Fonts used in computer setting are of two main types: bit-mapped and outline. **Bit-mapped fonts** are stored in the computer memory as the exact arrangement of pixels or printed dots required to produce the characters in a particular size on a screen or printer. **Outline fonts** are stored in the computer memory as a set of instructions for drawing the circles, straight lines, and curves that make up the outline of each character. They require a powerful computer because each character is separately generated from a set of instructions and this requires considerable computation. Bit-mapped fonts become very ragged in appearance if they are enlarged and so a separate set of bit maps is required for each font size. In contrast, outline fonts can be scaled to any size and maintain exactly the same appearance.

food anything eaten by human beings and other animals and plants to sustain life and health. The building blocks of food are nutrients, and humans can utilize the following nutrients: **carbohydrates**, as starches found in bread, potatoes, and pasta; as simple sugars in sucrose and honey; as fibres in cereals, fruit, and vegetables; **proteins** as from nuts, fish, meat, eggs, milk, and some vegetables; **fats** as found in most animal products (meat, lard, dairy products, fish), also in margarine, nuts and seeds, olives, and edible oils; **vitamins**, found in a wide variety of foods, except for vitamin B₁₂, which is found mainly in foods of animal origin; **minerals**, found in a wide variety of foods (for example, calcium from milk and broccoli, iodine from seafood, and iron from liver and green vegetables); **water** ubiquitous in nature; **alcohol**, found in fermented distilled beverages, from 40% in spirits to 0.01% in low-alcohol lagers and beers.

Food is needed both for energy, measured in calories or kilojoules, and nutrients, which are converted to body tissues. Some nutrients, such as fat, carbohydrate, and alcohol, provide mainly energy; other nutrients are important in other ways; for example, fibre is an aid to metabolism. Proteins provide energy and are necessary for building cell and tissue structure.

Food probably has a very great influence on the condition of men ... Who knows if a well-prepared soup was not responsible for the pneumatic pump or a poor one for a war?

The USA cut its FAO funding in 1990 from \$61.4 million to \$18 million because of its alleged politicization.

food chain in ecology, a sequence showing the feeding relationships between organisms in a particular ecosystem. Each organism depends on the next lowest member of the chain for its food.

Energy in the form of food is shown to be transferred from autotrophs, or producers, which are principally plants and photosynthetic microorganisms, to a series of heterotrophs, or consumers. The heterotrophs comprise the herbivores, which feed on the producers; carnivores, which feed on the herbivores; and decomposers, which break down the dead bodies and waste products of all four groups (including their own), ready for recycling.

In reality, however, organisms have varied diets, relying on different kinds of foods, so that the food chain is an oversimplification. The more complex food web shows a greater variety of relationships, but again emphasizes that energy passes from plants to herbivores to carnivores.

food chain The complex interrelationships between animals and plants in a food chain. Food chains are normally only three or four links long. This is because most of the energy at each link is lost in respiration, and so cannot be passed on to the next link.

Environmentalists have used the concept of the food chain to show how poisons and other forms of pollution can pass from one animal to another, threatening rare species. For example, the pesticide DDT has been found in lethal concentrations in the bodies of animals at the top of the food chain, such as the golden eagle *Aquila chrysaetos*.

food irradiation the exposure of food to low-level γ irradiation to kill microorganisms; a technique used in food technology. Irradiation is highly effective, and does not make the food any more radioactive than it is naturally. Irradiated food is used for astronauts and immunocompromised patients in hospitals. Some vitamins are partially destroyed, such as vitamin C, and it would be unwise to eat only irradiated fruit and vegetables.

The main cause for concern is that it may be used by unscrupulous traders to 'clean up' consignments of food, particularly shellfish, with high bacterial counts. Bacterial toxins would remain in the food, so that it could still cause illness, although irradiation would have removed signs of live bacteria. Stringent regulations would be needed to prevent this happening. Other damaging changes may take place in the food, such as the creation of free radicals, but research so far suggests that the process is relatively safe.

food poisoning any acute illness characterized by vomiting and diarrhoea and caused by eating food contaminated with harmful bacteria (for example, *Cholera*), poisonous food (for example, certain mushrooms, puffer fish), or poisoned food (such as lead or arsenic introduced accidentally during processing). A frequent cause of food poisoning is *Salmonella* bacteria. *Salmonella* comes in many forms, and strains are found in cattle, pigs, poultry, and eggs.

Deep freezing of poultry before the birds are properly cooked is a common cause of food poisoning. Attacks of salmonella also come from contaminated eggs that have been eaten raw or cooked only lightly. Pork may carry the roundworm *Trichinella*, and rye the parasitic fungus ergot. The most dangerous food poison is the bacillus that causes botulism. This is rare but leads to muscle paralysis and, often, death. Food irradiation is intended to prevent food poisoning.

food technology the application of science to the commercial processing of foodstuffs. Food is processed to make it more palatable or digestible, for which the traditional methods include boiling, frying, flour-milling, bread-, yoghurt-, and cheese-making, and brewing; or to prevent the growth of bacteria, moulds, yeasts, and other microorganisms; or to preserve it from spoilage caused by the action of enzymes within the food that change its chemical composition, resulting in changes in flavour, odour, colour, and texture. These changes are not always harmful or undesirable; examples of desirable changes are the ripening of cream in butter manufacture, flavour development of cheese, and the hanging of meat to tenderize the muscle fibres. Fatty or oily foods suffer oxidation of the fats, which makes them rancid.

Preservation enables foods that are seasonally produced to be available all the year. Traditional forms of food preservation include salting, smoking, pickling, drying, bottling, and preserving in sugar. Modern food technology also uses many novel processes and additives, which allow a wider range of foodstuffs to be preserved. All foods undergo some changes in quality and nutritional value when subjected to preservation processes. No preserved food is identical in quality to its fresh counterpart, hence only food of the highest quality should be preserved.

In order to grow, bacteria, yeasts, and moulds need moisture, oxygen, a suitable temperature, and food. The various methods of food preservation aim to destroy the microorganisms within the food, to remove one or more of the conditions essential for their growth, or to make the foods unsuitable for their growth. Adding large amounts of salt or sugar reduces the amount of water available to microorganisms, because the water tied up by these solutes cannot be used for microbial growth. This is the principle in salting meat and fish, and in the manufacture of jams and jellies. These conditions also inhibit the enzyme activity in food. Preservatives may also be developed in the food by the controlled growth of microorganisms to produce fermentation that may make

alcohol, or acetic or lactic acid. Examples of food preserved in this way are vinegar, sour milk, yoghurt, sauerkraut, and alcoholic beverages.

Refrigeration below 5°C/41°F (or below 3°C/37°F for cooked foods) slows the processes of spoilage, but is less effective for foods with a high water content. This process cannot kill microorganisms, nor stop their growth completely, and a failure to realize its limitations causes many cases of food poisoning. Refrigerator temperatures should be checked as the efficiency of the machinery (see refrigeration) can decline with age, and higher temperatures are dangerous.

Deep freezing (-18°C/-1°F or below) stops almost all spoilage processes, except residual enzyme activity in uncooked vegetables and most fruits, which are blanched (dipped in hot water to destroy the enzymes) before freezing. Preservation by freezing works by rendering the water in foodstuffs unavailable to microorganisms by converting it to ice. Microorganisms cannot grow or divide while frozen, but most remain alive and can resume activity once defrosted. Some foods are damaged by freezing, notably soft fruits and salad vegetables, the cells of which are punctured by ice crystals, leading to loss of crispness. Fatty foods such as cow's milk and cream tend to separate. Freezing has little effect on the nutritive value of foods, though a little vitamin C may be lost in the blanching process for fruit and vegetables. Various processes are used for deep freezing foods commercially.

Pasteurization is used mainly for milk. By holding the milk at 72°C/161.6°F for 15 seconds, all disease-causing bacteria can be destroyed. Less harmful bacteria survive, so the milk will still go sour within a few days.

Ultra-heat treatment is used to produce UHT milk. This process uses higher temperatures than pasteurization, and kills all bacteria present, giving the milk a long shelf life but altering the flavour.

Drying is effective because both microorganisms and enzymes need water to be active. This is one of the oldest, simplest, and most effective ways of preserving foods. In addition, drying concentrates the soluble ingredients in foods, and this high concentration prevents the growth of bacteria, yeasts, and moulds. Dried food will deteriorate rapidly if allowed to become moist, but provided they are suitably packaged, products will have a long shelf life. Traditionally, foods were dried in the sun and wind, but commercially today, products such as dried milk and instant coffee are made by spraying the liquid into a rising column of dry, heated air; solid foods, such as fruit, are spread in layers on a heated surface.

Freeze-drying is carried out under vacuum. It is less damaging to food than straight dehydration in the sense that foods reconstitute better, and is used for quality instant coffee and dried vegetables. The foods are fast frozen, then dried by converting the ice to vapour under very low pressure. The foods lose much of their weight, but retain the original size and shape. They have a spongy texture, and rapidly reabsorb liquid when reconstituted. Refrigeration is unnecessary during storage; the shelf life is similar to dried foods, provided the product is not allowed to become moist. The success of the method is dependent on a fast rate of freezing, and rapid conversion of the ice to vapour. Hence, the most acceptable results are obtained with thin pieces of food, and the method is not recommended for pieces thicker than 3 cm/1 in. Fruit, vegetables, meat, and fish have proved satisfactory. This method of preservation is commercially used but the products are most often used as constituents of composite dishes, such as packed meals.

Canning relies on high temperatures to destroy microorganisms and enzymes. The food is sealed in a can to prevent recontamination. The effect of heat processing on the nutritive value of food is variable. For instance, the vitamin-C content of green vegetables is much reduced, but, owing to greater acidity, in fruit juices vitamin C is quite well retained. There is also a loss of 25-50% of water-soluble vitamins if the liquor is not used. Vitamin B (thiamine) is easily destroyed by heat treatment, particularly in alkaline conditions. Acid products retain thiamine well, because they require only minimum heat during sterilization. The sterilization process seems to have little effect on retention of vitamins A and B₂. During storage of canned foods, the proportion of vitamins B and C decreases gradually. Drinks may be canned to preserve the carbon dioxide that makes them fizzy.

Pickling utilizes the effect of acetic (ethanoic) acid, found in vinegar, in stopping the growth of moulds. In sauerkraut, lactic acid, produced by bacteria, has the same effect. Similar types of nonharmful, acid-generating bacteria are used to make yoghurt and cheese.

Curing of meat involves soaking in salt (sodium chloride) solution, with saltpetre (sodium nitrate) added to give the meat its pink colour and characteristic taste. Bacteria convert the nitrates in cured meats to nitrites and nitrosamines, which are potentially carcinogenic to humans.

Irradiation is a method of preserving food by subjecting it to low-level radiation (see food irradiation).

Puffing is a method of processing cereal grains. They are subjected to high pressures, then suddenly ejected into a normal atmospheric pressure, causing the grain to expand sharply. This is used to make puffed wheat cereals and puffed rice cakes.

Chemical treatments are widely used, for example in margarine manufacture, in which hydrogen is bubbled through vegetable oils in the presence of a catalyst to produce a more solid, spreadable fat. The catalyst is later removed. Chemicals introduced in processing that remain in the food are known as **food additives** and include flavourings, preservatives, anti-oxidants, emulsifiers, and colourings.

food test any of several types of simple test, easily performed in the laboratory, used to identify the main classes of food.

starch-iodine test Food is ground up in distilled water and iodine is added. A dense black colour indicates that starch is present.

sugar-Benedict's test Food is ground up in distilled water and placed in a test tube with Benedict's reagent. The tube is then heated in a boiling water bath. If glucose is present the colour changes from blue to brick-red.

protein-Biuret test Food is ground up in distilled water and a mixture of copper(II) sulphate and sodium hydroxide is added. If protein is present a mauve colour is seen.

foot in geometry, point where a line meets a second line to which it is perpendicular.

foot imperial unit of length (symbol ft), equivalent to 0.3048 m, in use in Britain since Anglo-Saxon times. It originally represented the length of a human foot. One foot contains 12 inches and is one-third of a yard.

foot-and-mouth disease contagious eruptive viral disease of cloven-hoofed mammals, characterized by blisters in the mouth and around the hooves. In cattle it causes deterioration of milk yield and abortions. It is an airborne virus, which makes its eradication extremely difficult.

foot-candle unit of illuminance, now replaced by the lux. One foot-candle is the illumination received at a distance of one foot from an international candle. It is equal to 10.764 lux.

foot-pound imperial unit of energy (ft-lb), defined as the work done when a force of one pound moves through a distance of one foot. It has been superseded for scientific work by the joule: one foot-pound equals 1.356 joule.

footprint in computing, the area on the desk or floor required by a computer or other peripheral device.

footprint of a satellite, the area of the Earth over which its signals can be received.

footrot contagious disease of sheep caused by a bacterium and spreading easily in warm, wet conditions. It is characterized by inflammation and lameness and is controlled by vaccination, foot-bathing, and segregation.

forage crop plant that is grown to feed livestock; for example, grass, clover, and kale (a form of cabbage). Forage crops cover a greater area of the world than food crops, and grass, which dominates this group, is the world's most abundant crop, though much of it is still in an unimproved state.

foraminifera any marine protozoan of the order Foraminifera, with shells of calcium carbonate. Their shells have pores through

which filaments project. Some form part of the plankton, others live on the sea bottom.

The many-chambered *Globigerina* is part of the plankton. Its shells eventually form much of the chalky ooze of the ocean floor.

forbidden line in astronomy, emission line seen in the spectra of certain astronomical objects that are not seen under the conditions prevailing in laboratory experiments. They indicate that the hot gas emitting them is at extremely low density. Forbidden lines are seen, for example, in the tenuous gas of the Sun's corona, in HII regions, and in the nucleuses of certain active galaxies.

force any influence that tends to change the state of rest or the uniform motion in a straight line of a body. The action of an unbalanced or resultant force results in the acceleration of a body in the direction of action of the force, or it may, if the body is unable to move freely, result in its deformation (see Hooke's law). Force is a vector quantity, possessing both magnitude and direction; its SI unit is the newton.

According to Newton's second law of motion the magnitude of a resultant force is equal to the rate of change of momentum of the body on which it acts; the force F producing an acceleration a m s⁻² on a body of mass m kilograms is therefore given by: $F = ma$ See also Newton's laws of motion.

force feedback in virtual reality, realistic simulation of the physical sense of touch. This is an area of active research, as many applications of virtual reality are useless or impossible without it.

For example, force feedback is essential in medical training systems to teach the students how hard to press with a scalpel in delicate areas of the human body. Even simulated games need force feedback in order to allow objects to respond realistically to falling or being hit.

force multiplier machine designed to multiply a small effort in order to move a larger load. The number of times a machine multiplies the effort is called its mechanical advantage. Examples of a force multiplier include crowbar, wheelbarrow, nutcrackers, and bottle opener.

force ratio the magnification of a force by a machine; see mechanical advantage.

forces, fundamental in physics, the four fundamental interactions believed to be at work in the physical universe. There are two long-range forces: gravity, which keeps the planets in orbit around the Sun, and acts between all particles that have mass; and the electromagnetic force, which stops solids from falling apart, and acts between all particles with electric charge. There are two very short-range forces which operate only inside the atomic nucleus: the weak nuclear force, responsible for the reactions that fuel the Sun and for the emission of beta particles from certain nuclei; and the strong nuclear force, which binds together the protons and neutrons in the nuclei of atoms. The relative strengths of the four forces are: strong, 1; electromagnetic, 10⁻²; weak, 10⁻⁶; gravitational, 10⁻⁴⁰. By 1971, US physicists Steven Weinberg and Sheldon Glashow, Pakistani physicist Abdus Salam, and others had developed a theory that suggested that the weak and electromagnetic forces were aspects of a single force called the electroweak force; experimental support came from observation at CERN in the 1980s. Physicists are now working on theories to unify all four forces.

People can have the Model T in any colour - so long as it's black.

HENRY FORD US automobile manufacturer.
A Nevins Ford

Fordism mass production characterized by a high degree of job specialization, as typified by the Ford Motor Company's early use of assembly lines. Mass-production techniques were influenced by US management consultant F W Taylor's book *Principles of Scientific Management* 1911.

Post-Fordism management theory and practice emphasize flexibility and autonomy of decisionmaking for nonmanagerial staff. It is concerned more with facilitating and coordinating tasks than with control.

forensic entomology branch of forensic science, involving the study of insects on and around the corpse. Insects rapidly infest a corpse, and do so in an accepted sequence beginning with flies laying eggs. Further insects follow to feed on the decomposing flesh and fly maggots. Forensic entomologists are able to determine time of death by analysing insect colonization. They can also tell whether or not a corpse has been moved by examining the faunal community in the 'seepage area' beneath the body.

FORENSIC ENTOMOLOGY

Cocaine speeds up the growth of certain insects. This enables forensic entomologists to determine if a corpse is that of a cocaine user.

forensic medicine in medicine, branch of medicine concerned with the resolution of crimes. Examples of forensic medicine include the determination of the cause of death in suspicious circumstances or the identification of a criminal by examining tissue found at the scene of a crime. Forensic psychology involves the establishment of a psychological profile of a criminal that can assist in identification.

forensic science the use of scientific techniques to solve criminal cases. A multidisciplinary field embracing chemistry, physics, botany, zoology, and medicine, forensic science includes the identification of human bodies or traces. Ballistics (the study of projectiles, such as bullets), another traditional forensic field, makes use of such tools as the comparison microscope and the electron microscope.

Traditional methods such as fingerprinting are still used, assisted by computers; in addition, blood analysis, forensic dentistry,

voice and speech spectrograms, and genetic fingerprinting are increasingly applied. Chemicals, such as poisons and drugs, are analysed by chromatography. ESDA (electrostatic document analysis) is a technique used for revealing indentations on paper, which helps determine if documents have been tampered with. Forensic entomology is also a branch of forensic science.

forest area where trees have grown naturally for centuries, instead of being logged at maturity (about 150–200 years). A natural, or old-growth, forest has a multistorey canopy and includes young and very old trees (this gives the canopy its range of heights). There are also fallen trees contributing to the very complex ecosystem, which may support more than 150 species of mammals and many thousands of species of insects.

The Pacific forest of the west coast of North America is one of the few remaining old-growth forests in the temperate zone.

It consists mainly of conifers and is threatened by logging – less than 10% of the original forest remains.

forest fly external blood-sucking parasite, chiefly of horses. It is about 8 mm/0.3 in long and bears brown and yellow flecks.

classification The forest fly *Hippobosca equina* is a member of the insect family Hippoboscidae in order Diptera, class Insecta, phylum Arthropoda.

forestry the science of forest management. Recommended forestry practice aims at multipurpose crops, allowing the preservation of varied plant and animal species as well as human uses (lumbering, recreation). Forestry has often been confined to the planting of a single species, such as a rapid-growing conifer providing softwood for paper pulp and construction timber, for which world demand is greatest. In tropical countries, logging contributes to the destruction of rainforests, causing global environmental problems. Small unplanned forests are woodland.

The earliest planned forest dates from 1368 at Nürnberg, Germany; in Britain, planning of forests began in the 16th century. In the UK, Japan, and other countries, forestry practices have been criticized for concentration on softwood conifers to the neglect of native hardwoods.

Forensic Science: Recent Advances

BY JOHN BROAD

The scientific support for Inspector Morse

The forensic scientist has to provide evidence that will stand scrutiny in a court of law. This is why crime laboratories need to keep up with the latest research and maintain the highest standards.

Every contact leaves a trace. The ordinary microscope is still a vital instrument for examining trace evidence – hairs, fibres, fragments of glass or paint – but the scanning electron microscope is also used. It provides high magnification with good resolution, and can also incorporate a microprobe that identifies the actual elements, particularly metallic ones, in the surface being examined.

Surface elements absorb electrons and emit X-rays, which the microprobe converts into an X-ray emission spectrum with a characteristic pattern that reveals the elements present. In this way, it is possible to detect and identify particles invisible to the optical microscope, such as those scattered from a firearm when discharged. These particles can indicate the type and make of ammunition used.

Anti-crime antibodies

Advances have also been made in analytical techniques called immunoassays, which use antibodies to detect and measure drugs, poisons, proteins, and even explosives such as TNT and Semtex. When a foreign chemical, such as a disease organism,

enters the human body, antibodies are produced that recognize and react with the foreign substance.

The same process occurs in animals, which can be used to produce antibodies against a wide variety of chemicals. An animal is injected with a target substance, such as cocaine, and the resulting antibodies can be separated and used to recognize the substance against a background of body fluids, or in a body swab.

When trying to detect a target compound, such as the presence of explosive residue on a person's hands, it is vital to take account of possible contamination, since the substance might have been picked up casually. Also, it is important that the method used detects the target compound and no other. The value of antibodies is that they are specific to the compound that triggered their production. With other analytical methods, such as thin-layer chromatography, care has to be taken to eliminate other compounds that could show the same experimental result.

DNA fingerprinting

One impressive recent scientific advance is DNA fingerprinting, or DNA profiling. This has been used effectively in assault, rape, and murder cases and in paternity disputes. It figured prominently in the O J Simpson trial. For forensic purposes two DNA fingerprints are necessary – one from the suspect and another taken from the crime scene. There must be a convincing match to establish a link.

DNA profiling involves using special enzymes to cut up precisely

a sample of DNA extracted from body cells. Only a very small amount of DNA – from just a few cells – is needed; the polymerase chain reaction (PCR) can amplify it into sufficient material to profile. The resulting 'bits' are separated by gel electrophoresis and can be blotted onto a special membrane, marked radioactively with specialized probes and then visualized as the familiar sequence of bars (known as an autoradiograph). Alternatively, the DNA bands can be labelled or highlighted in the actual gel then scanned with a laser. The result is a graphical print out showing peaks where the bands occur. These peaks can be converted into digital codes for storage on a computer. This is the method employed in building up national DNA databases, which store, for rapid recall, the DNA profiles of known offenders, suspects, and tissue samples taken from crime scenes. Rapid comparison can establish that a suspect could be linked with a number of scenes.

Controversies

Should blood for DNA profiling purposes be taken not only from suspects but from suspicious persons, unwanted persons, even undesirable persons? If a person refuses to submit to supplying a sample for DNA analysis (as is their entitlement) what inference should be drawn from this refusal? Should everyone be DNA profiled shortly after birth so that the ordinary citizen can more easily be monitored? Despite refinements and increased effectiveness, DNA profiling must be treated with caution. If two profiles convincingly match, they may not come from the same person. The chances of this are very small – but not as small as once thought. Identical twins have the same DNA profile, but DNA profiles of people from small communities with significant inbreeding can be deceptively similar. If two bands on adjacent profiles correspond, but not exactly, statistical analysis may be needed to decide if there is a match. In the end, despite the statistical back-up, the matching of two DNA profiles is a matter of expert opinion.

Electrostatic document analysis

Electrostatic document analysis (ESDA) is a recent technique used for revealing indentations on paper. Left on an underlying sheet, these indicate what has been written on the paper above.

The method uses a high electrostatic voltage to transfer the indentations onto imaging film where they are visualized by photographic toner. If the resulting impressions are markedly uneven – perhaps one half is more heavily indented than the other – then the writing under examination (on the top sheet) may have been written at two different times, showing that the document has been tampered with. The release of the 'Guildford Four' and the 'Birmingham Six' in the UK was clinched when the ESDA machine revealed 'doctored' written evidence at the original trial.

Computers on the beat

The increasing power of computers has been responsible for great advances in forensic science, as in other sciences. Computers have revolutionized the storage and retrieval of information. For example, all car registration numbers and owners' names are stored on computer for almost instant access. Information can be rapidly communicated to police officers in the field. This has increased the power of those who hold the information and, in addition to speeding the response to crime, has helped in the monitoring of 'undesirables' and in maintaining order on the streets.

Identification of a suspect fingerprint, by comparison with thousands stored on file, was once a time-consuming process. Nowadays, with a computer, the process takes minutes, even seconds. Even so, the final decision on fingerprint identification is still made visually by a trained expert. No matter how sophisticated the hardware, the human senses are still vital in forensic work.

The carnage on the roads

A vast amount of police time is consumed by road traffic problems. It would be correct to say that two scientific instruments – the Breathalyzer and the Radar Speed Device (or gun) have had more impact on the general public than all other forensic scientific

hardware put together. Scientific evidence presented in a court of law must be accurate, reliable, and based on thorough research in order to convince a Magistrate or jury. Confirmatory or back-up tests must be available when necessary. Scientific efforts designed to reduce the number of deaths and injuries caused by the drunk driver have resulted in the development of a roadside breath screening device; an evidential breath alcohol testing instrument; and a confirmatory blood test. The Breathalyzer relies on a fuel cell to estimate the level of alcohol in a driver's breath. The intoximeter, used in the police station, is based on the absorption of infra red light (at 3.4 microns) by alcohol molecules and accurately establishes the breath alcohol level. The confirmatory blood test employs headspace gas chromatography to find the blood alcohol concentration or BAC. All these procedures use a different scientific principle for their method of operation.

The radar speed device has aimed to bring about some reduction in the devastation caused by speeding, particularly on modern motorways and highways. Its operation depends upon the Doppler effect and its output – often a photograph and accompanying data when it is linked to a camera – is valid as evidence in a court of law. All radar speed devices are checked rigorously in order to maintain the required accuracy and reliability. More efficient, but much more expensive, is the laser speed device that relies on the reflection of impulses of light from a moving source to calculate speed. Both these devices are easy to operate and to carry around.

If public pressure results in the legislation of some, or maybe all, recreational drugs then scientists will be obliged to design roadside screening tests for particular, or all, drugs with back-up evidential and confirmatory procedures. Apparently it is much more dangerous to drive a vehicle when 'stoned' with drugs than when drunk. Work has already begun on these problems. Trials are due to start in the UK on the use of absorbent pads impregnated with special chemicals. When pressed against the skin, sweat diffuses into the pad and a colour reaction denotes the presence of a particular drug. This is a noninvasive technique, but for evidential testing, blood or urine would be required and subjected to an immune assay and perhaps chromatography or even mass spectrometry. In the USA, efforts have so far centred on urine testing and the opinion has been expressed that eventually each police car will be followed closely by a 'urine bus' or 'slush van'.

Surveillance techniques

The recent developments and use of sophisticated surveillance techniques seen in car parks, town centres, business premises and around the residences of the rich and powerful, bear testimony to the trend. Most notable is CCTV (closed circuit television). Whether this actually reduces crime or merely drives the criminals elsewhere is open to debate. However the concern raised about such techniques, which extend to telephone tapping, is about the invasion of privacy. This could represent one or many steps down the slippery slope of monitoring the innocent and the guilty going about their daily business. Apart from the implications of 'Big Brother', there is the perennial vexed question of who monitors those who do the monitoring?

A dream or a nightmare?

