictory ϕ steady-state theory.

Apart from those galaxies within the ϕ Local Group, all the galaxies we see display ϕ red shifts in their spectra, indicating that they are moving away from us. The farther we look into space, the greater are the observed red shifts, which implies that the more distant galaxies are receding at ever greater speeds.

This observation led to the theory of an expanding universe, first proposed by Edwin Hubble in 1929, and to Hubble's law, which states that the speed with which one galaxy moves away from another is proportional to its distance from it. Current data suggest that the galaxies are moving apart at a rate of 50–100 kps/30–60 mps for every million ϕ parsecs of distance.

INQUIRER'S GUIDE TO THE UNIVERSE

<http://sln.f.edu/planets/planets.html>

Web site designed for teachers and school students, with pages on 'space science fact' – the universe as humans know it today, and 'space science fiction' – the universe as humans imagine it might be. Features include planetary fact sheets, information about planets outside the Solar System, virtual trips to black holes and neutron stars, space quotes, and a course in spaceship design.

UNIX multiuser operating system designed for minicomputers but becoming increasingly popular on microcomputers, workstations, mainframes, and supercomputers.

UNIX was developed by AT&T's Bell Laboratories in the USA during the late 1960s, using the programming language C. It could therefore run on any machine with a C compiler, so ensuring its wide portability. Its wide range of functions and flexibility, together with the fact that it was available free 1976-1983, have made it widely used by universities and in commercial software.

In the 1990s, AT&T's Unix System Laboratories was taken over by Novell, which later sold it to the Santa Cruz Operation.

unleaded petrol petrol manufactured without the addition of çantiknock. It has a slightly lower octane rating than leaded petrol, but has the advantage of not polluting the atmosphere with lead compounds. Many cars can be converted to run on unleaded petrol by altering the timing of the engine, and most new cars are designed to do so.

Cars fitted with a çatalytic converter must use unleaded fuel. Aromatic hydrocarbons and alkenes are added to unleaded petrol instead of lead compounds to increase the octane rating. After combustion the hydrocarbons produce volatile organic compounds. These have been linked to cancer, and are involved in the formation of phytochemical smog. A low-lead fuel is less toxic than unleaded petrol for use in cars that are not fitted with a catalytic converter.

The use of unleaded petrol has been standard in the USA for some years.

unnilennium temporary name assigned to the element çmeitnerium, atomic number 109.

unnilhexium temporary name assigned to the element çseaborgium 1974-97.

unniloctium temporary name assigned to the element çhassium, atomic number 108.

unnilpentium temporary name assigned to the element çdubnium.

unnilquadium temporary name assigned to the element çrutherfordium 1964-97.

unnilseptium temporary name assigned to the element çbohrium 1964-97.

unsaturated compound chemical compound in which two adjacent atoms are linked by a double or triple covalent bond.

Examples are çalkenes and çalkynes, where the two adjacent atoms are both carbon, and çketones, where the unsaturation exists between atoms of different elements (carbon and oxygen). The laboratory test for unsaturated compounds is the addition of bromine water; if the test substance is unsaturated, the bromine water will be decolorized.

unsaturated solution solution that is capable of dissolving more solute than it already contains at the same temperature.

unshielded twisted pair (UTP) form of cabling used for çlocal area networks, now commonly used as an alternative to çcoaxial cable.

unstable equilibrium the state of equilibrium possessed by a body that will not remain at rest if displaced slightly, but will topple over into a new position; it will not return to its original rest position. See çstability.

ununilium synthesized radioactive element of the çtransactinide series, symbol Uun, atomic number 110, relative atomic mass 269. It was discovered in October 1994, detected for a millisecond, at the GSI heavy-ion cyclotron, Darmstadt, Germany, while lead atoms were bombarded with nickel atoms.

ununnilium synthesized radioactive element of the çtransactinide series, symbol Uuu, atomic number 111, relative atomic mass 272. It was detected at the GSI heavy-ion cyclotron,

Darmstadt, Germany, in December 1994, when bismuth-209 was bombarded with nickel.

upas tree SE Asian tree *Antiaris toxicaria* of the mulberry family Moraceae, with a poisonous latex used for arrows, and traditionally reputed to kill all who fell asleep under it.

upgrade in computing, improved version of an existing software program. Upgrades are sometimes available free or at low cost to registered owners of previous versions.

In an office environment, it is important to carry out software upgrades simultaneously on all machines. Files created using upgrades can rarely be opened by users running older programs.

UPS abbreviation for çuninterruptible power supply.

upthrust upward force experienced by all objects that are totally or partially immersed in a fluid (liquid or gas). It acts against the weight of the object, and, according to Archimedes' principle, is always equal to the weight of the fluid displaced by that object. An object will float when the upthrust from the fluid is equal to its weight (see çfloating).

uraninite uranium oxide, UO₂, an ore mineral of uranium, also known as **pitchblende** when occurring in massive form. It is black or brownish-black, very dense, and radioactive. It occurs in veins and as massive crusts, usually associated with granite rocks.

uranium hard, lustrous, silver-white, malleable and ductile, radioactive, metallic element of the çactinide series, symbol U, atomic number 92, relative atomic mass 238.029. It is the most abundant radioactive element in the Earth's crust, its decay giving rise to essentially all radioactive elements in nature; its final decay product is the stable element lead. Uranium combines readily with most elements to form compounds that are extremely poisonous. The chief ore is çpitchblende, in which the element was discovered by German chemist Martin Klaproth in 1789; he named it after the planet Uranus, which had been discovered in 1781.

Small amounts of certain compounds containing uranium have been used in the ceramics industry to make orange-yellow glazes and as mordants in dyeing; however, this practice was discontinued when the dangerous effects of radiation became known.

Uranium is one of three fissile elements (the others are thorium and plutonium). It was long considered to be the element with the highest atomic number to occur in nature. The isotopes U-238 and U-235 have been used to help determine the age of the Earth.

Uranium-238, which comprises about 99% of all naturally occurring uranium, has a half-life of 4.51×10^9 years. Because of its abundance, it is the isotope from which fissile plutonium is produced in breeder nuclear reactors. The fissile isotope U-235 has a half-life of 7.13×10^8 years and comprises about 0.7% of naturally occurring uranium; it is used directly as a fuel for çnuclear reactors and in the manufacture of nuclear weapons.

WHAT IS URANIUM?

<http://www.uic.com.au/uran.htm>

Comprehensive and informative page on uranium, its properties and uses, mainly in nuclear reactors and weapons, provided by the Uranium Information Council.

uranium ore material from which uranium is extracted, often a complex mixture of minerals. The main ore is uraninite (or pitchblende), UO₂, which is commonly found with sulphide minerals. The USA, Canada, and South Africa are the main producers in the West.

Uranus the seventh planet from the Sun, discovered by William çHerschel in 1781. It is twice as far out as the sixth planet, Saturn. Uranus has a mass 14.5 times that of Earth. The spin axis of Uranus is tilted at 98°, so that one pole points towards the Sun, giving extreme seasons.

URANUS

<http://www.hawastsoc.org/solar/eng/uranus.htm>

Did you know that Uranus tipped on its side? Find out more about Uranus, its rings, and its moons at this site. Also included are a table of statistics about the planet, photographs, and animations of it rotating.

mean distance from the Sun 2.9 billion km/1.8 billion mi

equatorial diameter 50,800 km/31,600 mi

rotation period 17.2 hr

year 84 Earth years

atmosphere deep atmosphere composed mainly of hydrogen and helium

surface composed primarily of hydrogen and helium but may also contain heavier elements, which might account for Uranus's mean density being higher than Saturn's

satellites 17 moons (two discovered in 1997); 11 thin rings around the planet's equator were discovered in 1977.

Uranus has a peculiar magnetic field, whose axis is tilted at 60° to its axis of spin, and is displaced about a third of the way from the planet's centre to its surface. Uranus spins from east to west, the opposite of the other planets, with the exception of Venus and possibly Pluto. The rotation rate of the atmosphere varies with latitude, from about 16 hours in mid-southern latitudes to longer than 17 hours at the equator.

Uranus's equatorial ring system comprises 11 rings. The ring furthest from the planet centre (51,000 km/31,800 mi), Epsilon, is 100 km/62 mi at its widest point. In 1995, US astronomers determined the ring particles contained long-chain hydrocarbons. Looking at the brightest region of Epsilon, they were also able to

calculate the precession of Uranus as 264 days, the fastest known precession in the Solar System.

urea $\text{CO}(\text{NH}_2)_2$ waste product formed in the mammalian liver when nitrogen compounds are broken down. It is filtered from the blood by the kidneys, and stored in the bladder as urine prior to release. When purified, it is a white, crystalline solid. In industry it is used to make urea-formaldehyde plastics (or resins), pharmaceuticals, and fertilizers.

ureter tube connecting the kidney to the bladder. Its wall contains fibres of smooth muscle whose contractions aid the movement of urine out of the kidney.

urethra in mammals, a tube connecting the bladder to the exterior. It carries urine and, in males, semen.

urial or *Punjab wild sheep* or *shapu* wild sheep that ranges from sea level near the Caspian Sea to 4,200 m/13,860 ft in Tibet. The male has massive horns up to 1 m/3.3 ft long.

classification The urial *Ovis vignei* is in family Bovidae, in order Artiodactyla.

uric acid $\text{C}_5\text{H}_4\text{N}_4\text{O}_3$ nitrogen-containing waste substance, formed from the breakdown of food and body protein.

It is only slightly soluble in water. Uric acid is the normal means by which most land animals that develop in a shell (birds, reptiles, insects, and land gastropods) deposit their waste products. The young are unable to get rid of their excretory products while in the shell and therefore store them in this insoluble form.

Humans and other primates produce some uric acid as well as urea, the normal nitrogenous waste product of mammals, adult amphibians, and many marine fishes. If formed in excess and not excreted, uric acid may be deposited in sharp crystals in the joints and other tissues, causing gout; or it may form stones (calculi) in the kidneys or bladder.

urinary system The human urinary system. At the bottom right, the complete system in outline; on the left, the arrangement of blood vessels connected to the kidney; at the top right, a detail of the network of vessels within a kidney.

urinary system system of organs that removes nitrogenous waste products and excess water from the bodies of animals. In vertebrates, it consists of a pair of kidneys, which produce urine; ureters, which drain the kidneys; and (in bony fishes, amphibians, some reptiles, and mammals) a bladder that stores the urine before its discharge. In mammals, the urine is expelled through the urethra; in other vertebrates, the urine drains into a common excretory chamber called a cloaca, and the urine is not discharged separately.

urine amber-coloured fluid filtered out by the kidneys from the blood. It contains excess water, salts, proteins, waste products in the form of urea, a pigment, and some acid.

The kidneys pass it through two fine tubes (ureters) to the bladder, which may act as a reservoir for up to 0.7 l/5 pt at a time. In mammals, it then passes into the urethra, which opens to the outside by a sphincter (constricting muscle) under voluntary control. In reptiles and birds, nitrogenous wastes are discharged as an almost solid substance made mostly of uric acid, rather than urea.

URL (abbreviation for *Uniform Resource Locator*) series of letters and/or numbers specifying the location of a document on the World-Wide Web. Every URL consists of a domain name, a description of the document's location within the host computer and the name of the document itself, separated by full stops and backslashes. Thus *The Times* Web site can be found at <http://www.the-times.co.uk/news/pages/home.html>, and a tribute to Elvis Presley is at <http://www.mit.edu:8001/activities/41West/elvis.html>. The complexity of URLs explains why bookmarks and links, which save the user from the chore of typing them in, are so popular.

Ursa Major Latin 'Great Bear' the third largest constellation in the sky, in the north polar region. Its seven brightest stars make up the familiar shape or asterism of the Big Dipper or Plough. The second star of the handle of the dipper, called Mizar, has a companion star, Alcor.

Two stars forming the far side of the bowl act as pointers to the north pole star, Polaris. Dubhe, one of them, is the constellation's brightest star.

Ursa Minor Latin 'Little Bear' small constellation of the northern hemisphere. It is shaped like a dipper, with the bright north pole star Polaris at the end of the handle.

Two other bright stars in this group, Beta and Gamma Ursae Minoris, are called 'the Guards' or 'the Guardians of the Pole'. The constellation also contains the orange subgiant Kochab, about 95 light years from Earth.

urticaria or *nettle rash* or *hives* irritant skin condition characterized by itching, burning, stinging, and the spontaneous appearance of raised patches of skin. Treatment is usually by antihistamines or steroids taken orally or applied as lotions. Its causes are varied and include allergy and stress.

URTICARIA

<http://biomed.nus.sg/nsc/urticari.html>

Excellent practical information about hives from Singapore's National Skin Centre. Information about its causes includes advice about diet. There are three photos of the condition and advice about treatment.

USB in computing, abbreviation for Universal Serial Bus.

USENET (contraction of *users' network*) the world's largest bulletin board system, which brings together people with common interests to exchange views and information. It consists of e-mail messages and articles organized into newsgroups. USENET is

uncensored and governed by the rules of netiquette.

user-friendly term used to describe the ease of use of a computer system, particularly for those with little understanding or familiarity with computers. Even for experienced users, user-friendly programs are quicker to learn.

user ID (contraction of *user identification*) name or nickname that identifies the user of a computer system or network. See also *password*.

user interface in computing, the procedures and methods through which the user operates a program. These might include menus, input forms, error messages, and keyboard procedures. A graphical user interface (GUI or WIMP) is one that makes use of icons (small pictures) and allows the user to make menu selections with a mouse.

A command line interface is a character-based interface in which a prompt is displayed on the screen at which the user types a command, followed by carriage return, at which point the command, if valid, is executed.

In a graphical user interface programs and files appear as icons (small pictures), user options are selected from pull-down menus, and data are displayed in windows (rectangular areas), which the operator can manipulate in various ways. The operator uses a pointing device, typically a mouse, to make selections and initiate actions.

The study of the ways in which people interact with computers is a subbranch of ergonomics. It aims to make it easier for people to use computers effectively and comfortably, and has become a focus of research for many national and international programmes.

US Naval Observatory US government observatory in Washington DC, which provides the nation's time service and publishes almanacs for navigators, surveyors, and astronomers. It contains a 66-cm/26-in refracting telescope opened in 1873. A 1.55-m/61-in reflector for measuring positions of celestial objects was opened in 1964 at Flagstaff, Arizona.

UTC abbreviation for coordinated universal time, the standard measurement of time.

uterus hollow muscular organ of female mammals, located between the bladder and rectum, and connected to the Fallopian tubes above and the vagina below. The embryo develops within the uterus, and in placental mammals is attached to it after implantation via the placenta and umbilical cord. The lining of the uterus changes during the menstrual cycle. In humans and other higher primates, it is a single structure, but in other mammals it is paired.

The outer wall of the uterus is composed of smooth muscle, capable of powerful contractions (induced by hormones) during childbirth.

utility program in computing, a systems program designed to perform a specific task related to the operation of the computer when requested to do so by the computer user. For example, a utility program might be used to compute a screen dump, format a disc, or convert the format of a data file so that it can be accessed by a different applications program.

UTP abbreviation for unshielded twisted pair.

U-tube U-shaped tube that may be partly filled with liquid and used as a manometer.

UUCP (abbreviation for *UNIX to UNIX Copy Program*) in computing, protocol which allows UNIX users to share files, read USENET articles and exchange e-mail. The system is based on computers regularly 'polling' (connecting to) each other to swap data. Polling can take place via an ordinary telephone connection or over the Internet.

UUencode in computing, utility program that converts a binary file (typically, a program or graphics file) into ASCII text suitable for inclusion in e-mail or USENET messages. The recipient then UUdecodes the text file, reverting it from ASCII to the original binary file.

UUNET Technologies, Inc US-based provider of Internet access. UUNET was the first commercial Internet Service Provider, founded in 1987; the company now has an international network of POPs and is a major backbone provider. It acquired PIPEX from Unipalm in 1996 and is now itself part of WorldCom Inc.

UV in physics, abbreviation for ultraviolet.

U-value measure of a material's heat-conducting properties. It is used in the building industry to compare the efficiency of insulating products, a good insulator having a low U-value. The U-value

of a material is defined as the rate at which heat is conducted through it per unit surface area per unit temperature-difference between its two sides; it is measured in watts per square metre per kelvin ($\text{W m}^{-2} \text{K}^{-1}$). In mathematical terms, it may be calculated as the rate of loss of heat/surface area \times temperature difference.

uvula muscular structure descending from the soft palate. Its length is variable (5–20 mm/0.2–0.8 in in humans). It is raised during swallowing and is sometimes used in the production of speech sounds.

v in physics, symbol for velocity.

V Roman numeral for *five*; in physics, symbol for ϕ volt.

vaccine any preparation of modified pathogens (viruses or bacteria) that is introduced into the body, usually either orally or by a hypodermic syringe, to induce the specific ϕ antibody reaction that produces ϕ immunity against a particular disease.

In 1796, Edward ϕ Jenner was the first to inoculate a child successfully with cowpox virus to produce immunity to smallpox. His method, the application of an infective agent to an abraded skin surface, is still used in smallpox inoculation.

The people – could you patent the Sun?

JONAS SALK US physician and microbiologist.

On being asked who owned the patent on his polio vaccine

Vector (contraction of *virtual actor*) in computing, animated character moved and voiced by an actor behind the scenes using a ϕ Waldo and dataglove to control the character.

vacuole in biology, a fluid-filled, membrane-bound cavity inside a cell. It may be a reservoir for fluids that the cell will secrete to the outside, or may be filled with excretory products or essential nutrients that the cell needs to store.

vacuum in general, a region completely empty of matter; in physics, any enclosure in which the gas pressure is considerably less than atmospheric pressure (101,325 pascals).

vacuum flask The vacuum flask allows no heat to escape from or enter its contents. It has double walls with a vacuum between to prevent heat loss by conduction. Radiation is prevented by silvering the walls. The vacuum flask was invented by Scottish chemist James Dewar in about 1872.

We must first discuss the nature of the vacuum; some writers deny its existence, but through experiments we will provide a true account.

HERON OF ALEXANDRIA Greek scientist.

Pneumatics bk1, ch 1

vacuum cleaner cleaning device invented in 1901 by the Scot Hubert Cecil Booth. Having seen an ineffective dust-blowing machine, he reversed the process so that his machine (originally on wheels, and operated from the street by means of tubes running into the house) operated by suction.

vacuum flask or *Dewar flask* or *Thermos flask* container for keeping things either hot or cold. It has two silvered glass walls with a vacuum between them, in a metal or plastic outer case. This design reduces the three forms of heat transfer: radiation (prevented by the silvering), conduction, and convection (both prevented by the vacuum). A vacuum flask is therefore equally efficient at keeping cold liquids cold or hot liquids hot.

vagina the lower part of the reproductive tract in female mammals, linking the uterus to the exterior. It admits the penis during sexual intercourse, and is the birth canal down which the baby passes during delivery.

valence electron in chemistry, an electron in the outermost shell of an ϕ atom. It is the valence electrons that are involved in the formation of ionic and covalent bonds (see ϕ molecule). The number of electrons in this outermost shell represents the maximum possible valence for many elements and matches the number of the group that the element occupies in the ϕ periodic table of the elements.

valency in chemistry, the measure of an element's ability to combine with other elements, expressed as the number of atoms of hydrogen (or any other standard univalent element) capable of uniting with (or replacing) its atoms. The number of electrons in the outermost shell of the atom dictates the combining ability of an element.

The elements are described as uni-, di-, tri-, and tetravalent when they unite with one, two, three, and four univalent atoms respectively. Some elements have *variable valency*: for example, nitrogen and phosphorus have a valency of both three and five. The valency of oxygen is two: hence the formula for water, H_2O (hydrogen being univalent).

valency shell in chemistry, outermost shell of electrons in an ϕ atom. It contains the valence electrons. Elements with four or more electrons in their outermost shell can show variable valency. Chlorine can show valencies of 1, 3, 5, and 7 in different compounds.

valerian any of a group of perennial plants native to the northern hemisphere, with clustered heads of fragrant tubular flowers in red, white, or pink. The root of the common valerian or garden heliotrope *V. officinalis* is used in medicine to relieve wind and to soothe or calm patients. (Genera *Valeriana* and *Centranthus*, family Valerianaceae.)

validation in computing, the process of checking input data to ensure that it is complete, accurate, and reasonable. Although it would be impossible to guarantee that only valid data are entered into a computer, a suitable combination of validation checks should ensure that most errors are detected.

Common validation checks include:

character-type check Each input data item is checked to ensure that it does not contain invalid characters.

For example, an input name might be checked to ensure that it contains only letters of the alphabet, or an input six-figure date might be checked to ensure it contains only numbers.

field-length check The number of characters in an input field is checked to ensure that the correct number of characters has been entered. For example, a six-figure date field might be checked to ensure that it does contain exactly six digits.

Vaccine: the First Vaccination

BY JULIAN ROWE

Introduction

Today, during their first few months of life, infants are routinely vaccinated against diphtheria, tetanus, whooping cough, and poliomyelitis. After one year, vaccination against measles, mumps, and rubella is also recommended. Thanks to such preventive medicine and to proper nutrition, the common infectious diseases of childhood have largely disappeared from the developed world; if they do occur, the consequences are not usually serious.

Vaccinations

The regular use of vaccination began in 1796 as a result of the pioneering work of Edward Jenner, a British physician (1749-1823). In the 18th century, smallpox was one of the commonest and most deadly diseases. Most people contracted it, and a face completely unscarred by the disease was rare. In 17th-century London, some 10% of all deaths were due to smallpox.

Because the disease was so common, it was well known that an earlier, nonfatal attack of smallpox conferred immunity in any following epidemics. In Eastern countries, people were deliberately exposed to mild forms of the disease. This method was brought back to England in 1721 by Lady Mary Wortley Montagu, wife of the British Ambassador to Turkey. She had her own children 'vaccinated' (the procedure was then called *variolation*), encountering much prejudice as a result.

Kill or cure?

In England, an epidemic of smallpox swept Gloucestershire in 1788, and *variolation* was widely practised. It involved scratching a vein in the arm of a healthy person, and working into it a small amount of matter from a smallpox pustule taken from a person with a mild attack of the disease. This risky procedure had two major disadvantages. The inoculated subject, unless isolated, was likely to start a fresh smallpox epidemic; and if the dose was too virulent, the resulting disease was fatal.

Edward Jenner had a country medical practice, and was familiar with both human and animal diseases. He noted that milkmaids often caught the disease *cowpox*, and inquired further. He saw that milking was regularly done by both men and maid-servants. The men, after changing the dressings on horses suffering from a disease called 'the grease', went on to milk the cows, thus infecting them at the same time. In due course, the cows became diseased, and in turn the milkmaids who milked them caught *cowpox*.

Jenner's observations

Jenner wrote: 'Thus the disease makes its progress from the horse to the nipple of the cow, and from the cow to the human subject.' He went on: 'What makes the *cowpox* virus so extremely singular is that the person who has been thus affected is for ever secure from the infection of the *smallpox*.' Jenner then describes a great number of instances, in proof of his observations. Here are some of them.

Case I. Joseph Merret, the undergardener to the Earl of Berkeley, had been a farmer's servant in 1770, and sometimes helped with the milking. He also attended the horses. Merret caught *cowpox*. In April 1795, he was treated during a general inoculation that took place. Jenner found that despite repeatedly inserting variolous matter into Merret's arm, it was impossible to infect him with *smallpox*. During the whole time his family had *smallpox*, Merret stayed with them, and remained perfectly healthy. Jenner was at pains to make sure that Merret had at no time previously caught *smallpox*.

Case II. Sarah Portlock nursed one of her own children who, in 1792, accidentally caught *smallpox*. She considered herself safe from infection, for as a farmer's servant 27 years previously, she had contracted *cowpox*. She remained in the same room as her child, and as in the previous case, *variolation* produced no disease.

Jenner then performed the experiment that was to make him famous, and give medicine vaccination, one of the most powerful weapons against disease.

The first vaccination

Case XVII. On 14 May 1796, Jenner selected a healthy eight-year-old boy and inoculated him with *cowpox*, taken from a sore in the hand of a dairymaid. He inserted the infected matter in two incisions, each about 25 mm/1 in long. The boy showed only mild symptoms: on the seventh day he complained of a slight headache, became a little chilly and suffered loss of appetite.

Then on 1 July 1796, Jenner inoculated the boy with variolous matter, inserting it in several slight punctures and incisions in both arms. No disease followed. The only symptoms the boy showed were those of someone who had recovered from *smallpox*, or had previously suffered from *cowpox*. Several months later, the boy was inoculated again with similar results.

Jenner published his results privately on the advice of Fellows of the Royal Society, who considered that he should not risk his reputation by presenting anything 'so much at variance with established knowledge'. However, in a few years, vaccination was a widespread practice.

control-total check The arithmetic total of a specific field from a group of records is calculated - for example, the hours worked by a group of employees might be added together - and then input with the data to which it refers. The program recalculates the control total and compares it with the one entered to ensure that entry errors have not been made.

hash-total check An otherwise meaningless control total is calculated - for example, by adding together account numbers. Even though the total has no arithmetic meaning, it can still be used to check the validity of the input account numbers.

parity check Parity bits are added to binary number codes to ensure that each number in a set of data has the same parity (that each binary number has an even number of 1s, for example). The binary numbers can then be checked to ensure that their parity remains the same. This check is often applied to data after they have been transferred from one part of the computer to another; for example, from a disc drive into the immediate-access memory. **check digit** A digit is calculated from the digits of a code number and then added to that number as an extra digit. For example, in

the ISBN (International Standard Book Number) 0 631 90057 8, the 8 is a check digit calculated from the book code number 063190057 and then added to it to make the full ISBN. When the full code number is input, the computer recalculates the check digit and compares it with the one entered. If the entered and calculated check digits do not match, the computer reports that an entry error of some kind has been made.

range check An input numerical data item is checked to ensure that its value falls in a sensible range. For example, an input two-digit day of the month might be checked to ensure that it is in the range 01 to 31.

Valley of Ten Thousand Smokes valley in SW Alaska, on the Alaska Peninsula, where in 1912 Mount Katmai erupted in one of the largest volcanic explosions ever known, although without loss of human life since the area was uninhabited. The valley was filled with ash to a depth of 200 m/660 ft. It was dedicated as the Katmai National Monument in 1918. Thousands of fissures on the valley floor continue to emit steam and gases.

valve in animals, a structure for controlling the direction of the blood flow. In humans and other vertebrates, the contractions of the beating heart cause the correct blood flow into the arteries because a series of valves prevents back flow. Diseased valves, detected as 'heart murmurs', have decreased efficiency. The tendency for low-pressure venous blood to collect at the base of limbs under the influence of gravity is counteracted by a series of small valves within the veins. It was the existence of these valves that prompted the 17th-century physician William Harvey to suggest that the blood circulated around the body.

valve or **electron tube** in electronics, a glass tube containing gas at low pressure, which is used to control the flow of electricity in a circuit. The electron tube valve was invented by US radio engineer Lee de Forest (1873-1961). Three or more metal electrodes are inset into the tube. By varying the voltage on one of them, called the **grid electrode**, the current through the valve can be controlled, and the valve can act as an amplifier.

Valves have been replaced for most applications by transistors. However, they are still used in high-power transmitters and amplifiers, and in some hi-fi systems.

valve device that controls the flow of a fluid. Inside a valve, a plug moves to widen or close the opening through which the fluid passes.

Common valves include the cone or needle valve, the globe valve, and butterfly valve, all named after the shape of the plug. Specialized valves include the one-way valve, which permits fluid flow in one direction only, and the safety valve, which cuts off flow under certain conditions.

valvular heart disease damage to the heart valves, leading to either narrowing of the valve orifice when it is open (stenosis) or leaking through the valve when it is closed (regurgitation).

Worldwide, rheumatic fever is the commonest cause of damage to the heart valves, but in industrialized countries it is being replaced by bacterial infection of the valves themselves (infective endocarditis) and ischaemic heart disease as the main causes. Valvular heart disease is diagnosed by hearing heart murmurs with a stethoscope, or by cardiac ultrasound.

vampire bat South and Central American bat of the family *Desmodontidae*, of which there are three species. The common vampire *Desmodus rotundus* is found from N Mexico to central Argentina; its head and body grow to 9 cm/3.5 in. Vampire bats feed on the blood of birds and mammals; they slice a piece of skin from a sleeping animal with their sharp incisor teeth and lap up the flowing blood. They chiefly approach their prey by flying low then crawling and leaping.

Vampire bats feed on all kinds of mammals including horses, cattle, and occasionally humans. The bite is painless and the loss of blood is small (about 1 cubic cm/0.06 cubic in); the victim seldom comes to any harm. Vampire bats are intelligent and among the few mammals to show altruistic behaviour (they adopt orphans and help other bats in need).

The other species are *Diaemus youngi*, the white-winged vampire, and *Diphylla ecaudata*, the hairy-legged vampire.

vanadium silver-white, malleable and ductile, metallic element, symbol V, atomic number 23, relative atomic mass 50.942. It occurs in certain iron, lead, and uranium ores and is widely distributed in small quantities in igneous and sedimentary rocks. It is used to make steel alloys, to which it adds tensile strength.

Spanish mineralogist Andrés del Río (1764-1849) and Swedish

chemist Nils Sefström (1787-1845) discovered vanadium independently, the former in 1801 and the latter in 1831. Del Río named it 'erythronium', but was persuaded by other chemists that he had not in fact discovered a new element; Sefström gave it its present name, after the Norse goddess of love and beauty, Vanadis (or Freya).

vanadium(V) oxide V_2O_5 or **vanadium pentoxide** crystalline compound used as a catalyst in the contact process for the manufacture of sulphuric acid.

Van Allen radiation belts The Van Allen belts of trapped charged particles are a hazard to spacecraft, affecting on-board electronics and computer systems. Similar belts have been discovered around the planets Mercury, Jupiter, Saturn, Uranus, and Neptune.

Van Allen radiation belts two zones of charged particles around the Earth's magnetosphere, discovered in 1958 by US physicist James Van Allen. The atomic particles come from the Earth's upper atmosphere and the solar wind, and are trapped by the Earth's magnetic field. The inner belt lies 1,000-5,000 km/620-3,100 mi above the Equator, and contains protons and electrons. The outer belt lies 15,000-25,000 km/9,300-15,500 mi above the Equator, but is lower around the magnetic poles. It contains mostly electrons from the solar wind.

van de Graaff, Robert Jemison (1901-1967)

US physicist who from 1929 developed a high-voltage generator, which in its modern form can produce more than a million volts.

van de Graaff generator electrostatic generator capable of producing a voltage of over a million volts. It consists of a continuous vertical conveyor belt that carries electrostatic charges (resulting from friction) up to a large hollow sphere supported on an insulated stand. The lower end of the belt is earthed, so that charge accumulates on the sphere. The size of the voltage built up in air depends on the radius of the sphere, but can be increased by enclosing the generator in an inert atmosphere, such as nitrogen.

van der Waals' law modified form of the gas laws that includes corrections for the non-ideal behaviour of real gases (the molecules of ideal gases occupy no space and exert no forces on each other). It is named after Dutch physicist J D van der Waals (1837-1923).

The equation derived from the law states that:

$$(P + \frac{a}{V^2})(V - b) = RT$$

where P , V , and T are the pressure, volume, and temperature (in kelvin) of the gas, respectively; R is the gas constant; and a and b are constants for that particular gas.

Van Allen, James Alfred (1914-)

US physicist whose instruments aboard the first US satellite Explorer 1 in 1958 led to the discovery of the Van Allen belts, two zones of intense radiation around the Earth. He pioneered high-altitude research with rockets after World War II.

van de Graaff generator US physicist Robert Jemison van de Graaff developed this high-powered generator that can produce more than a million volts. Experiments involving charged particles make use of van de Graaff generators as particle accelerators.

Vanguard early series of US Earth-orbiting satellites and their associated rocket launcher. *Vanguard 1* was the second US satellite, launched on 17 March 1958 by the three-stage Vanguard rocket. Tracking of its orbit revealed that the Earth is slightly pear-shaped. The series ended in September 1959 with *Vanguard 3*.

vanilla any of a group of climbing orchids native to tropical America but cultivated elsewhere, with large, fragrant white or yellow flowers. The dried and fermented fruit, or podlike capsules, of the species *V. planifolia* are the source of the vanilla flavouring used in cookery and baking. (Genus *Vanilla*.)

Annual world production of vanilla pods is estimated at 1,500 tonnes. Vanilla flavouring (vanillin) can now be produced artificially from waste sulphite liquor, a by-product of paper pulp-making.

vapour one of the three states of matter (see also *solid* and *liquid*). The molecules in a vapour move randomly and are far apart, the distance between them, and therefore the volume of the vapour, being limited only by the walls of any vessel in which they might be contained. A vapour differs from a gas only in that a vapour can be liquefied by increased pressure, whereas a gas cannot unless its temperature is lowered below its critical temperature; it then becomes a vapour and may be liquefied.

vapour density density of a gas, expressed as the mass of a given volume of the gas divided by the mass of an equal volume of a reference gas (such as hydrogen or air) at the same temperature and pressure. It is equal approximately to half the relative molecular weight (mass) of the gas.

vapour pressure pressure of a vapour given off by (evaporated from) a liquid or solid, caused by vibrating atoms or molecules continuously escaping from its surface. In an enclosed space, a maximum value is reached when the number of particles leaving the surface is in equilibrium with those returning to it; this is known as the saturated vapour pressure or equilibrium vapour pressure.

variable in computing, a quantity that can take different values. Variables can be used to represent different items of data in the course of a program.

A computer programmer will choose a symbol to represent each variable used in a program. The computer will then automatically assign a memory location to store the current value of each vari-

able, and use the chosen symbol to identify this location.

For example, the letter *P* might be chosen by a programmer to represent the price of an article. The computer would automatically reserve a memory location with the symbolic address *P* to store the price being currently processed.

Different programming languages place different restrictions on the choice of symbols used to represent variables. Some languages only allow a single letter followed, where required, by a single number. Other languages allow a much freer choice, allowing, for example, the use of the full word 'price' to represent the price of an article.

A **global variable** is one that can be accessed by any program instruction; a **local variable** is one that can only be accessed by the instructions within a particular subroutine.

variable in mathematics, a changing quantity (one that can take various values), as opposed to a *constant*. For example, in the algebraic expression $y = 4x^3 + 2$, the variables are x and y , whereas 4 and 2 are constants.

A variable may be dependent or independent. Thus if y is a function of x , written $y = f(x)$, such that $y = 4x^3 + 2$, the domain of the function includes all values of the independent variable x while the range (or co-domain) of the *function* is defined by the values of the dependent variable y .

variable-geometry wing technical name for what is popularly termed a *swing wing*, a type of movable aircraft wing.

variable star in astronomy, a star whose brightness changes, either regularly or irregularly, over a period ranging from a few hours to months or years. The *Cepheid* variables regularly expand and contract in size every few days or weeks.

Stars that change in size and brightness at less precise intervals include *long-period variables*, such as the red giant *δ* Mira in the constellation *Cetus* (period about 330 days), and *irregular variables*, such as some red supergiants. Eruptive variables emit sudden outbursts of light. Some suffer flares on their surfaces, while others, such as a *nova*, result from transfer of gas between a close pair of stars. A *supernova* is the explosive death of a star. In an *eclipsing binary*, the variation is due not to any change in the star itself, but to the periodic eclipse of a star by a close companion. The different types of variability are closely related to different stages of stellar evolution.

variance in statistics, the square of the *standard deviation*, the measure of spread of data. Population and sample variance are denoted by σ^2 or s^2 , respectively. Variance provides a measure of the dispersion of a set of statistical results about the mean or average value.

variation in biology, a difference between individuals of the same species, found in any sexually reproducing population. Variations may be almost unnoticeable in some cases, obvious in others, and can concern many aspects of the organism. Typically, variations in size, behaviour, biochemistry, or colouring may be found. The cause of the variation is genetic (that is, inherited), environmental, or more usually a combination of the two. The origins of variation can be traced to the recombination of the genetic material during the formation of the gametes, and, more rarely, to mutation.

I have called this principle, by which each slight variation, if useful, is preserved, by the term of Natural Selection.

CHARLES DARWIN British naturalist.
On the Origin of Species 1859

varicose veins or *varicosities* condition where the veins become swollen and twisted. The veins of the legs are most often affected; other vulnerable sites include the rectum (*haemorrhoids*) and testes.

Some people have an inherited tendency to varicose veins, and the condition often appears in pregnant women, but obstructed blood flow is the direct cause. They may cause a dull ache or may

be the site for thrombosis, infection, or ulcers. The affected veins can be injected with a substance that causes them to shrink, or surgery may be needed.

variegation description of plant leaves or stems that exhibit patches of different colours. The term is usually applied to plants that show white, cream, or yellow on their leaves, caused by areas of tissue that lack the green pigment chlorophyll. Variegated plants are bred for their decorative value, but they are often considerably weaker than the normal, uniformly green plant. Many will not breed true and require vegetative reproduction.

The term is sometimes applied to abnormal patchy colouring of petals, as in the variegated petals of certain tulips, caused by a virus infection. A mineral deficiency in the soil may also be the cause of variegation.

varve in geology, a pair of thin sedimentary beds, one coarse and one fine, representing a cycle of thaw followed by an interval of freezing, in lakes of glacial regions.

Each couplet thus constitutes the sedimentary record of a year, and by counting varves in glacial lakes a record of absolute time elapsed can be determined. Summer and winter layers often are distinguished also by colour, with lighter layers representing summer deposition, and darker layers being the result of dark clay settling from water while the lake is frozen.

vascular bundle in botany, strand of primary conducting tissue (a 'vein') in vascular plants, consisting mainly of water-conducting tissues, metaxylem and protoxylem, which together make up the primary xylem, and nutrient-conducting tissue, phloem. It extends from the roots to the stems and leaves. Typically the phloem is situated nearest to the epidermis and the xylem towards the centre of the bundle. In plants exhibiting secondary growth, the xylem and phloem are separated by a thin layer of vascular cambium, which gives rise to new conducting tissues.

vascular plant plant containing vascular bundles. Pteridophytes (ferns, horsetails, and club mosses), gymnosperms (conifers and cypresses), and angiosperms (flowering plants) are all vascular plants.

vas deferens in male vertebrates, a tube conducting sperm from the testis to the urethra. The sperm is carried in a fluid secreted by various glands, and can be transported very rapidly when the smooth muscle in the wall of the vas deferens undergoes rhythmic contraction, as in sexual intercourse.

vasectomy male sterilization; an operation to cut and tie the ducts (see vas deferens) that carry sperm from the testes to the penis. Vasectomy does not affect sexual performance, but the semen produced at ejaculation no longer contains sperm.

Some surgical attempts to reopen the duct have been successful, and some have opened spontaneously, thus making conception possible. Initially there were concerns of lower life expectancy due to increased risks of testicular or prostate cancer. However, a large-scale study in Boston in 1992 found that an increased rate of lung cancer was offset by a reduced rate of cardiovascular disease.

vector quantity A parallelogram of vectors. Vectors can be added graphically using the parallelogram rule. According to the rule, the sum of vectors p and q is the vector r which is the diagonal of the parallelogram with sides p and q .

VBLA (abbreviation for very long baseline array) in astronomy, a group of ten 25 m/82.5 ft radio telescopes spread across North America and Hawaii which operate as a single instrument using the technique of very long baseline interferometry (VLBI). The longest baseline (distance between pairs of telescopes) is about 8,000 km/4,970 mi.

VDU abbreviation for visual display unit.

vector graphics computer graphics that are stored in the computer memory by using geometric formulas. Vector graphics can be transformed (enlarged, rotated, stretched, and so on) without loss of picture resolution. It is also possible to select and transform any of the components of a vector-graphics display because each is separately defined in the computer memory. In these respects vector graphics are superior to raster graphics. Vector graphics are typically used for drawing applications, allowing the user to create and modify technical diagrams such as designs for houses or cars.

vector quantity any physical quantity that has both magnitude and direction (such as the velocity or acceleration of an object) as distinct from scalar quantity (such as speed, density, or mass), which has magnitude but no direction. A vector is represented either geometrically by an arrow whose length corresponds to its magnitude and points in an appropriate direction, or by two or three numbers representing the magnitude of its components.

Vectors can be added graphically by constructing a parallelogram of vectors (such as the parallelogram of forces commonly employed in physics and engineering).

If two forces p and q are acting on a body at A , then the parallelogram of forces is drawn to determine the resultant force and direction r , p , q , and r are vectors. In technical writing, a vector is denoted by bold type, underlined AB , or overlined AB .

Vega or Alpha Lyrae brightest star in the constellation Lyra and the fifth brightest star in the night sky. It is a blue-white star, 25 light years from Earth, with a luminosity 50 times that of the Sun.

In 1983 the Infrared Astronomy Satellite (IRAS) discovered a ring of dust around Vega, possibly a disc from which a planetary system is forming.

vegetative reproduction type of asexual reproduction in plants that relies not on spores, but on multicellular structures formed by the parent plant. Some of the main types are stolons and runners, gemmae, bulbils, sucker shoots produced from roots (such as in the creeping thistle *Cirsium arvense*), tubers, bulbs, corms, and rhizomes. Vegetative reproduction has long been exploited in horticulture and agriculture, with various methods employed to multiply stocks of plants. See also plant propagation.

vein in animals with a circulatory system, any vessel that carries blood from the body to the heart. Veins contain valves that prevent the blood from running back when moving against gravity. They always carry deoxygenated blood, with the exception of the veins leading from the lungs to the heart in birds and mammals, which carry newly oxygenated blood.

The term is also used more loosely for any system of channels that strengthens living tissues and supplies them with nutrients – for example, leaf veins (see vascular bundle), and the veins in insects' wings.

Vela bright constellation of the southern hemisphere near Carina, represented as the sails of a ship. It contains large wisps of gas – called the Gum nebula after its discoverer, the Australian astronomer Colin Gum (1924–1960) – believed to be the remains of one or more supernovae. Vela also contains the second optical pulsar (a pulsar that flashes at a visible wavelength) to be discovered.

Vela was originally regarded as part of Argo. Its four brightest stars are second-magnitude, one of them being Suhail, about 490 light years from Earth.

veldt subtropical grassland in South Africa, equivalent to the Pampas of South America.

velocity speed of an object in a given direction. Velocity is a vector quantity, since its direction is important as well as its magnitude (or speed).

The velocity at any instant of a particle travelling in a curved path is in the direction of the tangent to the path at the instant considered. The velocity v of an object travelling in a fixed direction may be calculated by dividing the distance s it has travelled by the time t taken to do so, and may be expressed as:

$$v = \frac{s}{t}$$

velocity ratio (VR) or distance ratio in a machine, the distance moved by the input force, or effort, divided by the distance moved by the output force, or load, in the same time. It follows that the velocities of the effort and the load are in the same ratio. Velocity ratio has no units. See also *mechanical advantage* and *efficiency*.

velvet worm or *peripatus* invertebrate with soft body (15–150 mm/0.5–5.9 in in length), velvety skin and paired unsegmented legs. They are found in leaf-litter in rainforests in Africa, Australia, Indonesia, Malaysia, and S America, and feed on small invertebrates. They are unlike any other invertebrates and so the 200 species occupy their own phylum, Onychophora. Velvet worms date back 400 million years and may be a 'missing link' between the arthropods (insects and crustaceans) and annelids (soft-bodied segmented worms, including earthworms). The 20–40 million-year-old fossils of two new kinds of velvet worm were discovered by US palaeontologists in 1996.

VELVET WORM

The mating technique of African velvet worms is bizarre. The male places sperm bundles anywhere along the female's body. Beneath the sperm bundle the skin dissolves forming a hole. The sperm can thus enter the female's body cavity, where it makes its way to her ovaries.

vena cava either of the two great veins of the trunk, returning deoxygenated blood to the right atrium of the heart. The superior vena cava, beginning where the arches of the two innominate veins join high in the chest, receives blood from the head, neck, chest, and arms; the inferior vena cava, arising from the junction of the right and left common iliac veins, receives blood from all parts of the body below the diaphragm.

venereal disease (VD) any disease mainly transmitted by sexual contact, although commonly the term is used specifically for gonorrhoea and syphilis, both occurring worldwide, and chancroid ('soft sore') and lymphogranuloma venereum, seen mostly in the tropics. The term *sexually transmitted disease (STD)* is more often used to encompass a growing list of conditions passed on primarily, but not exclusively, by sexual contact.

Venn, John (1834–1923)

English logician whose diagram, known as the Venn diagram, is much used in the teaching of elementary mathematics.

Venn diagram in mathematics, a diagram representing a *coset* or sets and the logical relationships between them. The sets are drawn as circles. An area of overlap between two circles (sets) contains elements that are common to both sets, and thus represents a third set. Circles that do not overlap represent sets with no elements in common (disjoint sets). The method is named after the British logician John Venn.

ventral surface the front of an animal. In vertebrates, the side furthest from the backbone; in invertebrates, the side closest to the

£ = set of whole numbers from 1 to 20

O = set of odd numbers

P = set of prime numbers

Venn diagram Sets and their relationships are often represented by Venn diagrams. The sets are drawn as circles – the area of overlap between the circles shows elements that are common to each set, and thus represent a third set. Here (a) is a Venn diagram of two intersecting sets and (b) a Venn diagram showing the set of whole numbers from 1 to 20 and the subsets P and O of prime and odd numbers, respectively. The intersection of P and O contains all the prime numbers that are also odd.

ground. The positioning of the main nerve pathways on the ventral side is a characteristic of invertebrates.

ventricle in zoology, either of the two lower chambers of the heart that force blood to circulate by contraction of their muscular walls. The term also refers to any of four cavities within the brain in which cerebrospinal fluid is produced.

Venturi tube device for measuring the rate of fluid flow through a pipe. It consists of a tube with a constriction (narrowing) in the middle of its length. The constriction causes a drop in pressure in the fluid flowing in the pipe. A pressure gauge attached to the constriction measures the pressure drop and this is used to find the rate of fluid flow.

Venturi tubes are also used in the carburettor of a motor car to draw petrol into the engine.

Venus second planet from the Sun. It can approach Earth to within 38 million km/24 million mi, closer than any other planet. Its mass is 0.82 that of Earth. Venus rotates on its axis more slowly

FACE OF VENUS HOME PAGE

<http://www.eps.mcgill.ca/~bud/craters/FaceOfVenus.html>

Overview and description of the surface of the planet Venus. It includes interactive databases of corona and craters, and many images.

than any other planet, from east to west, the opposite direction to the other planets (except Uranus and possibly Pluto).

mean distance from the Sun 108.2 million km/67.2 million mi

equatorial diameter 12,100 km/7,500 mi

rotation period 243 Earth days

year 225 Earth days

atmosphere Venus is shrouded by clouds of sulphuric acid droplets that sweep across the planet from east to west every four days. The atmosphere is almost entirely carbon dioxide, which traps the Sun's heat by the greenhouse effect and raises the planet's surface temperature to 480°C/900°F, with an atmospheric pressure of 90 times that at the surface of the Earth.

surface consists mainly of silicate rock and may have an interior structure similar to that of Earth: an iron-nickel core, a mantle composed of more mafic rocks (rocks made of one or more ferromagnesian, dark-coloured minerals), and a thin siliceous outer crust. The surface is dotted with deep impact craters. Some of Venus's volcanoes may still be active.

satellites no moons

The first artificial object to hit another planet was the Soviet probe *Venera* 3, which crashed on Venus on 1 March 1966. Later *Venera* probes parachuted down through the atmosphere and landed successfully on its surface, analysing surface material and sending back information and pictures. In December 1978 a US Pioneer Venus probe went into orbit around the planet and mapped most of its surface by radar, which penetrates clouds. In 1992 the US space probe *Magellan* mapped 99% of the planet's surface to a resolution of 100 m/330 ft.

The largest highland area is Aphrodite Terra near the equator, half the size of Africa. The highest mountains are on the northern highland region of Ishtar Terra, where the massif of Maxwell Montes rises to 10,600 m/35,000 ft above the average surface level. The highland areas on Venus were formed by volcanoes.

Venus has an ion-packed tail 45 million km/28 million mi in length that stretches away from the Sun and is caused by the bombardment of the ions in Venus's upper atmosphere by the solar wind. It was first discovered in the late 1970s but it was not until 1997 that the Solar Heliospheric Observatory (SOHO) revealed its immense length.

Venus flytrap insectivorous plant belonging to the sundew family, native to the southeastern USA. Its leaves have two hinged surfaces that rapidly close together to trap any insect which brushes against the sensitive leaf hairs; digestive juices then break down the insect body so that it can be absorbed by the plant. (*Dionaea muscipula*, family Droseraceae.)

verbena any of a group of plants containing about 100 species, mostly found in the American tropics. The leaves are fragrant and the tubular flowers are arranged in close spikes in colours ranging from white to rose, violet, and purple. The garden verbenas are a hybrid annual. (Genus *Verbenas*, family Verbenaceae.)

verdigris green-blue coating of copper ethanoate that forms naturally on copper, bronze, and brass. It is an irritating, poisonous compound made by treating copper with ethanoic acid, and was formerly used in wood preservatives, antifouling compositions, and green paints.

verification in computing, the process of checking that data being input to a computer have been accurately copied from a source document.

This may be done visually, by checking the original copy of the data against the copy shown on the VDU screen. A more thorough method is to enter the data twice, using two different keyboard operators, and then to check the two sets of input copies against each other. The checking is normally carried out by the computer itself, any differences between the two copies being reported for correction by one of the keyboard operators.

Where large quantities of data have to be input, a separate machine called a **verifier** may be used to prepare fully verified tapes or discs for direct input to the main computer.

vermilion HgS red form of mercuric sulphide; a scarlet that occurs naturally as the crystalline mineral cinnabar.

vermin general term for animals destructive of crops and game, such as rats, mice, moles, weasels, and foxes. The word is also used of the insect parasites of people, such as lice and fleas.

vernal equinox see spring equinox.

vernization the stimulation of flowering by exposure to cold. Certain plants will not flower unless subjected to low temperatures during their development. For example, winter wheat will flower in summer only if planted in the previous autumn. However, by placing partially germinated seeds in low temperatures for several days, the cold requirement can be supplied artificially, allowing the wheat to be sown in the spring.

vernier device for taking readings on a graduated scale to a fraction of a division. It consists of a short divided scale that carries an index or pointer and is slid along a main scale. It was invented by Pierre Vernier.

Veronica software tool for searching for files on the Internet. Veronica is broadly similar to Archie, but whereas the latter searches anonymous ftp sites, Veronica searches Gopher servers.

verruca growth on the skin; see wart.

vertebra in vertebrates, an irregularly shaped bone that forms part of the vertebral column. Children have 33 vertebrae, 5 of which fuse in adults to form the sacrum and 4 to form the coccyx.

Vesalius, Andreas (1514–1564)

Belgian physician who revolutionized anatomy by performing postmortem dissections and making use of illustrations to teach anatomy. Vesalius upset the authority of Galen, and his book – the first real textbook of anatomy – marked the beginning of biology as a science.

Vesalius was taught anatomy in the Galenist tradition. Galen had never dissected a human body – all his accounts of the human anatomy were based on his research of the Barbary ape – although he was regarded as infallible and was venerated until the Renaissance. Vesalius was therefore taught principles of anatomy that had not been questioned for 1,300 years.

Dissatisfied with the instruction he had received, Vesalius resolved to make his own observations. His dissections of the human body (then illegal) enabled him to discover that Galen's system of medicine was based on fundamental anatomical errors. Vesalius disproved the widely held belief that men had one rib less than women. He also believed, contrary to Aristotle's theory of the heart being the centre of the mind and emotion, that the brain and the nervous system were the centre.

Vesalius's book *De humani corporis fabrica* (*On the Structure of the Human Body*) of 1543 employed talented artists to provide the illustrations and is one of the great books of the 16th century.

The quality of anatomical depiction introduced a new standard into all illustrated works, especially into medical books, and highlighted the need to introduce scientific method into the study of anatomy. Together with the main work of astronomer Copernicus, published in the same year, *On the Structure of the Human Body* marked the dawn of modern science.

There are 7 cervical vertebrae in the neck, 12 thoracic vertebrae in the thorax with the ribs attached, and 5 lumbar vertebrae in the lower back.

vertebral column the backbone, giving support to an animal and protecting its spinal cord. It is made up of a series of bones or vertebrae running from the skull to the tail, with a central canal containing the nerve fibres of the spinal cord. In tetrapods the vertebrae show some specialization with the shape of the bones varying according to position. In the chest region the upper or thoracic vertebrae are shaped to form connections to the ribs. The backbone is only slightly flexible to give adequate rigidity to the animal structure.

vertebrate any animal with a backbone. The 41,000 species of vertebrates include mammals, birds, reptiles, amphibians, and fishes. They include most of the larger animals, but in terms of numbers of species are only a tiny proportion of the world's animals. The zoological taxonomic group Vertebrata is a subgroup of the phylum Chordata.

A giant fossil conodont (an eel-like organism from the Cambrian period) was discovered in South Africa in 1995, and is believed to be one of the first vertebrates. Conodonts evolved 520 million years ago, predating the earliest fish by about 50 million years.

vertex (plural *vertices*) in geometry, a point shared by three or more sides of a solid figure; the point farthest from a figure's base; or the point of intersection of two sides of a plane figure or the two rays of an angle.

vertical spam in computing, on USENET, spam which consists of many, often repetitive, messages per day posted to the same newsgroup or small set of newsgroups. The effect is to drown out other, more useful, conversation in the newsgroup.

vertical takeoff and landing craft (VTOL) aircraft that can take off and land vertically. Helicopters, airships, and balloons can do this, as can a few fixed-wing aeroplanes, like the Conquest plane.

vertigo dizziness; a whirling sensation accompanied by a loss of any feeling of contact with the ground. It may be due to temporary disturbance of the sense of balance (as in spinning for too long on one spot), psychological reasons, disease such as labyrinthitis, or intoxication.

Very Large Array (VLA) largest and most complex single-site radio telescope in the world. It is located on the Plains of San Augustine, 80 km/50 mi west of Socorro, New Mexico. It consists of 27 dish antennae, each 25 m/82 ft in diameter, arranged along three equally spaced arms forming a Y-shaped array. Two of the arms are 21 km/13 mi long, and the third, to the north, is 19 km/11.8 mi long. The dishes are mounted on railway tracks enabling the configuration and size of the array to be altered as required.

Pairs of dishes can also be used as separate interferometers (see radio telescope), each dish having its own individual receivers that are remotely controlled, enabling many different frequencies to be studied. There are four standard configurations of antennae ranging from A (the most extended) through B and C to D. In the A configuration the antennae are spread out along the full extent of the arms and the VLA can map small, intense radio sources with high resolution. The smallest configuration, D, uses arms that are just 0.6 km/0.4 mi long for mapping larger sources. Here the resolution is lower, although there is greater sensitivity to fainter, extended fields of radio emission.

VESA local bus in computing, hardware configuration laid down by the Video Electronics Standards Association for computers based on the Intel 486 chip. It was rendered obsolete by the arrival of Pentium chips and the PCI bus.

vestigial organ in biology, an organ that remains in diminished form after it has ceased to have any significant function in the adult organism. In humans, the appendix is vestigial, having once had a digestive function in our ancestors.

Vesuvius Italian *Vesuvio* active volcano in Campania, Italy, 15

km/9 mi southeast of Naples, Italy; height 1,277 m/4,190 ft. In AD 79 it destroyed the cities of Pompeii, Herculaneum, and Stabiae.

vetch any of a group of trailing or climbing plants belonging to the pea family, usually having seed pods and purple, yellow, or white flowers, and including the fodder crop alfalfa (*Medicago sativa*). (Several genera, especially *Vicia*, family Leguminosae.)

VGA (abbreviation for *video graphics array*) in computing, a colour display system that provides either 16 colours on screen and a resolution of 640 × 480, or 256 colours with a resolution of 320 × 200. (SVGA (Super VGA) provides even higher resolution and more colours.)

VHF (abbreviation for *very high frequency*) referring to radio waves that have very short wavelengths (10 m–1 m). They are used for interference-free FM transmissions (see frequency modulation). VHF transmitters have a relatively short range because the waves cannot be reflected over the horizon like longer radio waves.

viburnum any of a group of small trees or shrubs belonging to the honeysuckle family, found in temperate and subtropical regions, including the wayfaring tree, the laurustinus, and the guelder rose of Europe and Asia, and the North American blackhaws and arrowwoods. (Genus *Viburnum*, family Caprifoliaceae.)

Vickers British engineering company, prominent in the manufacture of munitions. In addition to naval and land artillery, the company gave its name to the 'Vickers gun', a modified form of the Maxim machine gun, adopted by the British army in 1912, as well as to a series of aircraft in both world wars.

vicuna ruminant mammal *Lama vicugna* of the camel family that lives in herds on the Andean plateau. It can run at speeds of 50 kph/30 mph. It has good eyesight, fair hearing, and a poor sense of smell. Hunted close to extinction for its meat and soft brown fur, which was used in textile manufacture, the vicuna is now a protected species. Its populations are increasing thanks to strict conservation measures; by 1996 they had reached 100,000–200,000. The vicuna is listed on CITES Appendix 2 (vulnerable).

It is related to the alpaca, the guanaco, and the llama.

video accelerator card in computing, circuit board that contains a special microchip to process display data, freeing the central processing unit (CPU) for other tasks. A video accelerator card speeds up the performance of computers running Windows and other graphical user interfaces (GUIs) which place a heavy demand on processors.

video adapter in computing, an expansion board that allows display of graphics and colour. Commonly used video adapters for IBM PC-based systems are Hercules, CGA, EGA, VGA, XGA, and SVGA.

video adapter card in computing, circuit board that provides the data needed to create a display on a monitor. Common adapter cards include VGA and SVGA.

video camera or *camcorder* portable television camera that records moving pictures electronically on magnetic tape. It produces an electrical output signal corresponding to rapid line-by-line scanning of the field of view. The output is recorded on video cassette and is played back on a television screen via a video cassette recorder. See illustration on page 792.

video capture board in computing, expansion board for a personal computer which digitizes an incoming stream of analogue video. Video capture boards vary widely in the amount of data they can handle; the cheapest can handle only single frames, while the most expensive and full-featured can handle full-motion video. Once the video stream has been digitized, it can be stored, copied, digitally edited or retouched on the computer.

video cassette recorder (VCR) device for recording on and playing back video cassettes; see videotape recorder.

Video CD CD-ROM that conforms to Philips' White Book standard for displaying full-motion digital video using MPEG data compression.

video camera The heart of the video camera is the vidicon tube which converts light entering the front lens to an electrical signal. An image is formed on a light-sensitive surface at the front of the tube. The image is then scanned by an electron beam, to give an output signal corresponding to the image brightness. The signal is recorded as a magnetic track traversing the tape diagonally. The sound track, which records the sounds picked up by the microphone, runs along the edge of the tape.

VIDEO CASSETTE RECORDER

<http://bradley.bradley.edu/~fil/vcr.html>

'Point and click' site which answers common questions regarding home VHS equipment.

VIDEO RECORDER

The screening of videotapes in buses was banned in Turkey in June 1984 after a bus driver had tried to censor a love scene by holding his arm in front of the television while he was driving. Seventeen people died in the ensuing accident.

sion. Video CD is used to store films such as *Top Gun* on CD-ROM for playback on Philips CD-i players and personal computers or consoles equipped with an MPEG decoder in hardware and/or software.

videoconferencing in computing, system which allows people in different locations to interact via video and audio. It is essentially multi-party telephone conferencing with pictures. Older videoconferencing systems required expensive equipment set up in a special-purpose room. By the mid 1990s, newer systems became available for desktop videoconferencing using much cheaper equipment so that videoconferencing facilities could be deployed to individual users' desks.

video dialtone US legislation passed in October 1995, to allow telephone companies to sell information and video services as well as straight telephone connections. The result is expected to be increased competition in both telephone and television services.

video disc disc with pictures and sounds recorded on it, played back by laser. The video disc is a type of compact disc.

The video disc (originated by Scottish inventor John Logie Baird in 1928; commercially available from 1978) is chiefly used to provide commercial films for private viewing. Most systems use a 30 cm/12 in rotating vinyl disc coated with a reflective material. Laser scanning recovers picture and sound signals from the surface where they are recorded as a spiral of microscopic pits.

video file in computing, file, such as an MPEG or AVI file, that contains compressed video information.

video game electronic game played on a visual-display screen or, by means of special additional or built-in components, on the screen of a television set. The first commercially sold was a simple bat-and-ball game developed in the USA in 1972, but complex variants are now available in colour and with special sound effects.

video graphics card in computing, expansion board that gives personal computers their display capability. The video graphics card must match the display monitor in functionality.

video-on-demand (VOD) system for transmission of video by cable where specific videos can be selected from a choice button on the remote control that brings up a menu on screen. Once a choice has been selected a set-top box sends a query to the video server where the video is stored in compressed format. The server sends the video back through the system where it is decompressed by the set-top box. Trials were underway in Europe and USA in 1996.

videophone telephone allowing the sending and receiving of pictures as well as speech.

videotape recorder (VTR) device for recording pictures and sound on cassettes or spools of magnetic tape. The first commercial VTR was launched in 1956 for the television broadcasting industry, but from the late 1970s cheaper models developed for home use, to record broadcast programmes for future viewing and to view rented or owned video cassettes of commercial films.

Video recording works in the same way as audio (tape recording: the picture information is stored as a line of varying magnetism, or track, on a plastic tape covered with magnetic material. The main difficulty – the huge amount of information needed to reproduce a picture – is overcome by arranging the video track diagonally across the tape. During recording, the tape is wrapped around a drum in a spiral fashion. The recording head rotates inside the drum. The combination of the forward motion of the tape and the rotation of the head produces a diagonal track. The audio signal accompanying the video signal is recorded as a separate track along the edge of the tape.

Two video cassette systems were introduced to the mass market by Japanese firms in the 1970s, but the Betamax standard was first introduced in 1965. The Sony Betamax was technically superior, but Matsushita's VHS had larger marketing resources behind it and after some years became the sole system on the market. Super-VHS is an improved version of the VHS system, launched in 1989, with higher picture definition and colour quality.

videotext system in which information (text and simple pictures) is displayed on a television (video) screen. There are two basic systems, known as *teletext* and *videodata*. In the *teletext* system information is broadcast with the ordinary television signals, whereas in the *videodata* system information is relayed to the screen from a central data bank via the telephone network. Both systems require the use of a television receiver (or a connected VTR) with special decoder.

viewdata system of displaying information on a television screen in which the information is extracted from a computer data bank and transmitted via the telephone lines. It is one form of *videotext*. British Telecom (then part of the General Post Office) developed the first viewdata system, Prestel, 1975–79. Similar systems are used in other countries. Users have access to a large store of information, presented on the screen in the form of 'pages'.

Since viewdata uses telephone lines, it can become a two-way interactive information system, making possible, for example, home banking and shopping. In contrast, the only user input allowed by the *teletext* system is to select the information to be displayed.

However, viewdata systems have generally not been successful (the notable exception is France's Minitel) and interest has switched to the World Wide Web.

Viking probes two US space probes to Mars, each one consisting of an orbiter and a lander. They were launched on 20 August and 9 September 1975. They transmitted colour pictures and analysed the soil.

Viking 1 carried life detection labs and landed in the Chryse lowland area on 20 July 1976 for detailed research and photos. Designed to work for 90 days, it operated for six and a half years, going silent November 1982. *Viking 2* was similar in set-up to *Viking 1*; it landed in Utopia on 3 September 1976 and functioned for three and a half years.

villus plural villi small fingerlike projection extending into the interior of the small intestine and increasing the absorptive area of the intestinal wall. Digested nutrients, including sugars and amino acids, pass into the villi and are carried away by the circulating blood.

vincristine alkaloid extracted from the blue periwinkle plant *Vinca rosea*. Developed as an anticancer agent, it has revolutionized the treatment of childhood acute leukaemias; it is also included in chemotherapy regimens for some lymphomas (cancers arising in the lymph tissues) and lung and breast cancers. Side effects, such as nerve damage and loss of hair, are severe but usually reversible.

vine or **grapevine** any of a group of climbing woody plants, especially *V. vinifera*, native to Asia Minor and cultivated from antiquity. The fruits (grapes) are eaten or made into wine or other fermented drinks; dried fruits of certain varieties are known as raisins and currants. Many other species of climbing plant are also called vines. (Genus *Vitis*, family Vitaceae.)

violet any of a group of perennial herbaceous plants found in temperate regions; they have heart-shaped leaves and mauve, blue, or white five-petalled flowers, for example the dog violet *V. canina*, found on sandy heaths, and the fragrant sweet violet *V. odorata*. A pansy is a kind of violet. (Genus *Viola*, family Violaceae.)

viper any front-fanged venomous snake of the family Viperidae. Vipers range in size from 30 cm/1 ft to 3 m/10 ft, and often have diamond or jagged markings. Most give birth to live young.

There are 150 species of viper. The true vipers, subfamily Viperinae, abundant in Africa and SW Asia, include the adder *Vipera berus*, the African puff adder *Bitis arietans*, and the horned viper of North Africa *Cerastes cornutus*. The second subfamily Crotalinae includes the mostly New World pit vipers, such as rattlesnakes and copperheads of the Americas, which have a heat-sensitive pit between each eye and nostril.

Virginia creeper or **woodbine** E North American climbing vine belonging to the grape family, having tendrils, palmately compound leaves (made up of leaflets arranged like an open hand), green flower clusters, and blue berries eaten by many birds but inedible to humans. (*Parthenocissus quinquefolia*, family Vitaceae.)

Virgo zodiacal constellation of the northern hemisphere, the second largest in the sky. It is represented as a maiden holding an ear of wheat, marked by first-magnitude α Spica, Virgo's brightest star. The Sun passes through Virgo from late September to the end of October. In astrology, the dates for Virgo are between about 23 August and 22 September (see *precession*).