The aim of the forensic scientist is to link a suspect with a crime scene, victim or incident, using the very latest in scientific technology. If there is no suspect then data can be collected and stored only as far as time and money allow. Nothing further can be done until the breakthrough occurs as a result of a stroke of luck or a tip-off. In the end, all that is required for a watertight case might be available – a suspect whose name and address is known and an impressive array of evidence and statements. But if the suspect has gone to ground and all enquiries are met with a wall of silence, no amount of scientific evidence will find someone determined to 'melt away'. Maybe it would be wise to tag everybody electronically at birth and monitor their every move on a central computer. This would solve the problem of the vanishing suspect and the missing person, but is it a dream or a ghastly nightmare?

identity is shaped by his/her words as sent out via e-mail or public conferencing systems such as USENET, sending out a forged message in another person's name can seriously damage them. Forged messages are, however, used by the ©CancelMoose to manage ©spamming and keep it from spreading.

forging one of the main methods of shaping metals, which involves hammering or a more gradual application of pressure. A blacksmith hammers red-hot metal into shape on an anvil, and the traditional place of work is called a forge. The blacksmith's mechanical equivalent is the drop forge. The metal is shaped by the blows from a falling hammer or ram, which is usually accelerated by steam or air pressure. Hydraulic presses forge by applying pressure gradually in a squeezing action.

forms on the World Wide Web, facility for accepting structured user input and inserting it into a program such as a database. Most newer graphical Web browsers can handle forms, as can the older, text-based browser Lynx. Forms are needed to manage database queries at sites such as © AltaVista, and to fill out registration forms for those sites that require them.

Web page designers implement forms by using a special set of hypertext markup language (HTML) tags and attaching a script, which parses the data and feeds it to the program specified in a form the program can use. The results, such as a user name and password or a list of matches, are sent back to the user.

formula in chemistry, a representation of a molecule, radical, or ion, in which the component chemical elements are represented by their symbols. An empirical formula indicates the simplest ratio of the elements in a compound, without indicating how many of them there are or how they are combined. A molecular formula gives the number of each type of element present in one molecule. A structural formula shows the relative positions of the atoms and the bonds between them. For example, for ethanoic acid, the empirical formula is $\text{CH}_3\text{CO}_2\text{H}$, the molecular formula is $\text{C}_2\text{H}_4\text{O}_2$, and the structural formula is CH_3COOH .

formula in mathematics, a set of symbols and numbers that expresses a fact or rule. $A = \pi r^2$ is the formula for calculating the area of a circle. Einstein's famous formula relating energy and mass is $E = mc^2$.

forsythia any of a group of temperate eastern Asian shrubs, which bear yellow bell-shaped flowers in early spring before the leaves appear. (Genus *Forsythia*, family Oleaceae.)

FORTRAN (or *fortran*, acronym for *formula translation*) high-level computer-programming language suited to mathematical and scientific computations. Developed by John Backus at IBM in 1956, it is one of the earliest computer languages still in use. A recent version, Fortran 90, is now being used on advanced parallel computers. ©BASIC was strongly influenced by FORTRAN and is similar in many ways.

accumulation of sediment over millions of years at the bottom of the sea bed or an inland lake. Fossils may include footprints, an internal cast, or external impression. A few fossils are preserved intact, as with ©mammoths fossilized in Siberian ice, or insects trapped in tree resin that is today amber. The study of fossils is called ©palaeontology. Palaeontologists are able to deduce much of the geological history of a region from fossil remains.

About 250,000 fossil species have been discovered – a figure that is believed to represent less than 1 in 20,000 of the species that ever lived. Microfossils are so small they can only be seen with a microscope. They include the fossils of pollen, bone fragments, bacteria, and the remains of microscopic marine animals and plants, such as foraminifera and diatoms.

If A is a success in life, then A equals x plus y plus z. Work is x; y is play, and z is keeping your mouth shut.

fossil fuel fuel, such as coal, oil, and natural gas, formed from the fossilized remains of plants that lived hundreds of millions of years ago. Fossil fuels are a ©nonrenewable resource and will eventually run out. Extraction of coal and oil causes considerable environmental pollution, and burning coal contributes to problems of ©acid rain and the ©greenhouse effect.

four-colour process colour ©printing using four printing plates, based on the principle that any colour is made up of differing proportions of the primary colours blue, red, and green. The first stage in preparing a colour picture for printing is to produce separate films, one each for the blue, red, and green respectively in the picture (colour separations). From these separations three printing plates are made, with a fourth plate for black (for shading or outlines and type). Ink colours complementary to those represented on the plates are used for printing – yellow for the blue plate, cyan for the red, and magenta for the green.

Fourier, Jean Baptiste Joseph (1768–1830)

French applied mathematician whose formulation of heat flow in 1807 contains the proposal that, with certain constraints, any mathematical function can be represented by trigonometrical series. This principle forms the basis of Fourier analysis, used today in many different fields of physics. His idea, not immediately well received, gained currency and is embodied in his *Théorie analytique de la chaleur* / *The Analytical Theory of Heat* 1822.

Light, sound, and other wavelike forms of energy can be studied using Fourier's method, a developed version of which is now called harmonic analysis.

first through a series of steam-heated rollers, which dry it, and then between heavy calendar rollers, which give it a smooth finish.

Such machines can measure up to 90 m/300 ft in length, and are still in use.

four-stroke cycle the engine-operating cycle of most petrol and diesel engines. The 'stroke' is an upward or downward movement of a piston in a cylinder. In a petrol engine the cycle begins with the induction of a fuel mixture as the piston goes down on its first stroke. On the second stroke (up) the piston compresses the mixture in the top of the cylinder. An electric spark then ignites the mixture, and the gases produced force the piston down on its third, power, stroke. On the fourth stroke (up) the piston expels the burned gases from the cylinder into the exhaust.

fourth-generation language in computing, a type of programming language designed for the rapid programming of applications but often lacking the ability to control the individual parts of the computer. Such a language typically provides easy ways of designing screens and reports, and of using databases. Other 'generations' (the term implies a class of language rather than a chronological sequence) are machine code (first generation); assembly languages, or low-level languages (second); and conventional high-level languages such as BASIC and PASCAL (third).

fowl chicken or chickenlike bird. Sometimes the term is also used for ducks and geese. The red jungle fowl *Gallus gallus* is the ancestor of all domestic chickens. It is a forest bird of Asia, without the size or egg-laying ability of many domestic strains. Guinea fowl are of African origin.

FOX

The average British fox obtains only about a third of its food from hunting. The remainder is acquired by scavenging.

fox one of the smaller species of wild dog of the family Canidae, which live in Africa, Asia, Europe, North America, and South America. Foxes feed on a wide range of animals from worms to rabbits, scavenge for food, and also eat berries. They are very adaptable, maintaining high populations close to urban areas.

Most foxes are nocturnal, and make an underground den, or 'earth'. The common or red fox *Vulpes vulpes* is about 60 cm/2 ft long plus a tail (brush) 40 cm/1.3 ft long. The fur is reddish with black patches behind the ears and a light tip to the tail. Other foxes include the Arctic fox *Alopex lagopus*, the fennec, the grey foxes genus *Urocyon* of North and Central America, and the South American species *Dusicyon*, to which the extinct Falkland Islands dog belonged.

foxtail any of a group of flowering plants found in Europe and the Mediterranean region. They have showy spikes of bell-like flowers, and grow up to 1.5 m/5 ft high. (Genus *Digitalis*, family Scrophulariaceae.)

The wild species (*D. purpurea*), native to Britain, produces purple to reddish flowers. Its leaves were the original source of digitalis, a drug used for some heart problems.

foxhound small, keen-nosed hound, up to 60 cm/2 ft tall and black, tan, and white in colour. There are two recognized breeds: the English foxhound, bred for some 300 years to hunt foxes, and the American foxhound, not quite as stocky, used for foxes and other game.

fox terrier breed of terrier evolved for use in foxhunts to attack foxes in their earths (dens) where the larger foxhound was unable to reach them. Two types are distinguished – the smooth- and wire-haired; but both have a mainly white coat with large brown and/or black markings. They weigh about 8 kg/17.5 lb, stand up to 39 cm/15 in tall, and carry their short, usually docked, tails upright.

f.p.s. system system of units based on the foot, pound, and second as units of length, mass, and time, respectively. It has now been replaced for scientific work by the SI system.

fractal from Latin *fractus* 'broken' irregular shape or surface produced by a procedure of repeated subdivision. Generated on a computer screen, fractals are used in creating models of geographical or biological processes (for example, the creation of a coastline by erosion or accretion, or the growth of plants).

Sets of curves with such discordant properties were developed in the 19th century in Germany by Georg Cantor and Karl Weierstrass. The name was coined by the French mathematician Benoit Mandelbrot. Fractals are also used for computer art.

TO REMEMBER THE RULE OF DIVISION OF FRACTIONS:

THE NUMBER YOU ARE DIVIDING BY

fraction in chemistry, a group of similar compounds, the boiling points of which fall within a particular range and which are separated during fractional distillation (fractionation).

fraction from Latin *fractus* 'broken' in mathematics, a number that indicates one or more equal parts of a whole. Usually, the number of equal parts into which the unit is divided (denominator) is written below a horizontal line, and the number of parts comprising the fraction (numerator) is written above; thus $\frac{3}{4}$ or $\frac{1}{2}$. Such fractions are called vulgar or simple fractions. The denominator can never be zero.

A proper fraction is one in which the numerator is less than the denominator. An improper fraction has a numerator that is larger than the denominator, for example $\frac{5}{4}$. It can therefore be expressed as a mixed number, for example, $1\frac{1}{4}$. A combination such as $\frac{5}{0}$ is not regarded as a fraction (an object cannot be divided into zero equal parts), and mathematically any number divided by 0 is equal to infinity. A decimal fraction has as its denominator a power of 10, and these are omitted by use of the decimal point and notation, for example 0.04, which is $\frac{4}{100}$. The digits to the right of the decimal point indicate the numerators of vulgar fractions whose denominators are 10, 100, 1,000, and so on. Most fractions can be expressed exactly as decimal fractions ($\frac{1}{2} = 0.5333...$). Fractions are also known as the rational numbers; that is, numbers formed by a ratio. Integers may be expressed as fractions with a denominator of 1.

fractionating column device in which many separate distillations can occur so that a liquid mixture can be separated into its components.

Various designs exist but the primary aim is to allow maximum contact between the hot rising vapours and the cooling descending liquid. As the mixture of vapours ascends the column it becomes progressively enriched in the lower-boiling-point components, so these separate out first.

fractionating column Laboratory apparatus for fractional distillation. Fractional distillation is the main means of separating the components of crude oil.

This tomb holds Diophantus. Ah, how great a marvel! the tomb tells scientifically the measure of his life. God granted him to be a boy for the sixth part of his life, and adding a twelfth part to this, He clothed his cheeks with down; He lit him the light of wedlock after a seventh part, and five years after his marriage He granted him a son. Alas! late-born wretched child; after attaining the measure of half his father's life, chill Fate took him. After consoling his grief by this science of numbers for four years he ended his life.

fractionation or **fractional distillation** process used to split complex mixtures (such as crude oil) into their components, usually by repeated heating, boiling, and condensation; see *distillation*.

fragmentation in computing, the breaking up of files into many smaller sections stored on different parts of a disc. The computer operating system stores files in this way so that maximum use can be made of disc space. Each section contains a pointer to where the next section is stored. The file allocation table keeps a record of this.

Fragmentation slows down access to files. It is possible to defragment a disc by copying files. In addition, defragmentation programs, or disc optimizers, allow discs to be defragmented without the need for files to be copied to a second storage device.

frame a single photograph in a sequence representing motion, or movement, on film; in a network, a unit of data; in word processing or desktop publishing, a marked-out area on a page that can contain text or graphics.

What appears to be motion on a cinema or TV screen is actually a rapid sequence of single shots. Because of limitations in the human eye – known as the Phi phenomenon – those individual shots, if played in sequence at a rate of 24 to 30 frames per second, make the motion thus captured appear continuous.

frame buffer in computing, a buffer used to store a screen image.

frame relay in wide-area networks, a standard for the transmission of data that is optimized for high speeds up to about 1.5 Mbits/second.

francium radioactive metallic element, symbol Fr, atomic number 87, relative atomic mass 223. It is one of the alkali metals and occurs in nature in small amounts as a decay product of actinium. Its longest-lived isotope has a half-life of only 21 minutes. Francium was discovered and named in 1939 by Marguerite Perey to honour her country.

frangipani any of a group of tropical American trees, especially the species *P. rubra*, belonging to the dogbane family. Perfume is made from the strongly scented waxy flowers. (Genus *Plumeria*, family Apocynaceae.)

frankincense resin of various African and Asian trees, burned as incense. Costly in ancient times, it is traditionally believed to be one of the three gifts brought by the Magi to the infant Jesus. (Genus *Boswellia*, family Burseraceae.)

Frasch process process used to extract underground deposits of sulphur. Superheated steam is piped into the sulphur deposit and melts it. Compressed air is then pumped down to force the molten sulphur to the surface. The process was developed in the USA in 1891 by German-born Herman Frasch (1851–1914).

free fall the state in which a body is falling freely under the influence of gravity, as in freefall parachuting (skydiving). In a vacuum, a freely falling body accelerates at a rate of 9.806 m sec⁻² (32.174 ft sec⁻²); the value varies slightly at different latitudes and altitudes. A body falling through air, accelerates until it reaches a maximum speed called the *terminal velocity*; thereafter, there is no further acceleration.

In orbit, astronauts and spacecraft are still held by gravity and are in fact falling freely toward the Earth. Because of their speed (orbital velocity), the amount they fall towards the Earth just equals the amount the Earth's surface curves away; in effect they remain at the same height, apparently weightless.

Free-Net free community-based online system such as a network of public bulletin boards and/or municipally owned systems. Free-Net is a registered service mark of the National Public Telecomputing Network. The first Free-Net was set up in 1986 in Cleveland, Ohio, USA.

free radical in chemistry, an atom or molecule that has an unpaired electron and is therefore highly reactive. Most free radicals are very short-lived. They are by-products of normal cell chemistry and rapidly oxidize other molecules they encounter. Free radicals are thought to do considerable damage. They are neutralized by protective enzymes.

Free radicals are often produced by high temperatures and are found in flames and explosions.

freesia any of a South African group of plants belonging to the iris family, commercially grown for their scented, funnel-shaped flowers. (Genus *Freesia*, family Iridaceae.)

Free Software Foundation (FSF) US organization, based in Boston, which creates and distributes good-quality free software and utilities. FSF is the publisher of the GNU software, which includes compilers, operating systems, utilities, editors, databases, and PostScript viewers. All the software is free of licensing fees and restrictions.

The FSF was founded in 1983 by US artificial intelligence specialist Richard Stallman as a way of bringing back the cooperative spirit of the computing community's early days that had vanished by the early 1980s with the advent of widely sold proprietary software. The project's ultimate goal is to make commercial software obsolete by providing free software to do everything computer users want to do.

freeware in computing, free software which may or may not be in the public domain (see *public-domain software*). One of the best-known examples of freeware is the encryption program *Pretty Good Privacy* (PGP).

freeze-drying method of preserving food; see *food technology*. The product to be dried is frozen and then put in a vacuum chamber that forces out the ice as water vapour, a process known as sublimation.

Many of the substances that give products such as coffee their typical flavour are volatile, and would be lost in a normal drying process because they would evaporate along with the water. In the freeze-drying process these volatile compounds do not pass into the ice that is to be sublimed, and are therefore largely retained.

freeze-thaw form of physical weathering, common in mountains and glacial environments, caused by the expansion of water as it freezes. Water in a crack freezes and expands in volume by 9% as it turns to ice. This expansion exerts great pressure on the rock causing the crack to enlarge. After many cycles of freeze-thaw, rock fragments may break off to form scree slopes.

For freeze-thaw to operate effectively the temperature must fluctuate regularly above and below 0°C/32°F. It is therefore uncommon in areas of extreme and perpetual cold, such as the polar regions.

freezing change from liquid to solid state, as when water becomes ice. For a given substance, freezing occurs at a definite temperature, known as the **freezing point**, that is invariable under similar conditions of pressure, and the temperature remains at this point until all the liquid is frozen. The amount of heat per unit mass that has to be removed to freeze a substance is a constant for any given substance, and is known as the latent heat of fusion.

freezing point for any given liquid, the temperature at which any further removal of heat will convert the liquid into the solid state. The temperature remains at this point until all the liquid has solidified. It is invariable under similar conditions of pressure – for example, the freezing point of water under standard atmospheric pressure is 0°C/32°F.

freezing point, depression of lowering of a solution's freezing point below that of the pure solvent; it depends on the number of molecules of solute dissolved in it. For a single solvent, such as pure water, all solute substances in the same molar concentration produce the same lowering of freezing point. The depression d produced by the presence of a solute of molar concentration C is given by the equation $d = KC$, where K is a constant (called the cryoscopic constant) for the solvent concerned.

Antifreeze mixtures for car radiators and the use of salt to melt ice on roads are common applications of this principle. Animals in arctic conditions, for example insects or fish, cope with the extreme cold either by manufacturing natural 'antifreeze' and staying active, or by allowing themselves to freeze in a controlled fashion, that is, they manufacture proteins to act as nuclei for the formation of ice crystals in areas that will not produce cellular damage, and so enable themselves to thaw back to life again.

Measurement of freezing-point depression is a useful method of determining the molecular weights of solutes. It is also used to detect the illicit addition of water to milk.

frequency in physics, the number of periodic oscillations, vibrations, or waves occurring per unit of time. The SI unit of frequency is the hertz (Hz), one hertz being equivalent to one cycle per second.

Human beings can hear sounds from objects vibrating in the range 20–15,000 Hz. Ultrasonic frequencies well above 15,000 Hz can be detected by such mammals as bats. Infrasonic (low frequency sound) can be detected by some animals and birds. Pigeons

frequency modulation In FM radio transmission, the frequency of the carrier wave is modulated, rather than its amplitude (as in AM broadcasts). The FM system is not affected by the many types of interference which change the amplitude of the carrier wave, and so provides better quality reception than AM broadcasts.

Freud, Sigmund (1856–1939)

Austrian physician who pioneered the study of the unconscious mind. He developed the methods of free association and interpretation of dreams that are basic techniques of psychoanalysis. The influence of unconscious forces on people's thoughts and actions was Freud's discovery, as was his controversial theory of the repression of infantile sexuality as the root of neuroses in the adult. His books include *Die Traumdeutung/The Interpretation of Dreams* 1900, *Jenseits des Lustprinzips/Beyond the Pleasure Principle* 1920, *Das Ich und das Es/The Ego and the Id* 1923, and *Das Unbehagen in der Kultur/Civilization and its Discontents* 1930. His influence has permeated the world to such an extent that it may be discerned today in almost every branch of thought.

From 1886 to 1938 Freud had a private practice in Vienna, and his theories and writings drew largely on case studies of his own patients, who were mainly upper-middle-class, middle-aged women. Much of the terminology of psychoanalysis was coined by Freud, and many terms have passed into popular usage, not without distortion. His theories have changed the way people think about human nature and brought about a more open

approach to sexual matters. Antisocial behaviour is now understood to result in many cases from unconscious forces, and these new concepts have led to wider expression of the human condition in art and literature. Nevertheless, Freud's theories have caused disagreement among psychologists and psychiatrists, and his methods of psychoanalysis cannot be applied in every case.

can detect sounds as low as 0.1 Hz; elephants communicate using sounds as low as 1 Hz.

frequency in statistics, the number of times an event occurs. For example, when two dice are thrown repeatedly and the two scores added together, each of the numbers 2 to 12 may have a frequency of occurrence. The set of data including the frequencies is called a **frequency distribution**, usually presented in a frequency table or shown diagrammatically, by a frequency polygon.

frequency modulation (FM) method by which radio waves are altered for the transmission of broadcasting signals. FM varies the frequency of the carrier wave in accordance with the signal being transmitted. Its advantage over AM (amplitude modulation) is its better signal-to-noise ratio. It was invented by the US engineer Edwin Armstrong.

frequently asked questions in computing, expansion of the abbreviation FAQ.

The ideas of Freud were popularized by people who only imperfectly understood them, who were incapable of the great effort required to grasp them in their relationship to larger truths, and who therefore assigned to them a prominence out of all proportion to their true importance.

friction in physics, the force that opposes the relative motion of two bodies in contact. The coefficient of friction is the ratio of the force required to achieve this relative motion to the force pressing the two bodies together.

Friction is greatly reduced by the use of lubricants such as oil, grease, and graphite. Air bearings are now used to minimize friction in high-speed rotational machinery. In other instances friction is deliberately increased by making the surfaces rough – for example, brake linings, driving belts, soles of shoes, and tyres.

frilled lizard yellowish-brown Australian lizard with a large frill of skin to the sides of the neck and throat. The lizard is about 90 cm/35 in long.

When the lizard is angry or alarmed it erects its frill, which may be as much as 25cm/10 in in diameter, thus giving itself the appearance of being larger than it really is. Frilled lizards are generally tree-living but may spend some time on the ground, where they run with their forelimbs in the air.

classification The frilled lizard *Chlamydosaurus kingi* belongs to the family Agamidae, suborder Sauria, order Squamata, class Reptilia.

Frisch-Perle's memorandum document revealing, for the first time, how small the critical mass (the minimum quantity of substance required for a nuclear chain reaction to begin) of uranium needed to be if the isotope uranium-235 was separated from naturally occurring uranium; the memo thus implied the feasibility of using this isotope to make an atom bomb. It was written by Otto Frisch and Rudolf Peierls at the University of Birmingham in 1940.

fritillary in botany, any of a group of plants belonging to the lily family. The snake's head fritillary (*F. meleagris*) has bell-shaped flowers with purple-chequered markings. (Genus *Fritillaria*, family Liliaceae.)

fritillary in zoology, any of a large grouping of butterflies of the family Nymphalidae. Mostly medium-sized, fritillaries are usually orange and reddish with a black criss-cross pattern or spots above and with silvery spots on the underside of the hindwings.

They take their name from the Latin word *fritillus* ('dice box') because of their spotted markings.

frog any amphibian of the order Anura (Greek 'tailless'). There are about 24 different families of frog, containing more than 3,800

FROG

Certain frogs do not spend time as tadpoles. The female of a species of tiny Brazilian frog lays a single egg which hatches as a single froglet, rather than going through a tadpole phase first.

species. There are no clear rules for distinguishing between frogs and toads.

Frogs usually have squat bodies, with hind legs specialized for jumping, and webbed feet for swimming. Most live in or near water, though as adults they are air-breathing. A few live on land or even in trees. Their colour is usually greenish in the genus *Rana*, but other Ranidae are brightly coloured, for instance black and orange or yellow and white. Many use their long, extensible tongues to capture insects. The eyes are large and bulging. Frogs vary in size from the North American little grass frog *Limnaea ocellaris*, 12 mm/0.5 in long, to the giant aquatic frog *Telmatobius culeus*, 50 cm/20 in long, of Lake Titicaca, South America. Frogs are widespread, inhabiting all continents except Antarctica, and they have adapted to a range of environments including deserts, forests, grasslands, and even high altitudes, with some species in the Andes and Himalayas existing above 5,000 m/19,600 ft.

courtship and reproduction In many species the males attract the females in great gatherings, usually by croaking. In some tropical species, the male's inflated vocal sac may exceed the rest of his body in size. Other courtship 'lures' include thumping on the ground and 'dances'.

Some lay eggs in large masses (spawn) in water. The jelly surrounding the eggs provides support and protection and retains warmth. Some South American frogs build mud-pool 'nests', and African tree frogs make foam nests from secreted mucus. In other species, the eggs may be carried in pockets on the mother's back, brooded by the male in his vocal sac or, as with the Eurasian midwife toad *Alytes obstetricans*, wrapped round the male's hind legs until hatching.

life cycle The tadpoles hatch from the eggs in about a fortnight. At first they are fishlike animals with external gills and a long swimming tail, but no limbs. The first change to take place is the disappearance of the external gills and the development of internal gills, which are still later supplanted by lungs. The hind legs appear before the front legs, and the last change to occur is the diminution and final disappearance of the tail. The tadpole stage lasts about three or four months. At the end of this time the animal leaves the water. Some species, such as the edible frog, are always aquatic. By autumn the frog grows big and sluggish. It stores fat in a special gland in the abdomen; it is this fat that it lives on during hibernation. **species** Certain species of frog have powerful skin poisons (alkaloids) to deter predators. 'True frogs' are placed in the worldwide family Ranidae, with 800 species, of which the genus *Rana* is the best known. The North American bullfrog *Rana catesbeiana*, with a croak that carries for miles, is able to jump nine times its own length. The flying frogs, genus *Rhacophorus*, of Malaysia, using webbed fore and hind feet, can achieve a 12 m/40 ft glide. The hairy frog *Astylosternus robustus* is found in West Africa; it has long outgrowths on its flanks, which seem to aid respiration. A four-year rainforest study in E Madagascar revealed 106 new frog species in 1995. Indian zoologists discovered the first known leaf-eating frog in 1996, in Tamil Nadu, southern India. *R. hexadactyla* feeds mainly on leaves, flowers, and algae. New species are constantly being discovered. In 1997 a species *Eleutherodactylus pluvianus* was discovered in Bolivia; it is 4 cm long and ground-dwelling.

SOMEWHAT AMUSING WORLD OF FROGS

<http://www.csu.edu.au/faculty/commerce/account/frogs/frog.htm>

Fascinating facts about frogs – did you know, for example, that most frogs will drown eventually if denied access to land?

frogbit small water plant *Hydrocharis morsus-ranae* with submerged roots, floating leaves, and small green and white flowers.

frog hopper or *spittlebug* leaping plant-bug, of the family Cercopidae, in the same order (Homoptera) as leafhoppers and aphids. Frog hoppers live by sucking the juice from plants. The pale green larvae protect themselves (from drying out and from predators) by secreting froth ('cuckoo spit') from their anus.

frogmouth nocturnal bird, related to the nightjar, of which the commonest species, the tawny frogmouth *Podargus strigoides*, is found throughout Australia, including Tasmania. Well camouflaged, it sits and awaits its prey.

frond large leaf or leaflike structure; in ferns it is often pinnately divided. The term is also applied to the leaves of palms and less commonly to the plant bodies of certain seaweeds, liverworts, and lichens.

front in meteorology, the boundary between two air masses of different temperature or humidity. A cold front marks the line of advance of a cold air mass from below, as it displaces a warm air mass; a warm front marks the advance of a warm air mass as it rises up over a cold one. Frontal systems define the weather of the mid-latitudes, where warm tropical air is constantly meeting cold air from the poles.

Warm air, being lighter, tends to rise above the cold; its moisture is carried upwards and usually falls as rain or snow, hence the changeable weather conditions at fronts. Fronts are rarely stable and move with the air mass. An occluded front is a composite form, where a cold front catches up with a warm front and merges with it.

front-end processor small computer used to coordinate and control the communications between a large mainframe computer and its input and output devices.

frost condition of the weather that occurs when the air temperature is below freezing, 0°C/32°F. Water in the atmosphere is deposited as ice crystals on the ground or exposed objects. As cold air is heavier than warm, ground frost is more common than hoar frost, which is formed by the condensation of water particles in the same way that dew collects.

frostbite the freezing of skin or flesh, with formation of ice crystals leading to tissue damage. The treatment is slow warming of the affected area; for example, by skin-to-skin contact or with lukewarm water. Frostbitten parts are extremely vulnerable to infection, with the risk of gangrene.

FRS abbreviation for *Fellow of the Royal Society*.

fructose $C_6H_{12}O_6$ a sugar that occurs naturally in honey, the nectar of flowers, and many sweet fruits; it is commercially prepared from glucose.

It is a monosaccharide, whereas the more familiar cane or beet sugar is a disaccharide, made up of two monosaccharide units: fructose and glucose. It is sweeter than cane sugar and can be used to sweeten foods for people with diabetes.

fruit from Latin *frui* 'to enjoy' in botany, the ripened ovary in flowering plants that develops from one or more seeds or carpels and encloses one or more seeds. Its function is to protect the seeds during their development and to aid in their dispersal. Fruits are often edible, sweet, juicy, and colourful. When eaten they provide vitamins, minerals, and enzymes, but little protein. Most fruits are borne by perennial plants.

Fruits are divided into three agricultural categories on the basis of the climate in which they grow. Temperate fruits require a cold season for satisfactory growth; the principal temperate fruits are apples, pears, plums, peaches, apricots, cherries, and soft fruits, such as strawberries. Subtropical fruits require warm conditions but can survive light frosts; they include oranges and other citrus fruits, dates, pomegranates, and avocados. Tropical fruits cannot tolerate temperatures that drop close to freezing point; they include bananas, mangoes, pineapples, papayas, and litchis. Fruits can also be divided botanically into dry (such as the capsule, follicle, schizocarp, nut, caryopsis, pod or legume, clementine, and cherry) and those that become fleshy (such as the drupe and the berry). The fruit structure consists of the pericarp or fruit wall, which is usually divided into a number of distinct layers. Sometimes parts other than the ovary are incorporated into the fruit structure, resulting in a false fruit or pseudocarp, such as the apple and strawberry. True fruits include the tomato, orange, melon, and banana. Fruits may be dehiscent, which open to shed their seeds, or indehiscent, which remain unopened and are dispersed as a single unit. Simple fruits (for example, peaches) are derived from a single ovary, whereas compositae or multiple fruits (for example, blackberries) are formed from the ovaries of a number of flowers. In ordinary usage, 'fruit' includes only sweet, fleshy items; it excludes many botanical fruits such as acorns, bean pods, thistle-down, and cucumbers.

methods of seed dispersal Efficient seed dispersal is essential to avoid overcrowding and enable plants to colonize new areas; the natural function of a fruit is to aid in the dissemination of the seeds which it contains. A great variety of dispersal mechanisms exist: winged fruits are commonly formed by trees, such as ash and elm, where they are in an ideal position to be carried away by the wind; some wind-dispersed fruits, such as clematis and cotton, have plumes of hairs; others are extremely light, like the poppy, in which the capsule acts like a peppercorn and shakes out the seeds as it is blown about by the wind. Some fruits float on water; the coconut can be dispersed across oceans by means of its buoyant fruit. Geraniums, gorse, and squirting cucumbers have explosive mechanisms, by which seeds are forcibly shot out at dehiscence. Animals often act as dispersal agents either by carrying hooked or sticky fruits (burs) attached to their bodies, or by eating succulent fruits, the seeds passing through the alimentary canal unharmed.

front The boundaries between two air masses of different temperature and humidity. A warm front is when warm air displaces cold air; if cold air replaces warm air, it is a cold front.

fruit A fruit contains the seeds of a plant. Its outer wall is the *exocarp*, or *epicarp*; its inner layers are the *mesocarp* and *endocarp*. The orange is a *hesperidium*, a berry having a leathery rind and containing many seeds. The peach is a *drupe*, a fleshy fruit with a hard seed, or 'stone', at the centre. The apple is a *pome*, a fruit with a fleshy outer layer and a core containing the seeds.

Recorded world fruit production in the mid-1980s was approximately 300 million tonnes per year. Technical advances in storage and transport have made tropical fruits available to consumers in temperate areas, and fresh temperate fruits available all year in major markets.

frustule the cell wall of a diatom (microscopic alga). Frustules are intricately patterned on the surface with spots, ridges, and furrows, each pattern being characteristic of a particular species.

frustum from Latin for 'a piece cut off' in geometry, a 'slice' taken out of a solid figure by a pair of parallel planes. A conical frustum, for example, resembles a cone with the top cut off. The volume and area of a frustum are calculated by subtracting the volume or area of the 'missing' piece from those of the whole figure.

FSF in computing, abbreviation for the Free Software Foundation.

frustum The frustum, a slice taken out of a cone.

FSH abbreviation for follicle-stimulating hormone.

f-stop in photography, another name for f-number.

ft symbol for foot, a measure of distance.

FTP (abbreviation for *File Transfer Protocol*) in computing, rules for transferring files between computers on the Internet. The use of FTP avoids incompatibility between individual computers. To use FTP over the Internet, a user must have an Internet connection, an FTP client or World Wide Web browser, and an account on the system holding the files. Many commercial and noncommercial systems allow anonymous FTP either to distribute new versions of software products or as a public service.

FTPmail in computing, an FTP server that can be operated by e-mail. This service is useful for people with only limited access to the Internet.

fuchsia any shrub or herbaceous plant of a group belonging to the evening-primrose family. Species are native to South and Central America and New Zealand, and bear red, purple, or pink bell-shaped flowers that hang downwards. (Genus *Fuchsia*, family Onagraceae.)

The genus was named in 1703 after German botanist Leonhard Fuchs (1501–1566).

fuel any source of heat or energy, embracing the entire range of materials that burn in air (combustibles). A nuclear fuel is any material that produces energy by nuclear fission in a nuclear reactor.

fuel cell cell converting chemical energy directly to electrical energy.

It works on the same principle as a battery but is continually fed with fuel, usually hydrogen. Fuel cells are silent and reliable (no moving parts) but expensive to produce.

Hydrogen is passed over an electrode (usually nickel or platinum) containing a catalyst, which strips electrons off the atoms. These pass through an external circuit while hydrogen ions (charged atoms) pass through an electrolyte to another electrode, over which oxygen is passed. Water is formed at this electrode (as a by-product) in a chemical reaction involving electrons, hydrogen ions, and oxygen atoms. If the spare heat also produced is used for hot water and space heating, 80% efficiency in fuel is achieved.

fuel injection injecting fuel directly into the cylinders of an internal combustion engine, instead of by way of a carburettor. It is the standard method used in diesel engines, and is now becoming standard for petrol engines. In the diesel engine, oil is injected into the hot compressed air at the top of the second piston stroke and explodes to drive the piston down on its power stroke. In the petrol engine, fuel is injected into the cylinder at the start of the first induction stroke of the four-stroke cycle.

full duplex in computing, modem setting which means that two-way communication is enabled, so that everything you type is echoed back to the screen. See *duplex*.

fullerene form of carbon, discovered in 1985, based on closed cages of carbon atoms. The molecules of the most symmetrical of the fullerenes are called buckminsterfullerenes (or buckyballs). They are perfect spheres made up of 60 carbon atoms linked together in 12 pentagons and 20 hexagons fitted together like those of a spherical football. Other fullerenes, with 28, 32, 50, 70, and 76 carbon atoms, have also been identified.

Fullerenes can be made by arcing electricity between carbon rods. They may also occur in candle flames and in clouds of interstellar gas. Fullerene chemistry may turn out to be as important as organic chemistry based on the benzene ring. Already, new molecules based on the buckyball enclosing a metal atom, and 'buckytubes' (cylinders of carbon atoms arranged in hexagons), have been made. Applications envisaged include using the new molecules as lubricants, semiconductors, and superconductors, and as the starting point for making new drugs.

fuller's earth soft, greenish-grey rock resembling clay, but without clay's plasticity. It is formed largely of clay minerals, rich in

montmorillonite, but a great deal of silica is also present. Its absorbent properties make it suitable for removing oil and grease, and it was formerly used for cleaning fleeces ('fulling'). It is still used in the textile industry, but its chief application is in the purification of oils. Beds of fuller's earth are found in the southern USA, Germany, Japan, and the UK.

full-motion video (FMV) in computing, video system that can display continuous motion. Some slow-speed CD-ROM drives and low-bandwidth networks are unable to handle the mass of data required for full-motion video, so video playback tends to jerk unevenly.

fulmar any of several species of petrels of the family Procellariidae, which are similar in size and colour to herring gulls. The northern fulmar *Fulmarus glacialis* is found in the North Atlantic and visits land only to nest, laying a single egg.

fulminate any salt of fulminic (cyanic) acid (HCN), the chief ones being silver and mercury. The fulminates detonate (are exploded by a blow); see ϕ detonator.

FULMAR

The world's official oldest wild bird is over 50 years old. It is a female fulmar, which nests each year on an uninhabited Orkney island. She has been monitored

fumitory any of a group of plants native to Europe and Asia. The common fumitory (*F. officinale*) grows to 50 cm/20 in and produces pink flowers tipped with blackish red; it has been used in medicine for stomach and liver complaints. (Genus *Fumaria*, family Fumariaceae.)

function in computing, a small part of a program that supplies a specific value – for example, the square root of a specified number, or the current date. Most programming languages incorporate a number of built-in functions; some allow programmers to write their own. A function may have one or more arguments (the values on which the function operates). A function key on a keyboard is one that, when pressed, performs a designated task, such as ending a program.

function in mathematics, a function f is a non-empty set of ordered pairs ($x, f(x)$) of which no two can have the same first element. Hence, if $f(x) = x^2$ two ordered pairs are $(-2, 4)$ and $(2, 4)$. The set of all first elements in a function's ordered pairs is called the domain; the set of all second elements is the range. In the algebraic expression $y = 4x^3 + 2$, the dependent variable y is a function of the independent variable x , generally written as $f(x)$.

Functions are used in all branches of mathematics, physics, and science generally; for example, the formula $t = 2\pi/(U/g)$ shows that for a simple pendulum the time of swing t is a function of its length l and of no other variable quantity (π and g , the acceleration due to gravity, are ϕ constants).

Form and function are a unity, two sides of one coin. In order to enhance function, appropriate form must exist or be created.

functional group in chemistry, a small number of atoms in an arrangement that determines the chemical properties of the group and of the molecule to which it is attached (for example, the carboxyl group COOH, or the amine group NH₂). Organic compounds can be considered as structural skeletons, with a high carbon content, with functional groups attached.

functional programming computer programming based largely on the definition of ϕ functions. There are very few functional programming languages, HOPE and ML being the most widely used, though many more conventional languages (for example, C) make extensive use of functions.

function key key on a keyboard that, when pressed, performs a designated task, such as ending a computer program.

fundamental constant physical quantity that is constant in all circumstances throughout the whole universe. Examples are the electric charge of an electron, the speed of light, Planck's constant, and the gravitational constant.

Physical constants, or fundamental constants, are standardized values whose parameters do not change.

fundamental particle another term for ϕ elementary particle.

fundamental vibration standing wave of the longest wavelength that can be established on a vibrating object such as a stretched string or air column. The sound produced by the fundamental vibration is the lowest-pitched (usually dominant) note heard.

The fundamental vibration of a string has a stationary ϕ node at each end and a single ϕ antinode at the centre where the amplitude of vibration is greatest.

fungicide any chemical ϕ pesticide used to prevent fungus diseases in plants and animals. Inorganic and organic compounds containing sulphur are widely used.

fungus (plural *fungi*) any of a unique group of organisms that includes moulds, yeasts, rusts, smuts, mildews, mushrooms, and toadstools. About 50,000 species have been identified. They are not considered to be plants for three main reasons: they have no leaves or roots; they contain no chlorophyll (green colouring) and are therefore unable to make their own food by ϕ photosynthesis; and they reproduce by ϕ spores. Some fungi are edible but many are highly poisonous; they often cause damage and sometimes disease

FUNGUS

Leaf-cutter ants feed their larvae on a fungus that they cultivate themselves in underground gardens. The ants depend on the fungus for food, and the fungus cannot reproduce without the ants. When a new queen takes flight to establish another colony, she takes some of the fungus with her in a special mouth pouch.

to the organic matter they live and feed on, but some fungi are exploited in the production of food and drink (for example, yeasts in baking and brewing) and in medicine (for example, penicillin). (Kingdom Fungi.)

Fungi are either parasites, existing on living plants or animals, or saprotrophs, living on dead matter. Many of the most serious plant diseases are caused by fungi, and several fungi attack humans and animals. Athlete's foot, thrush, and ringworm are fungal diseases.

Before the classification Fungi came into use, they were included within the division Thallophyta, along with algae and bacteria. Two familiar fungi are bread mould, which illustrates the typical many-branched body (mycelium) of the organism, made up of threadlike chains of cells called hyphae; and mushrooms, which are the sexually reproductive fruiting bodies of an underground mycelium.

The mycelium of a true fungus is made up of many intertwined hyphae. When the fungus is ready to reproduce, the hyphae become closely packed into a solid mass called the fruiting body, which is usually small and inconspicuous but can be very large; mushrooms, toadstools, and bracket fungi are all examples of large fruiting bodies. These carry and distribute the spores. Most species of fungi reproduce both asexually (on their own) and sexually (involving male and female parents).

fur the pelt of certain animals. Fur is an excellent insulating material and so has been used as clothing. This is, however, vociferously criticized by many groups on humane grounds, as the methods of breeding or trapping animals are often cruel. Mink, chinchilla, and

sable are among the most valuable, the wild furs being finer than the farmed.

Fur such as mink is made up of a soft, thick, insulating layer called underfur and a top layer of longer, lustrous guard hairs.

Furs have been worn since prehistoric times and have long been associated with status and luxury (ermine traditionally worn by royalty, for example), except by certain ethnic groups like the Inuit. The fur trade had its origin in North America, where in the late 17th century the Hudson's Bay Company was established. The chief centres of the fur trade are New York, London, St Petersburg, and Kastoria in Greece. It is illegal to import furs or skins of endangered species listed by CITES (such as the leopard). Many synthetic fibres are widely used as substitutes.

furlong unit of measurement, originating in Anglo-Saxon England, equivalent to 220 yd (201.168 m).

A furlong consists of 40 rods, poles, or perches; 8 furlongs equal one statute mile. Its literal meaning is 'furrow-long', and refers to the length of a furrow in the common field characteristic of medieval farming.

furnace structure in which fuel such as coal, coke, gas, or oil is burned to produce heat for various purposes. Furnaces are used in conjunction with boilers for heating, to produce hot water, or steam for driving turbines – in ships for propulsion and in power stations for generating electricity. The largest furnaces are those used for smelting and refining metals, such as the blast furnace, electric furnace, and open-hearth furnace.

fuse in electricity, a wire or strip of metal designed to melt when excessive current passes through. It is a safety device that halts surges of current which would otherwise damage equipment and cause fires. In explosives, a fuse is a cord impregnated with chemicals so that it burns slowly at a predetermined rate. It is used to set off a main explosive charge, sufficient length of fuse being left to allow the person lighting it to get away to safety.

fusel oil liquid with a characteristic unpleasant smell, obtained as a by-product of the distillation of the product of any alcoholic fermentation, and used in paints, varnishes, essential oils, and plastics. It is a mixture of fatty acids, alcohols, and esters.

fusion in physics, the fusing of the nuclei of light elements, such as hydrogen, into those of a heavier element, such as helium. The resultant loss in their combined mass is converted into energy. Stars and thermonuclear weapons are powered by nuclear fusion.

fuzzy logic in mathematics and computing, a form of knowledge representation suitable for notions (such as 'hot' or 'loud') that cannot be defined precisely but depend on their context. For example, a jug of water may be described as too hot or too cold, depending on whether it is to be used to wash one's face or to make tea.

The central idea of fuzzy logic is probability of set membership. For instance, referring to someone 175 cm/5 ft 9 in tall, the statement 'this person is tall' (or 'this person is a member of the set of tall people') might be about 70% true if that person is a man, and about 85% true if that person is a woman.

gabbro mafic (consisting primarily of dark-coloured crystals) igneous rock formed deep in the Earth's crust. It contains pyroxene and calcium-rich feldspar, and may contain small amounts of olivine and amphibole. Its coarse crystals of dull minerals give it a speckled appearance.

Gabbro is the plutonic version of basalt (that is, derived from magma that has solidified below the Earth's surface), and forms in large, slow-cooling intrusions.

Gabcikovo Dam hydroelectric dam on the river Danube, at the point where it crosses the frontier between Hungary and the Slovak Republic. A treaty agreeing to its construction was signed by Hungary and Czechoslovakia in 1977, but work was suspended in 1989 after Hungary withdrew its support for a scheme to divert water from the river. Czechoslovakia resumed work 1991, despite warnings from scientists and environmentalists that the scheme would destroy valuable wetlands in the Danube valley.

A dramatic reduction in river flow resulted from Czechoslovakia's first attempts to divert water November 1992, prompting the setting-up of an investigative committee, under the auspices of the European Community, and involving both parties concerned, to reassess the project.

gadolinium silvery-white metallic element of the lanthanide series, symbol Gd, atomic number 64, relative atomic mass 157.25. It is found in the products of nuclear fission and used in electronic components, alloys, and products needing to withstand high temperatures.

Gaia hypothesis theory that the Earth's living and nonliving systems form an inseparable whole that is regulated and kept adapted for life by living organisms themselves. The planet therefore

functions as a single organism, or a giant cell. The hypothesis was elaborated by British scientist James Lovelock and first published in 1968.

galactic coordinates in astronomy, a system for measuring the position of astronomical objects on the ðcelestial sphere with reference to the galactic equator (or ðgreat circle).

Galactic latitude (symbol b) is measured in degrees from the galactic equator (b = 0°) to the north (b = 90°) and south (b = - 90°) galactic poles.

Galactic longitude (symbol l) is measured in degrees eastward (l = 0° to 360°) from a fixed point in the constellation of ðSagittarius that approximates to the centre of the Galaxy. Galactic coordinates are often used when astronomers are studying the distribution of material in the ðGalaxy.

galactic halo in astronomy, the outer, sparsely populated region of a galaxy, roughly spheroid in shape and extending far beyond the bulk of the visible stars. In our own Galaxy, the halo contains the globular clusters, and may harbour large quantities of ðdark matter.

galaxy congregation of millions or billions of stars, held together by gravity. Spiral galaxies, such as the ðMilky Way, are flattened in shape, with a central bulge of old stars surrounded by a disc of younger stars, arranged in spiral arms like a Catherine wheel.

galaxy Galaxies were classified by US astronomer Edwin Hubble in 1925. He placed the galaxies in a 'tuning-fork' pattern, in which the two prongs correspond to the barred and non-barred spiral galaxies.

Barred spirals are spiral galaxies that have a straight bar of stars across their centre, from the ends of which the spiral arms emerge. The arms of spiral galaxies contain gas and dust from which new stars are still forming.

Elliptical galaxies contain old stars and very little gas. They include the most massive galaxies known, containing a trillion stars. At least some elliptical galaxies are thought to be formed by mergers between spiral galaxies. There are also irregular galaxies. Most galaxies occur in clusters, containing anything from a few to thousands of members.

Our own Galaxy, the Milky Way, is about 100,000 light years in diameter, and contains at least 100 billion stars. It is a member of a small cluster, the Local Group. The Sun lies in one of its spiral arms, about 25,000 light years from the centre.

By the end of a five-year study in 1995, US astronomers had identified 600 previously uncatalogued galaxies, mostly 200–400 million light years away, leading to the conclusion that there may be 30–100% more galaxies than previously estimated. Two galax-

ies were discovered obscured by galactic dust at the edge of the Milky Way. One, named MB1, is a spiral galaxy 17,000 light years across; the other, MB2, is an irregular-shaped dwarf galaxy about 4,000 light years across. In 1996 US astronomers discovered a further new galaxy 17 million light years away. The galaxy NGC2915 is a blue compact dwarf galaxy and 95% of its mass is in the form of dark matter. In 1997 an international team of astronomers detected the furthest known object in the universe, which is a galaxy lying 13 billion light years away.

galena mineral consisting of lead sulphide, PbS, the chief ore of lead. It is lead-grey in colour, has a high metallic lustre and breaks into cubes because of its perfect cubic cleavage. It may contain up to 1% silver, and so the ore is sometimes mined for both metals. Galena occurs mainly among limestone deposits in Australia, Mexico, Russia, Kazakhstan, the UK, and the USA.

Galileo (1564–1642)

properly *Galileo Galilei* Italian mathematician, astronomer, and physicist. He developed the astronomical telescope and was the first to see sunspots, the four main satellites of Jupiter, and the appearance of Venus going through phases, thus proving it was orbiting the Sun. Galileo discovered that freely falling bodies, heavy or light, have the same, constant acceleration and that this acceleration is due to gravity. He also determined that a body moving on a perfectly smooth horizontal surface would neither speed up nor slow down. He invented a thermometer, a hydrostatic balance, and a compass, and discovered that the path of a projectile is a parabola.

Galileo's work founded the modern scientific method of deducing laws to explain the results of observation and experiment, although the story of his dropping cannonballs from the Leaning Tower of Pisa is questionable. His observations were an unwelcome refutation of the ideas of the Greek philosopher Aristotle taught at the church-run universities, largely because they made plausible for the first time the Sun-centred theory of Polish astronomer Nicolaus Copernicus. Galileo's persuasive *Dialogo sopra i due massimi sistemi del mondo* (Dialogues on the Two Chief Systems of the World 1632) was banned by the church authorities in Rome and he was made to recant by the Inquisition. Evangelista Torricelli is the most famous of his pupils.

astronomy and the invention of the telescope In July 1609, hearing that a Dutch scientist had made a telescope, Galileo worked out the principles involved and made a number of telescopes. He compiled fairly accurate tables of the orbits of four of Jupiter's satellites and proposed that their frequent eclipses could serve as a means of determining longitude on land and at sea. His observations on sunspots and Venus going through phases supported Copernicus's theory that the Earth rotated and orbited the Sun.

Galileo's results published in *Sidereus Nuncius* (The Starry Messenger 1610) were revolutionary.

He believed, however – following both Greek and medieval tradition – that orbits must be circular, not elliptical, in order to maintain the fabric of the cosmos in a state of perfection. This preconception prevented him from deriving a full formulation of the law of inertia, which was later to be

attributed to the contemporary French mathematician René Descartes.

the pendulum Galileo made several fundamental contributions to mechanics. He rejected the impetus theory that a force or push is required to sustain motion. While watching swinging lamps in Pisa cathedral, Galileo determined that each oscillation of a pendulum takes the same amount of time despite the difference in amplitude, and recognized the potential importance of this observation to timekeeping. In a later publication, he presented his derivation that the square of the period of a pendulum varies with its length (and is independent of the mass of the pendulum bob).

mechanics and the law of falling bodies Galileo discovered before Newton that two objects of different weights – an apple and a melon, for instance – falling from the same height would hit the ground at the same time. He realized that gravity not only causes a body to fall, but also determines the motion of rising bodies and, furthermore, that gravity extends to the centre of the Earth. Galileo then showed that the motion of a projectile is made up of two components: one component consists of uniform motion in a horizontal direction, and the other component is vertical motion under acceleration or deceleration due to gravity.

Galileo used this explanation to refute objections to Copernicus. The Church argued that a turning Earth would not carry along birds and clouds. Galileo explained that motion of a bird, like a projectile, has a horizontal component that is provided by the motion of the Earth and that this horizontal component of motion always exists to keep such objects in position even though they are not attached to the ground.

Galileo came to an understanding of uniform velocity and uniform acceleration by measuring the time it takes for bodies to move various distances. He had the brilliant idea of slowing vertical motion by measuring the movement of balls rolling down inclined planes, realizing that the vertical component of this motion is a uniform acceleration due to gravity. It took Galileo many years to arrive at the correct expression of the law of falling bodies, which he presented in *Discorsi e dimostrazioni matematiche intorno a due nuove scienze* (Discourses and Mathematical Discoveries Concerning Two New Sciences 1638 as:

$$s = \frac{1}{2}at^2$$

where s is speed, a is the acceleration due to gravity, and t is time. He found that the distance travelled by a falling body is proportional to the square of the time of descent.

A summation of his life's work, *Discourses* also included the facts that the trajectory of a projectile is a parabola, and that the law of falling bodies is perfectly obeyed only in a vacuum, and that air resistance always causes a uniform terminal velocity to be reached.

Galileo spacecraft launched from the space shuttle *Atlantis* October 1989, on a six-year journey to Jupiter. *Galileo's* probe entered the atmosphere of Jupiter December 1995. It radioed information back to the orbiter for 57 minutes before it was destroyed by atmospheric pressure. The orbiter will continue circling Jupiter until 1997. Despite technical problems data is still being relayed to Earth, but very slowly. The first pictures of Jupiter are due July 1996.

It flew past Venus February 1990 and passed within 970 km/600 mi of Earth December 1990, using the gravitational fields of these two planets to increase its velocity. It flew past the asteroids Gaspra in 1991 and Ida in 1993, taking close-up photographs.

At the end of July 1995, and 55 million km/34 million mi from Jupiter, *Galileo* entered a dust storm and began detecting up to 20,000 particles a day (previously the maximum detected was 200). The dust is associated with Jupiter, and may come from the planet itself, its rings, or its satellites.

gall abnormal outgrowth on a plant that develops as a result of attack by insects or, less commonly, by bacteria, fungi, mites, or nematodes. The attack causes an increase in the number of cells or

an enlargement of existing cells in the plant. Gall-forming insects generally pass the early stages of their life inside the gall.

Gall wasps are responsible for the conspicuous bud galls forming on oak trees, 2.5–4 cm/1–1.5 in across, known as 'oak apples'. The organisms that cause galls are host-specific. Thus, for example, gall wasps tend to parasitize oaks, and sawflies willows.

gall bladder small muscular sac, part of the digestive system of most, but not all, vertebrates. In humans, it is situated on the underside of the liver and connected to the small intestine by the bile duct. It stores bile from the liver.

galley ship powered by oars, and usually also equipped with sails. Galleys typically had a crew of hundreds of rowers arranged in banks. They were used in warfare in the Mediterranean from antiquity until the 18th century.