Virgo contains the nearest large cluster of galaxies to us, 50 million light years away, consisting of about 3,000 galaxies centred on the giant elliptical galaxy M87. Also in Virgo is the nearest quasar, 3C 273, an estimated 3 billion light years away.

virion the smallest unit of a mature *virus*.

virtual in computing, without physical existence. Most computers have *virtual* memory, making their immediate-access memory seem larger than it is. *Virtual* reality is a computer simulation of a whole physical environment.

virtual community in computing, group of people joined by using the same electronic conferencing system. The sense of *virtual* community can be extremely strong, going beyond simply exchanging mutually useful information to helping with real-life events such as family illnesses and financial crises.

virtual corporation company with no real-life headquarters but whose employees and/or individual contractors are linked via telecommunications.

virtual memory in computing, a technique whereby a portion of the computer backing storage, or external, *memory* is used as an extension of its immediate-access, or internal, memory. The contents of an area of the immediate-access memory are stored on, say, a hard disc while they are not needed, and brought back into

main memory when required.

The process, called paging or segmentation, is controlled by the computer operating system and is hidden from the programmer, to whom the computer's internal memory appears larger than it really is. The technique can be successfully implemented only if very fast backing store is available, so that 'pages' of memory can be rapidly switched into and out of the immediate-access memory.

For a successful technology, reality must take precedence over public relations, for Nature cannot be fooled.

RICHARD FEYNMAN US physicist.
What Do You Care What Other People Think

virtual reality advanced form of computer simulation, in which a participant has the illusion of being part of an artificial environment. The participant views the environment through two tiny television screens (one for each eye) built into a visor. Sensors detect movements of the participant's head or body, causing the apparent viewing position to change. Gloves (datagloves) fitted with sensors may be worn, which allow the participant seemingly to pick up and move objects in the environment.

The technology is still under development but is expected to have widespread applications; for example, in military and surgical training, architecture, and home entertainment.

WHAT IS VIRTUAL REALITY?

<http://www.cms.dmu.ac.uk/~cph/VR/whatisvr.html>

Text-based introduction to VR and an information resource list. The site covers all major aspects of the subject, and also provides a great many literature and Internet references for further reading.

Virtual Reality Modelling Language in computing, method of displaying three-dimensional images on a Web page, usually abbreviated to cVRML.

virus in computing, a piece of software that can replicate and transfer itself from one computer to another, without the user being aware of it. Some viruses are relatively harmless, but others can damage or destroy data.

Viruses are written by anonymous programmers, often maliciously, and are spread on floppy discs, CD-ROMs and via networks. Most viruses hide in the boot sectors of floppy or hard discs or infect program files, but more recently there has been a huge growth in macro viruses that infect Microsoft Word or Excel. Antivirus software can be used to detect and destroy well-known viruses, but new viruses continually appear and these may bypass existing antivirus programs.

Computer viruses may be programmed to operate on a particular date, such as Dark Avenger's Michelangelo Virus, which was triggered on 6 March 1992 (the anniversary of the birth of Italian artist Michelangelo) and erased hard discs. An estimated 5,000-10,000 PCs were affected.

virus infectious particle consisting of a core of nucleic acid (DNA or RNA) enclosed in a protein shell. Viruses are acellular and able to function and reproduce only if they can invade a living cell to use the cell's system to replicate themselves. In the process they may disrupt or alter the host cell's own DNA. The healthy human body reacts by producing an antiviral protein, interferon, which prevents the infection spreading to adjacent cells.

Many viruses mutate continuously so that the host's body has little chance of developing permanent resistance; others transfer between species, with the new host similarly unable to develop resistance. The viruses that cause AIDS and Lassa fever are both thought to have 'jumped' to humans from other mammalian hosts.

Among diseases caused by viruses are canine distemper, chickenpox, common cold, herpes, influenza, rabies, smallpox, yellow fever, AIDS, and many plant diseases. Recent evidence implicates viruses in the development of some forms of cancer (see oncogenes). Bacteriophages are viruses that infect bacterial cells.

Retroviruses are of special interest because they have an RNA genome and can produce DNA from this RNA by a process called reverse transcription.

Viroids, discovered in 1971, are even smaller than viruses; they consist of a single strand of nucleic acid with no protein coat. They may cause stunting in plants and some rare diseases in animals, including humans.

It is debatable whether viruses and viroids are truly living organisms, since they are incapable of an independent existence. Outside the cell of another organism they remain completely inert. The origin of viruses is also unclear, but it is believed that they are degenerate forms of life, derived from cellular organisms, or pieces of nucleic acid that have broken away from the genome of some higher organism and taken up a parasitic existence.

Antiviral drugs are difficult to develop because viruses replicate by using the genetic machinery of host cells, so that drugs tend to affect the host cell as well as the virus. Acyclovir (used against the herpes group of diseases) is one of the few drugs so far developed that is successfully selective in its action. It is converted to its active form by an enzyme that is specific to the virus, and it then specifically inhibits viral replication. Some viruses have shown developing resistance to the few antiviral drugs available.

Viruses have recently been found to be very abundant in seas and lakes, with between 5 and 10 million per millilitre of water at most sites tested, but up to 250 million per millilitre in one polluted lake. These viruses infect bacteria and, possibly, single-celled algae. They may play a crucial role in controlling the survival of bacteria and algae in the plankton.

viscacha Argentinian Pampas and scrubland-dwelling rodent *Lagotomus maximus* of the chinchilla family. It is up to 70 cm/2.2 ft long with a 20 cm/8 in tail, and weighs 7 kg/15 lb. It is grey and black and has a large head and small ears. Viscachas live in warrens of up to 30 individuals. They are usually nocturnal and feed on grasses, roots, and seeds.

Four species of Mountain viscacha genus *Lagidium*, also called Peruvian hares, are smaller and have long ears and tails and are found in rocky places feeding by day on sparse vegetation.

viscera general term for the organs contained in the chest and abdominal cavities.

viscose yellowish, syrupy solution made by treating cellulose with sodium hydroxide and carbon disulphide. The solution is then regenerated as continuous filament for the making of rayon and as cellophane.

viscosity in physics, the resistance of a fluid to flow, caused by its internal friction, which makes it resist flowing past a solid surface or other layers of the fluid. It applies to the motion of an object moving through a fluid as well as the motion of a fluid passing by an object.

Fluids such as pitch, treacle, and heavy oils are highly viscous; for the purposes of calculation, many fluids in physics are considered to be perfect, or nonviscous.

vision defect any abnormality of the eye that causes less-than-perfect sight. Common defects are short-sightedness or myopia; long-sightedness or hypermetropia; lack of accommodation or presbyopia; and astigmatism. Other eye defects include colour blindness.

vision system computer-based device for interpreting visual signals from a video camera. Computer vision is important in robotics where sensory abilities would considerably increase the flexibility and usefulness of a robot.

Although some vision systems exist for recognizing simple shapes, the technology is still in its infancy.

Visual Basic Microsoft computer language based on BASIC.

VISUAL PATHWAY

<http://www.hhmi.org/senses/b/b150.htm>

As part of a much larger site called 'Seeing, Hearing, and Smelling the World', here is a page explaining the way light travels from the eye to the brain and how it is converted into images our brain can understand. This site makes good use of images and animations to help with the explanations, so it is best viewed with an up-to-date browser.

visual display unit (VDU) computer terminal consisting of a keyboard for input data and a screen for displaying output. The oldest and most popular type of VDU screen is the cathode-ray tube (CRT), which uses essentially the same technology as a television screen. Other types use plasma display technology and liquid-crystal displays.

visualization in computing, turning numerical data into graphics. A simple example is to create a bar chart from a set of sales fig-

ures; more complex types of visualization include fractals and other forms of computer-generated art.

visual programming in computing, programming method that uses a system of graphics, instead of text, to build software.

vitalism the idea that living organisms derive their characteristic properties from a universal life force. In the 20th century, this view is associated with the French philosopher Henri Bergson.

vitamin any of various chemically unrelated organic compounds that are necessary in small quantities for the normal functioning of the human body. Many act as coenzymes, small molecules that enable enzymes to function effectively. Vitamins must be supplied by the diet because the body cannot make them. They are normally present in adequate amounts in a balanced diet. Deficiency of a vitamin may lead to a metabolic disorder ('deficiency disease'), which can be remedied by sufficient intake of the vitamin. They are generally classified as **water-soluble** (B and C) or **fat-soluble** (A, D, E, and K). See separate entries for individual vitamins, also nicotinic acid, folic acid, and pantothenic acid.

Scurvy (the result of vitamin C deficiency) was observed at least 3,500 years ago, and sailors from the 1600s were given fresh sprouting cereals or citrus-fruit juices to prevent or cure it. The

Vitamins

| Vitamin | Name | Main dietary sources | Established benefit | Deficiency symptoms |
|-----------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| A | retinol | dairy products, egg yolk, liver; also formed in body from β -carotene, a pigment present in some leafy vegetables | aids growth; prevents night blindness and xerophthalmia (a common cause of blindness among children in developing countries); helps keep the skin and mucous membranes resistant to infection | night blindness; rough skin; impaired bone growth |
| B ₁ | thiamin | germ and bran of seeds and grains, yeast | essential for carbohydrate metabolism and health of nervous system | beriberi; Korsakov's syndrome |
| B ₂ | riboflavin | eggs, liver, milk, poultry, broccoli, mushrooms | involved in energy metabolism; protects skin, mouth, eyes, eyelids, mucous membranes | inflammation of tongue and lips; sores in corners of the mouth |
| B ₆ | pyridoxine/part othenic acid/biotin | meat, poultry, fish, fruits, nuts, whole grains, leafy vegetables, yeast extract | important in the regulation of the central nervous system and in protein metabolism; helps prevent anaemia, skin lesions, nerve damage | dermatitis; neurological problems; kidney stones |
| B ₁₂ | cyanocobalamin | liver, meat, fish, eggs, dairy products, soybeans | involved in synthesis of nucleic acids, maintenance of myelin sheath around nerve fibres; efficient use of folic acid | anaemia, neurological disturbance |
| folic acid | nicotinic acid (or niacin) | green leafy vegetables, liver, peanuts; cooking and processing can cause serious losses in food | involved in synthesis of nucleic acids; helps protect against cervical dysplasia (precancerous changes in the cells of the uterine cervix) | megaloblastic anaemia |
| C | | meat, yeast extract, some cereals; also formed in the body from the amino acid tryptophan | maintains the health of the skin, tongue, and digestive system | pellagra |
| D | ascorbic acid | citrus fruits, green vegetables, tomatoes, potatoes; losses occur during storage and cooking | prevents scurvy, loss of teeth; fights haemorrhage; important in synthesis of collagen (constituent of connective tissue); aids in resistance to some types of virus and bacterial infections | scurvy |
| E | calciferol, cholecalciferol | liver, fish oil, dairy products, eggs; also produced when skin is exposed to sunlight | promotes growth and mineralization of bone | rickets in children; osteomalacia in adults |
| K | tocopherol | vegetable oils, eggs, butter, some cereals, nuts | prevents damage to cell membranes | anaemia |
| | phytonadione, menaquinone | green vegetables, cereals, fruits, meat, dairy products | essential for blood clotting | haemorrhagic problems |

concept of scurvy as a deficiency disease, however, caused by the absence of a specific substance, emerged later. In the 1890s a Dutch doctor, Christiaan Eijkman, discovered that he could cure hens suffering from a condition like beriberi by feeding them on whole-grain, rather than polished, rice. In 1912 Casimir Funk, a Polish-born biochemist, had proposed the existence of what he called 'vitamines' (vital amines), but it was not fully established until about 1915 that several deficiency diseases were preventable and curable by extracts from certain foods. By then it was known that two groups of factors were involved, one being water-soluble and present, for example, in yeast, rice-polishings, and wheat germ, and the other being fat-soluble and present in egg yolk, butter, and fish-liver oils. The water-soluble substance, known to be effective against beriberi, was named vitamin B. The fat-soluble vitamin complex was at first called vitamin A. As a result of analytical techniques these have been subsequently separated into their various components, and others have been discovered.

vitamin A another name for β retinol.

vitamin B₁ another name for β thiamine.

vitamin B₁₂ another name for β cyanocobalamin.

vitamin B₂ another name for β riboflavin.

vitamin B₆ another name for β pyridoxine.

vitamin C another name for β ascorbic acid.

vitamin D another name for β cholecalciferol.

vitamin E another name for β tocopherol.

vitamin H another name for β biotin.

vitamin K another name for β phytomenadione.

vitreous humour transparent jellylike substance behind the lens of the vertebrate eye. It gives rigidity to the spherical form of the eye and allows light to pass through to the retina.

vitriol any of a number of sulphate salts. Blue, green, and white vitriols are copper, ferrous, and zinc sulphate, respectively. Oil of vitriol is sulphuric acid.

viviparous in animals, a method of reproduction in which the embryo develops inside the body of the female from which it gains nourishment (in contrast to β oviparous and β ovoviviparous). Vivipary is best developed in placental mammals, but also occurs in some arthropods, fishes, amphibians, and reptiles that have placental structures. In plants, it is the formation of young plantlets or bulbils instead of flowers. The term also describes seeds that germinate prematurely, before falling from the parent plant.

Premature germination is common in mangrove trees, where the seedlings develop sizable spearlike roots before dropping into the swamp below; this prevents their being washed away by the tide.

vivisection literally, cutting into a living animal. Used originally to mean experimental surgery or dissection practised on a live subject, the term is often used by antivivisection campaigners to include any experiment on animals, surgical or otherwise.

There are people who do not object to eating mutton chop – people who do not even object to shooting pheasant with the considerable chance that it may be only wounded and may have to die after lingering pain, unable to obtain its proper nutriment – and yet consider it something monstrous to introduce under the skin of a guinea pig a little inoculation of some microbe to ascertain its action. These seem to me the most inconsistent views.

JOSEPH LISTER English surgeon.
British Medical Journal 1897

VLBI (abbreviation for *very long baseline interferometry*) in radio astronomy, a method of obtaining high-resolution images of astronomical objects by combining simultaneous observations made by two or more radio telescopes thousands of kilometres apart. The maximum resolution that can be achieved is proportional to the longest baseline in the array (the distance between any pair of telescopes), and inversely proportional to the radio wavelength being used.

VLF in physics, abbreviation for very low β frequency. VLF radio waves have frequencies in the range 3–30 kHz.

VLSI (abbreviation for *very large-scale integration*) in electronics, the early-1990s level of advanced technology in the micro-miniaturization of β integrated circuits, and an order of magnitude smaller than β LSI (large-scale integration).

VMS in computing, operating system created in 1978 by β DEC for its VAX minicomputers. VMS was for many years a popular operating system for hackers (see β hacking), although it has now been largely eclipsed by β UNIX.

V numbers in computing, series of β protocols issued by the CCITT defining the rate at which modems transfer data. The numbers have come to designate a modem's speed: V.32 modems transmit at up to 9,600 β bits per second (bps); V.32bis at up to 14,400 bps and V.34 at up to 28,800 bps.

vocal cords the paired folds, ridges, or cords of tissue within a mammal's larynx, and a bird's syrinx. Air constricted between the folds or membranes makes them vibrate, producing sounds. Muscles in the larynx change the pitch of the sounds produced, by adjusting the tension of the vocal cords.

voice sound produced through the mouth and by the passage of air between the β vocal cords. In humans the sound is much amplified by the hollow sinuses of the face, and is modified by the movements of the lips, tongue, and cheeks.

voice input in computing and electronics, an alternative name for β speech recognition.

voice mail β electronic mail including spoken messages and audio. Messages can also be generated electronically using β speech synthesis. In offices, voice mail systems are often included in computerized telephone switchboards.

voice modem in computing, β modem which handles voice as well as data communications, so that it can be used to add the capabilities of a β voice mail system to a personal computer.

Primarily aimed at small and home-based businesses, voice modems use a built-in β DSP and typically also include fax facilities.

voice output in computing and electronics, an alternative name for β speech synthesis.

voice-to-MIDI converter microphone which sends human vocal input to a synthesizer. This system of singing to run a synthesizer does not work well unless the singer has perfect pitch, so it is not commonly used.

vol abbreviation for volume.

volatile in chemistry, term describing a substance that readily passes from the liquid to the vapour phase. Volatile substances have a high β vapour pressure.

volatile memory in computing, β memory that loses its contents when the power supply to the computer is disconnected.

volcanic rock another name for β extrusive rock, igneous rock formed on the Earth's surface.

volcano crack in the Earth's crust through which hot magma (molten rock) and gases well up. The magma is termed lava when it reaches the surface. A volcanic mountain, usually cone shaped with a crater on top, is formed around the opening, or vent, by the

composite
volcanocinder
cone

shield volcano

volcano There are two main types of volcano, but three distinctive cone shapes. Composite volcanoes emit a stiff, rapidly solidifying lava which forms high, steep-sided cones. Volcanoes that regularly throw out ash build up flatter domes known as cinder cones. The lava from a shield volcano is not ejected violently, flowing over the crater rim forming a broad low profile.

build-up of solidified lava and ashes (rock fragments). Most volcanoes arise on plate margins (see plate tectonics), where the movements of plates generate magma or allow it to rise from the mantle beneath. However, a number are found far from plate-margin activity, on 'hot spots' where the Earth's crust is thin.

There are two main types of volcano:

Composite volcanoes, such as Stromboli and Vesuvius in Italy, are found at destructive plate margins (areas where plates are being pushed together), usually in association with island arcs and coastal mountain chains. The magma is mostly derived from plate

material and is rich in silica. This makes a very stiff lava such as andesite, which solidifies rapidly to form a high, steep-sided volcanic mountain. The magma often clogs the volcanic vent, causing violent eruptions as the blockage is blasted free, as in the eruption of Mount St Helens, USA, in 1980. The crater may collapse to form a caldera.

Shield volcanoes, such as Mauna Loa in Hawaii, are found along the rift valleys and ocean ridges of constructive plate margins (areas where plates are moving apart), and also over hot spots. The magma is derived from the Earth's mantle and is quite free-flowing. The lava formed from this magma – usually basalt – flows for some distance over the surface before it sets and so forms broad low volcanoes. The lava of a shield volcano is not ejected violently but simply flows over the crater rim.

The type of volcanic activity is also governed by the age of the volcano. The first stages of an eruption are usually vigorous as the magma forces its way to the surface. As the pressure drops and the vents become established, the main phase of activity begins, composite volcanoes giving pyroclastic debris and shield volcanoes giving lava flows. When the pressure from below ceases, due to exhaustion of the magma chamber, activity wanes and is confined to the emission of gases and in time this also ceases. The volcano then enters a period of quiescence, after which activity may resume after a period of days, years, or even thousands of years. Only when the root zones of a volcano have been exposed by erosion can a volcano be said to be truly extinct.

Many volcanoes are submarine and occur along mid-ocean ridges. The chief terrestrial volcanic regions are around the Pacific rim (Cape Horn to Alaska); the central Andes of Chile (with the world's highest volcano, Gualatiri, 6,060 m/19,900 ft); North Island, New Zealand; Hawaii; Japan; and Antarctica. There are more than 1,300 potentially active volcanoes on Earth. Volcanism has helped shape other members of the Solar System, including the Moon, Mars, Venus, and Jupiter's moon Io.

vole any of various rodents of the family Cricetidae, subfamily Microtinae, distributed over Europe, Asia, and North America, and related to hamsters and lemmings. They are characterized by stout bodies and short tails. They have brown or grey fur, and blunt noses, and some species reach a length of 30 cm/12 in. They feed on grasses, seeds, aquatic plants, and insects. Many show remarkable fluctuations in numbers over 3–4 year cycles.

The most common genus is *Microtus*, which includes 45 species distributed across North America and Eurasia.

Volkswagen (VW) German 'the people's car' German car manufacturer. The original VW, with its distinctive beetle shape, was

Volta, Alessandro, Giuseppe Antonio Anastasio, Count (1745–1827)

Italian physicist who invented the first electric cell (the voltaic pile, in 1800), the electrophorus (an early electrostatic generator, in 1775), and an electroscope.

studies of gas and vapour In 1776 Volta discovered methane by examining marsh gas found in Lago Maggiore. He then made the first accurate estimate of the proportion of oxygen in the air by exploding air with hydrogen to remove the oxygen. In about 1795, Volta recognized that the vapour pressure of a liquid is independent of the pressure of the atmosphere and depends only on temperature.

Mary Evans Picture Library

MTU VOLCANOES PAGE

<http://www.geo.mtu.edu/volcanoes/>

Excellent volcano page provided by Michigan Technological University. Includes a world map of volcanic activity with information on recent eruptions, the latest research in remote sensing of volcanoes, and many spectacular photographs.

Major Volcanoes Active in the 20th Century by Region

| Volcano | Height m | ft | Location | *Date |
|------------------------------|-------------|--------|---------------------------------------|-------|
| Africa | | | | |
| Cameroon | 4,096 | 13,353 | isolated mountain, Cameroon | 1986 |
| Nyiragongo | 3,470 | 11,385 | Virungu, Democratic Republic of Congo | 1994 |
| Nyamuragira | 3,056 | 10,028 | Democratic Republic of Congo | 1994 |
| Ol Doinyo Lengai | 2,886 | 9,469 | Tanzania | 1993 |
| Lake Nyos | 918 | 3,011 | Cameroon | 1986 |
| Ert'a Ale | 503 | 1,650 | Ethiopia | 1995 |
| Antarctica | | | | |
| Erebus | 4,093 | 13,200 | Ross Island, McMurdo Sound | 1995 |

*Date of last eruption

produced in Germany in 1938, to a design by Ferdinand Porsche. It was still in production in Latin America in the late 1980s, by which time it had exceeded 20 million sales.

volt SI unit of electromotive force or electric potential, symbol V. A small battery has a potential of 1.5 volts, whilst a high-tension transmission line may carry up to 765,000 volts. The domestic electricity supply in the UK is 230 volts (lowered from 240 volts in 1995); it is 110 volts in the USA.

The absolute volt is defined as the potential difference necessary to produce a current of one ampere through an electric circuit with a resistance of one ohm. It can also be defined as the potential difference that requires one joule of work to move a positive charge of one coulomb from the lower to the higher potential. It is named after the Italian scientist Alessandro Volta.

voltage commonly used term for potential difference (pd) or electromotive force (emf).

voltage amplifier electronic device that increases an input signal in the form of a voltage or potential difference, delivering an output signal that is larger than the input by a specified ratio.

voltmeter instrument for measuring potential difference (voltage). It has a high internal resistance (so that it passes only a small current), and is connected in parallel with the component across which potential difference is to be measured. A common type is constructed from a sensitive current-detecting moving-coil galvanometer placed in series with a high-value resistor (multiplier). To measure an AC (alternating current) voltage, the circuit must usually include a rectifier; however, a moving-iron instrument can be used to measure alternating voltages without the need for such a device.

volume in geometry, the space occupied by a three-dimensional solid object. A prism (such as a cube) or a cylinder has a volume equal to the area of the base multiplied by the height. For a pyra-

volume of a **cube**
 $= \text{length}^3$
 $= l^3$

volume of a **cuboid**
 $= \text{length} \times \text{breadth} \times \text{height}$
 $= l \times b \times h$

volume of a **cylinder**
 $= \pi \times (\text{radius of cross section})^2 \times \text{height}$
 $= \pi r^2 h$

volume of a **cone**
 $= \frac{1}{3} \pi \times (\text{radius of cross section})^2 \times \text{height}$
 $= \frac{1}{3} \pi r^2 h$

volume of a **sphere**
 $= \frac{4}{3} \pi \text{radius}^3$
 $= \frac{4}{3} \pi r^3$

TO REMEMBER THAT IF AN OBJECT FLOATS, IT DISPLACES WATER EQUAL TO ITS MASS, BUT IF IT SINKS, IT DISPLACES WATER EQUAL TO ITS VOLUME.

THINK OF A PEBBLE, MADE OF NEUTRONIUM. IT IS SMALL, BUT IT WEIGHS A LOT. IF IT WERE TO DISPLACE WATER EQUAL TO ITS MASS, THEN WHEN YOU THREW THIS LITTLE PEBBLE INTO A SWIMMING POOL, ALL THE WATER WOULD HAVE TO JUMP OUT OF THE SWIMMING POOL. SO IT MUST ONLY DISPLACE WATER EQUAL TO ITS VOLUME.

mid or cone, the volume is equal to one-third of the area of the base multiplied by the perpendicular height. The volume of a sphere is equal to $\frac{4}{3} \times \pi r^3$, where r is the radius. Volumes of irregular solids may be calculated by the technique of integration. See illustration on page 795.

volumetric analysis procedure used for determining the concentration of a solution. A known volume of a solution of unknown concentration is reacted with a solution of known concentration (standard). The standard solution is delivered from a burette so the volume added is known. This technique is known as titration. Often an indicator is used to show when the correct proportions have reacted. This procedure is used for acid-base, redox, and certain other reactions involving solutions.

Volvox genus of small, colonial, chlorophyll-containing, flagellate protozoa, common in ponds, and resembling green algae.

classification Volvox belongs to order Volvocida, class Phytomastigophora, subphylum Mastigophora, phylum Sarcinomastigophora.

Voskhod Russian 'ascend' Soviet spacecraft used in the mid-1960s; it was modified from the single-seat Vostok, and was the first spacecraft capable of carrying two or three cosmonauts. During Voskhod 2's flight in 1965, Aleksii Leonov made the first space walk.

Vostok Russian 'east' first Soviet spacecraft, used 1961-63. Vostok was a metal sphere 2.3 m/7.5 ft in diameter, capable of carrying one cosmonaut. It made flights lasting up to five days. Vostok 1 carried the first person into space, Yuri Gagarin.

Voyager probes two US space probes. *Voyager 1*, launched on 5 September 1977, passed Jupiter in March 1979, and reached Saturn in November 1980. *Voyager 2* was launched earlier, on 20 August 1977, on a slower trajectory that took it past Jupiter in July 1979, Saturn in August 1981, Uranus in January 1986, and Neptune in August 1989. Like the Pioneer probes, the Voyagers are on their way out of the Solar System; at the start of 1995, *Voyager 1* was 8.8 billion km/5.5 billion mi from Earth, and *Voyager 2* was 6.8 billion km/4.3 billion mi from Earth. Their tasks now include helping scientists to locate the position of the heliopause, the boundary at which the influence of the Sun gives way to the forces exerted by other stars.

Both Voyagers carry specially coded long-playing records called *Sounds of Earth* for the enlightenment of any other civilizations that might find them.

vPoP (acronym for *virtual point of presence*) telephone link which enables users to connect to a distant point of presence (PoP) for the price of a local call.

VR abbreviation for velocity ratio.

VRAM (acronym for *video random-access memory*) form of RAM that allows simultaneous access by two different devices, so

that graphics can be handled at the same time as data are updated. VRAM improves graphic display performance.

VR browser in computing, application that enables PC users to 'walk through' a virtual reality scene on their monitors.

VRML (acronym for *Virtual Reality Modelling Language*) in computing, method of displaying three-dimensional images on a Web page. VRML, which functions as a counterpart to HTML, is a platform-independent language that creates a virtual reality scene which users can 'walk' through and follow links much like a conventional Web page.

In some contexts, VRML can replace conventional computer interfaces with their icons, menus, files, and folders. It is possible to use VRML to create, for example, a virtual museum with all the elements of a real museum, including corridors, display cases and multimedia demonstrations. Other possibilities include a Web market containing stalls with goods that can be 'handled' using a mouse, or a virtual library of 'books' which can be taken off 'shelves'.

VSTOL (abbreviation for *vertical/short takeoff and landing*) aircraft capable of taking off and landing either vertically or using a very short length of runway (see STOL). Vertical takeoff requires a vector-control system that permits the thrust of the aircraft engine to be changed from horizontal to vertical for takeoff and back again to horizontal to permit forward flight. An alternative VSTOL technology developed in the USA involves tilting the wings of the aircraft from vertical to horizontal and along with them the aircraft propellers, thus changing from vertical lift to horizontal thrust.

The first VSTOL was the Convair XFY-1 in 1954. The British Harrier fighter bomber is the most successful VSTOL aircraft. It is now manufactured under licence in the USA and provides integral air support for the US Marines. In addition to the UK's Royal Air Force and Royal Navy, the Indian, Spanish, and Italian navies are equipped with the Harrier. It was used in the 1982 Falklands conflict and the 1991 Gulf War.

VT-100 in computing, type number of a simple character-based computer terminal originally supplied by DEC (Digital Equipment Corporation). VT-100 terminal emulation is commonly provided in personal computer communications software and may be useful for logging on to minicomputers and networks via the Internet.

vulcanization technique for hardening rubber by heating and chemically combining it with sulphur. The process also makes the rubber stronger and more elastic. If the sulphur content is increased to as much as 30%, the product is the inelastic solid known as ebonite. More expensive alternatives to sulphur, such as selenium and tellurium, are used to vulcanize rubber for specialized products such as vehicle tyres. The process was discovered accidentally by US inventor Charles Goodyear in 1839 and patented in 1844.

Accelerators can be added to speed the vulcanization process, which takes from a few minutes for small objects to an hour or more for vehicle tyres. Moulded objects are often shaped and vulcanized simultaneously in heated moulds; other objects may be vulcanized in hot water, hot air, or steam.

Vulpecula small constellation in the northern hemisphere just south of Cygnus, represented as a fox. It contains a major planetary nebula, the Dumbbell, and the first pulsar (pulsating radio source) to be discovered.

vulture any of various carrion-eating birds of prey in the order Falconiformes, with naked heads and necks, strong hooked bills, and keen senses of sight and smell. Vultures are up to 1 m/3.3 ft long, with wingspans of up to 3.7 m/12 ft. The plumage is usually dark, and the head brightly coloured.

The vulture's eyes are adapted to give an overall view with a magnifying area in the centre, enabling it to locate possible food sources and see the exact site in detail.

W abbreviation for west; in physics, symbol for watt.

W3 Consortium (W3C) computing industry group which seeks to promote standards and co-ordinate developments in the World Wide Web. Founded in 1994 and based at the Massachusetts Institute of Technology (MIT), the Consortium is directed by Tim Berners-Lee, inventor of the Web. The W3 Consortium is behind many initiatives, including the HTML (hypertext markup language) standard for building Web pages and the ϕ PICS content rating system.

wadi in arid regions of the Middle East, a steep-sided valley containing an intermittent stream that flows in the wet season.

wafer in microelectronics, a 'superchip' some 8–10 cm/3–4 in in diameter, for which wafer-scale integration (WSI) is used to link the equivalent of many individual ϕ silicon chips, improving reliability, speed, and cooling.

wagtail slim, narrow-billed bird of the genus *Motacilla*, in the family Motacillidae, order Passeriformes, about 18 cm/7 in long, with a characteristic flicking movement of the tail. There are about 30 species, found mostly in Eurasia and Africa.

WAIS (abbreviation for *Wide Area Information Server*) software tool for searching for and retrieving information from a range of archives on the ϕ Internet.

wait state situation when the ϕ central processing unit or a ϕ bus is idle. Wait states are necessary because system components run at different speeds.

Waldo in computing, a mechanical device, such as a gripper arm, that follows the movements of a human limb. Waldoes were developed by the nuclear industry in the 1940s for handling hazardous substances at a safe distance, and were named after a 1942 story by science-fiction writer Robert Heinlein.

Waldsterben German 'forest death' tree decline related to air pollution, common throughout the industrialized world. It appears to be caused by a mixture of pollutants; the precise chemical mix varies between locations, but it includes acid rain, ozone, sulphur dioxide, and nitrogen oxides.

Waldsterben was first noticed in the Black Forest of Germany during the late 1970s, and is spreading to many Third World countries, such as China.

Walkman trade name of a personal stereo manufactured by the Sony corporation. Introduced in 1980, it was the first easily portable cassette player with headphones, and the name Walkman is often used as a generic term.

walkthrough in computing, another name for ϕ lythrough.

wall artificial barrier of brick or stone. Walls are normally built to protect property, but in upland areas they frequently replace hedges or fences as field boundaries.

wallaby any of various small and medium-sized members of the ϕ kangaroo family.

Wallace line imaginary line running down the Lombok Strait in SE Asia, between the island of Bali and the islands of Lombok and Sulawesi. It was identified by English naturalist Alfred Russel

Wallace as separating the S Asian (Oriental) and Australian biogeographical regions, each of which has its own distinctive animals.

Subsequently, others have placed the boundary between these two regions at different points in the Malay archipelago, owing to overlapping migration patterns.

wallflower European perennial cottage garden plant with fragrant spikes of red, orange, yellow, brown, or purple flowers in spring. (*Cheiranthus cheiri*, family Cruciferae.)

wallpaper in computing, design used as a background 'desktop pattern' on ϕ graphical user interfaces (GUIs), such as Microsoft Windows or Apple's Mac OS, and visible when no ϕ windows are open. Users can choose from a range of different wallpapers, including plain colours, textures and repeating patterns, or design their own.

wall pressure in plants, the mechanical pressure exerted by the cell contents against the cell wall. The rigidity (turgor) of a plant often depends on the level of wall pressure found in the cells of the stem. Wall pressure falls if the plant cell loses water.

walnut deciduous tree, probably originating in SE Europe and now widely cultivated elsewhere. It can grow up to 30 m/100 ft high, and produces a full crop of edible nuts about twelve years after planting; the timber is used in furniture and the oil is used in cooking. (*Juglans regia*, family Juglandaceae.)

walrus Arctic marine carnivorous mammal *Odobenus rosmarus* of the same family (Otaridae) as the eared ϕ seals. It can reach 4 m/13 ft in length, and weigh up to 1,400 kg/3,000 lb. It has webbed flippers, a bristly moustache, and large tusks. It is gregarious except at breeding time and feeds mainly on molluscs. It has been hunted for its ivory tusks, hide, and blubber; the Alaskan walrus is close to extinction.