France maintained a fleet of some 40 galleys, crewed by over 10,000 convicts, until 1748. The maximum speed of a galley is estimated to have been only four knots (7.5 kph/4.5 mph), because only 20% of the rower's effort was effective, and galleys could not be used in stormy weather because of their very low waterline.

gallium grey metallic element, symbol Ga, atomic number 31, relative atomic mass 69.72. It is liquid at room temperature. Gallium arsenide (GaAs) crystals are used in microelectronics, since electrons travel a thousand times faster through them than through silicon. The element was discovered in 1875 by Lecoq de Boisbaudran (1838–1912).

gallium arsenide compound of gallium and arsenic, formula GaAs, used in lasers, photocells, and microwave generators. Its semiconducting properties make it a possible rival to silicon for use in microprocessors. Chips made from gallium arsenide require less electric power and process data faster than those made from silicon.

gall midge minute and fragile long-legged flies, with longish hairy antennae. The larvae are small maggots, ranging in colour from white or yellow, to orange and bright red, that feed on developing fruits which become deformed and decay, and frequently produce galls on plants.

Some forms live within galls formed by other insects, such as beetles, or other species of Cecidomyiidae. The *chessian* fly of North America and New Zealand, is a pest of wheat. The *pearl* midge *Contarinia pryorata* is a serious fruit pest in Europe.

classification Gall midges are in the family Cecidomyiidae (suborder Nematocera) of the insect order Diptera, class Insecta, phylum Arthropoda.

gallon imperial liquid or dry measure, equal to 4.546 litres, and subdivided into four quarts or eight pints. The US gallon is equivalent to 3.785 litres.

gallstone pebblelike, insoluble accretion formed in the human gall bladder or bile ducts from cholesterol or calcium salts present in bile. Gallstones may be symptomless or they may cause pain, indigestion, or jaundice. They can be dissolved with medication or removed, either by means of an endoscope or, along with the gall bladder, in an operation known as cholecystectomy.

gall wasp small (only a few millimetres long), dark-coloured insect with a compressed abdomen. Most gall wasps form galls, though a few live within the galls formed by other species; these are called *inquilines*. Others feed on gall-formers and *inquilines*. **classification** Gall wasps are in the family Cynipidae, order Hymenoptera, class Insecta, phylum Arthropoda.

The exact reactions which lead to gall formation in the host plant are little understood. Basically it is a reaction of the cells of the plant to the presence of the larva.

complex life history The oak-apple gall is caused by species *Biorhiza pallida* and both winged males and wingless or vestigial-winged females emerge from these galls. After mating the females lay their eggs in the root of the same host plant, thus producing root galls. In the following spring only wingless females are produced. These females climb up the oak tree and produce the characteristic oak-apples, thus repeating the life cycle.

Rose galls are often produced by *Diptolepis rosae*. These gall wasps usually reproduce asexually; the females are about 4 mm/0.2 in long; parts of their abdomens and legs are yellow-red, while the rest of the body is black. Males of this species have been observed only rarely. The galls are a mass of reddish filaments within which are found a number of sealed chambers enclosing larvae. The larvae feed on the gall tissue.

galvanizing process for rendering iron rust-proof, by plunging it into molten zinc (the dipping method), or by electroplating it with zinc.

galvanometer instrument for detecting small electric currents by their magnetic effect.

games console computer capable only of playing games, which are supplied as cartridges or CD-ROM discs that slot directly into the console.

gamete cell that functions in sexual reproduction by merging with another gamete to form a zygote. Examples of gametes include sperm and egg cells. In most organisms, the gametes are haploid (they contain half the number of chromosomes of the parent), owing to reduction division or meiosis.

In higher organisms, gametes are of two distinct types: large immobile ones known as eggs or egg cells (see ovum) and small ones known as sperm. They come together at fertilization. In some lower organisms the gametes are all the same, or they may belong to different mating strains but have no obvious differences in size or appearance.

game theory group of mathematical theories, developed in 1944 by Oscar Morgenstern (1902-1977) and John Von Neumann, that seeks to abstract from invented game-playing scenarios and their outcome the essence of situations of conflict and/or cooperation in the real political, business, and social world.

A feature of such games is that the rationality of a decision by one player will depend on what the others do; hence game theory has particular application to the study of oligopoly (a market largely controlled by a few producers).

A theory is a good theory if it satisfies two requirements: it must accurately describe a large class of observations on the basis of a model that contains only a few arbitrary elements, and it must make definite predictions about the results of future predictions.

gametophyte the haploid generation in the life cycle of a plant that produces gametes; see alternation of generations.

gamma radiation very high-frequency electromagnetic radiation, similar in nature to X-rays but of shorter wavelength, emitted by the nuclei of radioactive substances during decay or by the interactions of high-energy electrons with matter. Cosmic gamma rays have been identified as coming from pulsars, radio galaxies, and quasars, although they cannot penetrate the Earth's atmosphere.

Gamma rays are stopped only by direct collision with an atom and are therefore very penetrating; they can, however, be stopped by about 4 cm/1.5 in of lead or by a very thick concrete shield. They are less ionizing in their effect than alpha and beta particles, but are dangerous nevertheless because they can penetrate deeply into body tissues such as bone marrow. They are not deflected by either magnetic or electric fields.

Gamma radiation is used to kill bacteria and other microorganisms, sterilize medical devices, and change the molecular structure of plastics to modify their properties (for example, to improve their resistance to heat and abrasion).

gamma-ray astronomy the study of gamma rays from space. Much of the radiation detected comes from collisions between

hydrogen gas and cosmic rays in our Galaxy. Some sources have been identified, including the Crab nebula and the Vela pulsar (the most powerful gamma-ray source detected).

Gamma rays are difficult to detect and are generally studied by use of balloon-borne detectors and artificial satellites. The first gamma-ray satellites were *SAS II* (1972) and *COS B* (1975), although gamma-ray detectors were carried on the *Apollo 15* and *16* missions. *SAS II* failed after only a few months, but *COS B* continued working until 1982, carrying out a complete survey of the galactic disc.

ganglion (plural *ganglia*) solid cluster of nervous tissue containing many cell bodies and synapses, usually enclosed in a tissue sheath; found in invertebrates and vertebrates.

In many invertebrates, the central nervous system consists mainly of ganglia connected by nerve cords. The ganglia in the head (cerebral ganglia) are usually well developed and are analogous to the brain in vertebrates. In vertebrates, most ganglia occur outside the central nervous system.

gangrene death and decay of body tissue (often of a limb) due to bacterial action; the affected part gradually turns black and causes blood poisoning.

Gangrene sets in as a result of loss of blood supply to the area. This may be due to disease (diabetes, atherosclerosis), an obstruction of a major blood vessel (as in thrombosis), injury, or frostbite. Bacteria colonize the site unopposed, and a strong risk of blood poisoning often leads to surgical removal of the tissue or the affected part (amputation).

gannet any of three species of North Atlantic seabirds; the largest is *Sula bassana*. When fully grown, it is white with buff colouring on the head and neck; the beak is long and thick and compressed at the point; the wings are black-tipped with a span of 1.7 m/5.6 ft. It breeds on cliffs in nests made of grass and seaweed, laying a single white egg. Gannets feed on fish that swim near the surface, such as herrings and pilchards. (Family Sulidae, order Pelecaniformes.)

Diving swiftly and sometimes from a considerable height upon their prey, they enter the water with closed wings and neck outstretched. They belong to the same family as the booby.

The gannets are the largest seabirds of the North Atlantic; they are found also in the southeast Pacific and in temperate waters off Africa.

gannet The Cape gannet *Morus capensis*. It forms dense breeding colonies around the coasts of S Africa, incubating its single egg with its feet. Gannets are accomplished 'plunge divers' and make a spectacular sight when fishing. Premaphotos Wildlife

Ganymede in astronomy, the largest moon of the planet Jupiter, and the largest moon in the Solar System, 5,260 km/3,270 mi in diameter (larger than the planet Mercury). It orbits Jupiter every 7.2 days at a distance of 1.1 million km/700,000 mi. Its surface is a mixture of cratered and grooved terrain. Molecular oxygen was identified on Ganymede's surface in 1994.

The space probe *Galileo* detected a magnetic field around Ganymede in 1996; this suggests it may have a molten core. *Galileo* photographed Ganymede at a distance of 7,448 km/4,628 mi. The resulting images were 17 times clearer than those taken by *Voyager 2* in 1979, and show the surface to be extensively cratered and ridged, probably as a result of forces similar to those that create mountains on Earth. *Galileo* also detected molecules containing both carbon and nitrogen on the surface March 1997. Their presence may indicate that Ganymede harboured life at some time.

gar any of a group of primitive bony fishes, which also includes (sturgeons). Gar have long, beaklike snouts and elongated bodies covered in heavy, bony scales. All four species of gar live in freshwater rivers and lakes of the Mississippi drainage. See also (needlefish). (Order Semionotiformes.)

gardenia any of a group of subtropical and tropical trees and shrubs found in Africa and Asia, belonging to the madder family, with evergreen foliage and flattened rosettes of fragrant waxen-looking flowers, often white in colour. (Genus *Gardenia*, family Rubiaceae.)

garfish European marine fish with a long spearlike snout. The common garfish (*Belone belone*) has an elongated body measuring 75 cm/2.5 ft in length. (Family Belontiidae, order Belontiiformes.)

garlic perennial Asian plant belonging to the lily family, whose strong-smelling and sharp-tasting bulb, made up of several small segments, or cloves, is used in cooking. The plant has white flowers. It is widely cultivated and has been used successfully as a fungicide in the cereal grass (sorghum). It also has antibacterial properties. (*Allium sativum*, family Liliaceae.)

In tests carried out in 1994, US doctors found freshly pressed garlic extract killed a number of bacteria, including drug-resistant strains, even when diluted to one part in 250. Its effectiveness is probably due to allicin, a simple organic disulphide.

garnet group of silicate minerals with the formula $X_2Y_3(SiO_4)_3$, where X is calcium, magnesium, iron, or manganese, and Y is usually aluminium or sometimes iron or chromium. Garnets are used as semiprecious gems (usually pink to deep red) and as abrasives. They occur in metamorphic rocks such as gneiss and schist.

Garnets consisting of neodymium, yttrium, and aluminium (referred to as Nd-YAG) produce infrared laser light when sufficiently excited. Nd-YAG lasers are inexpensive and used widely in industry and scientific research.

garpike freshwater bony fish. It has an elongated snout and its body is covered with thick scales. Garpikes are predators found in North America.

classification Garpikes are in the family Lepisosteidae, order Lepisosteiformes, class Osteichthyes.

gas in physics, a form of matter, such as air, in which the molecules move randomly in otherwise empty space, filling any size or shape of container into which the gas is put.

A sugar-lump sized cube of air at room temperature contains 30

trillion molecules moving at an average speed of 500 metres per second (1,800 kph/1,200 mph). Gases can be liquefied by cooling, which lowers the speed of the molecules and enables attractive forces between them to bind them together.

gas collection method used to collect a gas in a laboratory preparation. The properties of the gas, and whether it is required dry, dictate the method used. Dry ammonia is collected by downward displacement of air.

gas constant in physics, the constant R that appears in the equation $PV = nRT$, which describes how the pressure P , volume V , and temperature T of an ideal gas are related (n is the amount of gas in moles). This equation combines Boyle's law and Charles's law.

R has a value of 8.3145 joules per kelvin per mole.

gas-cooled reactor type of nuclear reactor; see (advanced gas-cooled reactor).

gas engine internal-combustion engine in which a gas (coal gas, producer gas, natural gas, or gas from a blast furnace) is used as the fuel.

The first practical gas engine was built in 1860 by Jean Etienne Lenoir, and the type was subsequently developed by Nikolaus August Otto, who introduced the (four-stroke cycle).

gas exchange movement of gases between an organism and the atmosphere, principally oxygen and carbon dioxide. All aerobic organisms (most animals and plants) take in oxygen in order to burn food and manufacture (ATP). The resultant oxidation reactions release carbon dioxide as a waste product to be passed out into the environment. Green plants also absorb carbon dioxide during (photosynthesis), and release oxygen as a waste product.

Specialized respiratory surfaces have evolved during evolution to make gas exchange more efficient. In humans and other tetrapods (four-limbed vertebrates), gas exchange occurs in the (lungs), aided by the breathing movements of the ribs. Many adult amphibians and terrestrial invertebrates can absorb oxygen directly through the skin. The bodies of insects and some spiders contain a system of air-filled tubes known as (tracheae). Fish have (gills) as their main respiratory surface. In plants, gas exchange generally takes place via the (stomata) and the air-filled spaces between the cells in the interior of the leaf.

gas giant in astronomy, any of the four large outer (planets) of the Solar System, (Jupiter), (Saturn), (Uranus), and (Neptune), which consist largely of gas and have no solid surface.

gas laws physical laws concerning the behaviour of gases. They include (Boyle's law) and (Charles's law), which are concerned with the relationships between the pressure, temperature, and volume of an ideal (hypothetical) gas. These two laws can be combined to give the general or universal gas law, which may be expressed as:

$$(\text{pressure} \times \text{volume})/\text{temperature} = \text{constant}$$

Van der Waals' law includes corrections for the nonideal behaviour of real gases.

gasohol motor fuel that is 90% petrol and 10% ethanol (alcohol). The ethanol is usually obtained by fermentation, followed by distillation, using maize, wheat, potatoes, or sugar cane. It was used in early cars before petrol became economical, and its use was revived during the 1940s war shortage and the energy shortage of the 1970s, for example in Brazil.

gasoline the US term for (petrol).

gas syringe graduated piece of glass apparatus used to measure accurately the volumes of gases.

gastroenteritis inflammation of the stomach and intestines, giving rise to abdominal pain, vomiting, and diarrhoea. It may be caused by food or other poisoning, allergy, or infection. Dehydration may be severe and it is a particular risk in infants.

much as some birds now swallow grit and pebbles to grind food in their crop. Once the animal has decayed, smooth round stones remain – often the only clue to their past use is the fact that they are geologically different from their surrounding strata.

gastropod any member of a very large group of molluscs (soft-bodied invertebrate animals). Gastropods have a single shell (in a spiral or modified spiral form) and eyes on stalks, and they move on a flattened, muscular foot. They have well-developed heads and rough, scraping tongues called radulae. Some are marine, some freshwater, and others land creatures, but they all tend to live in damp places. (Class Gastropoda.)

gas turbine engine in which burning fuel supplies hot gas to spin a turbine. The most widespread application of gas turbines has been in aviation. All jet engines (see under jet propulsion) are modified gas turbines, and some locomotives and ships also use gas turbines as a power source.

They are also used in industry for generating and pumping purposes.

In a typical gas turbine a multivaned compressor draws in and compresses air. The compressed air enters a combustion chamber at high pressure, and fuel is sprayed in and ignited. The hot gases produced escape through the blades of (typically) two turbines and spin them around. One of the turbines drives the compressor; the other provides the external power that can be harnessed.

Gates, Bill (William) Henry, III (1955–) US businessman and computer programmer. He co-founded Microsoft Corporation in 1975 and was responsible for supplying MS-DOS, the operating system and the Basic language that IBM used in the IBM PC.

In 1997 Gates controlled a \$39.8 billion shareholding in Microsoft, making him the world's richest individual.

When the IBM deal was struck in 1980, Microsoft did not actually have an operating system, but Gates bought one from another company, renamed it MS-DOS, and modified it to suit IBM's new computer. Microsoft also retained the right to sell MS-DOS to other computer manufacturers, and because the IBM PC was not only successful but easily copied by other manufacturers, MS-DOS found its way onto the vast majority of PCs. The revenue from MS-DOS helped Microsoft to expand into other areas of software, guided by Gates.

gateway in computing, the point of contact between two wide-area networks.

gauge any scientific measuring instrument – for example, a wire gauge or a pressure gauge. The term is also applied to the width of a railway or tramway track.

gauge boson or **field particle** any of the particles that carry the four fundamental forces of nature (see forces, fundamental).

Gauge bosons are elementary particles that cannot be subdivided, and include the photon, the graviton, the gluons, and the weakons.

gaur Asiatic wild ox, dark grey-brown in colour with white 'socks' and standing 2 m/6 ft tall at the shoulders. It originally roamed across a vast area of land stretching from India to SE Asia and Malaysia, but population numbers and the area where it can be found are now much smaller. (Species *Bos gaurus*.)

gauss c.g.s. unit (symbol Gs) of magnetic induction or magnetic flux density, replaced by the SI unit, the tesla, but still commonly used. It is equal to one line of magnetic flux per square centimetre. The Earth's magnetic field is about 0.5 Gs, and changes to it over time are measured in gammas (one gamma equals 10^{-5} gauss).

gavial large reptile related to the crocodile. It grows to about 7 m/23 ft long, and has a very long snout with about 100 teeth in its jaws. Gavials live in rivers in northern India, where they feed on fish and frogs. They have been extensively hunted for their skins, and are now extremely rare. (Species *Gavialis gangeticus*.)

gayal species of ox found in the highland regions of east India and Burma. The animal is often found wild, but just as frequently in a

semi-domesticated condition. It is smaller than the gaur, and its horns are much straighter.

The gayal and the gaur frequently interbreed.

classification The gayal *Bos frontalis* is in family Bovidae (cattle and antelopes) of order Artiodactyla.

Gay-Lussac, Joseph Louis (1778–1850)

French physicist and chemist who investigated the physical properties of gases, and discovered new methods of producing sulphuric and oxalic acids. In 1802 he discovered the approximate rule for the expansion of gases now known as Charles's law; see also gas laws.

gazelle any of a number of lightly built, fast-running antelopes found on the open plains of Africa and southern Asia. (Especially species of the genus *Gazella*.)

gear toothed wheel that transmits the turning movement of one shaft to another shaft. Gear wheels may be used in pairs, or in threes if both shafts are to turn in the same direction. The gear ratio – the ratio of the number of teeth on the two wheels – determines the torque ratio, the turning force on the output shaft compared with the turning force on the input shaft. The ratio of the angular velocities of the shafts is the inverse of the gear ratio.

The common type of gear for parallel shafts is the spur gear, with straight teeth parallel to the shaft axis. The helical gear has teeth cut along sections of a helix or corkscrew shape; the double form of the helix gear is the most efficient for energy transfer. Bevel gears, with tapering teeth set on the base of a cone, are used to connect intersecting shafts.

gecko any of a group of lizards. Geckos are common worldwide in warm climates, and have large heads and short, stout bodies. Many have no eyelids. Their sticky toe pads enable them to climb vertically and walk upside down on smooth surfaces in their search for flies, spiders, and other prey. (Family Gekkonidae.)

There are about 850 known species of gecko. There are 102 Australian species, 17 new species having been discovered there

GECKO

One species of Hawaiian gecko reproduces without sex to create all-female populations. These females have fewer parasites (and thus better health) than their mixed-gender neighbours.

1986–96. A new species of gecko *Tarentola mindiae* was identified in Egypt's Western Desert in 1997.

geebung Australian shrub or tree of the genus *Persoonia* of the Proteaceae family with small bell-shaped cream or yellow flowers.

geek in computing, stereotypical exceptionally bright, obsessive computer user or programmer. See also *canorak* and *nerd*.

Geiger, Hans (Wilhelm) (1882–1945)

German physicist who produced the Geiger counter. He spent the period 1906–12 in Manchester, England, working with Ernest Rutherford on radioactivity. In 1908 they designed an instrument to detect and count alpha particles, positively charged ionizing particles produced by radioactive decay.

In 1928 Geiger and Walther Müller produced a more sensitive version of the counter, which could detect all kinds of ionizing radiation.

Geiger counter any of a number of devices used for detecting nuclear radiation and/or measuring its intensity by counting the number of ionizing particles produced (see *radioactivity*). It detects the momentary current that passes between electrodes in a suitable gas when a nuclear particle or a radiation pulse causes the ionization of that gas. The electrodes are connected to electronic devices that enable the number of particles passing to be measured. The increased frequency of measured particles indicates the intensity of radiation. The device is named after the German physicist Hans Geiger.

The Geiger–Müller, Geiger–Klempner, and Rutherford–Geiger counters are all devices often referred to loosely as Geiger counters.

Geissler tube high-voltage discharge tube in which traces of gas ionize and conduct electricity. Since the electrified gas takes on a luminous colour characteristic of the gas, the instrument is also used in spectroscopy. It was developed in 1858 by the German physicist Heinrich Geissler.

gel solid produced by the formation of a three-dimensional cage structure, commonly of linked large-molecular-mass polymers, in which a liquid is trapped. It is a form of colloid. A gel may be a jelly-like mass (pectin, gelatin) or have a more rigid structure (silica gel).

gelignite type of dynamite.

gem mineral valuable by virtue of its durability (hardness), rarity, and beauty, cut and polished for ornamental use, or engraved. Of 120 minerals known to have been used as gemstones, only about 25 are in common use in jewellery today; of these, the diamond, emerald, ruby, and sapphire are classified as precious, and all the others semiprecious; for example, the topaz, amethyst, opal, and aquamarine.

Among the synthetic precious stones to have been successfully produced are rubies, sapphires, emeralds, and diamonds (first produced by General Electric in the USA in 1955). Pearls are not technically gems.

Gemini prominent zodiacal constellation in the northern hemisphere represented as the twins Castor and Pollux. Its brightest star is α Pollux. Castor is a system of six stars. The Sun passes through Gemini from late June to late July. Each December, the Gemini meteors radiate from Gemini. In astrology, the dates for Gemini are between about 21 May and 21 June (see *precession*).

Gemini project US space programme (1965–66) in which astronauts practised rendezvous and docking of spacecraft, and working outside their spacecraft, in preparation for the Apollo Moon landings.

Gemini spacecraft carried two astronauts and were launched by Titan rockets.

gemma (plural *gemmae*) unit of vegetative reproduction, consisting of a small group of undifferentiated green cells. Gemmae are found in certain mosses and liverworts, forming on the surface of the plant, often in cup-shaped structures, or gemmae cups. Gemmae are dispersed by splashes of rain and can then develop into new plants. In many species, gemmation is more common than reproduction by spores.

gembok species of antelope that inhabits the desert regions of southern Africa. It stands about 1.2 m/4 ft in height, and its general colour is greyish. Its horns are just over 1 m/3.3 ft long.

classification The gembok *Oryx gazella* is in family Bovidae, order Artiodactyla.

gene unit of inherited material, encoded by a strand of ϕ DNA and transcribed by ϕ RNA. In higher organisms, genes are located on the ϕ chromosomes. A gene consistently affects a particular character in an individual – for example, the gene for eye colour. Also termed a Mendelian gene, after Austrian biologist Gregor ϕ Mendel, it occurs at a particular point, or locus, on a particular chromosome and may have several variants, or alleles, each specifying a particular form of that character – for example, the alleles for blue or brown eyes. Some alleles show dominance. These mask the effect of other alleles, known as recessive.

In the 1940s, it was established that a gene could be identified with a particular length of DNA, which coded for a complete protein molecule, leading to the 'one gene, one enzyme' principle. Later it was realized that proteins can be made up of several polypeptide chains, each with a separate gene, so this principle was modified to 'one gene, one polypeptide'. However, the fundamental idea remains the same, that genes produce their visible effects simply by coding for proteins; they control the structure of those proteins via the genetic code, as well as the amounts produced and the timing of production.

In modern genetics, the gene is identified either with the ϕ cistron (a set of ϕ codons that determines a complete polypeptide) or with the unit of selection (a Mendelian gene that determines a particular character in the organism on which natural selection can act). Genes undergo mutation and recombination to produce the variation on which natural selection operates.

We are survival machines – robot vehicles blindly programmed to preserve the selfish molecules known as genes. This is a truth which still fills me with astonishment.

RICHARD DAWKINS English zoologist.
The Selfish Gene Preface

gene amplification technique by which selected DNA from a single cell can be duplicated indefinitely until there is a sufficient amount to analyse by conventional genetic techniques.

Gene amplification uses a procedure called the polymerase chain reaction. The sample of DNA is mixed with a solution of enzymes called polymerases, which enable it to replicate, and with a plentiful supply of nucleotides, the building blocks of DNA. The mixture is repeatedly heated and cooled. At each warming, the double-stranded DNA present separates into two single strands, and with each cooling the polymerase assembles a new paired strand for each single strand. Each cycle takes approximately 30 minutes to complete, so that after 10 hours there is one million times more DNA present than at the start.

The technique has been used to analyse DNA from a man who died in 1959, showing the presence of sequences from the HIV virus in his cells. It can also be used to test for genetic defects in a single cell taken from an embryo, before the embryo is reimplanted in *in vitro* fertilization.

gene bank collection of seeds or other forms of genetic material, such as tubers, spores, bacterial or yeast cultures, live animals and

plants, frozen sperm and eggs, or frozen embryos. These are stored for possible future use in agriculture, plant and animal breeding, or in medicine, genetic engineering, or the restocking of wild habitats where species have become extinct. Gene banks will be increasingly used as the rate of extinction increases, depleting the Earth's genetic variety (biodiversity).

gene imprinting genetic phenomenon whereby a small number of genes function differently depending on whether they were inherited from the father or the mother. If two copies of an imprinted gene are inherited from one parent and none from the other, a genetic abnormality results, whereas no abnormality occurs if, as is normal, a copy is inherited from both parents. Gene imprinting is known to play a part in a number of genetic disorders and childhood diseases, for example, the Prader-Willi syndrome (characterized by mild mental retardation and compulsive eating).

gene pool total sum of alleles (variants of genes) possessed by all the members of a given population or species alive at a particular time.

General Electric US electrical and electronics company founded in 1878 in New Jersey as the Edison Electric Light Company to back the experiments of the inventor Thomas Edison. In 1892 the company merged with a competitor to form General Electric. Its headquarters are in Fairfield, Connecticut.

generate in mathematics, to produce a sequence of numbers from either the relationship between one number and the next or the relationship between a member of the sequence and its position. For example, $un+1 = 2un$ generates the sequence 1, 2, 4, 8, ...; $an = n(n+1)$ generates the sequence of numbers 2, 6, 12, 20, ...

generation in computing, stage of development in computer electronics (see computer generation) or a class of programming language (see fourth-generation language).

generator machine that produces electrical energy from mechanical energy, as opposed to an electric motor, which does the opposite. A simple generator (dynamo) consists of a wire-wound coil (armature) that is rotated between the poles of a permanent magnet. The movement of the wire in the magnetic field induces a current in the coil by electromagnetic induction, which can be fed by means of a commutator as a continuous direct current into an external circuit. Slip rings instead of a commutator produce an alternating current, when the generator is called an alternator.

genet any of several small, nocturnal, carnivorous mammals belonging to the mongoose and civet family. Most species live in Africa, but *G. genet* is also found in Europe and the Middle East. It is about 50 cm/1.6 ft long with a 45 cm/1.5 ft tail, and greyish yellow in colour with rows of black spots. It is a good climber. (Genus *Genetta*, family Viverridae.)

gene therapy medical technique for curing or alleviating inherited diseases or defects; certain infections, and several kinds of cancer in which affected cells from a sufferer would be removed from the body, the cDNA repaired in the laboratory (genetic engineering), and the functioning cells reintroduced. In 1990 a genetically engineered gene was used for the first time to treat a patient.

The first human being to undergo gene therapy, in 1990, was one of the so-called 'bubble babies' - a four-year-old American girl suffering from a rare enzyme (ADA) deficiency that cripples the immune system. Unable to fight off infection, such children are nursed in a germ-free bubble; they usually die in early childhood.

Cystic fibrosis is the commonest inherited disorder and the one most keenly targeted by genetic engineers; it has been pioneered in patients in the USA and UK. Gene therapy is not the final answer to inherited disease; it may cure the patient but it cannot prevent him

or her from passing on the genetic defect to any children. However, it does hold out the promise of a cure for various other conditions, including heart disease and some cancers; US researchers have successfully used a gene gun to target specific tumour cells. In 1995 tumour growth was halted in mice when DNA-coated gold bullets were fired into tumour cells.

By the end of 1995, although 600 people had been treated with gene therapy, nobody had actually been cured. Even in the ADA trials, the most successful to date, the children were still receiving injections of synthetic ADA, possibly the major factor in their improvement.

genetic code the way in which instructions for building proteins, the basic structural molecules of living matter, are 'written' in the genetic material cDNA. This relationship between the sequence of bases (the subunits in a DNA molecule) and the sequence of amino acids (the subunits of a protein molecule) is the basis of heredity. The code employs codons of three bases each; it is the same in almost all organisms, except for a few minor differences recently discovered in some protozoa.

Only 2% of DNA is made up of base sequences, called exons, that code for proteins. The remaining DNA is known as 'junk' DNA or introns.

genetic disease any disorder caused at least partly by defective genes or chromosomes. In humans there are some 3,000 genetic diseases, including cystic fibrosis, Down's syndrome, haemophilia, Huntington's chorea, some forms of anaemia, spina bifida, and Tay-Sachs disease.

genetic engineering deliberate manipulation of genetic material by biochemical techniques. It is often achieved by the introduction of new cDNA, usually by means of a virus or plasmid. This can be for pure research, cDNA therapy, or to breed functionally specific plants, animals, or bacteria. These organisms with a foreign gene added are said to be transgenic (see transgenic organism). At the beginning of 1995 more than 60 plant species had been genetically engineered, and nearly 3,000 transgenic crops had been field-tested.

practical uses In genetic engineering, the splicing and recombination of genes is used to increase knowledge of cell function and reproduction, but it can also achieve practical ends. For example, plants grown for food could be given the ability to fix nitrogen, found in some bacteria, and so reduce the need for expensive fertilizers, or simple bacteria may be modified to produce rare drugs. A foreign gene can be inserted into laboratory cultures of bacteria to generate commercial biological products, such as synthetic insulin, hepatitis-B vaccine, and interferon. Gene splicing was invented in 1973 by the US scientists Stanley Cohen and Herbert Boyer, and patented in the USA in 1984.

new developments Developments in genetic engineering have led to the production of growth hormone, and a number of other bone-marrow stimulating hormones. New strains of animals have also been produced; a new strain of mouse was patented in the USA in 1989 (the application was rejected in the European Patent Office). A vaccine against a sheep parasite (a larval tapeworm) has been developed by genetic engineering; most existing vaccines protect against bacteria and viruses.

The first genetically engineered food went on sale in 1994; the 'Flavr Savr' tomato, produced by the US biotechnology company Calgene, was available in California and Chicago.

safety measures There is a risk that when transplanting genes between different types of bacteria (*Escherichia coli*, which lives in the human intestine, is often used) new and harmful strains might be produced. For this reason strict safety precautions are observed, and the altered bacteria are disabled in some way so they are unable to exist outside the laboratory.

genetic fingerprinting or **genetic profiling** technique used for determining the pattern of certain parts of the genetic material cDNA that is unique to each individual. Like conventional fingerprinting, it can accurately distinguish humans from one another, with the exception of identical siblings from multiple births. It can be applied to as little material as a single cell.

Genetic fingerprinting involves isolating DNA from cells, then comparing and contrasting the sequences of component chemicals between individuals. The DNA pattern can be ascertained from a sample of skin, hair, or semen. Although differences are minimal (only 0.1% between unrelated people), certain regions of DNA, known as hypervariable regions, are unique to individuals.

genetics branch of biology concerned with the study of heredity and variation; it attempts to explain how characteristics of living organisms are passed on from one generation to the next. The science of genetics is based on the work of Austrian biologist Gregor Mendel whose experiments with the cross-breeding (hybridization) of peas showed that the inheritance of characteristics and traits takes place by means of discrete 'particles' (genes). These are present in the cells of all organisms, and are now recognized as being the basic units of heredity. All organisms possess genotypes (sets of variable genes) and phenotypes (characteristics produced by certain genes). Modern geneticists investigate the structure, function, and transmission of genes.

Before the publication of Mendel's work in 1865, it had been assumed that the characteristics of both parents were blended during inheritance, but Mendel showed that the genes remain intact, although their combinations change. As a result of his experiments with the cultivation of the common garden pea, Mendel introduced the concept of hybridization (see monohybrid inheritance). Since Mendel, the study of genetics has advanced greatly, first through breeding experiments and light-microscope observations (classical genetics), later by means of biochemical and electron microscope studies (molecular genetics).

In 1944, Canadian-born bacteriologist Oswald Avery, together with his colleagues at the Rockefeller Institute, Colin MacLeod and Maclyn McCarty, showed that the genetic material was deoxyribonucleic acid (DNA), and not protein as was previously thought. A further breakthrough was made in 1953 when James Watson and Francis Crick published their molecular model for the structure of DNA, the double helix, based on X-ray diffraction photographs. The following decade saw the cracking of the genetic code. The genetic code is said to be universal since the same code applies to all organisms from bacteria and viruses to higher plants and animals, including humans. Today the deliberate manipulation of genes by biochemical techniques, or genetic engineering, is commonplace.

genetic screening in medicine, the determination of the genetic make-up of an individual to determine if he or she is at risk of developing a hereditary disease later in life. Genetic screening can also be used to determine if an individual is a carrier for a particular genetic disease and, hence, can pass the disease on to any children. Genetic counselling should be undertaken at the same time as genetic screening of affected individuals. Diseases that can be screened for include cystic fibrosis, Huntington's chorea, and certain forms of cancer.

genitalia reproductive organs of sexually reproducing animals, particularly the external/visible organs of mammals: in males, the penis and the scrotum, which contains the testes, and in females, the clitoris and vulva.

genome the full complement of genes carried by a single (haploid) set of chromosomes. The term may be applied to the genetic information carried by an individual or to the range of genes found in a given species. The human genome is made up of 75,000 genes.

The first fully decoded genome in a life domain to which humans belong was announced in 1997. Scientists completed a genetic blueprint for *Saccharomyces cerevisiae*, common brewer's yeast, which shares a high number with genetic sequences

with humans. The scientists produced a map of all the yeast's genes and the full genetic coding. Genomes have been identified for seven organisms, including the bacteria *Haemophilus influenzae* and *Escherichia coli*, and the mycoplasmas *Mycoplasma genitalium* and *Mycoplasma pneumoniae*.

We are built to make mistakes, coded for error.

genotype the particular set of alleles (variants of genes) possessed by a given organism. The term is usually used in conjunction with phenotype, which is the product of the genotype and all environmental effects. See also nature-nurture controversy.

genus (plural *genera*) group of species with many characteristics in common.

Thus all doglike species (including dogs, wolves, and jackals) belong to the genus *Canis* (Latin 'dog').

Species of the same genus are thought to be descended from a common ancestor species. Related genera are grouped into families.

geochemistry science of chemistry as it applies to geology. It deals with the relative and absolute abundances of the chemical elements and their isotopes in the Earth, and also with the chemical changes that accompany geologic processes.

geochronology the branch of geology that deals with the dating of the Earth by studying its rocks and contained fossils. The geochronological time chart is a result of these studies. Absolute dating methods involve the measurement of radioactive decay over time in certain chemical elements found in rocks, whereas relative dating methods establish the sequence of deposition of various rock layers by identifying and comparing their contained fossils.

geode in geology, a subspherical cavity into which crystals have grown from the outer wall into the centre. Geodes often contain very well-formed crystals of quartz (including amethyst), calcite, or other minerals.

geodesic dome hemispherical dome, a type of space-frame, whose surface is formed out of short rods arranged in triangles. The rods lie on geodesics (the shortest lines joining two points on a curved surface). This type of dome allows large spaces to be enclosed using the minimum of materials, and was patented by US engineer Buckminster Fuller in 1954.

geodesy methods of surveying the Earth for making maps and correlating geological, gravitational, and magnetic measurements. Geodesic surveys, formerly carried out by means of various measuring techniques on the surface, are now commonly made by using radio signals and laser beams from orbiting satellites (see global positioning system).

geographical information system (GIS) computer software that makes possible the visualization and manipulation of spatial data, and links such data with other information such as customer records.

geography the study of the Earth's surface; its topography, climate, and physical conditions, and how these factors affect people and society. It is usually divided into physical geography, dealing with landforms and climates, and human geography, dealing with the distribution and activities of peoples on Earth.

history Early preclassical geographers concentrated on map-making, surveying, and exploring. In classical Greece theoretical ideas first became a characteristic of geography. Aristotle and Pythagoras believed the Earth to be a sphere, Eratosthenes was the first to calculate the circumference of the world, and Herodotus investigated the origin of the Nile floods and the relationship between climate and human behaviour.

During the medieval period the study of geography progressed

little in Europe, but the Muslim world retained much of the Greek tradition, embellishing the 2nd-century maps of Ptolemy. During the early Renaissance the role of the geographer as an explorer and surveyor became important once again.

The foundation of modern geography as an academic subject stems from the writings of Friedrich Humboldt and Johann Ritter, in the late 18th and early 19th centuries, who for the first time defined geography as a major branch of scientific inquiry.

geological time time scale embracing the history of the Earth from its physical origin to the present day. Geological time is traditionally divided into eons (Archaean or Archaeozoic, Proterozoic, and Phanerozoic in ascending chronological order), which in turn are subdivided into eras, periods, epochs, ages, and finally chronons.

The terms eon, era, period, epoch, age and chron are geochronological units representing intervals of geological time. Rocks representing an interval of geological time comprise a **chronostratigraphic unit**. Each of the hierarchical geochronological terms has a chronostratigraphic equivalent. Thus, rocks formed during an eon (a geochronological unit) are members of an eonothem (the chronostratigraphic unit equivalent of eon). Rocks of an era belong to an erathem. The chronostratigraphic equivalents of period, epoch, age, and chron are system, series, stage, and chronozone, respectively.

Having in the natural history of this earth, seen a succession of worlds, we may conclude that there is a system in nature. ... The result, therefore of our present enquiry is, that we find no vestige of a beginning - no prospect of an end.

geology science of the Earth, its origin, composition, structure, and history. It is divided into several branches: **mineralogy** (the minerals of Earth), **petrology** (rocks), **stratigraphy** (the deposition of successive beds of sedimentary rocks), **palaeontology** (fossils), and **tectonics** (the deformation and movement of the Earth's crust).

Geology is regarded as part of earth science, a more widely embracing subject that brings in meteorology, oceanography, geophysics, and geochemistry.

geomagnetic reversal another term for **ölpolar reversal**.

geometric mean in mathematics, the n th root of the product of n positive numbers. The geometric mean m of two numbers p and q is such that $m = \sqrt[n]{p \times q}$. For example, the mean of 2 and 8 is $\sqrt[2]{2 \times 8} = \sqrt{16} = 4$.

geometric progression or **geometric sequence** in mathematics, a sequence of terms (progression) in which each term is a constant multiple (called the common ratio) of the one preceding it. For example, 3, 12, 48, 192, 768, ... is a geometric progression with a common ratio 4, since each term is equal to the previous term multiplied by 4. Compare **arithmetic progression**.

The sum of n terms of a geometric series

$$1 + r + r^2 + r^3 + \dots + r^{n-1}$$

is given by the formula

$$S_n = (1 - r^n)/(1 - r)$$

for all $r \neq 1$. For $r = 1$, the geometric series can be summed to infinity:

$$S_\infty = 1/(1 - r).$$

In nature, many single-celled organisms reproduce by splitting in two so that one cell gives rise to 2, then 4, then 8 cells, and so on, forming a geometric sequence 1, 2, 4, 8, 16, 32, ..., in which the common ratio is 2.

geometric tortoise South African tortoise *Psammobates geometricus* which grows to only 10–12 cm/4–5 in in length. It is acutely threatened by the loss of its habitat, which has shrunk to just 4% of the reptile's original range. Remaining areas are mainly fragmented and have been invaded by alien plant species that the tortoise is unable to eat.

geometry branch of mathematics concerned with the properties of space, usually in terms of plane (two-dimensional) and solid (three-dimensional) figures. The subject is usually divided into pure geometry, which embraces roughly the plane and solid geometry dealt with in Greek mathematician Euclid's *Stoicheia*/*Elements*, and analytical or coordinate geometry, in which problems are solved using algebraic methods. A third, quite distinct, type includes the non-Euclidean geometries.

pure geometry This is chiefly concerned with properties of figures that can be measured, such as lengths, areas, and angles and is therefore of great practical use. An important idea in Euclidean geometry is the idea of congruence. Two figures are said to be congruent if they have the same shape and size (and area). If one figure is imagined as a rigid object that can be picked up, moved and placed on top of the other so that they exactly coincide, then the two figures are congruent. Some simple rules about congruence may be stated: two line segments are congruent if they are of equal length; two triangles are congruent if their corresponding sides are equal in length or if two sides and an angle in one is equal to those in the other; two circles are congruent if they have the same radius; two polygons are congruent if they can be divided into congruent triangles assembled in the same order.

The idea of picking up a rigid object to test congruence can be expressed more precisely in terms of elementary 'movements' of figures: a translation (or glide) in which all points move the same distance in the same direction (that is, along parallel lines); a rotation through a defined angle about a fixed point; a reflection (equivalent to turning the figure over).

Two figures are congruent to each other if one can be transformed into the other by a sequence of these elementary movements. In Euclidean geometry a fourth kind of movement is also studied; this is the enlargement in which a figure grows or shrinks in all directions by a uniform scale factor. If one figure can be transformed into another by a combination of translation, rotation, reflection, and enlargement then the two are said to be similar. All circles are similar. All squares are similar. Triangles are similar if corresponding angles are equal.

coordinate geometry A system of geometry in which points, lines, shapes, and surfaces are represented by algebraic expressions. In plane (two-dimensional) coordinate geometry, the plane

is usually defined by two axes at right angles to each other, the horizontal x -axis and the vertical y -axis, meeting at 0, the origin. A point on the plane can be represented by a pair of Cartesian coordinates, which define its position in terms of its distance along the x -axis and along the y -axis from 0. These distances are respectively the x and y coordinates of the point.

Lines are represented as equations; for example, $y = 2x + 1$ gives a straight line, and $y = 3x^2 + 2x$ gives a parabola (a curve). The graphs of varying equations can be drawn by plotting the coordinates of points that satisfy their equations, and joining up the points. One of the advantages of coordinate geometry is that geometrical solutions can be obtained without drawing but by manipulating algebraic expressions. For example, the coordinates of the point of intersection of two straight lines can be determined by finding the unique values of x and y that satisfy both of the equations for the lines, that is, by solving them as a pair of simultaneous equations. The curves studied in simple coordinate geometry are the conic sections (circle, ellipse, parabola, and hyperbola), each of which has a characteristic equation.

Geometry probably originated in ancient Egypt, in land measurements necessitated by the periodic inundations of the river Nile, and was soon extended into surveying and navigation. Early geometers were the Greek mathematicians Thales, Pythagoras, and Euclid. Analytical methods were introduced and developed by the French philosopher René Descartes in the 17th century. From the 19th century, various non-Euclidean geometries were devised by Carl Friedrich Gauss, János Bolyai, and Nikolai Lobachevsky. These were later generalized by Bernhard Riemann and found to have applications in the theory of relativity.

geomorphology branch of geology that deals with the nature and origin of surface landforms such as mountains, valleys, plains, and plateaus.

geophagy eating soil. It is a practice found in many animal species but the reasons for geophagy are poorly understood. Canadian and Japanese researchers established 1996, that chimpanzees eat earth containing clay minerals to combat diarrhoea and other digestive ailments. Other primates are also thought to eat earth for health reasons.

geophysics branch of earth science using physics to study the Earth's surface, interior, and atmosphere. Studies also include winds, weather, tides, earthquakes, volcanoes, and their effects.

geostationary orbit circular path 35,900 km/22,300 mi above the Earth's Equator on which a satellite takes 24 hours, moving from west to east, to complete an orbit, thus appearing to hang stationary over one place on the Earth's surface. Geostationary orbits are used particularly for communications satellites and weather satellites. They were first thought of by the author Arthur C. Clarke. A geosynchronous orbit lies at the same distance from Earth but is inclined to the Equator.

geothermal energy energy extracted for heating and electricity generation from natural steam, hot water, or hot dry rocks in the Earth's crust. Water is pumped down through an injection well where it passes through joints in the hot rocks. It rises to the surface through a recovery well and may be converted to steam or run through a heat exchanger. Dry steam may be directed through turbines to produce electricity. It is an important source of energy in volcanically active areas such as Iceland and New Zealand.

geothermal energy Geothermal energy is derived from the natural heat present below the surface of the Earth. Cool water is pumped down where it is heated up in large underground reservoirs before being pumped back to the surface.

geranium any of a group of plants either having divided leaves and white, pink, or purple flowers (geraniums), or having a hairy stem, and white, pink, red, or black-purple flowers (pelargoniums). Some geraniums are also called cranesbills. (Genera *Geranium* and *Pelargonium*, family Geraniaceae.)

gerbil any of numerous rodents with elongated back legs, good at hopping or jumping. Gerbils range from mouse- to rat-size, and have hairy tails. Many of the 13 genera live in dry, sandy, or sparsely vegetated areas of Africa and Asia. (Family Cricetidae.)

The Mongolian jird or gerbil (*Meriones unguiculatus*) is a popular pet.

geriatrics medical speciality concerned with diseases and problems of the elderly.

germ colloquial term for a microorganism that causes disease, such as certain bacteria and viruses. Formerly, it was also used to mean something capable of developing into a complete organism (such as a fertilized egg, or the embryo of a seed).

germanium brittle, grey-white, weakly metallic (metalloid) element, symbol Ge, atomic number 32, relative atomic mass 72.6. It belongs to the silicon group, and has chemical and physical properties between those of silicon and tin. Germanium is a semiconductor material and is used in the manufacture of transistors and integrated circuits. The oxide is transparent to infrared radiation, and is used in military applications. It was discovered in 1886 by German chemist Clemens Winkler (1838–1904).

In parts of Asia, germanium and plants containing it are used to treat a variety of diseases, and it is sold in the West as a food supplement despite fears that it may cause kidney damage.

German measles or **rubella** mild, communicable virus disease, usually caught by children. It is marked by a sore throat, pinkish rash, and slight fever, and has an incubation period of two to three weeks. If a woman contracts it in the first three months of pregnancy, it may cause serious damage to the unborn child.

German shepherd or **Alsatian** breed of dog. It is about 63 cm/25 in tall and has a wolflike appearance, a thick coat with many varieties of colouring, and a distinctive way of moving. German shepherds are used as police dogs because of their courage and intelligence.

They were introduced from Germany into Britain and the USA after World War I.

German silver or **nickel silver** silvery alloy of nickel, copper, and zinc. It is widely used for cheap jewellery and the base metal for silver plating. The letters EPNS on silverware stand for electroplated nickel silver.

germination in botany, the initial stages of growth in a seed, spore, or pollen grain. Seeds germinate when they are exposed to favourable external conditions of moisture, light, and temperature, and when any factors causing dormancy have been removed.

The process begins with the uptake of water by the seed. The embryonic root, or radicle, is normally the first organ to emerge, followed by the embryonic shoot, or plumule. Food reserves, either within the endosperm or from the cotyledons, are broken down to nourish the rapidly growing seedling. Germination is considered to have ended with the production of the first true leaves.

germ layer in embryology, a layer of cells that can be distinguished during the development of a fertilized egg. Most animals

have three such layers: the inner, middle, and outer. These differentiate to form the various body tissues.

The inner layer (endoderm) gives rise to the gut, the middle one (mesoderm) develops into most of the other organs, while the outer one (ectoderm) gives rise to the skin and nervous system. Simple animals, such as sponges, lack a mesoderm.

germ-line therapy hypothetical application of gene therapy to sperm and egg cells to remove the risk of an inherited disease being passed to offspring. It is controversial because of the fear it will be used to produce 'designer babies', and may result in unforeseen side effects.

Gestalt *German 'form'* concept of a unified whole that is greater than, or different from, the sum of its parts; that is, a complete structure whose nature is not explained simply by analysing its constituent elements. A chair, for example, will generally be recognized as a chair despite great variations between individual chairs in such attributes as size, shape, and colour.

Gestalt psychology regards all mental phenomena as being arranged in organized, structured wholes, as opposed to being composed of simple sensations. For example, learning is seen as a reorganizing of a whole situation (often involving insight), as opposed to the behaviourists' view that it consists of associations between stimuli and responses. Gestalt psychologists' experiments show that the brain is not a passive receiver of information, but that it structures all its input in order to make sense of it, a belief that is now generally accepted; however, other principles of Gestalt psychology have received considerable criticism.

The term 'Gestalt' was first used in psychology by the Austrian philosopher and psychologist Christian von Ehrenfels in 1890. Max Wertheimer, Wolfgang Köhler, and Kurt Koffka (1886–1941) were founders of Gestalt psychology.

gestation in all mammals except the monotremes (platypus and spiny anteaters), the period from the time of implantation of the embryo in the uterus to birth. This period varies among species; in humans it is about 266 days, in elephants 18–22 months, in cats about 60 days, and in some species of marsupial (such as opossum) as short as 12 days.

gesture recognition in computing, technique whereby a computer accepts human gestures transmitted via hardware such as a DataGlove as meaningful input to which it can respond. Gesture recognition is a key technology needed in the development of virtual reality systems if they are to allow humans to interact fully and naturally with objects in computerized worlds.

geyser natural spring that intermittently discharges an explosive column of steam and hot water into the air due to the build-up of steam in underground chambers. One of the most remarkable geysers is Old Faithful, in Yellowstone National Park, Wyoming, USA. Geysers also occur in New Zealand and Iceland.

g-force force that pilots and astronauts experience when their craft accelerate or decelerate rapidly. One *g* is the ordinary pull of gravity.

Early astronauts were subjected to launch and reentry forces of up to six *g* or more; in the space shuttle, more than three *g* is experienced on liftoff. Pilots and astronauts wear *g*-suits that prevent their blood pooling too much under severe *g*-forces, which can lead to unconsciousness.

gibberellin plant growth substance (see also *auxin*) that promotes stem growth and may also affect the breaking of dormancy in certain buds and seeds, and the induction of flowering. Application of gibberellin can stimulate the stems of dwarf plants to additional growth, delay the ageing process in leaves, and promote the production of seedless fruit (*parthenocarp*).

gibbon any of a group of several small southern Asian apes. The common or *lar gibbon* (*H. lar*) is about 60 cm/2 ft tall, with a body that is hairy except for the buttocks, which distinguishes it from other types of apes. Gibbons have long arms and no tail. They spend most of their time in trees and are very agile when swinging from branch to branch. On the ground they walk upright, and are more easily caught by predators. (Genus *Hylobates*, including the subgenus *Symphalangus*.)

The siamang (*S. syndactylus*) is the largest of the gibbons, growing to 90 cm/36 in tall; it is entirely black. Gibbons are found from Assam through the Malay peninsula to Borneo, but are becoming rare, with certain species classified as endangered.

Gibbs's function in ϕ thermodynamics, an expression representing part of the energy content of a system that is available to do external work, also known as the free energy *G*. In an equilibrium system at constant temperature and pressure, $G = H - TS$, where *H* is the enthalpy (heat content), *T* the temperature, and *S* the ϕ entropy (decrease in energy availability). The function was named after US physicist Josiah Willard Gibbs.

Giganotosaurus carolinii carnivorous dinosaur of the ϕ Cretaceous period. They weighed 6–8 tonnes and were about 12.5 m/40 ft in length, making them the largest predators ever to walk the Earth. *Giganotosaurus* lived in Patagonia about 97 million years ago. Argentinian palaeontologists discovered about 70% of its skeleton in 1995.

GIGO (acronym for *garbage in, garbage out*) expression used in computing to emphasize that inaccurate input data will result in inaccurate output data.

GII abbreviation for the ϕ Global Information Infrastructure.

gila monster lizard native to the southwestern USA and Mexico. It is one of the only two existing venomous lizards, the other being the Mexican bearded lizard of the same genus. It has poison glands in its lower jaw, but its bite is not usually fatal to humans. (Species *Heloderma suspectum*.)

gill in biology, the main respiratory organ of most fishes and immature amphibians, and of many aquatic invertebrates. In all types, water passes over the gills, and oxygen diffuses across the gill membranes into the circulatory system, while carbon dioxide passes from the system out into the water.

In aquatic insects, these gases diffuse into and out of air-filled canals called tracheae.

gill imperial unit of volume for liquid measure, equal to one-quarter of a pint or 5 fluid ounces (0.142 litre). It is used in selling alcoholic drinks.

In S England it is also called a nogg, but in N England the large nogg is used, which is two gills.

gillyflower old name for the ϕ arnation and related plants, used in the works of Chaucer, Shakespeare, and Spenser.

giraffe world's tallest mammal. It stands over 5.5 m/18 ft tall, the neck accounting for nearly half this amount. The giraffe has two to four small, skin-covered, hornlike structures on its head and a long, tufted tail. The fur has a mottled appearance and is reddish brown and cream. Giraffes are found only in Africa, south of the Sahara Desert. They eat leaves and vegetation that is out of reach of smaller mammals, and are ruminants; that is, they chew the cud. (Species *Giraffa camelopardalis*, family Giraffidae.)

gizzard muscular grinding organ of the digestive tract, below the ϕ crop of birds, earthworms, and some insects, and forming part of the ϕ stomach. The gizzard of birds is lined with a hardened horny layer of the protein keratin, preventing damage to the muscle layer during the grinding process. Most birds swallow sharp grit which aids maceration of food in the gizzard.

glacial trough or *U-shaped valley* steep-sided, flat-bottomed valley formed by a glacier. The erosive action of the glacier and of the debris carried by it results in the formation not only of the trough itself but also of a number of associated features, such as truncated spurs (projections of rock that have been sheared off by the ice) and hanging valleys (smaller glacial valleys that enter the trough at a higher level than the trough floor). Features characteristic of glacial deposition, such as drumlins and eskers, are commonly found on the floor of the trough, together with linear lakes called ribbon lakes.

glacial deposition A glacier picks up large boulders and rock debris from the valley and deposits them at the snout of the glacier when the ice melts. Some deposited material is carried great distances by the ice to form erratics.

glacier tongue of ice, originating in mountains in snowfields above the snowline, which moves slowly downhill and is constantly replenished from its source. The geographic features produced by the erosive action of glaciers are characteristic and include glacial troughs (U-shaped valleys), cirques, and arêtes. In lowlands, the laying down of moraine (rocky debris once carried by glaciers) produces a variety of landscape features.