WALRUS

[http://www.seaworld.org/
animal_bytes/walrusab.html](http://www.seaworld.org/animal_bytes/walrusab.html)

Illustrated guide to the walrus including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

WAN abbreviation for wide area ϕ network.

wand in ϕ virtual reality, simple input device to allow users to interact with unseen objects in three dimensions.

Wankel engine rotary petrol engine developed by the German engineer Felix Wankel (1902–1988) in the 1950s. It operates according to the same stages as the ϕ four-stroke petrol engine cycle, but these stages take place in different sectors of a figure-eight chamber in the space between the chamber walls and a triangular rotor. Power is produced once on every turn of the rotor. The Wankel engine is simpler in construction than the four-stroke piston petrol engine, and produces rotary power directly (instead of via a crankshaft). Problems with rotor seals have prevented its widespread use.

wapiti or *elk* species of deer *Cervus canadensis*, native to North America, Europe, and Asia, including New Zealand. It is reddish-brown in colour, about 1.5 m/5 ft at the shoulder, weighs up to 450 kg/1,000 lb, and has antlers up to 1.2 m/4 ft long. It is becoming increasingly rare.

waratah Australian shrub or tree of the family Proteaceae, including the crimson-flowered *Telopea speciosissima*, floral emblem of New South Wales.

warble fly large, brownish, hairy flies, with mouthparts that are reduced or vestigial. The larva is a large maggot covered with

spines. They cause myiasis (invasion of the tissues by fly larvae) in animals.

In agriculture, warble flies are pests, causing damage to livestock, where their presence can retard growth, reduce milk and meat yield, and render hides worthless.

The larvae of *Oestrus oris* normally invade the nasal cavities of sheep and goats, and those of *Hypoderma* are skin parasites of cattle and other animals, causing 'ulcers' in the skin, a condition called warbles. In humans *Oestrus* invasion is rare, except for shepherds and goat herders, and the larva is more often noticed attempting to penetrate the eye than the nasal cavities. *Hypoderma* attempts to follow its normal pattern, migrating from the site of the bite to the shoulders or neck.

classification Warble flies are in family Oestridae, order Diptera, class Insecta, phylum Arthropoda.

warbler any of two families of songbirds, order Passeriformes. The Old World warblers are in the family Sylviidae, while the New World warblers are members of the Parulidae.

American or wood warblers (family Parulidae) are small, insect-eating birds, often brightly coloured, such as the yellow warbler, prothonotary warbler, and dozens of others. This group is sometimes placed in the same family (Emberizidae) as sparrows and juncos. Old World warblers (family Sylviidae) are typically slim and dull-plumaged above, lighter below, insectivorous, and fruit-eating, overwhelmingly represented in Eurasia and Africa. These are sometimes considered a subgroup of the same family (Muscicapidae) that includes thrushes.

wArEz in computing, slang for pirated games or other applications that can be downloaded using FTP.

warfarin poison that induces fatal internal bleeding in rats; neutralized with sodium hydroxide, it is used in medicine as an anticoagulant in the treatment of thrombosis; it prevents blood clotting by inhibiting the action of vitamin K. It can be taken orally and begins to act several days after the initial dose.

Warfarin is a crystalline powder, $C_{19}H_{16}O_6$. Heparin may be given in treatment at the same time and discontinued when warfarin takes effect. It is often given as a preventive measure, to reduce the risk of thrombosis or embolism after major surgery.

warning coloration in biology, an alternative term for aposematic coloration.

VIRAL WARTS

<http://biomed.nus.sg/nsc/viral.html>

Excellent practical information about warts from Singapore's National Skin Centre. Various treatment methods, none of them foolproof, are described. There is advice for patients who have cryotherapy and reassurance to suffers that warts are not cancerous. There are three photos of various kinds of warts.

wart protuberance composed of a local overgrowth of skin. The common wart (*Verruca vulgaris*) is due to a virus infection. It usually disappears spontaneously within two years, but can be treated with peeling applications, burning away (cautery), freezing (cryosurgery), or laser treatment.

wart hog African wild pig *Phacochoerus aethiopicus*, which has a large head with a bristly mane, fleshy pads beneath the eyes, and four large tusks. It has short legs and can grow to 80 cm/2.5 ft at the shoulder.

washing soda $Na_2CO_3 \cdot 10H_2O$ (chemical name sodium carbonate decahydrate) substance added to washing water to 'soften' it (see hard water).

Washington Convention alternative name for CITES, the international agreement that regulates trade in endangered species.

WASP

Wasps use tools. After laying her eggs, the female sand wasp sometimes uses a small pebble to smooth sand over the entrance to her nest to seal it.

wasp any of several families of winged stinging insects of the order Hymenoptera, characterized by a thin stalk between the thorax and the abdomen. Wasps can be social or solitary. Among social wasps, the queens devote themselves to egg laying, the fertilized eggs producing female workers; the males come from unfertilized eggs and have no sting. The larvae are fed on insects, but the mature wasps feed mainly on fruit and sugar. In winter, the fertilized queens hibernate, but the other wasps die.

waste materials that are no longer needed and are discarded. Examples are household waste, industrial waste (which often contains toxic chemicals), medical waste (which may contain organisms that cause disease), and nuclear waste (which is radioactive). By recycling, some materials in waste can be reclaimed for further use. In 1990 the industrialized nations generated 2 billion tonnes of waste. In the USA, 40 tonnes of solid waste are generated annually per person, roughly twice as much as in Europe or Japan.

There has been a tendency to increase the amount of waste generated per person in industrialized countries, particularly through the growth in packaging and disposable products, creating a 'throwaway society'.

waste disposal depositing of waste. Methods of waste disposal vary according to the materials in the waste and include incineration, burial at designated sites, and dumping at sea. Organic waste can be treated and reused as fertilizer (see sewage disposal). Nuclear waste and toxic waste are usually buried or dumped at sea, although this does not negate the danger.

environmental pollution Waste disposal is an increasing problem in the late 20th century. Environmental groups, such as Greenpeace and Friends of the Earth, are campaigning for more recycling, a change in lifestyle so that less waste (from packaging and containers, to nuclear materials) is produced, and safer methods of disposal.

Although incineration cuts down on landfill and can produce heat as a useful by-product it is still a wasteful method of disposal in comparison with recycling. For example, recycling a plastic bottle saves twice as much energy as is obtained by burning it.

waste disposal, USA The USA burns very little of its rubbish as compared with other industrialized countries. Most of its waste, 80%, goes into landfills. Many of the country's landfill sites will have to close in the 1990s because they do not meet standards to protect groundwater.

watch portable timepiece. In the early 20th century increasing miniaturization, mass production, and convenience led to the watch moving from the pocket to the wrist. Watches were also subsequently made waterproof, antimagnetic, self-winding, and shock-resistant. In 1957 the electric watch was developed, and in the 1970s came the digital watch, which dispensed with all moving parts.

history Traditional mechanical watches with analogue dials (hands) are based on the invention by Peter Henlein (1480-1542) of the mainspring as the energy store. By 1675 the invention of the balance spring allowed watches to be made small enough to move from waist to pocket. By the 18th century pocket-watches were

WARTHOG

http://www.seaworld.org/animal_bytes/warthogab.html

Illustrated guide to the warthog including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

accurate, and by the 20th century wristwatches were introduced. In the 1950s battery-run electromagnetic watches were developed; in the 1960s electronic watches were marketed, which used the piezoelectric oscillations of a quartz crystal to mark time and an electronic circuit to drive the hands. In the 1970s quartz watches without moving parts were developed – the solid-state watch with a display of digits. Some included a tiny calculator and such functions as date, alarm, stopwatch, and reminder beeps.

water H_2O liquid without colour, taste, or odour. It is an oxide of hydrogen with a relative molecular mass of 18. Water begins to freeze at $0^\circ C$ or $32^\circ F$, and to boil at $100^\circ C$ or $212^\circ F$. When liquid, it is virtually incompressible; frozen, it expands by $\frac{1}{11}$ of its volume. At $4^\circ C/39.2^\circ F$, one cubic centimetre of water has a mass of one gram; this is its maximum density, forming the unit of specific gravity. It has the highest known specific heat, and acts as an efficient solvent, particularly when hot. Most of the world's water is in the sea; less than 0.01% is fresh water.

Water covers 70% of the Earth's surface and occurs as standing (oceans, lakes) and running (rivers, streams) water, rain, and vapour and supports all forms of life on Earth.

According to two UN reports in January 1997 large areas of the globe will start running critically short of water in the next 30 years. Total worldwide water consumption has been growing at 2.5% a year, roughly twice as fast as population, and by 1997 had reached 4,200 cubic kilometres annually. Water consumption has risen sixfold during the 20th century. Growing demands for this resource could lead to future conflicts as many rivers cross national boundaries.

water beetle aquatic beetle with an oval, flattened, streamlined shape. The head is sunk into the thorax and the hindlegs are flattened into flippers for swimming; there is a wide variation in size within the species; they are usually dark or black in colour and the entire body has a resplendent sheen. Both the adults and larvae are entirely aquatic, and are common in still, fresh waters such as ponds and lakes.

classification Water beetles are in family Dytiscidae in the order Coleoptera, class Insecta, phylum Arthropoda.

Both adults and larvae are carnivorous. The larvae have a particularly fierce appearance with sickle-shaped mandibles, or jaws. These mandibles have holes at their tips through which the larva secretes digestive enzymes when it catches its prey. So to a great extent digestion is external, the body fluids of its victim being sucked up via the holes and the channels in the mandibles. The pupal stage is terrestrial, being spent under the soil. There are some 4,000 species within this family.

The adult beetles return to the water surface periodically to replenish their supply of air, which is trapped under their wing cases.

water boatman any water bug of the family Corixidae that feeds on plant debris and algae. It has a flattened body 1.5 cm/0.6 in long, with oarlike legs.

The name is sometimes also used for the backswimmers, genus *Notonecta*, which are superficially similar, but which can fly and which belong to a different family (Notonectidae) of bugs.

water-borne disease disease associated with poor water supply. In the Third World four-fifths of all illness is caused by water-borne diseases, with diarrhoea being the leading cause of childhood death. Malaria, carried by mosquitoes dependent on stagnant water for breeding, affects 400 million people every year and kills 5 million. Polluted water is also a problem in industrialized nations, where industrial dumping of chemical, hazardous, and radioactive wastes causes a range of diseases from headache to cancer.

waterbuck any of several African antelopes of the genus *Kobus* which usually inhabit swampy tracts and reedbeds. They vary in size from about 1.8m/6 ft to 2.1 m/7.25 ft long, are up to 1.4 m/4.5 ft tall at the shoulder, and have long brown fur. The large curved horns, normally carried only by the males, have corrugated surfaces. Some species have white patches on the buttocks. Lechwe, kor, and defassa are alternative names for some of the species.

water bug any of a number of aquatic bugs where all stages of the life cycle (adult, larval, and egg) occur in the water; the eggs are usually attached to the stems or leaves of water plants. In contrast to the land bugs, which have quite distinctly noticeable antennae, the antennae of water bugs are hidden. In general, water bugs are also less brightly coloured; they are usually varying shades of black or brown, and tend to inhabit the bottom strata of ponds, lakes, and streams. They may or may not have wings.

classification Water bugs belong to the suborder Heteroptera, order Hemiptera, class Insecta, phylum Arthropoda.

The largest water bugs, giant waterbugs, belong to the family Belostomatidae. They found in Australia, India, China, and South America. They are over 10 cm/4 in long, and prey on insects, tadpoles, and small fish.

water closet (WC) alternative name for toilet.

watercress perennial aquatic plant found in Europe and Asia and cultivated for its pungent leaves which are used in salads. (*Nasturtium officinale*, family Cruciferae.)

water cycle About one-third of the solar energy reaching the Earth is used in evaporating water. About 380,000 cubic km/95,000 cubic mi is evaporated each year. The entire contents of the oceans would take about one million years to pass through the water cycle.

waterfall When water flows over hard rock and soft rock, the soft rocks erode creating waterfalls. As the erosion processes continue, the falls move backwards, in the opposite direction of the water

water cycle or **hydrological cycle** in ecology, the natural circulation of water through the biosphere. Water is lost from the Earth's surface to the atmosphere either by evaporation caused by the Sun's heat on the surface of lakes, rivers, and oceans, or through the transpiration of plants. This atmospheric water is carried by the air moving across the Earth, and condenses as the air cools to form clouds, which in turn deposit moisture on the land and sea as rain or snow. The water that collects on land flows to the ocean in streams and rivers. See illustration on page 803.

waterfall cascade of water in a river or stream. It occurs when a river flows over a bed of rock that resists erosion; weaker rocks downstream are worn away, creating a steep, vertical drop and a plunge pool into which the water falls. Over time, continuing erosion causes the waterfall to retreat upstream forming a deep valley, or gorge.

water flea any aquatic crustacean in the order Cladocera, of which there are over 400 species. The commonest species is *Daphnia pulex*, used in the pet trade to feed tropical fish.

waterfowl any water bird, but especially any member of the family Anatidae, which consists of ducks, geese, and swans.

water gas fuel gas consisting of a mixture of carbon monoxide and hydrogen, made by passing steam over red-hot coke. The gas was once the chief source of hydrogen for chemical syntheses such as the Haber process for making ammonia, but has been largely superseded in this and other reactions by hydrogen obtained from natural gas.

water glass common name for sodium metasilicate (Na_2SiO_3). It is a colourless, jellylike substance that dissolves readily in water to give a solution used for preserving eggs and fireproofing porous materials such as cloth, paper, and wood. It is also used as an adhesive for paper and cardboard and in the manufacture of soap and silica gel, a substance that absorbs moisture.

water hyacinth tropical aquatic plant belonging to the pickerelweed family. In one growing season 25 plants can produce 2 million new plants. It is liable to choke waterways, removing nutrients from the water and blocking out the sunlight, but it can be used to purify sewage-polluted water as well as in making methane gas, compost, concentrated protein, paper, and baskets. Originating in South America, it now grows in more than 50 countries. (*Eichhornia crassipes*, family Pontederiaceae.)

water lily any of a group of aquatic plants belonging to the water lily family. The fleshy roots are embedded in mud and the large round leaves float on the surface of the water. The cup-shaped flowers may be white, pink, yellow, or blue. (Genera *Nymphaea* and *Nuphar*, family Nymphaeaceae.)

water meadow irrigated meadow. By flooding the land for part of each year, increased yields of hay are obtained. Water meadows were common in Italy, Switzerland, and England (from 1523) but have now largely disappeared.

water measurer slender long-legged wingless bug found on the water surface or on vegetation skirting the water. They are carnivorous, feeding on animals such as water fleas. They walk slowly and gracefully on the water surface using their long legs, their bodies held above the surface film.

classification The water measurers belong to the family Hydrometridae order Hemiptera class Insecta, phylum Arthropoda.

watermelon large melon belonging to the gourd family, native to tropical Africa, with a dark green rind and reddish juicy flesh studded with a large number of black seeds. It is widely cultivated in subtropical regions. (*Citrullus vulgaris*, family Cucurbitaceae.)

water mill machine that harnesses the energy in flowing water to produce mechanical power, typically for milling (grinding) grain. Water from a stream is directed against the paddles of a water wheel to make it turn. Simple gearing transfers this motion to the

millstones. The modern equivalent of the water wheel is the water turbine, used in hydroelectric power plants.

Although early step wheels were used in ancient China and Egypt, and parts of the Middle East, the familiar vertical water wheel came into widespread use in Roman times. There were two types: **undershot**, in which the wheel simply dipped into the stream, and the more powerful **overshot**, in which the water was directed at the top of the wheel. The Domesday Book records over 7,000 water mills in Britain. Water wheels remained a prime source of mechanical power until the development of a reliable steam engine in the 1700s, not only for milling, but also for metalworking, crushing and grinding operations, and driving machines in the early factories. The two were combined to form paddlewheel steamboats in the 18th century.

water of crystallization water chemically bonded to a salt in its crystalline state. For example, in copper(II) sulphate, there are five moles of water per mole of copper sulphate: hence its formula is $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. This water is responsible for the colour and shape of the crystalline form. When the crystals are heated gently, the water is driven off as steam and a white powder is formed.

water pollution any addition to fresh or sea water that disrupts biological processes or causes a health hazard. Common pollutants include nitrates, pesticides, and sewage (see *sewage disposal*), although a huge range of industrial contaminants, such as chemical byproducts and residues created in the manufacture of various goods, also enter water – legally, accidentally, and through illegal dumping.

In 1980 the UN launched the 'Drinking Water Decade', aiming for cleaner water for all by 1990. However, in 1994 it was estimated that approximately half of all people in the developing world did not have safe drinking water. A 1995 World Bank report estimated that some 10 million deaths in developing countries were caused annually by contaminated water.

water scorpion water bug in which the first pair of legs are modified into prehensile organs for grasping prey. They are carnivorous and feed on smaller insects. The prey is held securely between their first pair of legs while the water scorpion sucks up its body fluids. **classification** Water scorpion are in family Nepidae in order Hemiptera, class Insecta, phylum Arthropoda.

Another characteristic feature of these bugs is their respiratory tube. While the bug remains at the bottom of the water, the respiratory tube reaches up to the surface, thus renewing its supply of air. The respiratory tube itself has quite a complex structure. It is made up of two grooved canals locked together by minute hairs or bristles, which give it the appearance of a single tube. At the base of the tube there are two respiratory spiracles or 'air-diffusing holes'. This respiratory tube is often wrongly believed to be a stinging organ, hence the name of water scorpion.

water softener any substance or unit that removes the hardness from water. Hardness is caused by the presence of calcium and magnesium ions, which combine with soap to form an insoluble scum, prevent lathering, and cause deposits to build up in pipes and cookware (kettle fur). A water softener replaces these ions with sodium ions, which are fully soluble and cause no scum.

waterspout funnel-shaped column of water and cloud that is drawn from the surface of the sea or a lake by a cyclone.

water supply distribution of water for domestic, municipal, or industrial consumption. Water supply in sparsely populated regions usually comes from underground water rising to the surface in natural springs, supplemented by pumps and wells. Urban sources are deep artesian wells, rivers, and reservoirs, usually formed from enlarged lakes or dammed and flooded valleys, from which water is conveyed by pipes, conduits, and aqueducts to filter beds. As water seeps through layers of shingle, gravel, and sand, harmful organisms are removed and the water is then distributed by pumping or gravitation through mains and pipes.

water treatment Often other substances are added to the water, such as chlorine and fluoride; aluminium sulphate, a clarifying

agent, is the most widely used chemical in water treatment. In towns, domestic and municipal (road washing, sewage) needs account for about 135 l/30 gal per head each day. In coastal desert areas, such as the Arabian peninsula, desalination plants remove salt from sea water. The Earth's waters, both fresh and saline, have been polluted by industrial and domestic chemicals, some of which are toxic and others radioactive (see *water pollution*).

drought A period of prolonged dry weather can disrupt water supply and lead to drought. The area of the world subject to serious droughts, such as the Sahara, is increasing because of destruction of forests, overgrazing, and poor agricultural practices. A World Bank report in 1995 warned that a global crisis was imminent: chronic water shortages were experienced by 40% of the world's population, notably in the Middle East, northern and sub-Saharan Africa, and central Asia. 1.4 billion people (25 % of the population) had no access to safe drinking water in 1997.

water table the upper level of ground water (water collected underground in porous rocks). Water that is above the water table will drain downwards; a spring forms where the water table cuts the surface of the ground. The water table rises and falls in response to rainfall and the rate at which water is extracted, for example, for irrigation and industry.

In many irrigated areas the water table is falling due to the extraction of water. Below N China, for example, the water table is sinking at a rate of 1 m/3 ft a year. Regions with high water tables and dense industrialization have problems with pollution of the water table. In the USA, New Jersey, Florida, and Louisiana have water tables contaminated by both industrial wastes and saline seepage from the ocean.

Watson, James Dewey (1928–)

US biologist. His research on the molecular structure of DNA and the genetic code, in collaboration with Francis Crick, earned him a shared Nobel prize in 1962. Based on earlier works, they were able to show that DNA formed a double helix of two spiral strands held together by base pairs.

Crick and Watson published their work on the proposed structure of DNA in 1953, and explained how genetic information could be coded.

May Evans Picture Library

It is necessary to be slightly underemployed if you want to do something significant.

JAMES WATSON US biologist.
The Eighth Day of Creation

watt SI unit (symbol W) of power (the rate of expenditure or consumption of energy) defined as one joule per second. A light bulb, for example, may use 40, 60, 100, or 150 watts of power; an electric heater will use several kilowatts (thousands of watts). The watt is named after the Scottish engineer James Watt.

Watt, James (1736–1819)

Scottish engineer who developed the steam engine in the 1760s, making Thomas Newcomen's engine vastly more efficient by cooling the used steam in a condenser separate from the main cylinder. He eventually made a double-acting machine that supplied power with both directions of the piston and developed rotary motion. He also invented devices associated with the steam engine, artistic instruments and a copying process, and devised the horsepower as a description of an engine's rate of working. The modern unit of power, the watt, is named after him.

At Glasgow University, Watt was asked to repair a small working model of Newcomen's steam engine, which was temperamental and difficult to operate without air entering the cylinder and destroying the vacuum. It was also extremely costly to run in terms of the coal required to keep a sufficient head of steam in a practical engine. In Newcomen's engine, the steam in the cylinder was condensed by a jet of water, creating a vacuum. The vacuum, in turn, was filled during the power stroke by the atmosphere pressing the piston to the bottom of the cylinder. On each stroke the cylinder was

heated by the steam and cooled by the injected water, thus absorbing a tremendous amount of heat. Watt investigated the properties of steam and made measurements of boilers and pistons. He had the idea of a separate condenser (separate from the piston) that would allow the cylinder to be kept hot, and the condenser fairly cold by lagging, thus improving the thermal efficiency.

Working with manufacturer Matthew Boulton in 1782, Watt improved his machine by making it double-acting. Using a mechanical linkage known as 'parallel motion' and an extra set of valves, the engine was made to drive on both the forward and backward strokes of the piston, and a 'sun-and-planet' gear (also devised by Watt) allowed rotary motion to be produced. This new and highly adaptable engine was quickly adopted by cotton and woollen mills.

During the period 1775–90, Watt invented an automatic centrifugal governor, which cut off the steam when the engine began to work too quickly and turned it on again when it had slowed sufficiently. He also devised a steam engine indicator that showed steam pressure and the degree of vacuum within the cylinder. Because of the secretarial duties connected with his business, Watt invented a way of copying letters and drawings with a chemical process that was displaced only with the advent of the typewriter and photocopier.

Watt devised a rational method to rate the capability of his engines by considering the rate at which horses worked. After many experiments, he concluded that a 'horsepower' was 33,000 lb (15,000 kg) raised through 1 ft (0.3 m) each minute. The English-speaking world used horsepower to describe the capability of an engine until recent years.

Mary Evans Picture Library

The absolute watt is defined as the power used when one joule of work is done in one second. In electrical terms, the flow of one ampere of current through a conductor whose ends are at a potential difference of one volt uses one watt of power (watts = volts \times amperes).

wattle any of certain species of *Acacia* in Australia, where their fluffy golden flowers are the national emblem. The leathery leaves are adapted to drought conditions and avoid loss of water through transpiration by turning their edges to the direct rays of the sun. Wattles are used for tanning leather and in fencing.

WAV (abbreviation of *Windows Waveform*) in computing, audio file format for IBM-compatible PCs, widely used to distribute sounds over the Internet. WAV files, which contain a digitized recording of a sound, bear the suffix .wav.

wave in the oceans, a ridge or swell formed by wind or other causes. The power of a wave is determined by the strength of the wind and the distance of open water over which the wind blows (the fetch). Waves are the main agents of coastal erosion and deposition: sweeping away or building up beaches, creating spits and berms, and wearing down cliffs by their hydraulic action and by the corrosion of the sand and shingle that they carry. A tsunami (misleadingly called a 'tidal wave') is formed after a submarine earthquake.

As a wave approaches the shore it is forced to break as a result of friction with the sea bed. When it breaks on a beach, water and sediment are carried up the beach as **swash**; the water then drains back as **backwash**.

A **constructive wave** causes a net deposition of material on the shore because its swash is stronger than its backwash. Such waves tend to be low and have crests that spill over gradually as they break. The backwash of a **destructive wave** is stronger than its swash, and therefore causes a net removal of material from the shore. Destructive waves are usually tall and have peaked crests that

plunge downwards as they break, trapping air as they do so.

If waves strike a beach at an angle the beach material will be gradually moved along the shore (longshore drift), causing a deposition of material in some areas and erosion in others.

Atmospheric instability caused by the greenhouse effect and global warming appears to be increasing the severity of Atlantic storms and the heights of the ocean waves. Waves in the South Atlantic are shrinking – they are on average half a metre smaller than in the mid-1980s – and those in the Northeast Atlantic have doubled in size over the last 40 years. As the height of waves affects the supply of marine food, this could affect fish stocks, and there are also implications for shipping and oil and gas rigs in the North Atlantic, which will need to be strengthened if they are to avoid damage.

wave in physics, a disturbance travelling through a medium (or space). There are two types: in a longitudinal wave, such as a sound wave, the disturbance is parallel to the wave's direction of travel; in a transverse wave, such as an electromagnetic wave, it is perpendicular. The medium (for example the Earth, for seismic waves) is not permanently displaced by the passage of a wave. See also standing wave.

Physicists use the wave theory on Mondays, Wednesdays and Fridays, and the particle theory on Tuesdays, Thursdays and Saturdays.

WILLIAM HENRY BRAGG British physicist.
Attributed remark

wave-cut platform gently sloping rock surface found at the foot of a coastal cliff. Covered by water at high tide but exposed at low tide, it represents the last remnant of an eroded headland (see coastal erosion).

wave The low gentle crests of a constructive wave, with the energy of the wave flowing up the beach in a strong swash and depositing material, contrasts with the high steep crested more forceful motions of destructive waves which crash in at an angle to the beach directing all their energy into plunging waves which tear up the sand and shingle and carry it out with the strong backwash.

waveguide hollow metallic tube, either empty or containing a dielectric used to guide a high-frequency electromagnetic wave (microwave) travelling within it. The wave is reflected from the internal surfaces of the guide. Waveguides are extensively used in radar systems.

wavelength the distance between successive crests of a wave. The wavelength of a light wave determines its colour; red light has a wavelength of about 700 nanometres, for example. The complete range of wavelengths of electromagnetic waves is called the electromagnetic spectrum.

wave power power obtained by harnessing the energy of water waves. Various schemes have been advanced since 1973, when oil prices rose dramatically and an energy shortage threatened. In 1974 the British engineer Stephen Salter developed the duck – a floating boom whose segments nod up and down with the waves. The nodding motion can be used to drive pumps and spin generators. Another device, developed in Japan, uses an oscillating water column to harness wave power. A major breakthrough will be required if wave power is ever to contribute significantly to the world's energy needs, although several ideas have reached prototype stage.

A 75-kW wave-power generator off the Scottish island of Islay is one of only three in the world connected to a power grid. Since 1987 the British government has invested £1 million into this generator as a trial for a large-scale plant. In 1994 the Department of Trade and Industry announced that it would not help to fund a 600-kW version because the technology had 'limited potential', but a European grant rescued the project, and a second example is to be built.

wavetable synthesizer MIDI synthesizer that uses sampling – recordings of actual musical instruments – to create sounds. The authenticity of the sound source means that wavetable synthesizers can achieve very realistic results.

wax solid fatty substance of animal, vegetable, or mineral origin. Waxes are composed variously of esters, fatty acids, free alcohols, and solid hydrocarbons.

Mineral waxes are obtained from petroleum and vary in hardness from the soft petroleum jelly (or petrolatum) used in ointments to the hard paraffin wax employed for making candles and waxed paper for drinks cartons.

Animal waxes include beeswax, the wool wax lanolin, and spermaceti from sperm-whale oil; they are used mainly in cosmetics, ointments, and polishes. Another animal wax is tallow, a form of suet obtained from cattle and sheep's fat, once widely used to make candles and soap. Sealing wax is made from lac or shellac, a resinous substance obtained from secretions of scale insects.

Vegetable waxes, which usually occur as a waterproof coating on plants that grow in hot, arid regions, include carnauba wax (from the leaves of the carnauba palm) and candelilla wax, both of which are components of hard polishes such as car waxes.

waxbill any of a group of small, mainly African, seed-eating birds in the family Estrildidae, order Passeriformes, which also includes the grass finches of Australia. Waxbills grow to 15 cm/6 in long, are brown and grey with yellow, red, or brown markings, and have waxy-looking red or pink beaks.

They sometimes raise the young of whydahs, who lay their eggs in waxbill nests.

waxflower name given to Australian wildflowers of the genus *Eriostemon*.

wax moth greyish-brown moth with a wing span of about 3 cm/1.2 in that is a pest of beehives.

The adult female moth penetrates the hive and lays her eggs directly on the comb. The larvae feed on the wax, the pollen, and even, if there are many larvae, on the host's brood.

Proper care of the hive, and fumigating the combs before storing them, tends to keep wax moths under control.

classification Wax moths *Galleria mellonella* are in family Pyralidae, order Lepidoptera, class Insecta, phylum Arthropoda.

wax myrtle evergreen bush or tree *Myrica cerifera* of the barberry family, native to SE North America. Its fruit consists of greyish nutlets coated with a wax that is collected for making scented candles; 0.5 kg/1 lb of nutlets immersed in hot water yields about 115 g/4 oz of wax. The fruit is eaten by ground-dwelling birds such as the bobwhite and wild turkey.

waxwing any of several fruit-eating birds of the family Bombycillidae, order Passeriformes. They are found in the northern hemisphere. The Bohemian waxwing *Bombycilla garrulus* of North America and Eurasia is about 18 cm/7 in long, and is greyish-brown above with a reddish-chestnut crest, black streak at the eye, and variegated wings. It undertakes mass migrations in some years.

wayfaring tree European shrub belonging to the honeysuckle family, with clusters of fragrant white flowers, found on limy soils; it is naturalized in the northeastern USA. (*Viburnum lantana*, family Caprifoliaceae.)

weak acid acid that only partially ionizes in aqueous solution (see dissociation). Weak acids include ethanoic acid and carbonic acid. The pH of such acids lies between pH 3 and pH 6.

weak base base that only partially ionizes in aqueous solution (see dissociation); for example, ammonia. The pH of such bases lies between pH 8 and pH 10.

weak nuclear force or **weak interaction** one of the four fundamental forces of nature, the other three being gravity, the electromagnetic force, and the strong force. It causes radioactive beta decay and other subatomic reactions. The particles that carry the weak force are called weakons (or intermediate vector bosons).

and comprise the positively and negatively charged W particles and the neutral Z particle.

weakon or *intermediate vector boson* in physics, a ϕ gauge boson that carries the weak nuclear force, one of the fundamental forces of nature. There are three types of weakon, the positive and negative W particle and the neutral Z particle.

The assumption of a state of matter more finely subdivided than the atom of an element is a somewhat startling one.

J J THOMSON English physicist.
Royal Institution Lecture 1897

weapon any implement used for attack and defence, from simple clubs, spears, and bows and arrows in prehistoric times to machine guns and nuclear bombs in modern times. The first revolution in warfare came with the invention of gunpowder and the development of cannons and shoulder-held guns. Many other weapons now exist, such as grenades, shells, torpedoes, rockets, and guided missiles. The ultimate in explosive weapons are the atomic (fission) and hydrogen (fusion) bombs. They release the enormous energy produced when atoms split or fuse together. There are also chemical and bacteriological weapons, which release poisons or disease.

There floated through my mind a line from the Bhagavad Gita in which Krishna is trying to persuade the Prince to do his duty: 'I am become death, the shatterer of worlds'.

J ROBERT OPPENHEIMER US physicist.
On seeing the first atomic bomb explosion, quoted in
P Goodchild *Oppenheimer: The Father of the Atomic Bomb* 1983

weapons, nonlethal weapons designed to disable enemy troops or weaponry without fatalities.

The US nonlethal weapons programme is highly secretive but research in 1994 was believed to include low frequency noise to disorient troops, a highly adhesive foam to impede both machinery and people, and lasers to cause temporary blindness; production of these laser weapons was stopped in the USA in 1995, and the United Nations stated it was considering a ban on all such weapons.

The taser, a nonlethal stun weapon, is available commercially in the USA. It fires two darts connected to a wire that delivers a voltage sufficiently great to cause muscles to spasm, thereby temporarily disabling the target.

weasel any of various small, short-legged, lithe carnivorous mammals with bushy tails, especially the genus *Mustela*, found worldwide except Australia. They feed mainly on small rodents although some, like the mink *M. vison*, hunt aquatic prey. Most are 12–25 cm/5–10 in long, excluding the tail.

Included in this group are the North American long-tailed weasel, the northern hemisphere ermine or stoat, the Eurasian polecat, and the endangered North American black-footed ferret. In cold regions the coat colour of several species changes to white during the winter.

weather day-to-day variation of climatic and atmospheric conditions at any one place, or the state of these conditions at a place at any one time. Such conditions include humidity, precipitation, temperature, cloud cover, visibility, and wind. To a meteorologist the term 'weather' is limited to the state of the sky, precipitation, and visibility as affected by fog or mist. A region's climate is derived from the average weather conditions over a long period of time. See also climatology.

Weather forecasts, in which the likely weather is predicted for a particular area, based on meteorological readings, may be short-range (covering a period of one or two days), medium-range (five to seven days), or long-range (a month or so). Readings from a

DAN'S WILD WILD WEATHER PAGE

<http://www.whnt19.com/kidwx/index.html>

Excellent introduction to the weather for kids. It has pages dealing with everything from climate to lightning, from satellite forecasting to precipitation; all explained in a lively style with plenty of pictures.

series of scattered recording stations are collected and compiled on a weather map. Such a procedure is called synoptic forecasting. The weather map uses conventional symbols to show the state of the sky, the wind speed and direction, the kind of precipitation, and other details at each gathering station. Points of equal atmospheric pressure are joined by lines called isobars (lines joining places of equal pressure). The trends shown on such a map can be extrapolated to predict what weather is coming.

weather area any of the divisions of the sea around the British Isles for the purpose of weather forecasting for shipping. The areas are used to indicate where strong or gale-force winds are expected.

weathering process by which exposed rocks are broken down on the spot by the action of rain, frost, wind, and other elements of the weather. It differs from corrosion in that no movement or transportation of the broken-down material takes place. Two types of weathering are recognized: physical (or mechanical) and chemical. They usually occur together.

physical weathering This includes such effects as freeze-thaw (the splitting of rocks by the alternate freezing and thawing of water trapped in cracks) and exfoliation, or onion-skin weathering (flaking caused by the alternate expansion and contraction of rocks in response to extreme changes in temperature).

chemical weathering Involving a chemical change in the rocks affected, the most common form is caused by rainwater that has absorbed carbon dioxide from the atmosphere and formed a weak carbonic acid. This then reacts with certain minerals in the rocks and breaks them down. Examples are the solution of caverns in limestone terrains, and the breakdown of feldspars in granite to form china clay or kaolin.

Although physical and chemical weathering normally occur together, in some instances it is difficult to determine which type is involved. For example, exfoliation, which produces rounded boulders in arid regions, such as Ayers Rock in central Australia, may be caused by the daily physical expansion and contraction of the surface layers of the rock in the heat of the Sun, or by the chemical reaction of the minerals just beneath the surface during the infrequent rains of these areas.

Weathering

physical weathering

| | |
|---------------------|---------------------------------------------------------------------------------------------------------|
| temperature changes | weakening rocks by expansion and contraction |
| frost | wedging rocks apart by the expansion of water on freezing |
| unloading | the loosening of rock layers by release of pressure after the erosion and removal of those layers above |

chemical weathering

| | |
|-------------|---------------------------------------------------------------------------------------|
| carbonation | the breakdown of calcite by reaction with carbonic acid in rainwater |
| hydrolysis | the breakdown of feldspar into china clay by reaction with carbonic acid in rainwater |
| oxidation | the breakdown of iron-rich minerals due to rusting |
| hydration | the expansion of certain minerals due to the uptake of water |

weaver any small bird of the family Ploceidae, order Passeriformes; they are mostly about 15 cm/6 in long. The majority of weavers are African, a few Asian. The males use grasses to weave elaborate globular nests in bushes and trees. The nests are entered from beneath, and the male hangs from it calling and flapping his wings to attract a female. Their bodies are somewhat elongated and the tails long, and the prominent conical bill is very powerful. They eat insects and may eat cultivated grain. Males are often more brightly coloured than females.

Many kinds are polygamous, so build several nests, and some species build large communal nests with many chambers. One species, the red-bellied African quelea *Quelea quelea*, lives and breeds in flocks numbering many thousands of individuals; the flocks migrate to follow food sources. Their destructive power can equal that of locusts.

Web authoring tool in computing, software for creating Web pages. The basic Web authoring tool is HTML, the source code that determines how a Web page is constructed and how it looks. Other programs, such as Java and VRML, can also be incorporated to enhance Web pages with animations and interactive features. Commercial authoring tools include HoTMetaL PRO, NetObjects' Fusion, and Microsoft's Front Page.

Web browser in computing, client software that allows access to the World-Wide Web. See browser.

weber SI unit (symbol Wb) of magnetic flux (the magnetic field strength multiplied by the area through which the field passes). It is named after German chemist Wilhelm Weber. One weber equals 10^8 maxwells.

A change of flux at a uniform rate of one weber per second in an electrical coil with one turn produces an electromotive force of one volt in the coil.

Webmaster in computing, system administrator for a server on the World Wide Web.

Web page in computing, a hypertext document on the World Wide Web.

webspinner gregarious web-spinning insects that construct and live in silken tunnels. They are generally found living under stones or bark. There are 140 species, mainly tropical.

Webspinners are small and either brown or yellowish-brown, with smoky wings. The female is wingless and the males, usually, have two pairs of wings. Metamorphosis is absent in the females and slight in the males. The females take care of the eggs and young.

classification Webspinners are in order Embioptera, class Insecta, phylum Arthropoda.

webzine magazine published on the Web, instead of on paper. Notable examples include *FEED* (about culture and technology), *Slate* (a serious periodical funded by Microsoft), and *Suck* (satire).

wedge block of triangular cross-section that can be used as a simple machine. An axe is a wedge: it splits wood by redirecting the energy of the downward blow sideways, where it exerts the force needed to split the wood.

weedkiller or herbicide chemical that kills some or all plants. Selective herbicides are effective with cereal crops because they kill all broad-leaved plants without affecting grasslike leaves. Those that kill all plants include sodium chlorate and paraquat; see also Agent Orange. The widespread use of weedkillers in agriculture has led to an increase in crop yield but also to pollution of soil and water supplies and killing of birds and small animals, as well as creating a health hazard for humans.

weever fish any of a family (Trachinidae) of marine bony fish of the perch family, especially the genus *Trachinus*, with poison glands on the dorsal fin and gill cover that can give a painful sting. It grows up to 5 cm/2 in long, has eyes near the top of the head, and lives on sandy seabeds.

weevil any of a superfamily (Curculionioidea) of beetles, usually less than 6 mm/0.25 in long, and with a head prolonged into a downward beak, which is used for boring into plant stems and trees for feeding.

The larvae are usually white and the adults green, black, or

weevil The long down-turned snout or beak typical of the weevils is clearly seen on this *Rhinastus lateris* from the rainforests of Peru. This is a giant of its kind; most European weevils would fit comfortably on the tip of its snout. The larvae develop inside tree branches. Premaphotos Wildlife

brown. The grain weevil *Sitophilus granarius* is a serious pest of stored grain and the boll weevil *Anthonomus grandis* damages cotton crops.

Wegener, Alfred Lothar (1880–1930)

German meteorologist and geophysicist whose theory of continental drift, expounded in *Origin of Continents and Oceans* in 1915, was originally known as 'Wegener's hypothesis'. His ideas can now be explained in terms of plate tectonics, the idea that the Earth's crust consists of a number of plates, all moving with respect to one another.

May Evans Picture Library

weight the force exerted on an object by gravity. The weight of an object depends on its mass – the amount of material in it – and the strength of the Earth's gravitational pull, which decreases with height. Consequently, an object weighs less at the top of a mountain than at sea level. On the surface of the Moon, an object has only one-sixth of its weight on Earth, because the Moon's surface gravity is one-sixth that of the Earth.

weightlessness the apparent loss in weight of a body in free fall. Astronauts in an orbiting spacecraft do not feel any weight because they are falling freely in the Earth's gravitational field. It is incorrect to attribute weightlessness to the astronauts being beyond the influence of Earth's gravity. The same phenomenon can

be experienced in a falling lift or in an aircraft deliberately imitating the path of a freely falling object.

weights and measures see under C.G.S. system, F.P.S. system, M.K.S. system, SI units.

God has ordered all his creation by Weight and Measure.

JUSTUS VON LIEBIG German chemist.

Notice above entrance to Liebig's laboratory

Weill's disease or *leptospirosis* infectious disease of animals that is occasionally transmitted to human beings, usually by contact with water contaminated with rat urine. It is characterized by acute fever, and infection may spread to the brain, liver, kidneys, and heart. It has a 10% mortality rate.

The usual form occurring in humans is caused by a spiral-shaped bacterium (spirochete) that is a common parasite of rats. The condition responds poorly to antibiotics, and death may result.

Weimaraner breed of large gundog bred in the German state of Weimar at the end of the 18th century as a pointer. Its smooth coat is a striking silvery grey. It has an athletic build, stands up to 69 cm/27.5 in tall, and its tail is docked.

Weimaraners are unusual in having pale amber or even blue-grey eyes.

weir low wall built across a river to raise the water level.

welding joining pieces of metal (or nonmetal) at faces rendered plastic or liquid by heat or pressure (or both). The principal processes today are gas and arc welding, in which the heat from a gas flame or an electric arc melts the faces to be joined. Additional 'filler metal' is usually added to the joint.

Forge (or hammer) welding, employed by blacksmiths since early times, was the only method available until the late 19th century. Resistance welding is another electric method in which the weld is formed by a combination of pressure and resistance heating from an electric current. Recent developments include electric-slag, electron-beam, high-energy laser, and the still experimental radio-wave energy-beam welding processes.

WELL, the (acronym for *Whole Earth 'Electronic Link*) San Francisco-based electronic conferencing system. It was founded in 1984 by Stewart Brand, with Larry Brilliant, Matthew McClure, and Kevin Kelly (later founding editor of *Wired* magazine). The WELL includes among its 11,000 members a mix of leading journalists and writers, Grateful Dead fans, and technological inventors.

The WELL featured in the 1995 arrest of hacker Kevin Mitnick, and was the site where the first few Computers, Freedom, and Privacy conferences (annual gatherings to discuss the future impact of technology) were planned. The WELL was bought in 1994 by Reebok founder Bruce Katz.

Welsh corgi breed of dog with a foxlike head and pricked ears, originally bred for cattle herding. The coat is dense, with several varieties of colouring. Corgis are about 30 cm/12 in at the shoulder, and weigh up to 12 kg/27 lb.

There are two types of corgi, the Pembroke and the Cardigan. The Pembroke has a finely textured coat, yellowish or reddish brown, or sometimes black and tan, and has almost no tail. The Cardigan corgi has a short, rough coat, usually red and white, and a long furry tail. Their small size was an advantage because cattle were unable to bend low enough to gore them.

welwitschia woody plant found in the deserts of SW Africa. It has a long, water-absorbent taproot and can live for up to 100 years. (*Welwitschia mirabilis*, order Gnetales.)

Westerlies prevailing winds from the west that occur in both hemispheres between latitudes of about 35° and 60°. Unlike the trade winds, they are very variable and produce stormy weather.

The Westerlies blow mainly from the SW in the northern hemisphere and the NW in the southern hemisphere, bringing moist weather to the W coast of the landmasses in these latitudes.

West Highland terrier breed of small, stockily-built crierrier from Scotland with short legs and fairly long pure white coat. It stands about 28 cm/11 in tall.

weta flightless insect *Deinacrida rugosa*, 8.5 cm/3.5 in long, resembling a large grasshopper, found on offshore islands of New Zealand.

wetland permanently wet land area or habitat. Wetlands include areas of (marsh, fen, bog, flood plain, and shallow coastal areas. Wetlands are extremely fertile. They provide warm, sheltered waters for fisheries, lush vegetation for grazing livestock, and an abundance of wildlife. Estuaries and seaweed beds are more than 16 times as productive as the open ocean.

The term is often more specifically applied to a naturally flooding area that is managed for agriculture or wildlife. A water meadow, where a river is expected to flood grazing land at least once a year thereby replenishing the soil, is a traditional example.

WHALE

A whale's skull is made up of 30 bones (compared with 22 in the human skull).

whale any marine mammal of the order Cetacea. The only mammals to have adapted to living entirely in water, they have front limbs modified into flippers and no externally visible traces of hind limbs. They have horizontal tail flukes. When they surface to breathe, the hot air they breathe out condenses to form a 'spout' through the blowhole (single or double nostrils) in the top of the head. Whales are intelligent and have a complex communication system, known as 'songs'. They occur in all seas of the world.

The order is divided into two groups: the toothed whales (Odontoceti) and the baleen whales (Mysticeti). Toothed whales are predators, feeding on fish and squid. They include dolphins and porpoises, along with large forms such as sperm whales. The largest whales are the baleen whales, with plates of modified mucous membrane called baleen (whalebone) in the mouth; these strain the food, mainly microscopic plankton, from the water. Baleen whales include the finback and right whales, and the blue whale, the largest animal that has ever lived, of length up to 30 m/100 ft.

Whales have been hunted for hundreds of years (see whaling); today they are close to extinction. Of the 11 great whale species, 7 were listed as either endangered or vulnerable in 1996. Whale-watching, as an economic alternative to whaling, generated \$121 million worldwide in 1994.

whaling the hunting of whales. Whales have been killed by humans since at least the middle ages. There were hundreds of thousands of whales at the beginning of the 20th century, but the invention of the harpoon in 1870 and improvements in ships and mechanization have led to the near-extinction of several species of whale. Commercial whaling was largely discontinued in 1986, although Norway and Japan have continued commercial whaling. Traditional whaling areas include the coasts of Greenland and Newfoundland, but the Antarctic, in the summer months, supplies the bulk of the catch.

Practically the whole of the animal can be utilized in one form or another: whales are killed for whale oil (made from the thick layer of fat under the skin called 'blubber'), which is used as a lubricant, or for making soap, candles, and margarine; for the large reserve of oil in the head of the sperm whale, used in the leather industry; and for ambergris, a waxlike substance from the intestines of the sperm whale, used in making perfumes.

Whalebone was used by corset manufacturers and in the brush trade; there are now synthetic substitutes for all these products. Whales have also been killed for use in pet food manufacture in the USA and Europe, and as a food in Japan. The flesh and ground bones are used as soil fertilizers.

wheat cereal plant derived from the wild *Triticum*, a grass native to the Middle East. It is the chief cereal used in breadmaking and is widely cultivated in temperate climates suited to its growth. Wheat is killed by frost, and damp makes the grains soft, so warm, dry regions produce the most valuable grain.

The main wheat-producing areas of the world are the Ukraine, the prairie states of the USA, the Punjab in India, the prairie provinces of Canada, parts of France, Poland, S Germany, Italy, Argentina, and SE Australia. Flour is milled from the nutritious tissue surrounding the embryonic plant in the grain (the endosperm); the coatings of the grain produce bran. Semolina is also prepared from wheat; it is a by-product from the manufacture of fine flour.

wheatear small (15 cm/6 in long) migratory bird *Oenanthe oenanthe* of the family Muscipidae, order Passeriformes (which includes thrushes). Wheatears are found throughout the Old World and also breed in far northern parts of North America. The plumage is light grey above and white below with a buff tinge on the breast, a black face-patch, and black and white wings and tail. In flight a white patch on the lower back and tail is conspicuous. The wheatear's food consists chiefly of insects.

whelk any of various families of large marine snails with a thick spiral shell, especially the family Buccinidae. Whelks are scavengers, and also eat other shellfish. The largest grow to 40 cm/16 in long. Tropical species, such as the conches, can be very colourful.

why watery by-product of the cheesemaking process, which is drained off after the milk has been heated and (rennet (a curdling agent) added to induce its coagulation.

In Scandinavia, especially Norway, whey is turned into cheese, *mystost* and (from goat's whey) *qjast*. The flavour of whey cheese is sweet from added brown sugar and is an acquired taste.

whimbrel wading bird *Numenius phaeopus*, order Charadriiformes, with a medium-sized down-curved bill, streaked brown plumage, and striped head. About 40 cm/1.3 ft long, it breeds in the Arctic, and winters in Africa, S North America, South America, and S Asia. It is related to the curlew.

whiplash injury damage to the neck vertebrae and their attachments caused by a sudden backward jerk of the head and neck. It is most often seen in vehicle occupants as a result of the rapid deceleration experienced in a crash.

whippet breed of dog resembling a small greyhound. It grows to 56 cm/22 in at the shoulder, and 9 kg/20 lb in weight.

whippoorwill North American nightjar *Caprimulgus vociferus*, order Caprimulgiformes, so called from its cry during the nights of its breeding season. It is about 25 cm/10 in long, mottled tawny brown in colour, with a white collar on the throat, and long, stiff bristles at the base of the bill.

whip snake or *coachwhip* any of the various species of nonpoisonous slender-bodied tree-dwelling snakes of the New World genus *Masticophis*, family Colubridae. They are closely allied to members of the genus *Coluber* of SW North America, Eurasia, Australasia, and N Africa, some of which are called whip snakes in the Old World, but racers in North America.

Whip snakes grow to about 1.5 m/5 ft in length, move very quickly, and are partially tree-dwelling. They feed on rodents, small birds, lizards, sucker frogs, and insects. All lay eggs.

whirligig beetle aquatic steel-black beetle with an oval, flattened body. The second and third pairs of legs are exceptionally

short and broad, and are used for paddling in the water. About 400 species have been recorded.

classification The whirligig beetle is in the family Gyrinidae of order Coleoptera, class Insecta, phylum Arthropoda.

Whirligig beetles are usually found in groups whirling around on the water surface. When disturbed they dart into the water. Both adults and larvae are carnivorous, feeding on small insects that fall onto the water. The adults have well developed wings and are capable of flying from one pond to the next.

whirling disease parasitic disease of trout. The parasite *Myxobolus cerebralis* spends part of its life cycle in tubifex worms, before moving to trout where it consumes the cartilage causing eventual death. Infected fish start to swim in circles after their spines have been destroyed, hence the name.

whirlwind rapidly rotating column of air, often synonymous with a tornado. On a smaller scale it produces the dust-devils seen in deserts.

whitebait any of the fry (young) of various silvery fishes, especially cherring. It is also the name for a Pacific smelt *Osmerus mordax*.

whitebeam tree native to S Europe, usually found growing on chalk or limestone. It can reach 20 m/60 ft in height. It takes its name from the dense coat of short white hairs on the underside of the leaves. (*Sorbus aria*, family Rosaceae.)

white blood cell or *leucocyte* one of a number of different cells that play a part in the body's defences and give immunity against disease. Some (phagocytes and macrophages) engulf invading microorganisms, others kill infected cells, while lymphocytes produce more specific immune responses. White blood cells are colourless, with clear or granulated cytoplasm, and are capable of independent amoeboid movement. They occur in the blood, lymph, and elsewhere in the body's tissues.

Unlike mammalian red blood cells, they possess a nucleus. Human blood contains about 11,000 leucocytes to the cubic millimetre – about one to every 500 red cells.

White blood cell numbers may be reduced (leucopenia) by starvation, pernicious anaemia, and certain infections, such as typhoid and malaria. An increase in their numbers (leucocytosis) is a reaction to normal events such as digestion, exertion, and pregnancy, and to abnormal ones such as loss of blood, cancer, and most infections.

white dwarf small, hot star, the last stage in the life of a star such as the Sun. White dwarfs make up 10% of the stars in the Galaxy; most have a mass 60% of that of the Sun, but only 1% of the Sun's diameter, similar in size to the Earth. Most have surface temperatures of 8,000°C/14,400°F or more, hotter than the Sun. Yet, being so small, their overall luminosities may be less than 1% of that of the Sun. The Milky Way contains an estimated 50 billion white dwarfs.

whitefish any of various freshwater fish, genera *Coregonus* and *Prosopium*, of the salmon family, found in lakes and rivers of North America and Eurasia. They include the whitefish *C. clupeaformis* and cisco *C. artedii*.

whitefly tiny four-winged insect related to aphids and scale insects. The adults barely exceed a length of 3 mm/0.12 in; their wings are dusted with a powdery white wax which they secrete. In temperate countries they may be found in glasshouses, where they are pests of plants, such as cucumber and tomato. They are widely distributed in the tropics, where they attack citrus trees. They injure the plant by feeding on the sap and excreting honeydew, which encourages sooty black mould to grow.

classification Whiteflies are in family Aleyrodidae in order Hemiptera, class Insecta, phylum Arthropoda.

development In general the eggs are laid on the undersurface of leaves in a characteristic circular or arch-shape, and are attached to the leaves by means of a stalk. Each female lays about 100 eggs that hatch into first-instar larvae, which are oval-shaped, have

antennae, walking legs, and feed actively by means of their stylets and proboscis. The mobile first-instar larva moults into a rather immobile second-instar larva, which is similar in shape, but has much shorter legs and antennae; third and fourth instars follow; the fourth feeds initially, but then stops and secretes a case around itself which bears waxy filaments. The case splits along a characteristic T-shaped line of suture (dorsally) and the adult whitefly emerges.

whiteout 'fog' of grains of dry snow caused by strong winds in temperatures of between -18°C/0°F and -1°C/30°F. The uniform whiteness of the ground and air causes disorientation in humans.

white spirit colourless liquid derived from petrol; it is used as a solvent and in paints and varnishes.

whitethroat any of several Old World warblers of the genus *Sylvia* in the family Muscicapidae, order Passeriformes. They are found in scrub, hedges, and wood clearings of Eurasia in summer, migrating to Africa in winter. They are about 14 cm/5.5 in long.

whiting predatory fish *Merlangius merlangus* common in shallow sandy N European waters. It grows to 70 cm/2.3 ft.

Whittle, Frank (1907–1996)

British engineer. He patented the basic design for the turbojet engine in 1930. In the Royal Air Force he worked on jet propulsion 1937–46. In May 1941 the Gloster E 28/39 aircraft first flew with the Whittle jet engine. Both the German (first operational jet planes) and the US jet aircraft were built using his principles. He was knighted in 1948.

WHO acronym for *World Health Organization*.

whois in computing, searchable database of every registered domain and the names of their users. A special application, also called Whois, is needed to search the database.

whooping cough or *pertussis* acute infectious disease, seen mainly in children, caused by colonization of the air passages by the bacterium *Bordetella pertussis*. There may be catarrh, mild fever, and loss of appetite, but the main symptom is violent coughing, associated with the sharp intake of breath that is the characteristic 'whoop', and often followed by vomiting and severe nose bleeds. The cough may persist for weeks.

Although debilitating, the disease is seldom serious in older children, but infants are at risk both from the illness itself and from susceptibility to other conditions, such as pneumonia. During 1995, there were 355,000 deaths from whooping cough. Immunization lessens the incidence and severity of the disease: the whole cell (or 'killed') vaccine has been replaced by an acellular version, which is made up from the bacteria *Bordetella pertussis*, and has fewer side effects than its predecessor.

A new strain of the bacterium *Bordetella pertussis*, which had first appeared in about 1985, spread across Europe in 1997. It arose in the Netherlands and by October there were 2,785 cases there compared with 321 in 1995.

whortleberry a form of bilberry.

whydah any of various African birds of the genus *Vidua*, order Passeriformes, of the weaver family. They lay their eggs in the nests of waxbills, which rear the young. Young birds resemble young waxbills, but the adults do not resemble adult waxbills. Males have long tail feathers used in courtship displays.

wide-angle lens photographic lens of shorter focal length than normal, taking in a wider angle of view.

wide area network in computing, a ϕ network that connects computers distributed over a wide geographical area.

widget plastic device inserted into beer cans to give the beer a creamier head. Pressurized gas, trapped in the widget during canning, is released through a tiny nozzle when the can is opened. The first widget, introduced by Guinness in 1989, released pressurized nitrogen.

Wien's displacement law in physics, a law of radiation stating that the wavelength carrying the maximum energy is inversely proportional to the absolute temperature of a ϕ black body: the hotter a body is, the shorter the wavelength. It has the form $\lambda_{\max} T = \text{constant}$, where λ_{\max} is the wavelength of maximum intensity and T is the temperature. The law is named after German physicist Wilhelm Wien.

wigeon either of two species of dabbling duck of genus *Anas*, order Anseriformes. The American wigeon *A. americana*, about 48 cm/19 in long, is found along both coasts in winter and breeds inland. Males have a white-capped head and a green eye stripe.

wild card in computing, character which represents 'any character' in a search or command. When comparing ϕ strings, the computer does not seek a precise match for a wild card character. The most useful wildcards are ϕ , which matches any single character, and ϕ^* , which matches any number of characters, including zero. Hence the ϕ DOS commands DEL ϕ^* - delete all files - and COPY ϕ .DOC - copy all files with the filename extension 'DOC'.

wildebeest or *gnu* either of two species of African ϕ antelope, with a cowlike face, a beard and mane, and heavy curved horns in both sexes. The body is up to 1.3 m/4.2 ft high at the shoulder and slopes away to the hindquarters. (Genus *Connochaetes*.)

The **brindled wildebeest** *C. taurinus* is silver-grey with a dark face, mane, and tail tuft, and is found from Kenya southwards. Vast herds move together on migration. The **white-tailed wildebeest** *C. gnou* of South Africa almost became extinct, but was saved by breeding on farms.

wilderness area of uninhabited land that has never been disturbed by humans, usually located some distance from towns and cities. According to estimates by US group Conservation International, 52% (90 million sq km/35 million sq mi) of the Earth's total land area was still undisturbed in 1994.

wildebeest The brindled wildebeest *Connochaetes taurinus* is known for the huge migratory herds which can be observed each year in the Serengeti-Masai Mara plains in E Africa. It is a close grazer, so relies heavily on the renewal of the long grasses through regular burning. Premaphotos Wildlife

The self-eulogizing attempts of expatriates to impose the notion of wildlife as a treasured legacy overlook the reality that to most of a local impoverished and inert populace wildlife is considered an obstacle ...

DIAN FOSSEY US primatologist.
Gorillas in the Mist

wildlife trade international trade in live plants and animals, and in wildlife products such as skins, horns, shells, and feathers. The trade has made some species virtually extinct, and whole ecosystems (for example, coral reefs) are threatened. Wildlife trade is to some extent regulated by ϕ CITES (Convention on International Trade in Endangered Species).

Species almost eradicated by trade in their products include

Threatened Plants and Animals from the World Wildlife Trade

| Common name | Scientific name | Range | Reason threatened |
|---------------------------|-----------------------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alligator snapping turtle | <i>Macrochelys temminckii</i> | North America | used in canned turtle soup, a delicacy in some countries; also sold as pets |
| beluga sturgeon | <i>Huso huso</i> | Caspian Sea | caviar is a delicacy in many countries; the long life cycle of the fish makes the population more vulnerable |
| big leaf mahogany | <i>Swietenia macrophylla</i> king | Central and South America | mahogany wood is used for furniture in many countries |
| black rhino | <i>Diceros bicornis</i> | Africa | hunted for their horns, which are used in powdered form in oriental medicine |
| giant panda | <i>Ailuropoda melanaleca</i> | China | destruction of the bamboo forests, the natural habitat for pandas, makes the population more vulnerable; as does poaching and demand as zoo animals |
| goldenseal | <i>Hydrastis canadensis</i> | North America | used in herbal medicine as a 'natural antibiotic'; demand has increased as herbal medicine becomes more widespread |
| green-cheeked parrot | <i>Amazona viridiginohs</i> | Mexico | hunted and captured for pet trade; many birds die in transit |
| hawksbill turtle | <i>Eretmochelys imbricata</i> | tropical seas | the shell is used as tortoiseshell, although under an official ban in most places; the slow reproductive cycle of the turtle makes the population more vulnerable |
| mako shark | <i>Isurus oxyrinchus</i> | Atlantic, Pacific, and Indian oceans | shark meat is a delicacy in some countries; the slow reproductive cycle makes the population more vulnerable |
| tiger | <i>Panthera tigris</i> | Asia | destruction of jungle; hunted for bones and other parts for use in oriental medicine |

Source: Convention on International Trade in Endangered Species, World Wide Fund for Nature

many of the largest whales, crocodiles, marine turtles, and some wild cats. Until recently, some 2 million snake skins were exported from India every year. Populations of black rhino and African elephant have collapsed because of hunting for their horns and tusks (ivory), and poaching remains a problem in cases where trade is prohibited.

wild type in genetics, the naturally occurring gene for a particular character that is typical of most individuals of a given species, as distinct from new genes that arise by mutation.

will-o'-the-wisp light sometimes seen over marshy ground, believed to be burning gas containing methane from decaying organic matter.

An Australian scientist put forward the hypothesis in 1995 that the phenomenon may be caused by barn owls, which sometimes develop a ghostly glow due to a light-emitting honey fungus that they pick up from rotting trees.

willow any of a group of trees or shrubs containing over 350 species, found mostly in the northern hemisphere, flourishing in damp places. The leaves are often lance-shaped, and the male and female catkins are borne on separate trees. (Genus *Salix*, family Salicaceae.)

willowherb any of a group of perennial flowering plants belonging to the evening primrose family. The rosebay willowherb or fireweed *C. angustifolium* is common in woods and wasteland. It grows to 1.2 m/4 ft with tall upright spikes of red or purplish flowers. (Genera *Epilobium* and *Chamaenerion*, family Onagraceae.)

willow warbler bird *Phylloscopus trochilus*, family Muscicapidae, order Passeriformes. It is about 11 cm/4 in long, similar in appearance to the chiffchaff, but with a distinctive song. It is found in woods and shrubberies, and migrates from N Eurasia to Africa.

wilting the loss of rigidity (turgor) in plants, caused by a decreasing wall pressure within the cells making up the supportive tissues. Wilting is most obvious in plants that have little or no wood.

WIMP (abbreviation for *weak interacting massive particle*) hypothetical subatomic particle found in the Galaxy's dark matter. These particles could constitute the 80% of dark matter unaccounted for by χ MACHOs (massive astrophysical compact halo objects).

WIMP (acronym for *windows, icons, menus, pointing device*) in computing, another name for ϕ graphical user interface (GUI).

Winchester drive in computing, an old-fashioned term for ϕ hard disc.

WinCode in computing, program developed by US company Snappy Inc, that uses a process known as bit-shifting to UEncode and ϕ UDecode binary programs and files in 7-bit ASCII text so that they can be transmitted via online systems and over the Internet. Several other coding systems are also used, and recent versions of WinCode can handle most of the common formats. WinCode is a copyright program distributed as ϕ freeware.

wind the lateral movement of the Earth's atmosphere from high-pressure areas (anticyclones) to low-pressure areas (depression). Its speed is measured using an ϕ anemometer or by studying its

effects on, for example, trees by using the ϕ Beaufort scale. Although modified by features such as land and water, there is a basic worldwide system of ϕ trade winds, ϕ westerlies, and polar easterlies.

A belt of low pressure (the ϕ doldrums) lies along the Equator. The trade winds blow towards this from the horse latitudes (areas of high pressure at about 30° N and 30° S of the Equator), blowing from the NE in the northern hemisphere, and from the SE in the southern. The Westerlies (also from the horse latitudes) blow north of the Equator from the SW and south of the Equator from the NW.

Cold winds blow outwards from high-pressure areas at the poles. More local effects result from landmasses heating and cooling faster than the adjacent sea, producing onshore winds in the daytime and offshore winds at night.

The ϕ monsoon is a seasonal wind of S Asia, blowing from the SW in summer and bringing the rain on which crops depend. It blows from the NE in winter.

Famous or notorious warm winds include the chinook of the eastern Rocky Mountains, North America; the föhn of Europe's Alpine valleys; the sirocco (Italy)/khamsin (Egypt)/sharav (Israel), spring winds that bring warm air from the Sahara and Arabian deserts across the Mediterranean; and the Santa Ana, a periodic warm wind from the inland deserts that strikes the California coast.

The dry northerly bise (Switzerland) and the mistral, which strikes the Mediterranean area of France, are unpleasantly cold winds.

wind-chill factor or **wind-chill index** estimate of how much colder it feels when a wind is blowing. It is the sum of the temperature (in °F below zero) and the wind speed (in miles per hour). So for a wind of 15 mph at an air temperature of -5°F, the wind-chill factor is 20.

wind farm array of windmills or ϕ wind turbines used for generating electrical power. The world's largest wind farm at Altamont Pass, California, USA, consists of 6,000 wind turbines generating 1 TWh of electricity per year. Wind farms supply about 1.5% of California's electricity needs. To produce 1,200 megawatts of electricity (an output comparable with that of a nuclear power station), a wind farm would need to occupy around 370 sq km/140 sq mi.

Denmark has built the world's first offshore wind farm, off Vindeby on Lolland Island in the North Sea.

windmill mill with sails or vanes that, by the action of wind upon them, drive machinery for grinding corn or pumping water, for example. Wind turbines, designed to use wind power on a large scale, usually have a propeller-type rotor mounted on a tall shell tower. The turbine drives a generator for producing electricity.

Windmills were used in the East in ancient times, and in Europe they were first used in Germany and the Netherlands in the 12th century. The main types of traditional windmill are the post mill, which is turned around a post when the direction of the wind changes, and the tower mill, which has a revolving turret on top. It usually has a device (faintail) that keeps the sails pointing into the wind. In the USA windmills were used by the colonists and later a light type, with steel sails supported on a long steel girder shaft, was introduced for use on farms.

window in computing, a rectangular area on the screen of a graphical user interface. A window is used to display data and can be manipulated in various ways by the computer user.