Glaciers form where annual snowfall exceeds annual melting and drainage. The snow compacts to ice under the weight of the layers above.

Under pressure the ice moves plastically (changing its shape permanently). When a glacier moves over an uneven surface, deep crevasses are formed in rigid upper layers of the ice mass; if it reaches the sea or a lake, it breaks up to form icebergs. A glacier that is formed by one or several valley glaciers at the base of a mountain is called a piedmont glacier. A body of ice that covers a large land surface or continent, for example Greenland or Antarctica, and flows outward in all directions is called an ice sheet.

In Oct 1996 a volcano erupted under Europe's largest glacier, Vatnajökull in Iceland, causing flooding.

gladiolus any plant of a group of southern European and African cultivated perennials belonging to the iris family, with brightly coloured funnel-shaped flowers borne on a spike; the swordlike leaves spring from a corm (swollen underground stem). (Genus *Gladiolus*, family Iridaceae.)

gland specialized organ of the body that manufactures and secretes enzymes, hormones, or other chemicals. In animals, glands vary in size from small (for example, tear glands) to large (for example, the pancreas), but in plants they are always small, and may consist of a single cell. Some glands discharge their products internally, endocrine glands, and others, exocrine glands, externally. Lymph nodes are sometimes wrongly called glands.

glandular fever or **infectious mononucleosis** viral disease characterized at onset by fever and painfully swollen lymph nodes; there may also be digestive upset, sore throat, and skin rashes. Lassitude persists for months and even years, and recovery can be slow. It is caused by the Epstein-Barr virus.

glass transparent or translucent substance that is physically neither a solid nor a liquid. Although glass is easily shattered, it is one of the strongest substances known. It is made by fusing certain types of sand (silica); this fusion occurs naturally in volcanic glass (see obsidian).

In the industrial production of common types of glass, the type of sand used, the particular chemicals added to it (for example, lead, potassium, barium), and refinements of technique determine the type of glass produced. Types of glass include: soda glass; flint glass, used in cut-crystal ware; optical glass; stained glass; heat-resistant glass; and glasses that exclude certain ranges of the light spectrum. Blown glass is either blown individually from molten glass (using a tube up to 1.5 m/4.5 ft long), as in the making of expensive crafted glass, or blown automatically into a mould – for example, in the manufacture of light bulbs and bottles; pressed glass is simply pressed into moulds, for jam jars, cheap vases, and

light fittings; while sheet glass, for windows, is made by putting the molten glass through rollers to form a 'ribbon', or by floating molten glass on molten tin in the 'float glass' process; fiberglass is made from fine glass fibres. Metallic glass is produced by treating alloys so that they take on the properties of glass while retaining the malleability and conductivity characteristic of metals.

glass lizard another name for ocellular snake.

glass-reinforced plastic (GRP) a plastic material strengthened by glass fibres, sometimes erroneously called fiberglass. Glass-reinforced plastic is a favoured material for boat hulls and for the bodies and some structural components of high-performance cars and aircraft; it is also used in the manufacture of passenger cars.

Products are usually moulded, mats of glass fibre being sandwiched between layers of a polyester plastic, which sets hard when mixed with a curing agent.

glass snake or **glass lizard** any of a worldwide group of legless lizards. Their tails are up to three times the head-body length and are easily broken off. (Genus *Ophisaurus*, family Anguillidae.)

Glauber's salt crystalline sodium sulphate decahydrate $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, produced by the action of sulphuric acid on common salt. It melts at $87.8^\circ\text{F}/31^\circ\text{C}$; the latent heat stored as it solidifies makes it a convenient thermal energy store. It is used in medicine as a laxative.

glaucoma condition in which pressure inside the eye (intraocular pressure) is raised abnormally as excess fluid accumulates. It occurs when the normal outflow of fluid within the chamber of the eye (aqueous humour) is interrupted. As pressure rises, the optic nerve suffers irreversible damage, leading to a reduction in the field of vision and, ultimately, loss of eyesight.

The most common type, **chronic glaucoma**, usually affects people over the age of 40, when the trabecular meshwork (the filtering tissue at the margins of the eye) gradually becomes blocked and drainage slows down. The condition cannot be cured, but, in many cases, it is controlled by drug therapy. Laser treatment to the trabecular meshwork often improves drainage for a time; surgery to create an artificial channel for fluid to leave the eye offers more long-term relief. A tiny window may be cut in the iris during the same operation.

Acute glaucoma is a medical emergency. A precipitous rise in pressure occurs when the trabecular meshwork suddenly becomes occluded (blocked). This is treated surgically to remove the cause of the obstruction. Acute glaucoma is extremely painful. Treatment is required urgently since damage to the optic nerve begins within hours of onset.

Global Information Infrastructure (GII) in computing, planned worldwide high-bandwidth network. US vice president Al Gore proposed the GII in a 1994 speech to the International Telecommunications Union, saying that it would promote the functioning of democracy, help nations to cooperate with each other, and be the key to economic growth for national and international economies.

Global Network Navigator (GNN) in computing, subscription-based online service for the World Wide Web, pioneered by US book publishers O'Reilly & Associates and bought by America Online in 1995. Its Virtual Places software, released in 1996, allows users to interact with each other using avatars and live messages at any

Virtual Places-enabled site on the Web. GNN also offers news and resource listings.

global positioning system (GPS) US satellite-based navigation system, a network of 24 satellites in six orbits, each circling the Earth once every 24 hours. Each satellite sends out a continuous time signal, plus an identifying signal. To fix position, a user needs to be within range of four satellites, one to provide a reference signal and three to provide directional bearings. The user's receiver can then calculate the position from the difference in time between receiving the signals from each satellite.

The position of the receiver can be calculated to better than 0.5 m/1.6 ft, although only the US military can tap the full potential of the system. Other users can obtain a position to within 100 m/330 ft. This is accurate enough to be of use to boats, walkers, and motorists, and suitable receivers are on the market.

global variable in computing, a variable that can be accessed by any program instruction. See also local variable.

global warming an increase in average global temperature of approximately $1^\circ\text{F}/0.5^\circ\text{C}$ over the past century. Global temperature has been highly variable in Earth history and many fluctuations in global temperature have occurred in historical times, but this most recent episode of warming coincides with the spread of industrialization, prompting the hypothesis that it is the result of an accelerated greenhouse effect caused by atmospheric pollutants, especially carbon dioxide gas. Recent melting and collapse of the Larsen Ice Shelf, Antarctica, is a consequence of global warming. Melting of ice is expected to raise sea level in the coming decades.

Natural, perhaps chaotic, climatic variations have not been ruled out as the cause of the current global rise in temperature, but scientists are still assessing the likely influence of anthropogenic (human-made) pollutants. Assessing the impact of humankind on global climate is complicated by the natural variability on both geological and human time scales. The present episode of global warming has thus far still left England approximately 1°C cooler than during the peak of the so-called Medieval Warm Period (1000 to 1400 AD). The latter was part of a purely natural climatic fluctuation on a global scale. With respect to historical times, the interval between the Medieval Warm Period and the rise in temperatures we see today was unusually cold throughout the world.

In addition to a rise in average global temperature, global warming as caused seasonal variations to be more pronounced in recent decades. Examples are the most severe winter on record in the eastern US in 1976-77 and the record heat waves in the Netherlands and Denmark the following year.

A 1995 United Nations summit in Berlin agreed to take action to reduce gas emissions harmful to the environment. Delegates at the summit, from more than 120 countries, approved a two-year negotiating process aimed at setting specific targets and timetables for reducing nations' emissions of carbon dioxide and other greenhouse gases after the year 2000. The Kyoto Protocol of 1997 commits the world's industrialized countries to cut their annual emissions of harmful gases by 5.2% by 2012.

Global Positioning System

BY EDWARD YOUNG

Satellites

The Global Positioning System, or GPS, has become indispensable as a tool for navigation and scientific discovery. It relies on 24 satellites that can be accessed for accurate positioning by users all over the world. GPS is funded and controlled by the United States Department of Defense. Essential to the satellites are on-board atomic clocks accurate to 3 billionths of one second.

A Master Control site at Falcon Air Force Base in Colorado Springs, USA, sends data to each satellite. Ephemeris data consists of satellite positions. Almanac data consists of the projected orbits of each satellite and information about their overall status. Clock corrections are also transmitted as necessary. In turn the satellites routinely send signals to five monitor stations so that their positions can be tracked. The monitor stations also 'downlink' the Almanac information sent to the satellites from the Master Control site.

GPS satellites transmit two microwave carrier signals. The first high-frequency signal carries position and time data for civilian users worldwide. The US Department of Defense to limit horizontal and vertical accuracy to 100 and 156 meters respectively degrades this signal. A second lower-frequency signal can be used to correct for the effects of the ionosphere for more precise positioning by authorized users, including allied military, government agencies and approved civilian users.

Receivers

GPS receivers search for the coded high-frequency radio signals transmitted by the satellites. Once located, complete transmission from a satellite takes 12.5 minutes. The signal includes the position of the satellite and time at which the signal was sent. Transit time of the satellite radio signal gives the distance, or range, of the satellite from the receiver because the speed of electromagnetic radiation (radio waves) is known. Time passes more quickly for the satellites than on Earth, as predicted by Einstein's theory of

general relativity, and so 'relativistic' corrections to the transit time must be made. Signals from four satellites are required for precise positioning and time measurement.

Applications

GPS receivers are used on navigation of ships, motor vehicles, aircraft, space vehicles, and persons on the ground. In addition, the precise time information and radio signals that carry the information are useful for scientific experiments.

Geodetics is one example of a scientific discipline benefiting from GPS technology. The relative motions of Earth's tectonic plates cause mountains and earthquakes. Plate tectonic motions are in the order of millimetres per year. The small displacements over long time periods makes measuring tectonic motions by traditional geodetic methods laborious and time consuming. Scientists are now using signals by GPS satellites to track Earth's tectonic plates and to establish how they deform to form mountains, depressions, and earthquakes as they move. Measurements that might have taken months or years to perform by traditional geodetic methods can be obtained in just a few days with greater accuracy using GPS. In this application, referred to as space geodesy, the characteristics of the satellite radio waves themselves are used rather than the data they transmit. Slight differences in the phase, or wave-crest positions, of GPS radio waves detected by two receiver stations can be converted into the distance between the stations. In this way distances between points can be measured with millimeter accuracy if receivers are within approximately 30 kilometres of one another.

As part of one space geodesy study, changing topography and relative motions measured by GPS reveal where strain is building in the tectonically active Aegean region. This information is helping scientists to identify potential earthquake hazards. In a similar study, GPS is being used to establish the ever-changing elevation and position of the world's highest peak, Mount Everest.

globular cluster spherical or near-spherical star cluster containing from approximately 10,000 to millions of stars. More than a hundred globular clusters are distributed in a spherical halo around our Galaxy. They consist of old stars, formed early in the Galaxy's history. Globular clusters are also found around other galaxies.

glomerulus in the kidney, the cluster of blood capillaries at the threshold of the renal tubule, or nephron, responsible for filtering out the fluid that passes down the tubules and ultimately becomes urine. In the human kidney there are approximately one million tubules, each possessing its own glomerulus.

The structure of the glomerulus allows a wide range of substances including amino acids and sugar, as well as a large volume of water, to pass out of the blood. As the fluid moves through the tubules, most of the water and all of the sugars are reabsorbed, so that only waste remains, dissolved in a relatively small amount of water. This fluid collects in the bladder as urine.

glottis in medicine, narrow opening at the upper end of the larynx that contains the vocal cords.

glove box in high technology, a protective device used when handling toxic, radioactive, or sterile materials within an enclosure containing a window for viewing. Gloves fixed to ports in the walls of a box allow manipulation of objects within the box. The risk that the operator might inhale fine airborne particles of poisonous materials is removed by maintaining a vacuum inside the box, so that any airflow is inwards.

glow-worm wingless female of any of a large number of luminous beetles (fireflies). The luminous organs, situated under the abdomen, at the end of the body, give off a greenish glow at night and attract

winged males for mating. There are about 2,000 species of glow-worms, distributed worldwide. (Family Lampyridae.)

glucagon in biology, a hormone secreted by the alpha cells of the islets of Langerhans in the pancreas, which increases the concentration of glucose in the blood by promoting the breakdown of glycogen in the liver. Secretion occurs in response to a lowering of blood glucose concentrations.

Glucagon injections can be issued to close relatives of patients with diabetes who are being treated with insulin. Hypoglycaemia may develop in such patients in the event of inadequate control of diabetes. An injection of glucagon can be used to reverse hypoglycaemia before serious symptoms, such as unconsciousness, develop.

glucose or **dextrose** or **grape sugar** $C_6H_{12}O_6$ sugar present in the blood and manufactured by green plants during photosynthesis. The respiration reactions inside cells involves the oxidation of glucose to produce ATP, the 'energy molecule' used to drive many of the body's biochemical reactions.

In humans and other vertebrates optimum blood glucose levels are maintained by the hormone insulin.

GLOW-WORM

The simplest way to tell the sex of a glow-worm is by measuring the rate at which its emits light pulses. A male flashes once every 5.8 seconds, a female every 2.1 seconds.

Glucose is prepared in syrup form by the hydrolysis of cane sugar or starch, and may be purified to a white crystalline powder. Glucose is a monosaccharide sugar (made up of a single sugar unit), unlike the more familiar sucrose (cane or beet sugar), which is a disaccharide (made up of two sugar units: glucose and fructose).

glue type of ϕ adhesive.

glue ear or *secretory otitis media* condition commonly affecting small children, in which the Eustachian tube, which normally drains and ventilates the middle ear, becomes blocked with mucus. The resulting accumulation of mucus in the middle ear muffs hearing. It is the leading cause of deafness (usually transient) in children.

Glue ear resolves spontaneously after some months, but because the loss of hearing can interfere with a child's schooling the condition is often treated by a drainage procedure (myringotomy) and the surgical insertion of a small ventilating tube, or **grommet**, into the eardrum (tympanic membrane). This allows air to enter the middle ear, thereby enabling the mucus to drain freely once more along the Eustachian tube and into the back of the throat. The grommet is gradually extruded from the eardrum over several months, and the eardrum then heals naturally.

glue-sniffing or *solvent misuse* inhalation of the fumes from organic solvents of the type found in paints, lighter fuel, and glue, for their hallucinatory effects. As well as being addictive, solvents are dangerous for their effects on the user's liver, heart, and lungs. It is believed that solvents produce hallucinations by dissolving the cell membrane of brain cells, thus altering the way the cells conduct electrical impulses.

I am now convinced that theoretical physics is actual philosophy.

gluon in physics, a ϕ gauge boson that carries the ϕ strong nuclear force, responsible for binding quarks together to form the strongly interacting subatomic particles known as ϕ hadrons. There are eight kinds of gluon.

Gluons cannot exist in isolation; they are believed to exist in balls ('glueballs') that behave as single particles.

Glueballs may have been detected at CERN in 1995 but further research is required to confirm their existence.

gluten protein found in cereal grains, especially wheat and rye. Gluten enables dough to expand during rising. Sensitivity to gliadin, a type of gluten, gives rise to ϕ coeliac disease.

glyceride ϕ ester formed between one or more acids and glycerol (propan-1,2,3-triol). A glyceride is termed a mono-, di-, or triglyceride, depending on the number of hydroxyl groups from the glycerol that have reacted with the acids.

Glycerides, chiefly triglycerides, occur naturally as esters of ϕ fatty acids in plant oils and animal fats.

glycerine another name for ϕ glycerol.

glycerol or *glycerine* or *propan-1,2,3-triol* $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$ thick, colourless, odourless, sweetish liquid. It is obtained from vegetable and animal oils and fats (by treatment with acid, alkali, superheated steam, or an enzyme), or by fermentation of glucose, and is used in the manufacture of high explosives, in antifreeze solutions, to maintain moist conditions in fruits and tobacco, and in cosmetics.

glycine $\text{CH}_2(\text{NH}_2)\text{COOH}$ the simplest amino acid, and one of the main components of proteins. When purified, it is a sweet, colourless crystalline compound.

Glycine was found in 1994 in the star-forming region Sagittarius B2. The discovery is important because of its bearing on the origins of life on Earth.

glycogen polymer (a polysaccharide) of the sugar ϕ glucose made and retained in the liver as a carbohydrate store, for which reason it is sometimes called animal starch. It is a source of energy when needed by muscles, where it is converted back into glucose by the

hormone ϕ insulin and metabolized.

glycol or *ethylene glycol* or *ethane-1,2-diol* $\text{HOCH}_2\text{CH}_2\text{OH}$ thick, colourless, odourless, sweetish liquid. It is used in antifreeze solutions, in the preparation of ethers and esters (used for explosives), as a solvent, and as a substitute for glycerol.

glycoside in biology, compound containing a sugar and a non-sugar unit. Many glycosides occur naturally, for example, ϕ digitalis is a preparation of dried and powdered foxglove leaves that contains a mixture of cardiac glycosides. One of its constituents, digoxin, is used in the treatment of congestive heart failure and cardiac arrhythmias.

GM synthesizer in computing, synthesizer standard; see ϕ general MIDI.

GMT abbreviation for ϕ Greenwich Mean Time.

gnat any of a group of small two-winged biting insects belonging to the mosquito family. The eggs are laid in water, where they hatch into wormlike larvae, which pass through a pupal stage (see ϕ pupa) to emerge as adults. (Family Culicidae.)

Species include *Culex pipiens*, abundant in England; the carrier of malaria *Anopheles maculipennis*; and the banded mosquito *Aedes aegypti*, which transmits yellow fever.

Only the female is capable of drawing blood; the male does not have piercing jaws.

gneiss coarse-grained ϕ metamorphic rock, formed under conditions of high temperature and pressure, and often occurring in association with schists and granites. It has a foliated, or layered, structure consisting of thin bands of micas and/or amphiboles dark in colour alternating with bands of granular quartz and feldspar that are light in colour. Gneisses are formed during regional ϕ metamorphism; *paragneisses* are derived from metamorphism of sedimentary rocks and *orthogneisses* from metamorphism of granite or similar igneous rocks.

GNN in computing, abbreviation for ϕ Global Network Navigator.

gnu another name for ϕ wildebeest.

GNU in computing, suite of free UNIX-like software distributed by the ϕ Free Software Foundation. The software includes operating systems, compilers, text editors (such as EMACS), and other useful utilities.

goat ruminant mammal (it chews the cud), closely related to sheep. Both male and female goats have horns and beards. They are sure-footed animals, and feed on shoots and leaves more than on grass. (Genus *Capra*, family Bovidae.)

Domestic varieties are descended from the *scimitar-horned wild goat* (*C. aegagrus*) and have been kept for over 9,000 years in southern Europe and Asia. They are kept for milk or for mohair (angora and cashmere goats). Wild species include the ibex (*C. ibex*) of the Alps and markhor (*C. falconeri*) of the Himalayas, 1 m/3 ft high and with long twisted horns. The Rocky Mountain goat (*Oreamnos americanus*) is a 'goat antelope' and is not closely related to true goats.

goat moth large yellowish-grey or brown moth with irregular markings of white and black on the upper wings and a wingspan of about 7–8 cm/2.8–3 in. It is common in Europe and the Middle East. When the moth is frightened it emits a disagreeable odour like that of a male goat hence its name.

classification The goat moth *Cossus ligniperda* is in order Lepidoptera, class Insecta, phylum Arthropoda.

goblet cell in biology, cup-shaped cell present in the epithelium of the respiratory and gastrointestinal tracts. Goblet cells secrete mucin, the main constituent of mucus, which lubricates the mucous membranes of these tracts.

goby small marine bony fish. Nearly all gobies are found in the shallow coastal waters of the temperate and tropical oceans.

The first dorsal fin consists of a few flexible spines and the second dorsal fin is opposed to the anal fin. The caudal fin is generally rounded, with the pelvic fins united to form a cup-shaped sucker.

classification Gobies are in the family Gobiidae, order Perciformes, class Osteichthyes.

goitre enlargement of the thyroid gland seen as a swelling on the neck. It is most pronounced in simple goitre, which is caused by iodine deficiency. More common is toxic goitre or hyperthyroidism, caused by overactivity of the thyroid gland.

According to a World Health Organization's survey of 1997 up to 60% of people in some Indian states were suffering with goitre.

gold heavy, precious, yellow, metallic element; symbol Au, atomic number 79, relative atomic mass 197.0. It is unaffected by temperature changes and is highly resistant to acids. For manufacture, gold is alloyed with another strengthening metal (such as copper or silver), its purity being measured in carats on a scale of 24.

In 1990 the three leading gold-producing countries were South Africa, 605.4 tonnes; USA, 295 tonnes; and Russia, 260 tonnes. In 1989 gold deposits were found in Greenland with an estimated yield of 12 tonnes per year.

Gold occurs naturally in veins, but following erosion it can be transported and redeposited. It has long been valued for its durability, malleability, and ductility, and its uses include dentistry and jewellery. As it will not corrode, it is also used in the manufacture of electric contacts for computers and other electrical devices.

goldcrest smallest European bird, about 9 cm/3.5 in long and weighing 5 g/0.011 lb; a warbler. It is olive green, with a bright orange-yellow streak running from the beak to the back of the head and a black border above the eye. The tail is brown, marked with black and white, and the cheeks, throat, and breast are a greyish white. (Species *Regulus regulus*, family Muscicapidae, order Passeriformes.)

The goldcrest builds its nest in conifers. It is found all over Europe, particularly frequenting fir woods. In winter it can be found feeding with tit flocks, moving through deciduous woodlands.

golden-eye fly alternative name for green lacewing.

golden retriever breed of dog. See retriever.

goldenrod one of several tall and leafy North American perennial plants, belonging to the daisy family. Flower heads are mostly composed of many small yellow flowers, or florets. (Genus *Solidago*, family Compositae.)

goldenseal North American plant *Hydrastis canadensis* of the buttercup family whose thick yellow root is used medicinally as an astringent and a tonic. The root contains the alkaloid hydrastine, employed by herbalists to stop uterine bleeding.

golden section visually satisfying ratio, first constructed by the Greek mathematician Euclid and used in art and architecture. It is found by dividing a line AB at a point O such that the rectangle produced by the whole line and one of the segments is equal to the square drawn on the other segment. The ratio of the two segments is about 8:13 or 1:1.618, and a rectangle whose sides are in this ratio is called a golden rectangle. The ratio of consecutive Fibonacci numbers tends to the golden ratio.

In van Gogh's picture *Mother and Child*, for example, the Madonna's face fits perfectly into a golden rectangle.

goldfinch songbird found in Eurasia, North Africa, and North America. (Species *Carduelis carduelis*, family Fringillidae, order Passeriformes.)

goldfish fish belonging to the carp family, found in East Asia. It is greenish-brown in its natural state, but has been bred by the Chinese for centuries, taking on highly coloured and sometimes freakishly shaped forms. Goldfish can occur in a greater range of colours than any other animal tested. (Species *Carassius auratus*, family Cyprinidae.)

Golgi apparatus or *Golgi body* stack of flattened membranous sacs found in the cells of eukaryotes. Many molecules travel through the Golgi apparatus on their way to other organelles or to the endoplasmic reticulum. Some are modified or assembled inside the sacs. The Golgi apparatus is named after the Italian physician Camillo Golgi.

Goliath beetle large beetle found only in tropical countries. The biggest Goliath beetle *Goliathus giganteus*, found in equatorial Africa, may be more than 150 mm/6 in long and is one of the largest insects.

They lay their eggs in the rotting wood of trees, and most adults feed on the tender floral parts or suck the sap exuded from trees. Its 'brushed velvet' wingcases are maroon and the pronotum (shield) is black with roughly longitudinal white stripes.

classification Goliath beetles belong to the subfamily Cetoniinae of the family Scarabaeidae in order Coleoptera, class Insecta, phylum Arthropoda.

gonad the part of an animal's body that produces the sperm or egg cells (ova) required for sexual reproduction. The sperm-producing gonad is called a testis, and the egg-producing gonad is called an ovary.

gonadotrophin any hormone that supports and stimulates the function of the gonads (sex glands); some gonadotrophins are used as fertility drugs.

Gondwanaland or *Gondwana* southern landmass formed 200 million years ago by the splitting of the single world continent Pangaea. (The northern landmass was Laurasia.) It later fragmented into the continents of South America, Africa, Australia, and Antarctica, which then drifted slowly to their present positions. The baobab tree found in both Africa and Australia is a relic of this ancient land mass.

A database of the entire geology of Gondwanaland has been constructed by geologists in South Africa. The database, known as

golden section The golden section is the ratio $a:b$, equal to 8:13. A golden rectangle is one, like that shaded in the picture, that has its length and breadth in this ratio. These rectangles are said to be pleasant to look at and have been used instinctively by artists in their pictures.

Golgi, Camillo (1843–1926)

Italian cell biologist who produced the first detailed knowledge of the fine structure of the nervous system. He shared the 1906 Nobel Prize for Physiology or Medicine with Santiago Ramón y Cajal, who followed up Golgi's work.

Golgi's use of silver salts in staining cells proved so effective in showing up the components and fine processes of nerve cells that even the synapses – tiny gaps between the cells – were visible. The Golgi apparatus, a series of flattened membranous cavities found in the cytoplasm of cells, was first described by him in 1898.

gonorrhoea common sexually transmitted disease arising from infection with the bacterium *Neisseria gonorrhoea*, which causes inflammation of the genito-urinary tract. After an incubation period of two to ten days, infected men experience pain while urinating and a discharge from the penis; infected women often have no external symptoms.

Untreated gonorrhoea carries the threat of sterility to both sexes; there is also the risk of blindness in a baby born to an infected mother. The condition is treated with antibiotics, though ever-increasing doses are becoming necessary to combat resistant strains.

Good King Henry perennial plant belonging to the goosefoot family, growing to 50 cm/16 ft, with triangular leaves which are mealy when young. Spikes of tiny greenish-yellow flowers appear above the leaves in midsummer. (*Chenopodium bonus-henricus*, family Chenopodiaceae.)

Goonhilly British Telecom satellite-tracking station in Cornwall, England. It is equipped with a communications-satellite transmitter-receiver in permanent contact with most parts of the world.

goose any of several large aquatic birds belonging to the same family as ducks and swans. There are about 12 species, found in North America, Greenland, Europe, North Africa, and Asia north of the Himalayas. Both sexes are similar in appearance: they have short, webbed feet, placed nearer the front of the body than in other members of the family, and a slightly hooked beak. Geese feed entirely on grass and plants, build nests of grass and twigs on the ground, and lay 5–9 eggs, white or cream-coloured, according to the species. (Genera mainly *Anser* and *Branta*, family Anatidae, order Anseriformes.)

The **barnacle goose** (*B. leucopsis*) is about 60 cm/2 ft long and weighs about 2 kg/4.5 lb. It is black and white, mottled with blue and grey, and the beak is black. The **bean goose** (*A. fabalis*) is a grey species of European wild goose with an orange or yellow and black beak. It breeds in northern Europe and Siberia. The **Brent goose** (*B. bernicla*) is a small goose, black or brown, white, and grey in colour. It is almost completely herbivorous, feeding on eel grass and algae. The world population of Brent geese was 25,000 in 1996. The **greylag goose** (*A. anser*) is the ancestor of domesticated geese.

Other species include the **Canada goose** (*B. canadensis*) (common to North America and introduced into Europe in the 18th cen-

tury), the **pink-footed goose** (*A. brachyrhynchus*), the **white-fronted goose** (*A. albifrons*), and the **ne-ne** or **Hawaiian goose** (*B. sandvicensis*).

gooseberry edible fruit of a low-growing bush (*Ribes uva-crispa*) found in Europe and Asia, related to the currant. It is straggling in its growth, and has straight sharp spines in groups of three and rounded, lobed leaves. The flowers are green and hang on short stalks. The sharp-tasting fruits are round, hairy, and generally green, but there are reddish and white varieties.

goosefoot any of a group of plants belonging to the goosefoot family, closely related to spinach and beets. The seeds of white goosefoot (*C. album*) were used as food in Europe from Neolithic times, and also from early times in the Americas. White goosefoot grows to 1 m/3 ft tall and has lance- or diamond-shaped leaves and packed heads of small inconspicuous flowers. The green part is eaten as a spinach substitute. (Genus *Chenopodium*, family Chenopodiaceae.)

gopher any of a group of burrowing rodents. Gophers are a kind of ground squirrel represented by some 20 species distributed across western North America, Europe, and Asia. Length ranges from 15 cm/6 in to 90 cm/16 in, excluding the furry tail; colouring ranges from plain yellowish to striped and spotted species. (Genus *Citellus*, family Sciuridae.)

The name **pocket gopher** is applied to the eight genera of the North American family Geomyidae.

Gopher (derived from *go for*, alternatively, named for the mascot of the University of Minnesota, where it was invented) menu-based server on the Internet that indexes resources and retrieves them according to user choice via any one of several built-in methods such as GFTP or Telnet. Gopher servers can also be accessed via the World Wide Web and searched via special servers called GVeronica.

Gopherspace in computing, name for the knowledge base composed of all the documents indexed on all the Gophers in the world.

gopher tortoise land tortoise occurring in the southern USA. It has a domed shell and scaly legs. Its forelegs are flattened for digging the burrow where it lives. Gopher tortoises reach lengths of up to 37 cm/14.5 in.

classification The gopher tortoise *Gopherus polyphemus* is in family Cheloniidae, order Testudinae, class Reptilia.

Gordon setter breed of dog. See C setter.

gorge narrow steep-sided valley (or canyon) that may or may not have a river at the bottom. A gorge may be formed as a waterfall retreats upstream, eroding away the rock at the base of a river valley; or it may be caused by rejuvenation, when a river begins to cut downwards into its channel once again (for example, in response to a fall in sea level). Gorges are common in limestone country, where they may be formed by the collapse of the roofs of underground caverns.

gorilla largest of the apes, found in the dense forests of West Africa and mountains of central Africa. The male stands about 1.8 m/6 ft high and weighs about 200 kg/450 lbs. Females are about half this size. The body is covered with blackish hair, silvered on the back in older males. Gorillas live in family groups; they are vegetarian, highly intelligent, and will attack only in self-defence. They are dwindling in numbers, being shot for food by some local people, or by poachers taking young for zoos, but protective measures

are having some effect. (Species *Gorilla gorilla*.)

Gorillas construct stoutly built nests in trees for overnight use. The breast-beating movement, once thought to indicate rage, actually signifies only nervous excitement. There are three races – western lowland, eastern lowland, and mountain gorillas – and US scientists suggested in 1994 that there may be two separate species of gorilla.

gorse or **furze** or **whin** any of a group of plants native to Europe and Asia, consisting of thorny shrubs with spine-shaped leaves growing thickly along the stems and bright-yellow coconut-scented flowers. (Genus *Ulex*, family Leguminosae.)

GOSHAWK

The male goshawk mates up to 600 times with his partner for every clutch of eggs. This ensures that the sperm of any rival are completely swamped.

goshawk or **northern goshawk** woodland hawk similar in appearance to the peregrine falcon, but with shorter wings and legs. It is native to most of Europe, Asia, and North America, and is used in falconry. The male is much smaller than the female. It is ash grey on the upper part of the body and whitish underneath with brown horizontal stripes; it has a dark head and cheeks with a white stripe above the eye. The tail has dark bands across it. (Species *Accipiter gentilis*, order Falconiformes.)

Gossamer Albatross the first human-powered aircraft to fly across the English Channel, in June 1979. It was designed by Paul MacCready and piloted and pedalled by Bryan Allen. The Channel crossing took 2 hours 49 minutes. The same team was behind the first successful human-powered aircraft (*Gossamer Condor*) two years earlier.

Gouraud shading in computer animation, technique for calculating the correct colours and intensity of lighting playing on an on-screen three-dimensional object.

Gouraud shading works by measuring the colour and brightness at the vertices of the polygons that make up the object and mixing these to get values for the areas inside the polygons. Specialized hardware makes this process relatively fast. The technique is named after its inventor, Henri Gouraud and was developed 1973.

gourd any of a group of plants that includes melons and pumpkins. In a narrower sense, the name applies only to the genus *Lagenaria*, of which the bottle gourd or calabash (*L. siceraria*) is best known. (Family Cucurbitaceae.)

gout hereditary form of arthritis, marked by an excess of uric acid crystals in the tissues, causing pain and inflammation in one or more joints (usually of the feet or hands). Acute attacks are treated with anti-inflammatories.

The disease, ten times more common in men, poses a long-term threat to the blood vessels and the kidneys, so ongoing treatment may be needed to minimize the levels of uric acid in the bloodstream. It is aggravated by heavy drinking.

governor in engineering, any device that controls the speed of a machine or engine, usually by regulating the intake of fuel or steam.

Scottish inventor James Watt invented the steam-engine governor in 1788. It works by means of heavy balls, which rotate on the end of linkages and move in or out because of centrifugal force according to the speed of rotation. The movement of the balls closes or opens the steam valve to the engine. When the engine speed increases too much, the balls fly out, and cause the steam valve to close, so the engine slows down. The opposite happens when the engine speed drops too much.

GP in medicine, abbreviation for **general practitioner**.

GPF (abbreviation for **general protection fault**) in Windows 3.1, error message returned by a computer when it crashes. A GPF is

the same as a UAE (unexpected application error) in Windows 3.0. It often indicates that one application has tried to use memory reserved for another.

Graafian follicle fluid-filled capsule that surrounds and protects the developing egg cell inside the ovary during the menstrual cycle. After the egg cell has been released, the follicle remains and is known as a corpus luteum.

gradient on a graph, the slope of a straight or curved line. The slope of a curve at any given point is represented by the slope of the tangent at that point.

gradient of a curve

the gradient to a curve at any point is equal to the gradient of the tangent drawn touching that point

$$\text{gradient of } AB = \frac{\text{vertical distance}}{\text{horizontal distance}}$$

$$\frac{BC}{AC} = \tan \theta$$

gradient The gradient of a curve keeps changing, so in order to calculate the gradient you have to draw a straight line that touches a point on the curve (the tangent). The gradient for that point on the curve will then be the same as the gradient of the straight line.

grafting in medicine, the operation by which an organ or other living tissue is removed from one organism and transplanted into the same or a different organism.

In horticulture, it is a technique widely used for propagating plants, especially woody species. A bud or shoot on one plant, termed the scion, is inserted into another, the stock, so that they continue growing together, the tissues combining at the point of union. In this way some of the advantages of both plants are obtained.

Grafting is usually only successful between species that are closely related and is most commonly practised on roses and fruit trees. The grafting of nonwoody species is more difficult but it is sometimes used to propagate tomatoes and cacti. See also **transplant**.

grafting Grafting, a method of artificial propagation in plants, is commonly used in the propagation of roses and fruit trees. A relatively small part, the scion, of one plant is attached to another plant so that growth continues. The plant receiving the transplanted material is called the stock.

grain the smallest unit of mass in the three English systems (avoirdupois, troy, and apothecaries' weights) used in the UK and USA, equal to 0.0648 g. It was reputedly the weight of a grain of wheat. One pound avoirdupois equals 7,000 grains; one pound troy or apothecaries' weight equals 5,760 grains.

gram metric unit of mass; one-thousandth of a kilogram.

gramophone old-fashioned name for a record player or stereo. It was developed from US inventor Thomas Edison's phonograph, which remains the traditional US name.

grampus common name for Risso's dolphin, a slate-grey dolphin found in tropical and temperate seas. These dolphins live in large schools and can reach 4 m/13 ft in length. They have blunt snouts with only a few teeth, and feed on squid and small fish. The name grampus is sometimes also used for the killer whale. (Species *Grampus griseus*.)

Grande Dixence dam the world's highest dam, located in Switzerland, which measures 285 m/935 ft from base to crest. Completed in 1961, it contains 6 million cu m/8 million cu yd of concrete.

grand unified theory in physics, a sought-for theory that would combine the theory of the strong nuclear force (called quantum chromodynamics) with the theory of the weak nuclear and electromagnetic forces. The search for the grand unified theory is part of a larger programme seeking a unified field theory, which would combine all the forces of nature (including gravity) within one framework.

granite coarse-grained intrusive igneous rock, typically consisting of the minerals quartz, feldspar, and biotite mica. It may be pink or grey, depending on the composition of the feldspar. Granites are chiefly used as building materials.

Granites often form large intrusions in the core of mountain ranges, and they are usually surrounded by zones of metamorphic rock (rock that has been altered by heat or pressure). Granite areas have characteristic moorland scenery. In exposed areas the bedrock may be weathered along joints and cracks to produce a tor, consisting of rounded blocks that appear to have been stacked upon one another.

grape fruit of any grape vine, especially *V. vinifera*. (Genus *Vitis*, family Vitaceae.)

grapefruit round, yellow, juicy, sharp-tasting fruit of the evergreen grapefruit tree. The tree grows up to 10 m/more than 30 ft and has dark shiny leaves and large white flowers. The large fruits grow in grapelike clusters (hence the name). Grapefruits were first established in the West Indies and subsequently cultivated in Florida by the 1880s; they are now also grown in Israel and South Africa. Some varieties have pink flesh. (*Citrus paradisi*, family Rutaceae.)

graph pictorial representation of numerical data, such as statistical data, or a method of showing the mathematical relationship between two or more variables by drawing a diagram.

There are often two axes, or reference lines, at right angles intersecting at the origin – the zero point, from which values of the variables (for example, distance and time for a moving object) are assigned along the axes. Pairs of simultaneous values (the distance moved after a particular time) are plotted as points in the area between the axes, and the points then joined by a smooth curve to produce a graph. The horizontal axis is usually referred to as the *x*-axis, and the vertical axis as the *y*-axis.

Cartesian coordinates On a line graph values are plotted using coordinates, components used to define the position of a point by its perpendicular distance from a set of two or more axes, or reference lines. For a two-dimensional area defined by two axes at right angles, the coordinates of a point are given by its perpendicular distances from the *y*-axis and *x*-axis, written in the form (*x*, *y*). For example, a point P that lies three units from the *y*-axis and four units from the *x*-axis has Cartesian coordinates (3, 4).

straight-line graph This type of graph is produced by plotting the variables of a linear equation with the general form

$$y = mx + c$$

where *m* is the slope of the line represented by the equation and *c* is the *y*-intercept, or the value of *y* where the line crosses the *y*-axis in the Cartesian coordinate system.

histogram These are graphs used in statistics, showing frequency of data, in which the horizontal axis details discrete units or class boundaries, and the vertical axis represents the frequency. Blocks are drawn such that their areas (rather than their height as in a bar chart) are proportional to the frequencies within a class or across several class boundaries. There are no spaces between blocks.

the equation of the straight-line graph takes the form $y = mx + c$, where *m* is the gradient (slope) of the line, and *c* is the *y*-intercept (the value of *y* where the line cuts the *y*-axis) (for example, a graph of the equation $y = x + 4$ will have a gradient of 1 and will cut the *y*-axis at $y = 4$).

graph A graph is pictorial illustration of numerical data. It is a useful tool for interpreting data and is often used to spot trends or approximate a solution.

applications Graphs have many practical applications in all disciplines, for example **distance-time graphs** are used to describe the motion of a body by illustrating the relationship between the distance that it travels and the time taken. Plotting distance (on the vertical axis) against time (on the horizontal axis) produces a graph the gradient of which is the body's speed. If the gradient is constant (the graph is a straight line), the body has uniform or constant speed; if the gradient varies (the graph is curved), then so does the speed and the body may be said to be accelerating or decelerating.

Speed-time graphs are used to describe the motion of a body by illustrating how its speed or velocity changes with time. The gradient of the graph gives the object's acceleration: if the gradient is zero (the graph is horizontal) then the body is moving with constant speed or uniform velocity; if the gradient is constant, the body is moving with uniform acceleration. The area under the graph gives the total distance travelled by the body.

Conversion graphs are used for changing values from one unit to another, for example from Celsius to Fahrenheit, with the two axes representing the different units.

graphical user interface (GUI) or **WIMP** in computing, a type of user interface in which programs and files appear as icons (small pictures), user options are selected from pull-down menus, and data are displayed in windows (rectangular areas), which the operator can manipulate in various ways. The operator uses a pointing device, typically a mouse, to make selections and initiate actions.

The concept of the graphical user interface was developed by the Xerox Corporation in the 1970s, was popularized with the Apple Macintosh computers in the 1980s, and is now available on many types of computer – most notably as Windows, an operating system for IBM PC-compatible microcomputers developed by the software company Microsoft.

graphic equalizer control used in hi-fi systems that allows the distortions introduced in the sound output by unequal amplification of different frequencies to be corrected.

The frequency range of the signal is divided into separate bands, usually third-octave bands. The amplification applied to each band

is adjusted by a sliding contact; the position of the contact indicates the strength of the amplification applied to each frequency range.

graphic file format format in which computer graphics are stored and transmitted. There are two main types: **raster graphics** in which the image is stored as a bit map (arrangement of dots), and **vector graphics**, in which the image is stored using geometric formulas. There are many different file formats, some of which are used by specific computers, operating systems or applications. Some formats use file compression, particularly those that are able to handle more than one colour.

graphics used with computers, see **computer graphics**.

graphics board in computing, another name for **graphics card**.

graphics card in computing, a peripheral device that processes and displays graphics.

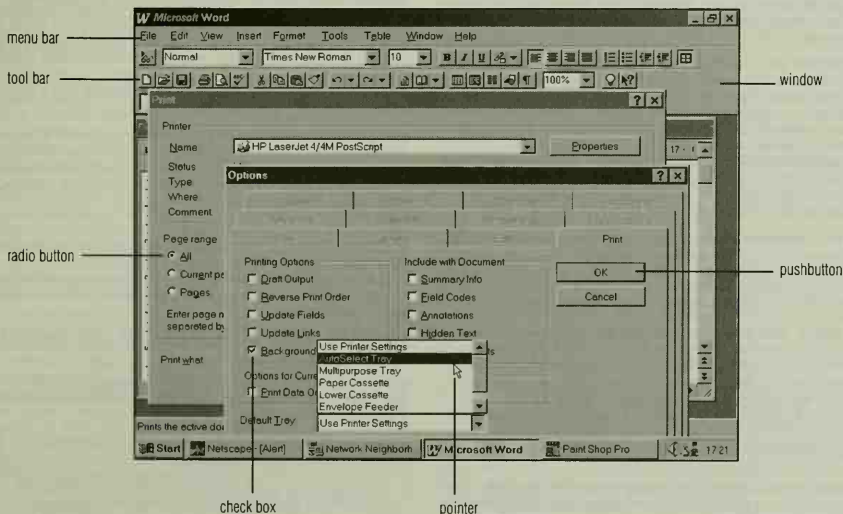

Graphics Interchange Format in computing, picture file format usually abbreviated to **GIF**.

graphics tablet or **bit pad** in computing, an input device in which a stylus or cursor is moved, by hand, over a flat surface. The computer can keep track of the position of the stylus, so enabling the operator to input drawings or diagrams into the computer.

A graphics tablet is often used with a form overlaid for users to mark boxes in positions that relate to specific registers in the computer, although recent developments in handwriting recognition may increase its future versatility.

graphite blackish-grey, laminar, crystalline form of **carbon**. It is used as a lubricant and as the active component of pencil lead.

The carbon atoms are strongly bonded together in sheets, but the bonds between the sheets are weak, allowing other atoms to enter regions between the layers causing them to slide over one another. Graphite has a very high melting point (3,500°C/6,332°F), and is a good conductor of heat and electricity. It absorbs neutrons and is therefore used to moderate the chain reaction in nuclear reactors.

graphical user interface A typical GUI, where the user is taken around the system by simply clicking on representative buttons or icons using the mouse.

graphics tablet A graphics tablet enables images drawn freehand to be translated directly to the computer screen.

graph plotter alternative name for a *plotter*.

grass any of a very large family of plants, many of which are economically important because they provide grazing for animals and food for humans in the form of cereals. There are about 9,000 species distributed worldwide except in the Arctic regions. Most are perennial, with long, narrow leaves and jointed, hollow stems; flowers with both male and female reproductive organs are borne on spikelets; the fruits are grainlike. Included in the family are bluegrass, wheat, rye, maize, sugarcane, and bamboo. (Family Gramineae.)

grasshopper any of several insects with strongly developed hind legs, enabling them to leap into the air. The hind leg in the male usually has a row of protruding joints that produce the characteristic chirping sound when rubbed against the hard wing veins. *Cicadas*, *crickets*, and *katydid*s are related to grasshoppers. (Families Acrididae and Tettigoniidae, order Orthoptera.)

The short-horned grasshoppers constitute the family Acrididae, and include locusts. All members of the family feed voraciously on vegetation. Eggs are laid in a small hole in the ground, and the unwinged larvae become adult after about six moults.

grass of Parnassus plant, unrelated to grasses, found growing in marshes and on wet moors in Europe and Asia. It is low-growing, with a rosette of heart-shaped stalked leaves, and has five-petalled white flowers with conspicuous veins growing singly on stem tips in late summer. (*Parnassia palustris*, family Parnassiaceae.)

grass snake olive-green, grey or brownish non-venomous snake *Natrix natrix* found near water in lowland areas with woodland. They are about 80 cm/32 in long and feed mainly on frogs, toads, and newts, which they hunt in the water. They are the largest British reptiles. There is also a grass snake in the USA.

The female lays 10–40 eggs within a pile of rotting vegetation, where they are incubated by the heat generated by the rotting process. Eggs are elongated, white, leathery, and about 3 cm/1 1/2 in long.

grass tree Australian plant belonging to the lily family. The tall, thick stems have a grasslike tuft at the top above which rises a flower spike resembling a spear; this often appears after bushfires and in some species can grow to a height of 3 m/10 ft. (Genus *Xanthorrhoea*, family Liliaceae.)

gravel coarse sediment consisting of pebbles or small fragments of rock, originating in the beds of lakes and streams or on beach-

es. Gravel is quarried for use in road building, railway ballast, and for an aggregate in concrete. It is obtained from quarries known as gravel pits, where it is often found mixed with sand or clay.

Some gravel deposits also contain placer deposits of metal ores (chiefly tin) or free metals (such as gold and silver).

gravimetric analysis in chemistry, a technique for determining, by weighing, the amount of a particular substance present in a sample. It usually involves the conversion of the test substance into a compound of known molecular weight that can be easily isolated and purified.

gravimetry study of the Earth's gravitational field. Small variations in the gravitational field (gravimetric anomalies) can be caused by varying densities of rocks and structure beneath the surface. Such variations are measured by a device called a gravimeter, which consists of a weighted spring that is pulled further downwards where the gravity is stronger (at a Bouguer anomaly). Gravimetry is used by geologists to map the subsurface features of the Earth's crust, such as underground masses of heavy rock such as granite, or light rock such as salt.

gravitational field the region around a body in which other bodies experience a force due to its gravitational attraction. The gravitational field of a massive object such as the Earth is very strong and easily recognized as the force of gravity, whereas that of an object of much smaller mass is very weak and difficult to detect. Gravitational fields produce only attractive forces.

gravitational field strength (symbol *g*) the strength of the Earth's gravitational field at a particular point. It is defined as the gravitational force in newtons that acts on a mass of one kilogram. The value of *g* on the Earth's surface is taken to be 9.806 N kg⁻¹.

The symbol *g* is also used to represent the acceleration of a freely falling object in the Earth's gravitational field.

Near the Earth's surface and in the absence of friction due to the air, all objects fall with an acceleration of 9.806 m s⁻².

gravitational lensing bending of light by a gravitational field, predicted by Einstein's general theory of relativity. The effect was first detected in 1917 when the light from stars was found to be bent as it passed the totally eclipsed Sun. More remarkable is the splitting of light from distant quasars into two or more images by intervening galaxies. In 1979 the first double image of a quasar produced by gravitational lensing was discovered and a quadruple image of another quasar was later found.

gravitational potential energy energy possessed by an object when it is placed in a position from which, if it were free to do so, it would fall under the influence of gravity. The gravitational potential energy *E_p* of an object of mass *m* kg placed at a height *h* m above the ground is given by the formula:

$$E_p = mgh$$

where *g* is the gravitational field strength in N kg⁻¹ of the Earth at the place.

In a hydroelectric power station, gravitational potential energy of water held in a high-level reservoir is used to drive turbines to produce electricity.

graviton in physics, the *g*-gauge boson that is the postulated carrier of the gravitational force.

gravity force of attraction that arises between objects by virtue of their masses. On Earth, gravity is the force of attraction between

GRAVITY

The maximum speed with which a falling raindrop can hit you is about 29 kmph/18 mph. In a vacuum, the further an object falls, the more speed it gains, but in the real world, air resistance eventually balances out the accelerating effect of gravity.

gravimetry The gravimeter is an instrument for measuring the force of gravity at a particular location. Variations in the force of gravity acting on a weight suspended by a spring cause the spring to stretch. The gravimeter is used in aerial surveys. Geological features such as intrusions and salt domes are revealed by the stretching of the spring.

any object in the Earth's gravitational field and the Earth itself. It is regarded as one of the four fundamental forces of nature, the other three being the electromagnetic force, the strong nuclear force, and the weak nuclear force. The gravitational force is the weakest of the four forces, but it acts over great distances. The particle that is postulated as the carrier of the gravitational force is the graviton.

One of the earliest gravitational experiments was undertaken by Nevil Maskelyne in 1774 and involved the measurement of the attraction of Mount Schiehallion (Scotland) on a plumb bob.

measuring forces of attraction An experiment for determining the force of attraction between two masses was first planned in the mid-18th century by the Reverend J. Mitchell, who did not live to work on the apparatus he had designed and completed. After Mitchell's death the apparatus came into the hands of Henry Cavendish, who largely reconstructed it but kept to Mitchell's original plan. The attracted masses consisted of two small balls, connected by a stiff wooden beam suspended at its middle point by a long, fine wire. The whole of this part of the apparatus was enclosed in a case, carefully coated with tinfoil to secure, as far as possible, a uniform temperature within the case. Irregular distribution of temperature would have resulted in convection currents of air which would have had a serious disturbing effect on the suspended system. To the beam was attached a small mirror with its plane vertical. A small glazed window in the case allowed any motion of the mirror to be observed by the consequent deviations of a ray of light reflected from it. The attracting masses consisted of two equal, massive lead spheres. Using this apparatus, Cavendish, in 1797, obtained for the gravitational constant G the value $6.6 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$. The apparatus was refined by Charles Vernon Boys and he obtained the improved value $6.6576 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$. The value generally used today is $6.6720 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$.

graving one of the three main printing methods, in which printing is done from a plate etched with a pattern of recessed cells in which the ink is held. The greater the depth of a cell, the greater the strength of the printed ink. Graving plates are expensive to make, but the process is economical for high-volume printing and reproduces illustrations well.

gray SI unit (symbol Gy) of absorbed radiation dose. It replaces the rad (1 Gy equals 100 rad), and is defined as the dose absorbed when one kilogram of matter absorbs one joule of ionizing radiation. Different types of radiation cause different amounts of damage for the same absorbed dose; the SI unit of dose equivalent is the sievert.

grayling freshwater fish with a long multirayed dorsal (back) fin and silver to purple body colouring. It is found in northern parts of Europe, Asia, and North America, where it was once common in the Great Lakes. (Species *Thymallus thymallus*, family Salmonidae.)

grayling butterfly butterfly widely distributed over the British Isles. It has dark brown wings with two black eye-spots on each of the forewings and one black eyespot centred with white on the hindwings. It is found on heaths and in dry stony places, especially on chalk and in clearings in woods.

classification The grayling butterfly *Hipparchia semele* is in order Lepidoptera, class Insecta, phylum Arthropoda.

Great Artesian Basin the largest area of artesian water in the world. It underlies much of Queensland, New South Wales, and South Australia, and in prehistoric times formed a sea. It has an area of 1,750,000 sq km/676,250 sq mi.

Great Bear popular name for the constellation Ursa Major.

great circle circle drawn on a sphere such that the diameter of the circle is a diameter of the sphere. On the Earth, all meridians of longitude are half great circles; among the parallels of latitude, only the Equator is a great circle.

The shortest route between two points on the Earth's surface is along the arc of a great circle. These are used extensively as air routes although on maps, owing to the distortion brought about by projection, they do not appear as straight lines.

Great Dane breed of large, short-haired dog, often fawn or brindle in colour, standing up to 76 cm/30 in tall, and weighing up to 70 kg/154 lb. It has a large head and muzzle, and small, erect ears. It was formerly used in Europe for hunting boar and stags.

Great Red Spot prominent oval feature, 14,000 km/8,500 mi wide and some 30,000 km/20,000 mi long, in the atmosphere of the planet Jupiter, south of the Equator. It was first observed in the 19th century. Space probes show it to be an anticlockwise vortex of cold clouds, coloured possibly by phosphorus.

Great Wall array of galaxies arranged almost in a perfect plane, consisting of some 2,000 galaxies (about 500 million \times 200 million light years across). It was discovered by US astronomers in Cambridge, Massachusetts, in 1989.

grebe any of a group of 19 species of water birds. The **great crested grebe** (*Podiceps cristatus*) is the largest of the Old World grebes. It feeds on fish, and lives on ponds and marshes in Europe, Asia, Africa, and Australia. It grows to 50 cm/20 in long and has a white breast, with chestnut and black feathers on its back and head. Dark ear tufts and a prominent collar or crest of feathers around the base of the head appear during the breeding season; these are lost in winter. (Family Podicipedidae, order Podicipediformes.)