Windows ϕ graphical user interface (GUI) from Microsoft that has become the standard for IBM PCs and clones.

There are three versions of Windows. Windows 95 is designed for homes and offices and retains maximum compatibility with programs written for the ϕ MS-DOS operating system. Windows NT is a 32-bit ϕ multituser and ϕ multitasking operating system designed for business use, especially on workstations and server computers, where it is seen as a rival to ϕ UNIX. Windows CE is a small operating system that supports a subset of the Windows applications programming interface. It is designed for handheld personal computers (HPCs) and consumer electronics products. Windows 95 is limited to Intel and x86-compatible processors but both NT and CE run on a variety of chips from different manufacturers.

NATIONAL WIND TECHNOLOGY CENTRE

<http://www.nrel.gov/wind/>

Source of information on the importance of tapping wind power and how to do it. This US Department of Energy site has reports on latest research. For children there is a wind energy quiz and details of educational materials. There is information about a number of authorities generating energy from wind power in various parts of world.

wind power The wind turbine is the modern counterpart of the windmill. The rotor blades are huge – up to 100 m/330 ft across – in order to extract as much energy as possible from the wind. Inside the turbine head, gears are used to increase the speed of the turning shaft so that the electricity generation is as efficient as possible.

Windows WAVEform in computing, audio file format commonly abbreviated to WAV.

wind power the harnessing of wind energy to produce power. The wind has long been used as a source of energy: sailing ships and windmills are ancient inventions. After the energy crisis of the 1970s wind turbines began to be used to produce electricity on a large scale.

wind tunnel test tunnel in which air is blown over, for example, a stationary model aircraft, motor vehicle, or locomotive to simulate the effects of movement. Lift, drag, and airflow patterns are observed by the use of special cameras and sensitive instruments. Wind-tunnel testing assesses aerodynamic design, prior to full-scale construction.

wind turbine windmill of advanced aerodynamic design connected to an electricity generator and used in wind-power installations. Wind turbines can be either large propeller-type rotors mounted on

a tall tower, or flexible metal strips fixed to a vertical axle at top and bottom.

The world's largest wind turbine is on Hawaii, in the Pacific Ocean. It has two blades 50 m/160 ft long on top of a tower 20 storeys high. An example of a propeller turbine is found at Tvind in Denmark and has an output of some 2 MW. Other machines use novel rotors, such as the 'egg-beater' design developed at Sandia Laboratories in New Mexico, USA.

wing in biology, the modified forelimb of birds and bats, or the membranous outgrowths of the exoskeleton of insects, which give the power of flight. Birds and bats have two wings. Bird wings have feathers attached to the fused digits ('fingers') and forearm bones, while bat wings consist of skin stretched between the digits. Most insects have four wings, which are strengthened by wing veins.

The wings of butterflies and moths are covered with scales. The hind pair of a fly's wings are modified to form two knoblike balancing organs (halteres).

WIN.INI (acronym for *Windows Initialization*) in computing, file used by Microsoft Windows to store a range of settings that in general govern the appearance of Windows and some Windows 3 applications. Changes made via Windows 3's Control Panel program are often stored in WIN.INI. In Windows 95 and later versions, control has been moved to the Registry.

Winsock (contraction of *Windows socket*) in computing, program that supplies an interface between Windows software and a TCP/IP application.

wintergreen any of a group of plants belonging to the heath family, especially the species *G. procumbens* of NE North America, which creeps underground and sends up tiny shoots. Oil of winter-

WIND TURBINES

<http://www.nrel.gov/wind/turbines.html>

Reports on latest wind turbine research. There are technical details of a variety of experimental turbines, information on the work of companies active in research and development, and speculation about the configurations of the kinds of turbines likely to become significant contributors to energy resources in the next century.

green, used in treating rheumatism, is extracted from its leaves. Wintergreen is also the name for various plants belonging to the wintergreen family *Pyrolaceae*, including the green *pipisewia C. maculata* of N North America, Europe, and Asia. (Genus *Gaultheria*, family *Ericaceae*; also genera *Pyrola*, *Chimaphila*, *Orthilia*, and *Moneses*, family *Pyrolaceae*.)

wire thread of metal, made by drawing a rod through progressively smaller-diameter dies. Fine-gauge wire is used for electrical power transmission; heavier-gauge wire is used to make load-bearing cables.

Gold, silver, and bronze wire has been found in the ruins of Troy and in ancient Egyptian tombs. From early times to the 14th century, wire was made by hammering metal into sheets, cutting thin strips, and making the strips round by hammering them. The Romans made wire by hammering heated metal rods.

Wire drawing was introduced in Germany in the 14th century. In this process, a metal rod is pulled (drawn) through a small hole in a mould (die). Until the 19th century this was done by hand; now all wire is drawn by machine. Metal rods are pulled through a series of progressively smaller tungsten carbide dies to produce large-diameter wire, and through diamond dies for very fine wire. The die is funnel-shaped, with one opening smaller than the diameter of the rod. The rod, which is pointed at one end, is coated with a lubricant to allow it to slip through the die. Pincers pull the rod through until it can be wound round a drum. The drum then rotates, drawing the wire through the die and winding it into a coil.

There are many kinds of wire for different uses: galvanized wire (coated with zinc), which does not rust; barbed wire and wire mesh for fencing; and wire cable, made by weaving thin wires into ropes. Needles, pins, nails, and rivets are made from wire.

Wired US computing magazine founded in 1993 by Jane Metcalfe and Louis Rossetto to serve as the voice of the 'digital revolution'. It is based in San Francisco.

wired gloves in computing, interface worn on the hands for virtual reality applications. The gloves detect the movement of the hands, enabling the user to 'touch' and 'move' objects in a virtual environment.

wire frame in computing, method of creating three-dimensional computerized animations by drawing a series of frames showing the moving image in outline, like a moving skeleton. When the designer is satisfied with the action of the wire-frame figure, he or she adds the 'skin', superimposing textures to give the final effect.

wireless original name for a radio receiver. In early experiments with transmission by radio waves, notably by Italian inventor Guglielmo Marconi in Britain, signals were sent in Morse code, as in telegraphy. Radio, unlike the telegraph, used no wires for transmission, and the means of communication was termed 'wireless telegraphy'.

wireworm larva of some species of click beetle. Wireworms are considered agricultural pests as they attack the seeds of many crops.

wisent another name for the European bison.

wisteria any of a group of climbing leguminous shrubs (see *Oleaceae*), including *W. sinensis*, native to the eastern USA and E Asia. Wisterias have hanging clusters of bluish, white, or pale mauve flowers, and pinnate leaves (leaflets on either side of the stem). They are grown against walls as ornamental plants. (Genus *Wisteria*, family *Leguminosae*.)

witch hazel any of a group of flowering shrubs or small trees belonging to the witch hazel family, native to North America and E Asia, especially *H. virginiana*. An astringent extract prepared from the bark or leaves is used in medicine as an eye lotion and a liniment to relieve pain or stiffness. (Genus *Hamamelis*, family *Hamamelidaceae*.)

wizard in computing, interactive tool developed by Microsoft that 'talks' users of a program through a complex operation, such as creating a template or a presentation. The wizard presents the

user with a series of dialog boxes asking simple questions in ordinary language, which the user answers by choosing radio buttons, checking boxes and entering information by keyboard.

The term wizard stems from programmers' slang, where it means an expert in a particular piece of software or hardware, capable of answering all manner of queries, fixing faults and dealing with emergencies.

woad biennial plant native to Europe, with arrow-shaped leaves and clusters of small yellow flowers. It was formerly cultivated for a blue dye extracted from its leaves. Ancient Britons used the blue dye as a body paint in battle. (*Isatis tinctoria*, family *Cruciferae*.)

wolf any of two species of large wild dogs of the genus *Canis*. The grey or timber wolf *C. lupus*, of North America and Eurasia, is highly social, measures up to 90 cm/3 ft at the shoulder, and weighs up to 45 kg/100 lb. It has been greatly reduced in numbers except for isolated wilderness regions. The red wolf *C. rufus*, generally more slender and smaller (average weight about 15 kg/35 lb) and tawny in colour, may not be a separate species, but a grey wolf-coyote hybrid. It used to be restricted to S central USA, but is now thought to be extinct in the wild.

WILD WOLVES

<http://www.pbs.org/wgbh/nova/wolves/>

'What's in a wolf's howl - a calling card, a warning, or an invitation? Hear the call of the wild, find out how wolves are making a comeback, and discover the ancient connection between dogs and wolves at this Web site.'

wolfish carnivorous marine fish in the genus *Anarrhichas*.

wolfarm alternative name for tungsten.

wolframite iron manganese tungstate, (Fe,Mn)WO₄, an ore mineral of tungsten. It is dark grey with a submetallic surface lustre, and often occurs in hydrothermal veins in association with ores of tin.

wolverine *Gulo gulo*, largest land member of the weasel family (Mustelidae), found in Europe, Asia, and North America.

It is stocky in build, and about 1 m/3.3 ft long. Its long, thick fur is dark brown on the back and belly and lighter on the sides. It covers food that it cannot eat with an unpleasant secretion. Destruction of habitat and trapping for its fur have greatly reduced its numbers.

womb common name for the uterus.

wombat any of a family (Vombatidae) of burrowing, herbivorous marsupials, native to Tasmania and S Australia. They are about 1 m/3.3 ft long, heavy, with a big head, short legs and tail, and coarse fur.

The two living species include the common wombat *Vombatus ursinus* of Tasmania and SE Australia, and *Lasiorhinus latifrons*, the plains wombat of S Australia.

wood the hard tissue beneath the bark of many perennial plants; it is composed of water-conducting cells, or secondary xylem, and gains its hardness and strength from deposits of lignin. Hardwoods, such as oak, and softwoods, such as pine, have commercial value as structural material and for furniture.

The central wood in a branch or stem is known as **heartwood** and is generally darker and harder than the outer wood; it consists only of dead cells. As well as providing structural support, it often contains gums, tannins, or pigments which may impart a characteristic colour and increased durability. The surrounding sapwood is the functional part of the xylem that conducts water.

The **secondary xylem** is laid down by the vascular cambium which forms a new layer of wood annually, on the outside of the existing wood and visible as an annual ring when the tree is felled; see *dendrochronology*.

Commercial wood can be divided into two main types: hardwood, containing xylem vessels and obtained from angiosperms (for example, oak), and softwood, containing only tracheids, obtained from gymnosperms (for example, pine). Although in general softwoods are softer than hardwoods, this is not always the case: balsa, the softest wood known, is a hardwood, while pitch pine, very dense and hard, is a softwood. A superhard wood is produced in wood-plastic combinations (WPC), in which wood is impregnated with liquid plastic (monomer) and the whole is then bombarded with gamma rays to polymerize the plastic.

woodcock either of two species of wading birds, genus *Scolopax*, of the family Scolopacidae, which have barred plumage and long bills, and live in wet woodland areas. They belong to the long-billed section of the snipes, order Charadriiformes.

woodland area in which trees grow more or less thickly; generally smaller than a forest. Temperate climates, with four distinct seasons a year, tend to support a mixed woodland habitat, with some conifers but mostly broad-leaved and deciduous trees, shedding their leaves in autumn and regrowing them in spring. In the Mediterranean region and parts of the southern hemisphere, the trees are mostly evergreen.

Temperate woodlands grow in the zone between the cold coniferous forests and the tropical forests of the hotter climates near the Equator. They develop in areas where the closeness of the sea keeps the climate mild and moist.

Old woodland can rival tropical rainforest in the number of species it supports, but most of the species are hidden in the soil. A study in Oregon, USA, in 1991 found that the soil in a single woodland location contained 8,900 arthropod species (such as insects, mites, centipedes, and millipedes), compared with only 143 species of reptile, bird, and mammal in the woodland above.

woodlouse crustacean of the order Isopoda. Woodlice have segmented bodies, flattened undersides, and 14 legs. The eggs are carried by the female in a pouch beneath the thorax. They often live in high densities: up to as many as 8,900 per sq m.

The hatchlings, called manca, have only 12 legs and must moult twice before gaining their final pair of legs.

Common in Britain are the genera *Oniscus* and *Porcellio*.

WEIRD AND WONDERFUL WORLD OF WOODLICE

<http://www.dryad.demon.co.uk/julies/woodlice.htm>

Comprehensive and entertaining guide to woodlice. Information is provided on history, predators, physiology, reproduction, behaviour, colour variations, recommended reading, and there are even tips on keeping them as pets.

woodmouse or **long-tailed field mouse** *Apodemus sylvaticus*, rodent that lives in woodlands, hedgerows, and sometimes open fields in Britain and Europe. About 9 cm/3.5 in long, with a similar length of tail, it is yellow-brown above, white below, and has long oval ears.

It is nocturnal and feeds largely on seeds, but eats a range of foods, including some insects.

woodpecker bird of the family Picidae, order Piciformes. They are adapted for climbing up the bark of trees, and picking out insects to eat from the crevices. The feet, though very short, are usually strong; the nails are broad and crooked and the toes placed in pairs, two forward and two backward. As an additional support their tail feathers terminate in points, and are uncommonly hard. Woodpeckers have a long extensible tongue, which has muscles enabling the bird to dart it forth and to retract it again quickly. There are about 200 species worldwide.

wood pitch by-product of charcoal manufacture, made from wood tar, the condensed liquid produced from burning charcoal

gases. The wood tar is boiled to produce the correct consistency. It has been used since ancient times for caulking wooden ships (filling in the spaces between the hull planks to make them watertight).

wood pulp wood that has been processed into a pulpy mass of fibres. Its main use is for making paper, but it is also used in making crayon and other cellulose fibres and plastics.

There are two methods of making wood pulp: mechanical and chemical. In the former, debarked logs are ground with water (to prevent charring) by rotating grinders; the wood fibres are physically torn apart. In the latter, log chips are digested with chemicals (such as sodium sulphite). The chemicals dissolve the material holding the fibres together.

wood wasp or **horntail** moderately large wasp that is black or metallic blue, often with yellow bandings. The long lanceolate ovipositor (egg-laying organ) of the female wood wasp is used for drilling holes into wood. Usually a single egg is deposited into each hole, and the larva on hatching bores through the heart wood causing much damage.

classification The wood wasp is in the family Siridae, suborder Symphyta, order Hymenoptera, class Insecta, phylum Arthropoda.

The common wood wasp *Sirex juvencus* is about 30 mm/1.1 in long and blue-black with a metallic sheen. The male may be distinguished from the female by its short triangular spine or horn at the tip of its abdomen and also by a brown-red stripe on its back. The female lays her eggs in conifers.

woodworm common name for the larval stage of certain wood-boring beetles. Dead or injured trees are their natural target, but they also attack structural timber and furniture.

Included are the furniture beetle *Anobium punctatum*, which attacks older timber; the powder-post beetle genus *Lyctus*, which attacks newer timber; the deathwatch beetle, whose presence always coincides with fungal decay; and wood-boring weevils. Special wood preservatives have been developed to combat woodworm infestation, which has markedly increased since about 1950.

wool the natural hair covering of the sheep, and also of the llama, angora goat, and some other mammals. The domestic sheep *Ovis aries* provides the great bulk of the fibres used in textile production. Lanolin is a by-product.

history Sheep have been bred for their wool since ancient times. Hundreds of breeds were developed in the Middle East, Europe, and Britain over the centuries, several dozen of which are still raised for their wool today. Most of the world's finest wool comes from the merino sheep, originally from Spain. In 1797 it was introduced into Australia, which has become the world's largest producer of merino wool; South Africa and South America are also large producers. Wools from crossbred sheep (usually a cross of one of the British breeds with a merino) are produced in New Zealand. Since the 1940s, blendings of wool with synthetic fibres have been developed for textiles.

woolly bear larva of the carpet beetle.

word in computing, a group of bits (binary digits) that a computer's central processing unit treats as a single working unit. The size of a word varies from one computer to another and, in general, increasing the word length leads to a faster and more powerful computer. In the late 1970s and early 1980s, most microcomputers were 8-bit machines. During the 1980s 16-bit microcomputers were introduced and 32-bit microcomputers are now available. Mainframe computers may be 32-bit or 64-bit machines.

Word word processing program for the PCs and Apple Macintoshes. See *Microsoft Word*.

WordPerfect word processing program for various computers produced by US software company WordPerfect Corp. It was first released in 1982 and by 1987 was the dominant *MS-DOS* word processor, rapidly eclipsing the previous leader, WordStar, by offering many more features, despite having the reputation of being difficult to learn.

WordPerfect Corp was slow to release a version of WordPerfect for Windows, and when it did appear in 1992 it suffered in compar-

ison with Microsoft Word. WordPerfect Corp was taken over by Novell, but the union was not a success, and most of its software was sold on cheaply to Corel.

word processing storage and retrieval of written text by computer. Word-processing software packages enable the writer to key in text and amend it in a number of ways. A print-out can be obtained or the text could be sent to another person or organization on disc or via electronic mail. Word processing has revolutionized the task of a typing secretary. Word-processing packages can be used with databases or graphics packages, and desktop publishing packages are available too.

word processor in computing, a program that allows the input, amendment, manipulation, storage, and retrieval of text; or a computer system that runs such software. Since word-processing programs became available to microcomputers, the method has largely replaced the typewriter for producing letters or other text. Typical facilities include insert, delete, cut and paste, reformat, search and replace, copy, print, mail merge, and spelling check.

The leading word-processing programs include Microsoft Word, the market leader, Lotus WordPro, and Corel WordPerfect.

work in physics, a measure of the result of transferring energy from one system to another to cause an object to move. Work should not be confused with energy (the capacity to do work, which is also measured in joules) or with power (the rate of doing work, measured in joules per second).

Work is equal to the product of the force used and the distance moved by the object in the direction of that force. If the force is F newtons and the distance moved is d metres, then the work W is given by:

$$W = Fd$$

For example, the work done when a force of 10 newtons moves an object 5 metres against some sort of resistance is 50 joules (50 newton-metres).

workgroup in computing, small group of computer users who need to share data and computer facilities.

workstation high-performance desktop computer with strong graphics capabilities, traditionally used for engineering (CAD and CAM), scientific research, and desktop publishing. From 1985-95, workstations were frequently based on fast RISC (reduced instruction-set computer) chips running the UNIX operating system. However, the market is under attack from 'Wintel' PCs with Intel Pentium processors running Microsoft Windows NT, which are cheaper and run PC software as well as workstation programs. By 1997, four of the five leading workstation manufacturers - DEC, Hewlett-Packard, IBM and Silicon Graphics Inc, but not Sun Microsystems - had committed to supporting NT.

World Wide Fund for Nature (WWF, formerly the World Wildlife Fund) international organization established in 1961 to raise funds for conservation by public appeal. Projects include conservation of particular species, for example, the tiger and giant panda, and special areas, such as the Simen Mountains, Ethiopia.

World-Wide Web (WWW) hypertext system for publishing information on the Internet. World-Wide Web documents ('Web pages') are text files coded using HTML to include text and graphics, and are stored on a Web server connected to the Internet.

Web pages may also contain dynamic objects and Java applets for enhanced animation, video, sound, and interactivity.

The Web server can be any computer, from the simplest Apple Macintosh to the largest mainframe, if Web server software is available.

Every Web page has a URL (Uniform Resource Locator) - a unique address (usually starting with <http://www>) which tells a browser program (such as Netscape Navigator or Microsoft Internet Explorer) where to find it. An important feature of the World-Wide Web is that most documents contain links enabling readers to follow whatever aspects of a subject interest them most. These links may connect to different computers all over the world. Interlinked or nested Web pages belonging to a single organization are known as a 'Web site'.

WORM WORLD

<http://www.nj.com/yucky/worm/index.html>

Lively guide for children, with information on topics such as worms' bodies, how to make a worm bin, and different types of worm, plus an art gallery and some worm jokes.

worm any of various elongated limbless invertebrates belonging to several phyla. Worms include the flatworms, such as flukes and tapeworms; the roundworms or nematodes, such as the earthworm and the hookworm; the marine ribbon worms or nemerteans; and the segmented worms or annelids.

In 1979, giant sea worms about 3 m/10 ft long, living within tubes created by their own excretions, were discovered in hydrothermal vents 2,450 m/8,000 ft beneath the Pacific NE of the Galapagos Islands.

WORM (acronym for *write once read many times*) in computing, a storage device, similar to a CD-ROM. The computer can write to the disc directly, but cannot later erase or overwrite the same area. WORMs are mainly used for archiving and backup copies.

worm in computing, virus designed to spread from computer to computer across a network. Worms replicate themselves while 'hiding' in a computer's memory, causing systems to 'crash' or slow down, but do not infect other programs or destroy data directly.

The most celebrated worm was the 'Internet worm' of November 1988. Released onto the Internet by Robert Morris, Jr., a graduate student at Cornell University, it infected some 6,000 systems via a loophole in UNIX e-mail and finger procedures. Morris claimed that a programming bug had caused the worm to replicate far more virulently than he had intended, and took swift measures to publish an 'antidote' on the network - but by then, many machines had already been disconnected from it. Morris was later convicted, fined, and sentenced to 400 hours community service.

wormwood any of a group of plants belonging to the daisy family and mainly found in northern temperate regions, especially the aromatic herb *A. absinthium*, the leaves of which are used in the alcoholic drink absinthe. Tarragon is closely related to wormwood. (Genus *Artemisia*, family Compositae.)

W particle in physics, an elementary particle, one of the weakons responsible for transmitting the weak nuclear force.

wrack any of the large brown seaweeds characteristic of rocky shores. The bladder wrack *F. vesiculosus* has narrow, branched

wrack Bladder wrack *Fucus vesiculosus* and flat wrack *F. spiralis* often grow together to form dense mats on rocks on the middle shore around the coasts of W Europe. Premaphotos Wildlife

fronds up to 1 m/3.3 ft long, with oval air bladders, usually in pairs on either side of the midrib or central vein. (Genus *Fucus*.)

wrasse any bony fish of the family Labridae, found in temperate and tropical seas. They are slender and often brightly coloured, with a single long dorsal fin. They have elaborate courtship rituals, and some species can change their colouring and sex. Species vary in size from 5 cm/2 in to 2 m/6.5 ft.

wren any of the family Troglodytidae of small birds of the order Passeriformes, with slender, slightly curved bills, and uptilted tails.

WREN

The testes of the tiny male Australian fairy wren account for one-tenth of his body weight. He can produce more sperm than any other bird, and ejaculates 8.3 billion sperm at a time. (A human male manages about 4 million.)

write-once technology in computing, technology that allows a user to write data onto an optical disc once. After that the data are permanent and can be read any number of times.

write protection device on discs and tapes that provides data security by allowing data to be read but not deleted, altered, or overwritten.

wrought iron fairly pure iron containing some beads of slag, widely used for construction work before the days of cheap steel. It is strong, tough, and easy to machine. It is made in a puddling furnace, invented by Henry Colt in England in 1784. Pig iron is remelted and heated strongly in air with iron ore, burning out the carbon in the metal, leaving relatively pure iron and a slag containing impurities. The resulting pasty metal is then hammered to remove

Wright brothers Orville (1871–1948) and Wilbur (1867–1912)

US inventors; brothers who pioneered piloted, powered flight. Inspired by Otto Lilienthal's gliding, they perfected their piloted glider in 1902. In 1903 they built a powered machine, a 12-hp 341-kg/750-lb plane, and became the first to make a successful powered flight, near Kitty Hawk, North Carolina. Orville flew 36.6 m/120 ft in 12 seconds; Wilbur, 260 m/852 ft in 59 seconds.

Mary Evans Picture Library

as much of the remaining slag as possible. It is still used in fences and gratings.

wt abbreviation for weight.

WWF abbreviation for World Wide Fund for Nature (formerly *World Wildlife Fund*).

WYSIWYG (acronym for *what you see is what you get*) in computing, a program that attempts to display on the screen a faithful representation of the final printed output. For example, a WYSIWYG word processor would show actual page layout – line widths, page breaks, and the sizes and styles of type.

x in computing, ϕ wild card character often used to describe versions of hardware or software. One might, therefore, refer to Windows 3.x (any version of Windows, from 3.0 to 3.31), or an x86 chip (any of the chips manufactured by ϕ Intel with serial numbers ending in 86).

X.25 in computing, communications protocol for sending ϕ packets of data over a network.

X.400 in computing, standard maintained by the ITU (International Telecommunications Union, formerly the ϕ CITT) which forms the basis for a message handling system. X.400 is used as a shorthand term for a number of recommendations and standards involved in running some electronic mail systems over telecommunications lines.

X.500 directory standards for network addresses, issued by the ϕ Comité Consultatif International Téléphonique et Télégraphique (CITT).

xanthophyll yellow pigment in plants that, like ϕ chlorophyll, is responsible for the production of carbohydrates by photosynthesis.

X chromosome larger of the two sex chromosomes, the smaller being the ϕ Y chromosome. These two chromosomes are involved in ϕ sex determination. Females have two X chromosomes, males have an X and a Y. Genes carried on the X chromosome produce the phenomenon of sex linkage.

Early in the development of a female embryo, one of the X chromosomes becomes condensed so that most of its genes are inactivated. If this inactivation is incomplete, skeletal defects and mental retardation result.

xenon Greek *xenos* 'stranger' colourless, odourless, gaseous, non-metallic element, symbol Xe, atomic number 54, relative atomic mass 131.30. It is grouped with the ϕ inert gases and was long believed not to enter into reactions, but is now known to form some compounds, mostly with fluorine. It is a heavy gas present in very small quantities in the air (about one part in 20 million).

Xenon is used in bubble chambers, light bulbs, vacuum tubes, and lasers. It was discovered in 1898 in a residue from liquid air by Scottish chemists William Ramsay and Morris Travers.

xerography dry, electrostatic method of producing images, without the use of negatives or sensitized paper, invented in the USA by Chester Carlson in 1938 and applied in the Xerox ϕ photocopier.

An image of the document to be copied is projected on to an electrostatically charged photo-conductive plate. The charge remains only in the areas corresponding to its image. The latent image on the plate is then developed by contact with ink powder, which adheres only to the image, and is then usually transferred to ordinary paper or some other flat surface, and quickly heated to form a permanent print.

Applications include document copying, enlarging from microfilm, preparing printing masters for offset litho printing and dye-line machines, making X-ray pictures, and printing high-speed computer output.

xerophyte plant adapted to live in dry conditions. Common adaptations to reduce the rate of ϕ transpiration include a reduction of leaf size, sometimes to spines or scales; a dense covering of hairs over the leaf to trap a layer of moist air (as in *edulis*); water

storage cells; sunken stomata; and permanently rolled leaves or leaves that roll up in dry weather (as in *marram* grass). Many desert cacti are xerophytes.

Xerox PARC Xerox Corporation's Palo Alto Research Center in California. During the 1970s and 1980s, Xerox PARC spawned a series of major computing innovations, including ϕ Ethernet networks and ϕ graphical user interfaces (GUIs). Laser printing, ϕ Smalltalk, and the first (never-manufactured) personal computer were also developed there.

Xerox never capitalized on these inventions, leaving entrepreneurs such as Steve Jobs and Bill ϕ Gates to bring them into the marketplace, but Xerox PARC remains at the cutting edge of computer innovations.

XGA (abbreviation for *extended graphics array*) in computing, colour display system which provides either 256 colours on screen and a resolution of $1,024 \times 768$ ϕ pixels or 25,536 colours with a resolution of 640×480 . This gives a much sharper image than, for example, ϕ VGA, which can display only 16 colours at 480 lines of 640 pixels.

XML (abbreviation for *eXtensible Markup Language*) in computing, a simplified subset of SGML for defining languages for specific purposes or specific industries for use on the World Wide Web. XML is more powerful than HTML but less cumbersome than SGML. XML has been developed through the ϕ W3 Consortium, and both Microsoft and Netscape are expected to support it in their version 5 browsers.

Xmodem in computing, an ϕ FTP ϕ protocol designed to make transmitting files via telephone speedy and error-free.

XON/XOFF in computing, control commands used when two devices ϕ handshake using a modem connection. XON starts or resumes transmission of data and XOFF pauses it. XON and XOFF can be manually activated by control-Q and control-S respectively.

X/Open in computing, multivendor computer industry body formed in 1984 to ratify and support the use of UNIX as an open operating system. In February 1996, X/Open merged with the Open Software Foundation to form The Open Group.

XOR (contraction of *exclusive or*) in computing, search filter meaning 'A or B, but not both'. Thus a search for 'chocolate xor biscuit' might yield 'chocolate', 'biscuit', 'chocolate cake' and 'shortbread biscuit' but never 'chocolate biscuit'. See also ϕ Boolean algebra.

X-ray band of electromagnetic radiation in the wavelength range 10^{-11} to 10^{-9} m (between gamma rays and ultraviolet radiation; see ϕ electromagnetic waves). Applications of X-rays make use of their short wavelength (as in ϕ X-ray diffraction) or their penetrating power (as in medical X-rays of internal body tissues). X-rays are dangerous and can cause cancer.

X-rays with short wavelengths pass through most body tissues, although dense areas such as bone prevent their passage, showing up as white areas on X-ray photographs. The X-rays used in ϕ radiotherapy have very short wavelengths that penetrate tissues deeply and destroy them.

X-rays were discovered by German experimental physicist Wilhelm Röntgen in 1895 and formerly called roentgen rays. They are produced when high-energy electrons from a heated filament

X-RAY

<http://www.nobel.se/laureates/physics-1901-1-bio.html>

Biography of Wilhelm Conrad Röntgen, the German physicist who first realized the huge potential of the electromagnetic field of X-rays. The presentation includes sections on Röntgen's early years and education, his academic career and scientific experiments, and the miraculous coincidences that led him to his great discovery of X-rays.

What is Medical Imaging?

BY CATHY WALSH

Wilhelm Conrad Röntgen, a physicist at the university of Würzburg, Germany, discovered 'a new kind of ray' on 8 November 1895. He called this radiation X-rays.

Röntgen was investigating the behaviour of cathode rays (electrons) in cathode ray tubes. The tube consisted of a glass envelope and when a high voltage discharge was passed through this tube, a faint light was produced. Röntgen had enclosed his cathode tube in black cardboard to prevent this light from escaping. He then darkened his laboratory room to be sure that there were no light leaks in the cardboard cover. Upon passing a high tension electric discharge through the tube, he noticed a faint light glowing. The source of the light was the fluorescence of a small piece of paper coated with barium platinocyanide. His conclusion was that some unknown type of ray was produced when the tube was energized. Thus, the great discovery of X-rays was made.

There is no doubt that Röntgen's scientific contemporaries were startled by his discovery, but you can imagine the reaction of the non-scientific population when they learned of the new ray that could see through solid objects! It has even been reported that shy Victorian ladies of the period started bathing with their clothes on because they suspected 'those wicked scientists' of watching through the walls.

Medical practitioners, however, soon realized the potential of the X-ray and its value for diagnosis. Developments in ultrasound and nuclear medicine mean that X-rays are no longer the only method of producing diagnostic images. The technological changes and scientific developments have led to the X-ray Department becoming a Medical Imaging Department.

There is a wide variety of imaging techniques undertaken in the modern Medical Imaging Department including those listed below.

Radiography

Images produced by X-rays for diagnosis. These images can be 'plain', showing only bony structures, or they can be 'contrast studies', showing soft tissue such as arteries and veins or organs such as the stomach or kidneys by means of an iodine or barium-based contrast agent introduced by an injection into a vein or by drinking a solution of the contrast agent. The final product, the 'radiograph' or 'X-ray', results when an X-ray cassette placed under the area of interest is exposed to a certain amount of X-ray energy. Once exposed a latent image is formed on the X-ray film within the cassette and requires processing to produce the actual image. The processing of radiographic film is rather like developing film from a standard camera—it involves the film being placed in a bath of developer at a certain temperature and for a certain amount of time, then it requires washing, fixing, washing again, and finally drying. This procedure has traditionally been done manually, but in the last 15–20 years it has become automated and in some departments a darkroom is no longer required.

Computed radiography

A technique for replacing conventional film systems with a digital image which can be viewed, stored and transmitted electronically.

Computed tomography (CT)

Images are again produced by X-rays but as their name suggests the images are computerized and show transverse sectional views through the human body. This is a very precise form of radiography and the thickness of the sectional image produced can range from 2 to 12 mm. The whole body can be imaged this way.

Magnetic resonance imaging

Images are produced by a strong magnet and radio waves rather than by X-rays. The patient is placed inside the magnet and radio waves are applied. Once the radio waves are stopped the patient gives off a signal which is transmitted to a computer which then produces the image. Once again the whole body can be examined with this method of image production. However, should the patient have metal implants such as plates or joints, they cannot be placed in the magnet.

Ultrasound scans

Images are produced by sound waves similar to sonar rather than X-rays. Ultrasound is used to image soft tissue structures such as the liver, gall bladder, spleen, kidneys and unborn babies in their mother's womb.

Nuclear medicine scans

Images are produced by the effect of a radioisotope taken by the patient, on different parts of the body. A computer detects the amount of isotope in the patient's body and an image showing the concentration of isotope is then produced. This form of imaging can be used to image bone, lungs and soft tissue organs such as the liver and spleen.

Technological advances have not only increased the number of imaging techniques available but have also enhanced how images are produced and how they are stored and distributed. Picture Archive and Communication Systems (PACS) enables images which are produced digitally, such as MRI, CT, and Nuclear Medicine images, to be stored on optical disc or digital linear tape. This in turn enables the images to be viewed on workstations which sit on the same network, whether those workstations are within the imaging department, on a ward or clinic in the hospital, or in a doctor's home or surgery.

The information obtained from these examinations can differentiate between different organs without the need for the patient to undergo surgical procedures. The ability to send images to the place where they are required as soon as they are produced saves time and personnel, which in these times of cost savings and the need to cut surgical waiting lists increases the importance of the Medical Imaging Department.

cathode strike the surface of a target (usually made of tungsten) on the face of a massive heat-conducting anode, between which a high alternating voltage (about 100 kV) is applied. See illustration on page 822.

One does not, by knowing all the physical laws as we know them today, immediately obtain an understanding of anything much.

RICHARD FEYNMAN US physicist.
The Character of Physical Law

X-ray astronomy detection of X-rays from intensely hot gas in the universe. Such X-rays are prevented from reaching the Earth's surface by the atmosphere, so detectors must be placed in rockets and satellites. The first celestial X-ray source, Scorpius X-1, was discovered by a rocket flight in 1962.

Since 1970, special satellites have been put into orbit to study X-rays from the Sun, stars, and galaxies. Many X-ray sources are believed to be gas falling on to neutron stars and black holes.

X-ray diffraction method of studying the atomic and molecular structure of crystalline substances by using X-rays. X-rays directed at such substances spread out as they pass through the crystals owing to diffraction (the slight spreading of waves around the

X-ray An X-ray image. The X-rays are generated by high-speed electrons impinging on a tungsten target. The rays pass through the specimen and on to a photographic plate or imager.

edge of an opaque object) of the rays around the atoms. By using measurements of the position and intensity of the diffracted waves, it is possible to calculate the shape and size of the atoms in the crystal. The method has been used to study substances such as cDNA that are found in living material.

X-ray diffraction analysis the use of X-rays to study the atomic and molecular structure of crystalline substances such as ceramics, stone, sediments, and weathering products on metals. The sample, as a single crystal or ground to powder, is exposed to X-rays at various angles; the diffraction patterns produced are then compared with reference standards for identification.

X-ray fluorescence spectrometry technique used to determine the major and trace elements in the chemical composition of such materials as ceramics, obsidian, and glass. A sample is bombarded with X-rays, and the wavelengths of the released energy, or fluorescent X-rays, are detected and measured. Different elements have unique wavelengths, and their concentrations can be estimated from the intensity of the released X-rays. This analysis may, for example, help an archaeologist in identifying the source of the material.

X-ray telescope in astronomy, a telescope designed to receive electromagnetic waves in the X-ray part of the spectrum. X-rays cannot be focused by lenses or mirrors in the same way as visible light, and a variety of alternative techniques is used to form images. Because X-rays cannot penetrate the Earth's atmosphere, X-ray telescopes are mounted on satellites, rockets, or high-flying balloons.

X Windows in computing, a networked window management system developed as part of Project Athena at the Massachusetts Institute of Technology in 1984. It has been adopted as a standard by the UNIX community but is platform-independent and versions exist for many different operating systems. X Windows enables a user to open windows into a number of different computers at the same time, either using an X Terminal or via X software running on a PC, a UNIX workstation or another computer. Although X Windows is not a graphical user interface, it provides software tools to support such interfaces: Motif is a popular UNIX GUI built on X.

X got its name because it started from an earlier MIT development called W. X Window System is now a trademark of The Open Group.

xylem tissue found in vascular plants, whose main function is to conduct water and dissolved mineral nutrients from the roots to other parts of the plant. Xylem is composed of a number of different types of cell, and may include long, thin, usually dead cells known as tracheids; fibres (sclerenchyma); thin-walled parenchyma cells; and conducting vessels.

In most angiosperms (flowering plants) water is moved through these vessels. Most gymnosperms and pteridophytes lack vessels and depend on tracheids for water conduction.

Non-woody plants contain only primary xylem, derived from the procambium, whereas in trees and shrubs this is replaced for the most part by secondary xylem, formed by secondary growth from the actively dividing vascular cambium. The cell walls of the secondary xylem are thickened by a deposit of lignin, providing mechanical support to the plant; see wood.

Yahoo! in computing, search engine for the World Wide Web, based on a catalogue of indexed resources. Yahoo!, for some time the only search engine on the Web, was created at Stanford University by post-graduate students David Filo and Jerry Yang.

The name – from Swift's *Gulliver's Travels* but found by searching a dictionary – is supposed to stand for Yet Another Hierarchical Official Oracle.

yak species of cattle *Bos grunniens*, family Bovidae, which lives in wild herds at high altitudes in Tibet. It stands about 2 m/6 ft at the shoulder and has long shaggy hair on the underparts. It has large, upward-curving horns and humped shoulders. It is in danger of becoming extinct.

In the wild, the yak is brown or black, but the domesticated variety, which is half the size of the wild form, may be white. It is used for milk, meat, leather, and as a beast of burden. The yak is protected from extremes of cold by its thick coat and by the heat produced from the fermentation in progress in its stomach.

Yale lock trademark for a key-operated pin-tumbler cylinder lock invented by US locksmith Linus Yale Jr (1821–1868) in 1865 and still widely used.

yam any of a group of climbing plants cultivated in tropical regions; the starchy tubers (underground stems) are eaten as a vegetable. The Mexican yam (*D. composita*) contains a chemical that is used in the contraceptive pill. (Genus *Dioscorea*, family Dioscoreaceae.)

yapok nocturnal opossum *Chironectes minimus* found in tropical South and Central America. It is about 33 cm/1.1 ft long, with a 40 cm/1.3 ft tail. It has webbed hind feet and thick fur, and is the only aquatic marsupial. The female has a watertight pouch.

yard unit (symbol yd) of length, equivalent to 3 feet (0.9144 m). In the USA, it is sometimes used to denote a cubic yard (0.7646 cubic meters), as of topsoil.

YARD

The foot, yard and inch owe their length to Henry I of England. He decreed that one yard was the length of his extended arm, measured from nose to fingertip.

yardang ridge formed by wind erosion from a dried-up riverbed or similar feature, as in Chad, China, Peru, and North America. On the planet Mars yardangs occur on a massive scale.

yarran small tree *Acacia homalophylla* found in E Australia useful as fodder and for firewood and fence posts.

yarrow or milfoil perennial herb belonging to the daisy family, with feathery, scented leaves and flat-topped clusters of white or pink flowers. It is native to Europe and Asia. (*Achillea millefolium*, family Compositae.)

yaws contagious tropical disease common in the West Indies, W Africa, and some Pacific islands, characterized by red, raspberry-

like eruptions on the face, toes, and other parts of the body, sometimes followed by lesions of the bones; these may progress to cause gross disfigurement. It is caused by a spirochete (*Treponema pertenue*), a bacterium related to the one that causes syphilis. Treatment is by antibiotics.

Y chromosome smaller of the two sex chromosomes. In male mammals it occurs paired with the other type of sex chromosome (X), which carries far more genes. The Y chromosome is the smallest of all the mammalian chromosomes and is considered to be largely inert (that is, without direct effect on the physical body). See also sex determination.

In humans, about one in 300 males inherits two Y chromosomes at conception, making him an XYY triploid. Few if any differences from normal XY males exist in these individuals, although at one time they were thought to be emotionally unstable and abnormally aggressive. In 1989 the gene determining that a human being is male was found to occur on the X as well as on the Y chromosome; however, it is not activated in the female.

yd abbreviation for yard.

year unit of time measurement, based on the orbital period of the Earth around the Sun. The tropical year, from one spring equinox to the next, lasts 365.2422 days. It governs the occurrence of the seasons, and is the period on which the calendar year is based. The sidereal year is the time taken for the Earth to complete one orbit relative to the fixed stars, and lasts 365.2564 days (about 20 minutes longer than a tropical year). The difference is due to the effect of precession, which slowly moves the position of the equinoxes. The calendar year consists of 365 days, with an extra day added at the end of February each leap year. Leap years occur in every year that is divisible by four, except that a century year is not a leap year unless it is divisible by 400. Hence 1900 was not a leap year, but 2000 will be.

other types of year A historical year begins on 1 January, although up to 1752, when the Gregorian calendar was adopted in England, the civil or legal year began on 25 March. The English fiscal/financial year still ends on 5 April, which is 25 March plus the 11 days added under the reform of the calendar in 1752. The regnal year begins on the anniversary of the sovereign's accession; it is used in the dating of acts of Parliament.

The anomalistic year is the time taken by any planet in making one complete revolution from perihelion to perihelion; for the Earth this period is about five minutes longer than the sidereal year due to the gravitational pull of the other planets.

year 2000 in computing, problem faced by computer professionals, the industry, and users towards the close of the 20th century because most computers use only 6 digits to record the date. Thus, 10 August 1962 is recorded as 10/08/62, 081062, or a similar format. Because the year is represented by only two characters, computers all over the world need reprogramming to prevent them assuming that the figures 00 stand for 1900 rather than 2000.

The consequences could be devastating, including pension funds and payrolls being unable to make payments, accounting systems refusing to issue cheques, landlords crediting tenants with 99 years rent and many companies going out of business. Action to minimize these problems started in the mid 1990s.

Science is built up with facts, as a house is with stones. But a collection of facts is no more a science than a heap of stones is a house.

JULES HENRI POINCARÉ French mathematician.

Science and Hypothesis 1905

Attributed remark

yeast one of various single-celled fungi (see fungus) that form masses of tiny round or oval cells by budding. When placed in a sugar solution the cells multiply and convert the sugar into alcohol and carbon dioxide. Yeasts are used as fermenting agents in baking, brewing, and the making of wine and spirits. Brewer's yeast (S.

cerevisiae) is a rich source of vitamin B. (Especially genus *Saccharomyces*; also other related genera.)

yeast artificial chromosome (YAC) fragment of ϕ DNA from the human genome inserted into a yeast cell. The yeast replicates the fragment along with its own DNA. In this way the fragments are copied to be preserved in a gene library. YACs are characteristically between 250,000 and 1 million base pairs in length. A ϕ cosmid works in the same way.

yeheb nut small tree found in Ethiopia and Somalia, formerly much valued for its nuts as a food source. Although cultivated as a food crop in Kenya and Sudan, it is now critically endangered in the wild and is only known to survive at three sites. Overgrazing by cattle and goats has prevented regrowth, and the taking of nuts for consumption prevents reseedling. Although reintroduction would be possible from cultivated trees, the continuing grazing pressure would make establishment unlikely without proper management. (*Cordeauxia adules*.)

yellow archangel flowering plant belonging to the mint family, found over much of Europe. It grows up to 60 cm/2 ft tall and has nettlelike leaves and rings, or whorls, of yellow flowers growing around the main stem; the lower lips of the flowers are streaked with red in early summer. (*Lamium galeobdolon*, family Labiatae.)

yellow fever or **yellow jack** acute tropical viral disease, prevalent in the Caribbean area, Brazil, and on the west coast of Africa. The yellow fever virus is an arbovirus transmitted by mosquitoes. Its symptoms include a high fever, headache, joint and muscle pains, vomiting, and yellowish skin (jaundice, possibly leading to liver failure); the heart and kidneys may also be affected. Mortality is high in serious cases.

Before the arrival of Europeans, yellow fever was not a problem because indigenous people had built up an immunity. The disease was brought under control after the discovery that it is carried by the mosquito *Aedes aegypti*. The first effective vaccines were produced by Max Theiler (1899-1972) of South Africa, for which he was awarded the 1951 Nobel Prize for Medicine. The World Health Organization estimates there are about 200,000 cases of yellow fever each year in Africa, with 30,000 deaths (1993).

YELLOW FEVER

<http://www.outbreak.org/cgi-unreg/dynaserve.exe/YellowFever/index.html>

Outbreak page on yellow fever. The Web site contains a section on frequently asked questions about the disease, and a section on current and recent outbreaks. The outbreaks section is updated regularly, often giving numbers of casualties and descriptions of operations by the World Health Organization to curb the spread of any outbreak.

yellowhammer Eurasian bird *Emberiza citrinella* of the bunting family Emberizidae, order Passeriformes. About 16.5 cm/6.5 in long, the male has a yellow head and underside, a chestnut rump, and a brown-streaked back. The female is duller.

yellow star-of-Bethlehem rare flowering plant *Gagea lutea*. It has clusters of stalked yellow flowers that appear in very early spring, and is found in damp ϕ loam, usually by woodland streams, mainly in N England.

Yerkes Observatory astronomical centre in Wisconsin, USA, founded by George Hale in 1897. It houses the world's largest refracting optical telescope, with a lens of diameter 102 cm/40 in.

yew any of a group of evergreen coniferous trees native to the northern hemisphere. The dark green flat needlelike leaves and bright red berrylike seeds are poisonous; the wood is hard and close-grained. (Genus *Taxus*, family Taxaceae.)

The western or Pacific yew (*T. brevifolia*) is native to North America. English yew (*T. baccata*) is widely cultivated as an ornamental tree. The wood was formerly used to make longbows.

The anticancer drug taxol is synthesized from the bark of the Pacific yew.

yield point or **elastic limit** the stress beyond which a material deforms by a relatively large amount for a small increase in stretching force. Beyond this stress, the material no longer obeys Hooke's law.

yolk store of food, mostly in the form of fats and proteins, found in the eggs of many animals. It provides nourishment for the growing embryo.

yolk sac sac containing the yolk in the egg of most vertebrates. The term is also used for the membranous sac formed below the developing mammalian embryo and connected with the umbilical cord.

Yorkshire terrier breed of toy dog from N England. Its long, straight coat is blue-black on the body and red or tan on the head, chest, and legs. It weighs just 3 kg/6.5 lb, and its body is long in proportion to its short legs.

ytterbium soft, lustrous, silvery, malleable and ductile element of the ϕ lanthanide series, symbol Yb, atomic number 70, relative atomic mass 173.04. It occurs with (and resembles) yttrium in gadolinite and other minerals, and is used in making steel and other alloys.

In 1878 Swiss chemist Jean-Charles de Marignac gave the name ytterbium (after the Swedish town of Ytterby, near where it was found) to what he believed to be a new element. French chemist Georges Urbain (1872-1938) discovered in 1907 that this was in fact a mixture of two elements: ytterbium and lutetium.

yttrium silver-grey, metallic element, symbol Y, atomic number 39, relative atomic mass 88.905. It is associated with and resembles the rare earth elements (ϕ lanthanides), occurring in gadolinite, xenotime, and other minerals. It is used in colour-television tubes and to reduce steel corrosion.

The name derives from the Swedish town of Ytterby, near where it was first discovered in 1788. Swedish chemist Carl Mosander (1797-1858) isolated the element in 1843.

yucca any of a group of plants belonging to the lily family, with over 40 species found in Latin America and the southwestern USA. The leaves are stiff and sword-shaped and the flowers, which grow on upright central spikes, are white and bell-shaped. (Genus *Yucca*, family Liliaceae.)

Yuccas grow in dry soils where nitrate salts, required for protein manufacture, are in short supply. They have therefore evolved the ability to use ammonia, absorbed from animal urine, instead. Feeding extracts of yucca to livestock has been shown to reduce unpleasant ammoniacal smells from factory farms.

Yukawa, Hideki (1907-1981)

Japanese physicist. In 1935 he discovered the strong nuclear force that binds protons and neutrons together in the atomic nucleus, and predicted the existence of the subatomic particle called the meson. He was awarded a Nobel prize in 1949.

Mary Evans Picture Library

Z

Z in physics, the symbol for **impedance** (electricity and magnetism).

zander fish *Stizostedion lucioperca*, a cross between the ϕ pike and the ϕ perch. It has a grey-green back, white underside, two dorsal fins and a wide mouth with fangs. It is about 60 cm/24 in long and weighs about 7.5 kg. It is a solitary and voracious predator and lays up to 2 million eggs per year on vegetation in slow-flowing or still water.

z-buffer in computing, ϕ buffer for storing depth information for displaying three-dimensional graphics. (Two-dimensional images may be displayed using x , y coordinates but the third dimension implies x , y and z .) In a graphics card, z -buffer memory keeps track of which onscreen elements are visible and which are hidden behind other objects.

zebra black and white striped member of the horse genus *Equus* found in Africa; the stripes serve as camouflage or dazzle and confuse predators. It is about 1.5 m/5 ft high at the shoulder, with a stout body and a short, thick mane. Zebras live in family groups and herds on mountains and plains, and can run at up to 60 kph/40 mph. Males are usually solitary.

The **mountain zebra** *E. zebra* was once common in Cape Colony and Natal and still survives in parts of South Africa and Angola. It has long ears and is silvery-white with black or dark-brown markings. Grey's zebra *E. grevyi*, at 1.6 m and 450 kg, is the largest member of the horse family. It has finer and clearer markings than the mountain zebra and inhabits Ethiopia and Somalia. Whereas other zebra species have a harem system, Grey's males defend territories that females pass through to graze. The species is class-

zebra The Cape mountain zebra *Equus hipposideros* zebra zebra. It now survives mainly in the Mountain Zebra National Park near Cradock in South Africa, having been saved from near extinction (numbers had been reduced to about 40 individuals). Hartmann's mountain zebra is more widely distributed in the semi-deserts of Namibia. Premaphotos Wildlife

sified as endangered. Burchell's or the common zebra *E. burchelli* is medium in size, has white ears, a long mane, and a full tail; it roams the plains north of the Orange River in South Africa.

zebu any of a species of ϕ cattle *Bos indicus* found domesticated in E Asia, India, and Africa. It is usually light-coloured, with large horns and a large fatty hump near the shoulders. It is used for pulling loads, and is held by some Hindus to be sacred. There are about 30 breeds.

Zebras have been crossbred with other species of cattle in hot countries to pass on their qualities of heat tolerance and insect resistance. In the USA, they are called Brahman cattle.

zeitgeber German 'time giver' in biology, signal that synchronizes ϕ circadian rhythms ensuring that internal and external time are linked. In most species the most important zeitgeber is light and dark changes during the cycle of night and day.

Zelenchukskaya site of the world's largest single-mirror optical telescope, with a mirror of 6 m/236 in diameter, in the Caucasus Mountains of Russia. At the same site is the RATAN 600 radio telescope, consisting of radio reflectors in a circle of 600 m/2,000 ft diameter. Both instruments are operated by the Academy of Sciences in St Petersburg.

zenith uppermost point of the celestial horizon, immediately above the observer; the nadir is below, diametrically opposite. See ϕ celestial sphere.

zeolite any of the hydrous aluminium silicates, also containing sodium, calcium, barium, strontium, or potassium, chiefly found in igneous rocks and characterized by a ready loss or gain of water. Zeolites are used as 'molecular sieves' to separate mixtures because they are capable of selective absorption. They have a high ion-exchange capacity and can be used to make petrol, benzene, and toluene from low-grade raw materials, such as coal and methanol.

Zeppelin, Ferdinand Adolf August Heinrich, Count von Zeppelin (1838–1917)

German airship pioneer. His first airship was built and tested in 1900. During World War I a number of zeppelins bombed England. They were also used for luxury passenger transport but the construction of hydrogen-filled airships with rigid keels was abandoned after several disasters in the 1920s and 1930s. Zeppelin also helped to pioneer large multi-engine bomber planes.

Mary Evans Picture Library

zero the number (written 0) that when added to any number leaves that number unchanged. It results when any number is subtracted from itself, or when any number is added to its negative. The product of any number with zero is itself zero.

zero wait state term applied to ϕ central processing units that run without wait states – that is, without waiting for slower chips.

Zhubov scale scale for measuring ice coverage, developed in the USSR. The unit is the **ball**; one ball is 10% coverage, two balls 20%, and so on.

zidovudine (formerly AZT) antiviral drug used in the treatment of AIDS. It is not a cure for AIDS but is effective in prolonging life; it does not, however, delay the onset of AIDS in people carrying the virus.

Zidovudine was developed in the mid-1980s and approved for use by 1987. Taken every four hours, night and day, it reduces the risk of opportunistic infection and relieves many neurological complications. However, frequent blood monitoring is required to control anaemia, a potentially life-threatening side effect of zidovudine. Blood transfusions are often necessary, and the drug must be withdrawn if bone-marrow function is severely affected.

A US trial in 1994 showed that the drug does provide some protection to babies born to HIV-positive mothers. The number of babies infected was reduced by two-thirds where mothers received zidovudine during pregnancy. Long-term effects of zidovudine on the babies' health remain to be determined.

ZIF socket (acronym for *zero insertion force socket*) socket on a computer's motherboard that enables a chip to be easily removed or inserted by use of a lever. ZIF sockets are usually only used for expensive microprocessors that are designed to be upgraded.

ZIFT (abbreviation for *zygote inter-Fallopian transfer*) modified form of *in vitro* fertilization in which the fertilized ovum is reintroduced into the mother's Fallopian tube before the ovum has undergone its first cell division. This mimics the natural processes of fertilization (which normally occurs in the Fallopian tube) and implantation more effectively than older techniques.

Zimbabwe or Great Zimbabwe *Shona* zimbabwe ('house of stone') extensive stone architectural ruins 27 km/17 mi SE of Victoria in Mashonaland, Zimbabwe. The site was occupied from the 3rd century AD, but the massive stone structures date from the 10th–15th centuries AD. They were probably the work of the Shona people, who established their rule in about AD 1000 and mined minerals for trading.

The new state of Zimbabwe took its name from these ruins, and the national emblem is a bird derived from soapstone sculptures of fish eagles found there. The site comprises hill ruins with the earliest dwellings (10th century AD), a series of stone-walled enclosures on a granite outcrop known as the Acropolis, a massive elliptical building, or Great Enclosure, with 10-m/30-ft stone walls, a ritual or political site known as the Temple, and a conical tower built in a later phase.

Porcelain of the Ming period and golden ornaments have been found in the ruins. Gold, copper, tin, and iron were all mined by the Shona.

zinc Germanic *zint* 'point' hard, brittle, bluish-white, metallic element, symbol Zn, atomic number 30, relative atomic mass 65.37. The principal ore is sphalerite or zinc blende (zinc sulphide, ZnS). Zinc is hardly affected by air or moisture at ordinary temperatures; its chief uses are in alloys such as brass and in coating metals (for example, galvanized iron). Its compounds include zinc oxide, used in ointments (as an astringent) and cosmetics, paints, glass, and printing ink.

Zinc is an essential trace element in most animals; adult humans have 2–3 g/0.07–0.1 oz zinc in their bodies. There are more than 300 known enzymes that contain zinc.

Zinc has been used as a component of brass since the Bronze Age, but it was not recognized as a separate metal until 1746, when it was described by German chemist Andreas Sigismund Marggraf (1709–1782). The name derives from the shape of the crystals on smelting.

zinc ore mineral from which zinc is extracted, principally sphalerite (Zn,FeS, but also zincite, ZnO₂, and smithsonite, ZnCO₃), all of which occur in mineralized veins. Ores of lead and zinc often occur together, and are common worldwide; Canada, the USA, and Australia are major producers.

zinc oxide ZnO white powder, yellow when hot, that occurs in nature as the mineral zincite. It is used in paints and as an anti-septic in zinc ointment; it is the main ingredient of calamine lotion.

zinc sulphide ZnS yellow-white solid that occurs in nature as the mineral sphalerite (also called zinc blende). It is the principal ore of zinc, and is used in the manufacture of fluorescent paints.

zinnia any of a group of annual plants belonging to the daisy family, native to Mexico and South America; notably the cultivated hybrids of *Z. elegans* with brightly coloured daisylike flowers. (Genus *Zinnia*, family Compositae.)

Zip drive in computing, portable disc drive manufactured by or under license from 3Com. Zip drives can store almost 100 megabytes on each 3.5-in disc.

zip fastener fastening device used in clothing, invented in the USA by Whitcomb Judson in 1891, originally for doing up shoes. It has two sets of interlocking teeth, meshed by means of a slide that moves up and down. It did not become widely used in the clothing industry until the 1930s.

zipped file in computing, a file that has been compressed using the ZIPKIP program.

zircon zirconium silicate, ZrSiO₄, a mineral that occurs in small quantities in a wide range of igneous, sedimentary, and metamorphic rocks. It is very durable and is resistant to erosion and weathering. It is usually coloured brown, but can be other colours, and when transparent may be used as a gemstone.

Zircons contain abundant radioactive isotopes of uranium and so are useful for uranium-lead dating to determine the ages of rocks.

zirconium Germanic *zircon*, from Persian *zargun* 'golden' lustrous, greyish-white, strong, ductile, metallic element, symbol Zr, atomic number 40, relative atomic mass 91.22. It occurs in nature as the mineral zircon (zirconium silicate), from which it is obtained commercially. It is used in some ceramics, alloys for wire and filaments, steel manufacture, and nuclear reactors, where its low neutron absorption is advantageous.

It was isolated in 1824 by Swedish chemist Jöns Berzelius. The name was proposed by English chemist Humphry Davy in 1808.

Zmodem in computing, ZFTP protocol for transferring files across the Internet or other communications link. It offers the facility to use wild cards to search files and to resume interrupted transfers where they left off.

zodiac zone of the heavens containing the paths of the Sun, Moon, and planets. When this was devised by the ancient Greeks, only five planets were known, making the zodiac about 16° wide. In astrology, the zodiac is divided into 12 signs, each 30° in extent: Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricorn, Aquarius, and Pisces. These do not cover the same areas of sky as the astronomical constellations.

The 12 astronomical constellations are uneven in size and do not between them cover the whole zodiac, or even the line of the ecliptic, much of which lies in the constellation of Ophiuchus.

zodiacal light cone-shaped light sometimes seen extending from the Sun along the ecliptic, visible after sunset or before sunrise. It is due to thinly spread dust particles in the central plane of the Solar System. It is very faint, and requires a dark, clear sky to be seen.

zooidogamy type of plant reproduction in which male gametes (antherozoids) swim in a film of water to the female gametes. Zooidogamy is found in algae, bryophytes, pteridophytes, and some gymnosperms (others use siphonogamy).

zone therapy alternative name for reflexology.

zoo (abbreviation for *zoological gardens*) place where animals are kept in captivity. Originally created purely for visitor entertainment and education, zoos have become major centres for the breeding of endangered species of animals; a 1984 report identified 2,000 vertebrate species in need of such maintenance. The Arabian oryx has already been preserved in this way; it was captured in 1962, bred in captivity, and released again in the desert in 1972, where it has flourished.

ZOONET IMAGE ARCHIVES

<http://www.mindspring.com/~zoonet/gallery.html>

Comprehensive collection of indexes to zoo galleries, with or without detailed text, and links to other animal pictures.

TO REMEMBER THE MAJOR CHARACTERISTICS OF LIVING ORGANISMS:

NEWMARKET RUNS EVERY GREAT RACE IN MAY.

NUTRITION, RESPIRATION, EXCRETION, GROWTH, REPRODUCTION, IRRITABILITY (RESPONSE TO CONDITIONS), MOVEMENT

Notable zoos exist in New York, San Diego, Toronto, Chicago, London, Paris, Berlin, Moscow, and Beijing (Peking). Many groups object to zoos because they keep animals in unnatural conditions alien to their habitat.

Anyone who has got any pleasure at all should try to put something back. Life is like a superlative meal and the world is like the maitre d'hotel. What I am doing is the equivalent of leaving a reasonable tip.

GERALD DURRELL British conservationist.
Guardian 1971

zoological colony in zoology, colony formed when an organism gives rise to several buds which adhere to the parent and continue to reproduce by budding. Such colonies are common among sponges and corals.

The freshwater hydra forms a temporary colony, while many other forms, including most corals, are permanently colonial. In many cases the individuals that make up a colony perform identical functions, but in the condition known as polymorphism, the functions are specialized and allotted to various members. Thus the individuality of the members is frequently lost, and they become almost like organs instead of whole living creatures; this happens, for instance in the Portuguese man-of-war.

zoology branch of biology concerned with the study of animals. It includes any aspect of the study of animal form and function – description of present-day animals, the study of evolution of animal

forms, anatomy, physiology, embryology, behaviour, and geographical distribution.

zoom lens photographic lens that, by variation of focal length, allows speedy transition from long shots to close-ups.

zoonosis any infectious disease that can be transmitted to humans by other vertebrate animals. Probably the most feared example is rabies. The transmitted microorganism sometimes causes disease only in the human host, leaving the animal host unaffected.

Z particle in physics, an elementary particle, one of the weakons responsible for carrying the weak nuclear force.

zucchini another name for the courgette, a type of marrow.

zwitterion ion that has both a positive and a negative charge, such as an amino acid in neutral solution. For example, glycine contains both a basic amino group (NH_2) and an acidic carboxyl group (COOH); when these are both ionized in aqueous solution, the acid group loses a proton to the amino group, and the molecule is positively charged at one end and negatively charged at the other.

zygote ovum (egg) after fertilization but before it undergoes cleavage to begin embryonic development.

What counts ... in science is to be not so much the first as the last.

ERWIN CHARGAFF Czech-born US biochemist.
Science 1971

Nobel Prize: Introduction

The Nobel Prizes were first awarded in 1901 under the will of Alfred B Nobel (1833–96), a Swedish chemist, who invented dynamite. The interest on the Nobel endowment fund is divided annually among the persons who have made the greatest contributions in the fields of physics, chemistry, medicine, literature, and world peace. The first four are awarded by academic committees based in Sweden, while the peace prize is awarded by a committee of the Norwegian parliament. A sixth prize, for economics, financed by the Swedish National Bank, was first awarded in 1969. The prizes have a large cash award and are given to organizations – such as the United Nations peacekeeping forces, which received the Nobel Peace Prize in 1988 – as well as to individuals.

Nobel Prize for Chemistry

| <i>Year</i> | <i>Winner(s)¹</i> | <i>Awarded for</i> |
|-------------|----------------------------------|----------------------------------------------------------------------------|
| 1901 | Jacobus van't Hoff (Netherlands) | laws of chemical dynamics and osmotic pressure |
| 1902 | Emil Fischer (Germany) | sugar and purine syntheses |
| 1903 | Svante Arrhenius (Sweden) | theory of electrolytic dissociation |
| 1904 | William Ramsay (UK) | discovery of inert gases in air and their locations in the periodic table |
| 1905 | Adolf von Baeyer (Germany) | work in organic dyes and hydroaromatic compounds |
| 1906 | Henri Moissan (France) | isolation of fluorine and adoption of electric furnace |
| 1907 | Eduard Buchner (Germany) | biochemical research and discovery of cell-free fermentation |
| 1908 | Ernest Rutherford (UK) | work in atomic disintegration, and the chemistry of radioactive substances |
| 1909 | Wilhelm Ostwald (Germany) | work in catalysis, and principles of equilibria and rates of reaction |
| 1910 | Otto Wallach (Germany) | work in allylic compounds |
| 1911 | Marie Curie (France) | discovery of radium and polonium, and the isolation and study of radium |
| 1912 | Victor Grignard (France) | discovery of Grignard reagent |
| | Paul Sabatier (France) | finding method of catalytic hydrogenation of organic compounds |
| 1913 | Alfred Werner (Switzerland) | work in bonding of atoms within molecules |
| 1914 | Theodore Richards (USA) | accurate determination of the atomic masses of many elements |
| 1915 | Richard Willstätter (Germany) | research into plant pigments, especially chlorophyll |
| 1916 | no award | |
| 1917 | no award | |

Nobel Prize for Chemistry (continued)

| Year | Winner(s) ¹ | Awarded for |
|------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1918 | Fritz Haber (Germany) | synthesis of ammonia from its elements |
| 1919 | no award | |
| 1920 | Walther Nernst (Germany) | |
| 1921 | Frederick Soddy (UK) | |
| 1922 | Francis Aston (UK) | |
| 1923 | Fritz Pregl (Austria) | work in thermochemistry work in radioactive substances, especially isotopes work in mass spectrometry of isotopes of radioactive elements, and elucidation of the whole-number rule method of microanalysis of organic substances |
| 1924 | no award | |
| 1925 | Richard Zsigmondy (Austria) | |
| 1926 | Theodor Svedberg (Sweden) | |
| 1927 | Heinrich Wieland (Germany) | |
| 1928 | Adolf Windaus (Germany) | |
| 1929 | Arthur Harden (UK) and Hans von Euler-Chelpin (Sweden) | |
| 1930 | Hans Fischer (Germany) | |
| 1931 | Carl Bosch (Germany) and Friedrich Bergius (Germany) | |
| 1932 | Irving Langmuir (USA) | |
| 1933 | no award | discovery of deuterium (heavy hydrogen) synthesis of new radioactive elements work in molecular structures by investigation of dipole moments and the diffraction of X-rays and electrons in gases work in carbohydrates and ascorbic acid (vitamin C) work in carotenoids, flavins, retinol (vitamin A) and riboflavin (vitamin B ₂) carotenoids and vitamins research work in sex hormones polymethylenes and higher terpenes |
| 1934 | Harold Urey (USA) | |
| 1935 | Irène and Frédéric Joliot-Curie (France) | |
| 1936 | Peter Debye (Netherlands) | |
| 1937 | Norman Haworth (UK) Paul Karrer (Switzerland) | |
| 1938 | Richard Kuhn (Germany) (declined) | |
| 1939 | Adolf Butenandt (Germany) (declined) Leopold Ruzicka (Switzerland) | |
| 1940 | no award | |
| 1941 | no award | |
| 1942 | no award | |
| 1943 | Georg von Hevesy (Hungary) | use of isotopes as tracers in chemical processes discovery of nuclear fission work in agriculture and nutrition, especially fodder preservation discovery of crystallization of enzymes preparation of pure enzymes and virus proteins investigation of biologically important plant products, especially alkaloids researches in electrophoresis and adsorption analysis, and discoveries concerning serum proteins work in chemical thermodynamics, especially at very low temperatures discovery and development of diene synthesis discovery and work in chemistry of transuranic elements development of partition chromatography discoveries in macromolecular chemistry study of nature of chemical bonds, especially in complex substances investigations into biochemically important sulphur compounds, and the first synthesis of a polypeptide hormone work in mechanism of chemical reactions work in nucleotides and nucleotide coenzymes determination of the structure of proteins, especially insulin discovery and development of polarographic methods of chemical analysis development of radiocarbon dating in archaeology, geology, and geography |
| 1944 | Otto Hahn (Germany) | |
| 1945 | Artturi Virtanen (Finland) | |
| 1946 | James Sumner (USA) John Northrop (USA) and Wendell Stanley (USA) | |
| 1947 | Robert Robinson (UK) | |
| 1948 | Arne Tiselius (Sweden) | |
| 1949 | William Giauque (USA) | |
| 1950 | Otto Diels (West Germany) and Kurt Alder (West Germany) | |
| 1951 | Edwin McMillan (USA) and Glenn Seaborg (USA) | |
| 1952 | Archer Martin (UK) and Richard Syngé (UK) | |
| 1953 | Hermann Staudinger (West Germany) | study of nature of chemical bonds, especially in complex substances investigations into biochemically important sulphur compounds, and the first synthesis of a polypeptide hormone work in mechanism of chemical reactions work in nucleotides and nucleotide coenzymes determination of the structure of proteins, especially insulin discovery and development of polarographic methods of chemical analysis development of radiocarbon dating in archaeology, geology, and geography study of assimilation of carbon dioxide by plants determination of structures of globular proteins chemistry and technology of high polymers crystallographic determination of the structures of biochemical compounds, notably penicillin and cyanocobalamin (vitamin B ₁₂) organic synthesis molecular orbital theory of chemical bonds and structures investigation of rapid chemical reactions by means of very short pulses of energy discovery of reciprocal relations, fundamental for the thermodynamics of irreversible processes concept and applications of conformation discovery of sugar nucleotides and their role in carbohydrate biosynthesis research on electronic structure and geometry of molecules, particularly free radicals work in amino-acid structure and biological activity of the enzyme ribonuclease |
| 1954 | Linus Pauling (USA) | |
| 1955 | Vincent du Vigneaud (USA) | |
| 1956 | Cyril Hinshelwood (UK) and Nikolay Semenov (USSR) | |
| 1957 | Alexander Todd (UK) | |
| 1958 | Frederick Sanger (UK) | |
| 1959 | Jaroslav Heyrovský (Czechoslovakia) | |
| 1960 | Willard Libby (USA) | |
| 1961 | Melvin Calvin (USA) | |
| 1962 | Max Perutz (UK) and John Kendrew (UK) | |
| 1963 | Karl Ziegler (West Germany) and Giulio Natta (Italy) | study of assimilation of carbon dioxide by plants determination of structures of globular proteins chemistry and technology of high polymers crystallographic determination of the structures of biochemical compounds, notably penicillin and cyanocobalamin (vitamin B ₁₂) organic synthesis molecular orbital theory of chemical bonds and structures investigation of rapid chemical reactions by means of very short pulses of energy discovery of reciprocal relations, fundamental for the thermodynamics of irreversible processes concept and applications of conformation discovery of sugar nucleotides and their role in carbohydrate biosynthesis research on electronic structure and geometry of molecules, particularly free radicals work in amino-acid structure and biological activity of the enzyme ribonuclease |
| 1964 | Dorothy Crowfoot Hodgkin (UK) | |
| 1965 | Robert Woodward (USA) | |
| 1966 | Robert Mulliken (USA) | |
| 1967 | Manfred Eigen (West Germany), Ronald Norrish (UK), and George Porter (UK) | |
| 1968 | Lars Onsager (USA) | |
| 1969 | Derek Barton (UK) and Odd Hassel (Norway) | |
| 1970 | Luis Federico Leloir (Argentina) | |
| 1971 | Gerhard Herzberg (Canada) | |
| 1972 | Christian Anfinsen (USA), Stanford Moore (USA), and William Stein (USA) | |

Nobel Prize for Chemistry (continued)

| Year | Winner(s) ¹ | Awarded for |
|------|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1973 | Ernst Fischer (West Germany) and Geoffrey Wilkinson (UK) | work in chemistry of organometallic sandwich compounds |
| 1974 | Paul Flory (USA) | studies of physical chemistry of macromolecules |
| 1975 | John Cornforth (UK) | work in stereochemistry of enzyme-catalysed reactions |
| | Vladimir Prelog (Switzerland) | work in stereochemistry of organic molecules and their reactions |
| 1976 | William Lipscomb (USA) | study of structure and chemical bonding of boranes (compounds of boron and hydrogen) |
| 1977 | Ilya Prigogine (Belgium) | work in thermodynamics of irreversible and dissipative processes |
| 1978 | Peter Mitchell (UK) | formulation of a theory of biological energy transfer and chemiosmotic theory |
| 1979 | Herbert Brown (USA) and Georg Wittig (West Germany) | use of boron and phosphorus compounds, respectively, in organic syntheses |
| 1980 | Paul Berg (USA) | biochemistry of nucleic acids, especially recombinant DNA |
| | Walter Gilbert (USA) and Frederick Sanger (UK) | base sequences in nucleic acids |
| 1981 | Kenichi Fukui (Japan) and Roald Hoffmann (USA) | theories concerning chemical reactions |
| 1982 | Aaron Klug (UK) | determination of crystallographic electron microscopy: structure of biologically important nucleic acid-protein complexes |
| 1983 | Henry Taube (USA) | study of electron-transfer reactions in inorganic chemical reactions |
| 1984 | Bruce Merrifield (USA) | development of chemical syntheses on a solid matrix |
| 1985 | Herbert Hauptman (USA) and Jerome Karle (USA) | development of methods of determining crystal structures |
| 1986 | Dudley Herschbach (USA), Yuan Lee (USA), and John Polanyi (Canada) | development of dynamics of chemical elementary processes |
| 1987 | Donald Cram (USA), Jean-Marie Lehn (France), and Charles Pedersen (USA) | development of molecules with highly selective structure-specific interactions |
| 1988 | Johann Deisenhofer (West Germany), Robert Huber (West Germany), and Hartmut Michel (West Germany) | discovery of three-dimensional structure of the reaction centre of photosynthesis |
| 1989 | Sidney Altman (USA) and Thomas Cech (USA) | discovery of catalytic function of RNA |
| 1990 | Elias James Corey (USA) | new methods of synthesizing chemical compounds |
| 1991 | Richard Ernst (Switzerland) | improvements in the technology of nuclear magnetic resonance (NMR) imaging |
| 1992 | Rudolph Marcus (USA) | theoretical discoveries relating to reduction and oxidation reactions |
| 1993 | Kary Mullis (USA) | invention of the polymerase chain reaction technique for amplifying DNA |
| | Michael Smith (Canada) | invention of techniques for splicing foreign genetic segments into an organism's DNA in order to modify the proteins produced |
| 1994 | George Olah (USA) | development of technique for examining hydrocarbon molecules |
| 1995 | F Sherwood Rowland (USA), Mario Molina (USA), and Paul Crutzen (Netherlands) | explaining the chemical process of the ozone layer |
| 1996 | Robert Curl, Jr (USA), Harold Kroto (UK), and Richard Smalley (USA) | discovery of fullerenes |
| 1997 | John Walker (UK), Paul Boyer (USA), and Jens Skou (Denmark) | study of the enzymes involved in the production of adenosine triphosphate (ATP), which acts as a store of energy in bodies called mitochondria inside cells |

¹ Nationality given is the citizenship of recipient at the time award was made.**Nobel Prize for Physics**

| Year | Winner(s) ¹ | Awarded for |
|------|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1901 | Wilhelm Röntgen (Germany) | discovery of X-rays |
| 1902 | Hendrik Lorentz (Netherlands) and Pieter Zeeman (Netherlands) | influence of magnetism on radiation phenomena |
| 1903 | Henri Becquerel (France) | discovery of spontaneous radioactivity |
| | Pierre Curie (France) and Marie Curie (France) | research on radiation phenomena |
| 1904 | John Strutt (Lord Rayleigh, UK) | densities of gases and discovery of argon |
| 1905 | Philipp von Lenard (Germany) | work on cathode rays |
| 1906 | Joseph J Thomson (UK) | theoretical and experimental work on the conduction of electricity by gases |
| 1907 | Albert Michelson (USA) | measurement of the speed of light through the design and application of precise optical instruments such as the interferometer |
| 1908 | Gabriel Lippmann (France) | photographic reproduction of colours by interference |
| 1909 | Guglielmo Marconi (Italy) and Karl Ferdinand Braun (Germany) | development of wireless telegraphy |
| 1910 | Johannes van der Waals (Netherlands) | equation describing the physical behaviour of gases and liquids |
| 1911 | Wilhelm Wien (Germany) | laws governing radiation of heat |
| 1912 | Nils Dalén (Sweden) | invention of light-controlled valves, which allow lighthouses and buoys to operate automatically |
| 1913 | Heike Kamerlingh Onnes (Netherlands) | studies of properties of matter at low temperatures |
| 1914 | Max von Laue (Germany) | discovery of diffraction of X-rays by crystals |
| 1915 | William Bragg (UK) and Lawrence Bragg (UK) | X-ray analysis of crystal structures |
| 1916 | no award | |
| 1917 | Charles Barkla (UK) | discovery of characteristic X-ray emission of the elements |
| 1918 | Max Planck (Germany) | formulation of quantum theory |

Nobel Prize for Physics (continued)

| Year | Winner(s) ¹ | Awarded for |
|------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| 1919 | Johannes Stark (Germany) | discovery of Doppler effect in rays of positive ions, and splitting of spectral lines in electric fields |
| 1920 | Charles Guillaume (Switzerland) | discovery of anomalies in nickel-steel alloys |
| 1921 | Albert Einstein (Switzerland) | theoretical physics, especially law of photoelectric effect |
| 1922 | Niels Bohr (Denmark) | discovery of the structure of atoms and radiation emanating from them |
| 1923 | Robert Millikan (USA) | discovery of the electric charge of an electron, and study of the photo-electric effect |
| 1924 | Karl Siegbahn (Sweden) | X-ray spectroscopy |
| 1925 | James Franck (Germany) and Gustav Hertz (Germany) | discovery of laws governing the impact of an electron upon an atom |
| 1926 | Jean Perrin (France) | confirmation of the discontinuous structure of matter |
| 1927 | Arthur Compton (USA) | transfer of energy from electromagnetic radiation to a particle |
| | Charles Wilson (UK) | invention of the Wilson cloud chamber, by which the movement of electrically charged particles may be tracked |
| 1928 | Owen Richardson (UK) | work on thermionic phenomena and associated law |
| 1929 | Louis Victor de Broglie (France) | discovery of the wavelike nature of electrons |
| 1930 | Chandrasekhara Raman (India) | discovery of the scattering of single-wavelength light when it is passed through a transparent substance |
| 1931 | no award | |
| 1932 | Werner Heisenberg (Germany) | creation of quantum mechanics |
| 1933 | Erwin Schrödinger (Austria) and Paul Dirac (UK) | development of quantum mechanics |
| 1934 | no award | |
| 1935 | James Chadwick (UK) | discovery of the neutron |
| 1936 | Victor Hess (Austria) | discovery of cosmic radiation |
| | Carl Anderson (USA) | discovery of the positron |
| 1937 | Clinton Davisson (USA) and George Thomson (UK) | diffraction of electrons by crystals |
| 1938 | Enrico Fermi (Italy) | use of neutron irradiation to produce new elements, and discovery of nuclear reactions induced by slow neutrons |
| 1939 | Ernest Lawrence (USA) | invention and development of the cyclotron, and production of artificial radioactive elements |
| 1940 | no award | |
| 1941 | no award | |
| 1942 | no award | |
| 1943 | Otto Stern (USA) | molecular-ray method of investigating elementary particles, and discovery of magnetic moment of proton |
| 1944 | Isidor Isaac Rabi (USA) | resonance method of recording the magnetic properties of atomic nuclei |
| 1945 | Wolfgang Pauli (Austria) | discovery of the exclusion principle |
| 1946 | Percy Bridgman (USA) | development of high-pressure physics |
| 1947 | Edward Appleton (UK) | physics of the upper atmosphere |
| 1948 | Patrick Blackett (UK) | application of the Wilson cloud chamber to nuclear physics and cosmic radiation |
| 1949 | Hideki Yukawa (Japan) | theoretical work predicting existence of mesons |
| 1950 | Cecil Powell (UK) | use of photographic emulsion to study nuclear processes, and discovery of pions (pi mesons) |
| 1951 | John Cockcroft (UK) and Ernest Walton (Ireland) | transmutation of atomic nuclei by means of accelerated subatomic particles |
| 1952 | Felix Bloch (USA) and Edward Purcell (USA) | precise nuclear magnetic measurements |
| 1953 | Frits Zernike (Netherlands) | invention of phase-contrast microscope |
| 1954 | Max Born (UK) | statistical interpretation of wave function in quantum mechanics |
| | Walther Bothe (West Germany) | coincidence method of detecting the emission of electrons |
| 1955 | Willis Lamb (USA) | structure of hydrogen spectrum |
| | Polykarp Kusch (USA) | determination of magnetic moment of the electron |
| 1956 | William Shockley (USA), John Bardeen (USA), and Walter Houser Brattain (USA) | study of semiconductors, and discovery of the transistor effect |
| 1957 | Tsung-Dao Lee (China) and Chen Ning Yang (China) | investigations of weak interactions between elementary particles |
| 1958 | Pavel Cherenkov (USSR), Ilya Frank (USSR), and Igor Tamm (USSR) | discovery and interpretation of Cherenkov radiation |
| 1959 | Emilio Segrè (USA) and Owen Chamberlain (USA) | discovery of the antiproton |
| 1960 | Donald Glaser (USA) | invention of the bubble chamber |
| 1961 | Robert Hofstadter (USA) | scattering of electrons in atomic nuclei, and structure of protons and neutrons |
| | Rudolf Mossbauer (West Germany) | resonance absorption of gamma radiation |
| 1962 | Lev Landau (USSR) | theories of condensed matter, especially liquid helium |
| 1963 | Eugene Wigner (USA) | discovery and application of symmetry principles in atomic physics |
| | Maria Goeppert-Mayer (USA) and Hans Jensen (Germany) | discovery of the shell-like structure of atomic nuclei |
| 1964 | Charles Townes (USA), Nikolai Basov (USSR), and Aleksandr Prokhorov (USSR) | work on quantum electronics leading to construction of oscillators and amplifiers based on maser-laser principle |
| 1965 | Shin'ichiro Tomonaga (Japan), Julian Schwinger (USA), and Richard Feynman (USA) | basic principles of quantum electrodynamics |
| 1966 | Alfred Kastler (France) | development of optical pumping, whereby atoms are raised to higher energy levels by illumination |
| 1967 | Hans Bethe (USA) | theory of nuclear reactions, and discoveries concerning production of energy in stars |

Nobel Prize for Physics (continued)

| <i>Year</i> | <i>Winner(s)¹</i> | <i>Awarded for</i> |
|-------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1968 | Luis Alvarez (USA) | elementary-particle physics, and discovery of resonance states, using hydrogen bubble chamber and data analysis |
| 1969 | Murray Gell-Mann (USA) | classification of elementary particles, and study of their interactions |
| 1970 | Hannes Alfvén (Sweden) | work in magnetohydrodynamics and its applications in plasma physics |
| 1971 | Louis Néel (France) | work in antiferromagnetism and ferromagnetism in solid-state physics |
| 1972 | Dennis Gabor (UK) | invention and development of holography |
| 1973 | John Bardeen (USA), Leon Cooper (USA), and John Robert Schrieffer (USA) | theory of superconductivity |
| 1974 | Leo Esaki (Japan) and Ivar Giaever (USA) | tunnelling phenomena in semiconductors and superconductors |
| | Brian Josephson (UK) | theoretical predictions of the properties of a supercurrent through a tunnel barrier |
| 1975 | Martin Ryle (UK) and Antony Hewish (UK) | development of radioastronomy, particularly the aperture-synthesis technique, and the discovery of pulsars |
| 1976 | Aage Bohr (Denmark), Ben Mottelson (Denmark), and James Rainwater (USA) | discovery of connection between collective motion and particle motion in atomic nuclei, and development of theory of nuclear structure |
| 1977 | Burton Richter (USA) and Samuel Ting (USA) | discovery of the psi meson |
| 1978 | Philip Anderson (USA), Nevill Mott (UK), and John Van Vleck (USA) | contributions to understanding electronic structure of magnetic and disordered systems |
| 1979 | Piotr Kapitza (USSR) | invention and application of low-temperature physics |
| | Arno Penzias (USA) and Robert Wilson (USA) | discovery of cosmic background radiation |
| 1979 | Sheldon Glashow (USA), Abdus Salam (Pakistan), and Steven Weinberg (USA) | unified theory of weak and electromagnetic fundamental forces, and prediction of the existence of the weak neutral current |
| 1980 | James W Cronin (USA) and Val Fitch (USA) | violations of fundamental symmetry principles in the decay of neutral kaon mesons |
| 1981 | Nicolaas Bloembergen (USA) and Arthur Schawlow (USA) | development of laser spectroscopy |
| | Kai Siegbahn (Sweden) | high-resolution electron spectroscopy |
| 1982 | Kenneth Wilson (USA) | theory for critical phenomena in connection with phase transitions |
| 1983 | Subrahmanyan Chandrasekhar (USA) | theoretical studies of physical processes in connection with structure and evolution of stars |
| | William Fowler (USA) | nuclear reactions involved in the formation of chemical elements in the universe |
| 1984 | Carlo Rubbia (Italy) and Simon van der Meer (Netherlands) | contributions to the discovery of the W and Z particles (weakons) |
| 1985 | Klaus von Klitzing (West Germany) | discovery of the quantized Hall effect |
| 1986 | Ernst Ruska (West Germany) | electron optics, and design of the first electron microscope |
| | Gerd Binnig (West Germany) and Heinrich Rohrer (Switzerland) | design of scanning tunnelling microscope |
| 1987 | Georg Bednorz (West Germany) and Alex Müller (Switzerland) | superconductivity in ceramic materials |
| 1988 | Leon M Lederman (USA), Melvin Schwartz (USA), and Jack Steinberger (USA) | neutrino-beam method, and demonstration of the doublet structure of leptons through discovery of muon neutrino |
| 1989 | Norman Ramsey (USA) | measurement techniques leading to discovery of caesium atomic clock |
| | Hans Dehmelt (USA) and Wolfgang Paul (Germany) | ion-trap method for isolating single atoms |
| 1990 | Jerome Friedman (USA), Henry Kendall (USA), and Richard Taylor (Canada) | experiments demonstrating that protons and neutrons are made up of quarks |
| 1991 | Pierre-Gilles de Gennes (France) | work on disordered systems including polymers and liquid crystals, development of mathematical methods for studying the behaviour of molecules in a liquid on the verge of solidifying |
| 1992 | Georges Charpak (France) | invention and development of detectors used in high-energy physics |
| 1993 | Joseph Taylor (USA) and Russell Hulse (USA) | discovery of first binary pulsar (confirming the existence of gravitational waves) |
| 1994 | Clifford Shull (USA) and Bertram Brockhouse (Canada) | development of technique known as 'neutron scattering' which led to advances in semiconductor technology |
| 1995 | Frederick Reines (USA) | discovery of the neutrino |
| | Martin Perl (USA) | discovery of the tau lepton |
| 1996 | David Lee (USA), Douglas Osheroff (USA), and Robert Richardson (USA) | discovery of superfluidity in helium-3 |
| 1997 | Claude Cohen-Tannoudji (France), William Phillips (USA), and Steven Chu (USA) | discovery of a way to slow down individual atoms using lasers for study in a near-vacuum |

¹ Nationality given is the citizenship of recipient at the time award was made.**Nobel Prize for Physiology or Medicine**

| <i>Year</i> | <i>Winner(s)¹</i> | <i>Awarded for</i> |
|-------------|------------------------------|---------------------------------------------------------------------------------------------------------------|
| 1901 | Emil von Behring (Germany) | discovery that the body produces antitoxins, and development of serum therapy for diseases such as diphtheria |
| 1902 | Ronald Ross (UK) | work on the role of the Anopheles mosquito in transmitting malaria |
| 1903 | Niels Finsen (Denmark) | discovery of the use of ultraviolet light to treat skin diseases |
| 1904 | Ivan Pavlov (Russia) | discovery of the physiology of digestion |
| 1905 | Robert Koch (Germany) | investigations and discoveries in relation to tuberculosis |

Nobel Prize for Physiology or Medicine (continued)

| Year | Winner(s) ¹ | Awarded for |
|------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 1906 | Camillo Golgi (Italy) and Santiago Ramón y Cajal (Spain) | discovery of the fine structure of the nervous system |
| 1907 | Charles Laveran (France) | discovery that certain protozoa can cause disease |
| 1908 | Ilya Mechnikov (Russia) and Paul Ehrlich (Germany) | work on immunity |
| 1909 | Emil Kocher (Switzerland) | work on the physiology, pathology, and surgery of the thyroid gland |
| 1910 | Albrecht Kossel (Germany) | study of cell proteins and nucleic acids |
| 1911 | Alvar Gullstrand (Sweden) | work on the refraction of light through the different components of the eye |
| 1912 | Alexis Carrel (France) | work on the techniques for connecting severed blood vessels and transplanting organs |
| 1913 | Charles Richet (France) | work on allergic responses |
| 1914 | Robert Bárány (Austria-Hungary) | work on the physiology and pathology of the equilibrium organs of the inner ear |
| 1915 | no award | |
| 1916 | no award | |
| 1917 | no award | |
| 1918 | no award | |
| 1919 | Jules Bordet (Belgium) | work on immunity |
| 1920 | August Krogh (Denmark) | discovery of the mechanism regulating the dilation and constriction of blood capillaries |
| 1921 | no award | |
| 1922 | Archibald Hill (UK) | work in the production of heat in contracting muscle |
| | Otto Meyerhof (Germany) | work in the relationship between oxygen consumption and metabolism of lactic acid in muscle |
| 1923 | Frederick Banting (Canada) and John Macleod (UK) | discovery and isolation of the hormone insulin |
| 1924 | Willem Einthoven (Netherlands) | invention of the electrocardiograph |
| 1925 | no award | |
| 1926 | Johannes Fibiger (Denmark) | discovery of a parasite <i>Spiroplasma carolinense</i> that causes cancer |
| 1927 | Julius Wagner-Jauregg (Austria) | use of induced malarial fever to treat paralysis caused by mental deterioration |
| 1928 | Charles Nicolle (France) | work on the role of the body louse in transmitting typhus |
| 1929 | Christiaan Eijkman (Netherlands) | discovery of a cure for beriberi, a vitamin-deficiency disease |
| | Frederick Hopkins (UK) | discovery of trace substances, now known as vitamins, that stimulate growth |
| 1930 | Karl Landsteiner (USA) | discovery of human blood groups |
| 1931 | Otto Warburg (Germany) | discovery of respiratory enzymes that enable cells to process oxygen |
| 1932 | Charles Sherrington (UK) and Edgar Adrian (UK) | discovery of function of neurons (nerve cells) |
| 1933 | Thomas Morgan (USA) | work on the role of chromosomes in heredity |
| 1934 | George Whipple (USA), George Minot (USA), and William Murphy (USA) | work on treatment of pernicious anemia by increasing the amount of liver in the diet |
| 1935 | Hans Spemann (Germany) | organizer effect in embryonic development |
| 1936 | Henry Dale (UK) and Otto Loewi (Germany) | chemical transmission of nerve impulses |
| 1937 | Albert Szent-Györgyi (Hungary) | investigation of biological oxidation processes and of the action of ascorbic acid (vitamin C) |
| 1938 | Corneille Heymans (Belgium) | mechanisms regulating respiration |
| 1939 | Gerhard Domagk (Germany) | discovery of the first antibacterial sulphonamide drug |
| 1940 | no award | |
| 1941 | no award | |
| 1942 | no award | |
| 1943 | Henrik Dam (Denmark) | discovery of vitamin K |
| | Edward Doisy (USA) | chemical nature of vitamin K |
| 1944 | Joseph Erlanger (USA) and Herbert Gasser (USA) | transmission of impulses by nerve fibres |
| 1945 | Alexander Fleming (UK) | discovery of the bactericidal effect of penicillin |
| | Ernst Chain (UK) and Howard Florey (Australia) | isolation of penicillin and its development as an antibiotic drug |
| 1946 | Hermann Muller (USA) | discovery that X-ray irradiation can cause mutation |
| 1947 | Carl Cori (USA) and Gerty Cori (USA) | production and breakdown of glycogen (animal starch) |
| | Bernardo Houssay (Argentina) | function of the pituitary gland in sugar metabolism |
| 1948 | Paul Müller (Switzerland) | discovery of the first synthetic contact insecticide DDT |
| 1949 | Walter Hess (Switzerland) | mapping areas of the midbrain that control the activities of certain body organs |
| | Antonio Egas Moniz (Portugal) | therapeutic value of prefrontal leucotomy in certain psychoses |
| 1950 | Edward Kendall (USA), Tadeus Reichstein (Switzerland), and Philip Hench (USA) | structure and biological effects of hormones of the adrenal cortex |
| 1951 | Max Theiler (South Africa) | discovery of a vaccine against yellow fever |
| 1952 | Selman Waksman (USA) | discovery of streptomycin, the first antibiotic effective against tuberculosis |
| 1953 | Hans Krebs (UK) | discovery of the Krebs cycle |
| | Fritz Lipmann (USA) | discovery of coenzyme A, a nonprotein compound that acts in conjunction with enzymes to catalyse metabolic reactions leading up to the Krebs cycle |
| 1954 | John Enders (USA), Thomas Weller (USA), and Frederick Robins (USA) | cultivation of the polio virus in the laboratory |
| 1955 | Hugo Theorell (Sweden) | work on the nature and action of oxidation enzymes |

Nobel Prize for Physiology or Medicine (continued)

| Year | Winner(s) ¹ | Awarded for |
|------|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1956 | André Courmand (USA), Werner Forssmann (West Germany), and Dickinson Richards (USA) | work on the technique for passing a catheter into the heart for diagnostic purposes |
| 1957 | Daniel Bovet (Italy) | discovery of synthetic drugs used as muscle relaxants in anaesthesia |
| 1958 | George Beadle (USA) and Edward Tatum (USA) Joshua Lederberg (USA) | discovery that genes regulate precise chemical effects work on genetic recombination and the organization of bacterial genetic material |
| 1959 | Severo Ochoa (USA) and Arthur Kornberg (USA) | discovery of enzymes that catalyse the formation of RNA (ribonucleic acid) and DNA (deoxyribonucleic acid) |
| 1960 | Macfarlane Burnet (Australia) and Peter Medawar (UK) | acquired immunological tolerance of transplanted tissues |
| 1961 | George Békésy (USA) | investigations into the mechanism of hearing within the cochlea of the inner ear |
| 1962 | Francis Crick (UK), James Watson (USA), and Maurice Wilkins (UK) | discovery of the double-helical structure of DNA and of the significance of this structure in the replication and transfer of genetic information |
| 1963 | John Eccles (Australia), Alan Hodgkin (UK), and Andrew Huxley (UK) | ionic mechanisms involved in the communication or inhibition of impulses across neuron (nerve cell) membranes |
| 1964 | Konrad Bloch (USA) and Feodor Lynen (West Germany) | work on the cholesterol and fatty-acid metabolism |
| 1965 | François Jacob (France), André Lwoff (France), and Jacques Monod (France) | genetic control of enzyme and virus synthesis |
| 1966 | Peyton Rous (USA) Charles Huggins (USA) | discovery of tumour-inducing viruses hormonal treatment of prostatic cancer |
| 1967 | Ragnar Granit (Sweden), Haldan Hartline (USA), and George Wald (USA) | physiology and chemistry of vision |
| 1968 | Robert Holley (USA), Har Gobind Khorana (USA), and Marshall Nirenberg (USA) | interpretation of genetic code and its function in protein synthesis |
| 1969 | Max Delbrück (USA), Alfred Hershey (USA), and Salvador Luria (USA) | replication mechanism and genetic structure of viruses |
| 1970 | Bernard Katz (UK), Ulf von Euler (Sweden), and Julius Axelrod (USA) | work on the storage, release, and inactivation of neurotransmitters |
| 1971 | Earl Sutherland (USA) | discovery of cyclic AMP, a chemical messenger that plays a role in the action of many hormones |
| 1972 | Gerald Edelman (USA) and Rodney Porter (UK) | work on the chemical structure of antibodies |
| 1973 | Karl von Frisch (Austria), Konrad Lorenz (Austria), and Nikolaas Tinbergen (UK) | work in animal behaviour patterns |
| 1974 | Albert Claude (USA), Christian de Duve (Belgium), and George Palade (USA) | work in structural and functional organization of the cell |
| 1975 | David Baltimore (USA), Renato Dulbecco (USA), and Howard Temin (USA) (material of the cell) | work on interactions between tumour-inducing viruses and the genetic |
| 1976 | Baruch Blumberg (USA) and Carleton Gajdusek (USA) | new mechanisms for the origin and transmission of infectious diseases |
| 1977 | Roger Guillemin (USA) and Andrew Schally (USA) Rosalyn Yalow (USA) | discovery of hormones produced by the hypothalamus region of the brain radioimmunoassay techniques by which minute quantities of hormone may be detected |
| 1978 | Werner Arber (Switzerland), Daniel Nathans (USA), and Hamilton Smith (USA) | discovery of restriction enzymes and their application to molecular genetics |
| 1979 | Allan Cormack (USA) and Godfrey Hounsfield (UK) | development of the computed axial tomography (CAT) scan |
| 1980 | Bany Benacerraf (USA), Jean Dausset (France), and George Snell (USA) | work on genetically determined structures on the cell surface that regulate immunological reactions |
| 1981 | Roger Sperry (USA) David Hubel (USA) and Torsten Wiesel (Sweden) | functional specialization of the brain's cerebral hemispheres work on visual perception |
| 1982 | Sune Bergström (Sweden), Bengt Samuelsson (Sweden), and John Vane (UK) | discovery of prostaglandins and related biologically active substances |
| 1983 | Barbara McClintock (USA) | discovery of mobile genetic elements |
| 1984 | Niels Jelinek (Denmark-UK), Georges Kohler (West Germany), and César Milstein (Argentina) (cell, monoclonal antibodies) | work on immunity and discovery of a technique for producing highly specific |
| 1985 | Michael Brown (USA) and Joseph L. Goldstein (USA) | work on the regulation of cholesterol metabolism |
| 1986 | Stanley Cohen (USA) and Rita Levi-Montalcini (USA-Italy) Susumu Tonegawa (Japan) | discovery of factors that promote the growth of nerve and epidermal cells work on the process by which genes alter to produce a range of different antibodies |
| 1988 | James Black (UK), Gertrude Elion (USA), and George Hitchings (USA) | work on the principles governing the design of new drug treatment |
| 1989 | Michael Bishop (USA) and Harold Varmus (USA) | discovery of oncogenes, genes carried by viruses that can trigger cancerous growth in normal cells |
| 1990 | Joseph Murray (USA) and Donald Thomas (USA) | pioneering work in organ and cell transplants |
| 1991 | Erwin Neher (Germany) and Bert Sakmann (Germany) | discovery of how gate-like structures (ion channels) regulate the flow of ions into and out of cells |
| 1992 | Edmond Fisher (USA) and Edwin Krebs (USA) | isolating and describing the action of the enzyme responsible for reversible protein phosphorylation, a major biological control mechanism |
| 1993 | Phillip Sharp (USA) and Richard Roberts (UK) | discovery of split genes (Genes interrupted by nonsense segments of DNA) |
| 1994 | Alfred Gilman (USA) and Martin Rodbell (USA) | discovery of a family of proteins (G-proteins) that translate messages – in the form of hormones or other chemical signals – into action inside cells |
| 1995 | Edward Lewis (USA), Eric Wieschaus (USA), and Christiane Nüsslein-Volhard (Germany) (fruit fly) | discovery of genes which control the early stages of the body's development |
| 1996 | Peter Doherty (Australia) and Rolf Zinkernagel (Switzerland) | discovery of how the immune system recognizes virus-infected cells |
| 1997 | Stanley Prusiner (USA) | discoveries, including the 'prion' theory, that could lead to new treatments of dementia-related diseases, including Alzheimer's and Parkinson's diseases |