Grebes have broad, flat feet, and the toes are partially webbed, the legs being set extremely far back on the body. The wings are short and rounded, there is practically no tail, and flight is low. Both sexes are similar in appearance.

greeking method used in desktop publishing and other page make-up systems for showing type below a certain size on screen. Rather than the actual characters being displayed, either a grey bar or graphics symbols are used. Greeking is usually employed when a general impression of the page lay-out is required.

green audit inspection of a company to assess the total environmental impact of its activities or of a particular product or process.

For example, a green audit of a manufactured product looks at the impact of production (including energy use and the extraction of raw materials used in manufacture), use (which may cause pollution and other hazards), and disposal (potential for recycling, and whether waste causes pollution).

Such 'cradle-to-grave' surveys allow a widening of the traditional scope of economics by ascribing costs to variables that are usually ignored, such as despoliation of the countryside or air pollution.

Green Bank site in West Virginia, USA, of the National Radio Astronomy Observatory. Its main instruments are a 43-m/140-ft fully steerable dish, opened in 1965, and three 26-m/85-ft dishes. A 90-m/300-ft partially steerable dish, opened in 1962, collapsed 1988 because of metal fatigue; a replacement dish, 100 m/330 ft across, was under construction in 1995.

greenbottle type of blowfly.

greenbrier or **cathbrier** any of several climbing woody vines of the genus *Smilax* of the lily family, having smooth, shiny green oval leaves and usually black berries. The prickly stems of these plants often form impenetrable thickets.

green computing the gradual movement by computer companies toward incorporating energy-saving measures in the design of systems and hardware. The increasing use of energy-saving devices, so that a computer partially shuts down during periods of inactivity, but can reactivate at the touch of a key, could play a significant role in energy conservation.

It is estimated that worldwide electricity consumption by computers amounts to 240 billion kilowatt hours per year, equivalent to the entire annual consumption of Brazil. In the USA, carbon dioxide emissions could be reduced by 20 million tonnes per year – equivalent to the carbon dioxide output of 5 million cars – if all computers incorporated the latest 'sleep technology' (which shuts down most of the power-consuming features of a computer if it is unused for any length of time).

Although it was initially predicted that computers would mean 'paperless offices', in practice the amount of paper consumed continues to rise. Other environmentally-costly features of computers include their rapid obsolescence, health problems associated with monitors and keyboards, and the unfavourable economics of component recycling.

greenfinch olive-green songbird common in Europe and North Africa. It has bright-yellow markings on the outer tail feathers and wings; males are much brighter in colour than females. (Species *Carduelis chloris*, family Fringillidae, order Passeriformes.)

greenfly plant-sucking insect, a type of aphid.

greenhouse effect The warming effect of the Earth's atmosphere is called the greenhouse effect. Radiation from the Sun enters the atmosphere but is prevented from escaping back into space by gases such as carbon dioxide (produced for example, by the burning of fossil fuels), nitrogen oxides (from car exhausts), and CFCs (from aerosols and refrigerators). As these gases build up in the atmosphere, the Earth's average temperature is expected to rise.

greenhouse effect phenomenon of the Earth's atmosphere by which solar radiation, trapped by the Earth and re-emitted from the surface as infrared radiation, is prevented from escaping by various gases in the air. Greenhouse gases trap heat because they readily absorb infrared radiation. The result is a rise in the Earth's temperature (global warming). The main greenhouse gases are carbon dioxide, methane, and chlorofluorocarbons (CFCs) as well as water vapour. Fossil-fuel combustion and forest fires are the principal causes of carbon dioxide build-up; methane is a byproduct of agriculture (rice, cattle, sheep).

The United Nations Environment Programme estimates that by 2025, average world temperatures will have risen by $1.5^{\circ}\text{C}/2.7^{\circ}\text{F}$ with a consequent rise of 20 cm/7.9 in in sea level. Low-lying areas and entire countries would be threatened by flooding and crops would be affected by the change in climate. However, predictions about global warming and its possible climatic effects are tentative and often conflict with each other.

At the 1992 Earth Summit it was agreed that by 2000 countries would stabilize carbon dioxide emissions at 1990 levels, but to halt the acceleration of global warming, emissions would probably need to be cut by 60%. Any increases in carbon dioxide emissions are expected to come from transport. The Berlin Mandate, agreed unanimously at the climate conference in Berlin in 1995, committed industrial nations to the continuing reduction of greenhouse gas emissions after 2000, when the existing pact to stabilize emissions runs out. The stabilization of carbon dioxide emissions at 1990 levels by 2000 will not be achieved by a number of developed countries, including Spain, Australia, and the USA, according to 1997 estimates. Australia is in favour of different targets for different nations, and refused to sign a communiqué at the South Pacific Forum meeting in the Cook Islands in 1997 which insisted on legally binding reductions in greenhouse gas emissions.

Dubbed the 'greenhouse effect' by Swedish scientist Svante Arrhenius, it was first predicted in 1827 by French mathematician Joseph Fourier.

Our planet is not fragile at its own time scale, and we, pitiful latecomers in the last microsecond of our planetary year, are stewards of nothing in the long run. Yet no political movement is more vital and timely than modern environmentalism – because we must save ourselves (and our neighbor species) from our own immediate folly.

STEPHEN JAY GOULD US palaeontologist and writer.

Bully for Brontosaurus 1991

green movement collective term for the individuals and organizations involved in efforts to protect the environment. The movement encompasses political parties such as the Green Party and organizations like Friends of the Earth and Greenpeace.

Despite a rapid growth of public support, and membership of environmental organizations running into many millions worldwide, political green groups have failed to win significant levels of the vote in democratic societies.

GreenNet in computing, international computer network used by environmental activists to exchange information and news.

Greenpeace international environmental pressure group, founded in 1971, with a policy of nonviolent direct action backed by scientific research. During a protest against French atmospheric nuclear testing in the South Pacific in 1985, its ship *Rainbow Warrior* was sunk by French intelligence agents, killing a crew member. In 1995 it played a prominent role in opposing the disposal of waste from an oil rig in the North Sea, and again attempted to disrupt French nuclear tests in the Pacific. In 1997 Greenpeace had a membership in 43 'chapters' worldwide.

green revolution in agriculture, the change in methods of arable farming instigated in the 1940s and 1950s in Third World countries. The intent was to provide more and better food for their populations, albeit with a heavy reliance on chemicals and machinery. It was abandoned by some countries in the 1980s. Much of the food

produced was exported as cash crops, so that local diet did not always improve.

The green revolution tended to benefit primarily those landowners who could afford the investment necessary for such intensive agriculture. Without a dosage of 70–90 kg/154–198 lb of expensive nitrogen fertilizers per hectare, the high-yield varieties will not grow properly. Hence, rich farmers tended to obtain bigger yields while smallholders were unable to benefit from the new methods.

In terms of production, the green revolution was initially successful in southeast Asia: India doubled its wheat yield in 15 years, and the rice yield in the Philippines rose by 75%. However, yields have levelled off in many areas; some countries that cannot afford the dams, fertilizers, and machinery required, have adopted intermediate technologies.

greenshank greyish shorebird of the sandpiper group. It has long olive-green legs and a long, slightly upturned bill, with white underparts and rump and dark grey wings. It breeds in northern Europe and regularly migrates through the Aleutian Islands, southwest of Alaska. (Species *Tringa nebularia*, family Scolopacidae, order Charadriiformes.)

Greenwich Mean Time (GMT) local time on the zero line of longitude (the *Greenwich meridian*), which passes through the Old Royal Observatory at Greenwich, London. It was replaced in 1986 by coordinated universal time (UTC), but continued to be used to measure longitudes and the world's standard time zones; see \mathcal{G} time.

grenadier another name for \mathcal{G} rat-tail, a deep-sea fish.

grep in computing, UNIX command that allows full-text searching within files. On the Net, grep is sometimes used as an all-purpose synonym for 'search'.

grevillea genus of almost exclusively Australian trees and shrubs of the family Proteaceae bearing attractive spider-flowers. There are some 250 species widely distributed throughout the continent.

greyhound ancient breed of dog, with a long narrow head, slight build, and long legs. It stands up to 75 cm/30 in tall. It is renowned for its swiftness, and can exceed 60 kph/40 mph. Greyhounds were bred to hunt by sight, their main quarry being hares. Hunting hares with greyhounds is the basis of the ancient sport of coursing. Track-based greyhound racing is a popular spectator sport.

The Italian greyhound is similar in build to the ordinary greyhound, but very much smaller, weighing only about 3.6 kg/8 lb.

grey matter in biology, those parts of the brain and spinal cord that are made up of interconnected and tightly packed nerve cell nuclei. The outer layers of the cerebellum contains most of the grey matter in the brain. It is the region of the brain that is responsible for advanced mental functions. Grey matter also constitutes the inner core of the spinal cord. This is in contrast to white matter, which is made of the axons of nerve cells.

grey scales method of representing continuous tone images on a screen or printer. Each dot in the \mathcal{G} bit map is represented by a number of bits and can have a different shade of grey. Compare with \mathcal{G} ithering when shades are simulated by altering the density and the pattern of black dots on a white background.

grid network of crossing parallel lines. Rectangular grids are used for drawing graphs. Isometric grids are used for drawing representations of solids in two dimensions in which lengths in the drawing match the lengths of the object.

grid network by which electricity is generated and distributed over a region or country. It contains many power stations and switching centres and allows, for example, high demand in one area to be met by surplus power generated in another.

The term is also used for any grating system, as in a cattle grid for controlling the movement of livestock across roads, and a conductor in a storage battery or electron gun.

grid reference a cadastral numbering system to specify location on a map. The numbers representing grid lines at the bottom of the

map (eastings) are given before those at the side (northings). Successive decimal digits refine the location within the grid system.

griffon small breed of dog originating in Belgium. Red, black, or black and tan in colour and weighing up to 5 kg/11 lb, griffons are square-bodied and round-headed. There are rough- and smooth-coated varieties.

The name is also applied to several larger breeds of hunting dogs with rough coats, including two bred in northern France to pursue wild boar.

griffon Bruxelloise breed of terrierlike toy dog originally bred in Belgium. It weighs up to 4.5 kg/10 lb and has a harsh and wiry coat that is red or black in colour. The smooth-haired form of the breed is called the *petit Brabançon*.

The griffon Bruxelloise has a large rounded head with semi-erect ears; large black eyes with black eye-rims; and a short nose surrounded with black hair that converges upwards to meet the hair round the eyes. Its chest is wide and deep; legs are straight and of medium length; the tail is traditionally docked and carried upwards.

griffon vulture Old World vulture found in southern Europe, west and central Asia, and parts of Africa. It has a bald head with a neck ruff, and is 1.1 m/3.5 ft long with a wingspan of up to 2.7 m/9 ft. (Species *Gyps fulvus*, family *Accipitridae*.)

grooming in biology, the use by an animal of teeth, tongue, feet, or beak to clean fur or feathers. Grooming also helps to spread essential oils for waterproofing. In many social species, notably monkeys and apes, grooming of other individuals is used to reinforce social relationships.

Groom Lake or *Area 51* dry lake-bed site in Nevada, USA, of US Air Force base used for the development of secret projects. In the 1980s it was used for testing of Stealth aircraft and Star Wars (Strategic Defense Initiative) projects and later for studying ex-Soviet aircraft purchased from Russia.

The base was established in the 1950s as a testing ground for the U-2 spy plane. In 1984 it was designated so secret that it no longer appeared on maps, and its existence was officially denied until 1992. Because of the strangely shaped aircraft and lights to be seen, the nearest public vantage point to Groom Lake has since 1989 attracted UFO watchers.

grosbeak any of various thick-billed finches. The pine grosbeak (*Pinicola enucleator*) breeds in Arctic forests. Its plumage is similar to that of the pine crossbill. (Family *Fringillidae*, order *Passeriformes*.)

ground beetle large, adorned, brilliantly metallic beetle. Ground beetles are mainly terrestrial with few species being capable of flight. About 20,000 species are known to exist; nearly all are carnivorous as adults and larvae.

The larvae are of particular economic importance, destroying large numbers of soil insects and worms.

classification ground beetles are in the family *Carabidae*, order *Coleoptera*, class *Insecta*, phylum *Arthropoda*.

ground controlled interception GCI British term for the ground command of fighter aircraft during and after the Battle of Britain 1940.

Using advanced radar, the British could see German air formations at considerable ranges which enabled ground controllers to direct fighter aircraft into the path of the enemy, doing away with the need to fly standing patrols across likely approaches.

groundnut another name for *peanut*.

groundwater water collected underground in porous rock strata and soils, it emerges at the surface as springs and streams. The groundwater's upper level is called the *water table*. Sandy or other kinds of beds that are filled with groundwater are called *aquifers*. Recent estimates are that usable ground water amounts to more than 90% of all the fresh water on Earth; however, keeping such supplies free of pollutants entering the recharge areas is a critical environmental concern.

Most groundwater near the surface moves slowly through the ground while the water table stays in the same place. The depth of the water table reflects the balance between the rate of infiltration, called recharge, and the rate of discharge at springs or rivers or pumped water wells. The force of gravity makes underground water run 'downhill' underground just as it does above the surface. The greater the slope and the permeability, the greater the speed. Velocities vary from 100 cm/40 in per day to 0.5 cm/0.2 in.

group in chemistry, a vertical column of elements in the periodic table. Elements in a group have similar physical and chemical properties; for example, the group 1 elements (the alkali metals: lithium, sodium, potassium, rubidium, caesium, and francium) are all highly reactive metals that form univalent ions. There is a gradation of properties down any group: in group 1, melting and boiling points decrease, and density and reactivity increase.

group in mathematics, a finite or infinite set of elements that can be combined by an operation; formally, a group must satisfy certain conditions. For example, the set of all integers (positive or negative whole numbers) forms a group with regard to addition because: (1) addition is associative, that is, the sum of two or more integers is the same regardless of the order in which the integers are added; (2) adding two integers gives another integer; (3) the set includes an identity element 0, which has no effect on any integer to which it is added (for example, $0 + 3 = 3$); and (4) each integer has an inverse (for instance, 7 has the inverse -7), such that the sum of an integer and its inverse is 0. Group theory is the study of the properties of groups.

grouper any of several species of large sea perch (spiny-finned fish), found in warm waters. Some species grow to 2 m/6.5 ft long, and can weigh 300 kg/660 lbs. (Family *Serranidae*.)

The spotted giant grouper (*Promicrops itaira*) is 2–2.5 m/6–8 ft long, may weigh over 300 kg/700 lb and is sluggish in movement. Formerly game fish, groupers are now commercially exploited as food.

groupware in computing, software designed to be used collaboratively by a small group of users, each with his/her own computer and a copy of the software. Examples of groupware are Lotus Notes and Novell GroupWise, both of which provide facilities for sending e-mail and sharing documents.

Standard business applications such as word processors are spoken of as 'groupware-enabled' if they provide facilities for a number of users to make revisions and incorporate them all into a final version. See also *computer-supported collaborative work*.

grouse plump fowl-like game bird belonging to a subfamily of the pheasant family, which also includes the ptarmigan, capercaillie, and prairie chicken. Grouse are native to North America and northern Europe. They spend most of their time on the ground. During the mating season the males undertake elaborate courtship displays in small individual territories (*leks*). (Subfamily *Tetraonidae*, family *Phasianidae*, order *Galliformes*.)

growth in biology, the increase in size and weight during the development of an organism. Growth is an increase in biomass (mass of organic material, excluding water) and is associated with cell division.

All organisms grow, although the rate of growth varies over a lifetime. Typically, an organism shows an S-shaped curve, in which growth is at first slow, then fast, then, towards the end of life, nonexistent. Growth may even be negative during the period before death, with decay occurring faster than cellular replacement.

The concept of an average, the equation to a curve, the description of a froth or cellular tissue, all come within the scope of mathematics for no other reason than that they are summations of more elementary principles or phenomena. Growth and Form are throughout of this composite nature; therefore the laws of mathematics are bound to underlie them, and her methods to be peculiarly fitted to interpret them.

growth and decay curve graph showing exponential change (growth where the increment itself grows at the same rate) as occurs with compound interest and populations.

growth ring another name for δ annual ring.

GRP abbreviation for δ glass-reinforced plastic.

grub legless larval stages of Coleoptera (beetles) and Hymenoptera (bees, ants and wasps). See δ larvae.

g-scale scale for measuring force by comparing it with the force due to δ gravity (*g*), often called *g*-force.

guan any of several large, pheasantlike birds native to the forests of South and Central America. They are sociable birds, almost the size of a turkey, with long, strong legs. Their colour is olive-green or brown. The family also includes the curassows. (Family Cracidae.)

guanaco hooved ruminant (cud-chewing) mammal belonging to the camel family, found in South America on the pampas and mountain plateaux. It grows up to 1.2 m/4 ft at the shoulder, with the head and body measuring about 1.5 m/5 ft in length. It is sandy brown in colour, with a blackish face, and has fine wool. It lives in small herds and is the ancestor of the domestic llama and alpaca. It is also related to the other wild member of the camel family, the vicuña. (Species *Lama guanaco*, family Camelidae.)

guano dried excrement of fish-eating birds that builds up under nesting sites. It is a rich source of nitrogen and phosphorus, and is widely collected for use as fertilizer. Some 80% comes from the sea cliffs of Peru.

guarana Brazilian woody climbing plant. A drink with a high caffeine content is made from its roasted seeds, and it is the source of the drug known as zoom in the USA. Starch, gum, and several oils are extracted from it for commercial use. (*Paullinia cupana*, family Sapindaceae.)

guard cell in plants, a specialized cell on the undersurface of leaves for controlling gas exchange and water loss. Guard cells occur in pairs and are shaped so that a pore, or stomata, exists between them. They can change shape with the result that the pore disappears. During warm weather, when a plant is in danger of losing excessive water, the guard cells close, cutting down evaporation from the interior of the leaf.

guava tropical American tree belonging to the myrtle family; the astringent yellow pear-shaped fruit is used to make guava jelly, or it can be stewed or canned. It has a high vitamin C content. (*Psidium guajava*, family Myrtaceae.)

gudgeon any of an Old World group of freshwater fishes of the carp family, especially the species *G. goby* found in Europe and northern Asia on the gravel bottoms of streams. It is olive-brown, spotted with black, and up to 20 cm/8 in long, with a distinctive barbel (sensory bristle, or 'whisker') at each side of the mouth. (Genus *Gobio*, family Cyprinidae.)

guelder rose or **snowball tree** cultivated shrub or small tree, native to Europe and North Africa, with round clusters of white flowers which are followed by shiny red berries. (*Viburnum opulus*, family Caprifoliaceae.)

guenon African monkey with characteristically greenish, yellow, or brown coat with brilliant markings. Guenons are slim and graceful in movement with very long tails that are not prehensile.

classification Guenons are in the genus *Cercopithecus*, family Cercopithecidae, order Primates.

GUI in computing, abbreviation for δ graphical user interface.

guillemot any of several diving seabirds belonging to the auk family that breed on rocky North Atlantic and Pacific coasts. The common guillemot (*U. aalge*) has a long straight beak and short tail and wings; the feet are three-toed and webbed, the feathers are sooty brown and white. It breeds in large colonies on sea cliffs. The black guillemot (*C. grylle*) of northern coasts is much smaller and mostly black in summer, with orange legs when breeding. Guillemots build no nest, but lay one large, almost conical egg. (Genera *Uria* and *Cephus*, family Alcidae, order Charadriiformes.)

guiltware or **nagware** in computing, variety of δ shareware software that attempts to make the user register (and pay for) the software by exploiting the user's sense of guilt.

On-screen messages are displayed, usually when the program is started, reminding users that they have an unregistered version of the program that they should pay for if they intend to continue using it. Some programs will also display the message at random intervals while the program is in use.

guinea fowl any of a group of chickenlike African birds, including the helmet guinea fowl (*Numida meleagris*), which has a horny growth on the head, white-spotted feathers, and fleshy cheek wattles (loose folds of skin). It is the ancestor of the domestic guinea fowl. Guinea fowl are mostly gregarious ground-feeders, eating insects, leaves, and snails; at night they roost in trees. (Family Numididae, order Galliformes.)

guinea pig species of δ cavy, a type of rodent.

Guinea worm parasitic, microscopic δ nematode worm found in

India and Africa, affecting some 650,000 people in Nigeria alone. It enters the body via drinking water and migrates to break out through the skin. (Species *Dracunculus medinensis*.)

Gulf Stream warm ocean δ current that flows north from the warm waters of the Gulf of Mexico. Part of the current is diverted east across the Atlantic, where it is known as the North Atlantic Drift, and warms what would otherwise be a colder climate in the British Isles and northwestern Europe.

gull any of a group of seabirds that are usually 25–75 cm/10–30 in long, white with grey or black on the back and wings, and have large beaks. Immature birds are normally a mottled brown colour. Gulls are sociable, noisy birds and they breed in colonies. (Genus principally *Larus*, subfamily Larinae, family Laridae, order Charadriiformes.)

gull The sharp, heavy beak typical of gulls can be clearly seen on this lesser black-backed gull. Premaphotos Wildlife

The common black-headed gull (*L. ridibundus*), common on both sides of the Atlantic Ocean, is grey and white with (in summer) a dark-brown head and a red beak; it breeds in large colonies on wetlands, making a nest of dead rushes and laying, on average, three eggs. The great black-headed gull (*L. ichthyæetus*) is native to Asia. The herring gull (*L. argentatus*), common in the northern hemisphere, has white and pearl-grey plumage and a yellow beak. The oceanic great black-backed gull (*L. marinus*), found in the Atlantic, is over 75 cm/2.5 ft long.

The kelp gull or Southern black-backed gull (*L. dominicanus*) is common throughout the southern hemisphere. It feeds mainly on limpets, which are swallowed whole, with the shell later spat out and left in a heap around the nest area.

gum in botany, complex polysaccharides (carbohydrates) formed by many plants and trees, particularly by those from dry regions. They form four main groups: plant exudates (gum arabic); marine plant extracts (agar); seed extracts; and fruit and vegetable extracts. Some are made synthetically.

Gums are tasteless and odourless, insoluble in alcohol and ether but generally soluble in water. They are used for adhesives, fabric sizing, in confectionery, medicine, and calico printing.

gum in mammals, the soft tissues surrounding the base of the teeth. Gums are liable to inflammation (gingivitis) or to infection by microbes from food deposits (periodontal disease).

gum arabic substance obtained from certain species of *Acacia* trees, especially *A. senegal*, with uses in medicine, confectionery, and adhesive manufacture.

gumtree common name for the *Eucalyptus* tree.

gun any kind of firearm or any instrument consisting of a metal tube from which a projectile is discharged; see also *ôpistol* and *ôsmall arms*.

gun metal type of *ôbronze*, an alloy high in copper (88%), also containing tin and zinc, so-called because it was once used to cast cannons. It is tough, hard-wearing, and resists corrosion.

gunpowder or **black powder** the oldest known *ôexplosive*, a mixture of 75% potassium nitrate (saltpetre), 15% charcoal, and 10% sulphur. Sulphur ignites at a low temperature, charcoal burns readily, and the potassium nitrate provides oxygen for the explosion. As gunpowder produces lots of smoke and burns quite slowly, it has progressively been replaced since the late 19th century by high explosives, although it is still widely used for quarry blasting, fuses, and fireworks. Gunpowder has high activation energy; a gun based on gunpowder alone requires igniting by a flint or a match.

Gunpowder is believed to have been invented in China in the 10th century, but may also have been independently discovered by the Arabs. Certainly the Arabs produced the first known working gun, in 1304. Gunpowder was used in warfare from the 14th century but it was not generally adapted to civil purposes until the 17th century, when it began to be used in mining.

guppy brightly coloured fish *Poecilia reticulata*, with an elongated body and round tail fin, measuring about 6 cm/2.25 in in length. It occurs naturally in fresh and brackish water in parts of South America and the West Indies. Guppies have also been introduced into many other tropical areas as a natural pest control because they feed on mosquito and other insect larvae. The guppy gives birth to live young, and is a popular aquarium species.

gurnard any of a group of coastal fish that creep along the sea bottom with the help of three fingerlike appendages detached from the pectoral fins. Gurnards are both tropical and temperate zone fish. (Genus *Trigla*, family Triglidae.)

gut or **alimentary canal** in the *ôdigestive* system, the part of an animal responsible for processing food and preparing it for entry into the blood.

The gut consists of a tube divided into segments specialized to perform different functions. The front end (the mouth) is adapted for food intake and for the first stages of digestion. The stomach is a storage area, although digestion of protein by the enzyme pepsin starts here; in many herbivorous mammals this is also the site of

Gutenberg, Johannes (Gensfleisch) (c. 1398–1468)

German printer, the inventor of printing from movable metal type (although Laurens Janszoon Coster has a rival claim), based on the Chinese wood-block-type method.

Gutenberg began work on the process in the 1440s and in 1450 set up a printing business in Mainz. By 1456 he had produced the first printed Bible (known as the Gutenberg Bible). It is not known what other books he printed.

He punched and engraved a steel character (letter shape) into a piece of copper to form a mould which he filled with molten metal. The letters were in the Gothic style and of equal height. By 1500, more than 180 European towns had working presses of this kind.

cellulose digestion. The small intestine follows the stomach and is specialized for digestion and for absorption. The large intestine, consisting of the colon, caecum, and rectum, has a variety of functions, including cellulose digestion, water absorption, and storage of faeces. From the gut nutrients are carried to the liver via the hepatic portal vein, ready for assimilation by the cells.

gutta-percha juice of various tropical trees of the *sapodilla* family (such as the Malaysian *Palauquium gutta*), which can be hardened to form a flexible, rubbery substance used for electrical insulation, dentistry, and golf balls; it has now been largely replaced by synthetic materials.

guttation secretion of water on to the surface of leaves through specialized pores, or *ôhydathodes*. The process occurs most frequently during conditions of high humidity when the rate of transpiration is low. Drops of water found on grass in early morning are often the result of guttation, rather than dew. Sometimes the water contains minerals in solution, such as calcium, which leaves a white crust on the leaf surface as it dries.

gymnosperm Greek '*naked seed*' in botany, any plant whose seeds are exposed, as opposed to the structurally more advanced *ôangiosperms*, where they are inside an ovary. The group includes conifers and related plants such as cycads and ginkgos, whose seeds develop in *ôcones*. Fossil gymnosperms have been found in rocks about 350 million years old.

gynaecology medical speciality concerned with disorders of the female reproductive system.

gynoecium or **gynaecium** collective term for the female reproductive organs of a flower, consisting of one or more *ôcarpels*, either free or fused together.

gyre circular surface rotation of ocean water in each major sea (a type of *ôcurrent*). Gyres are large and permanent, and occupy the northern and southern halves of the three major oceans. Their movements are dictated by the prevailing winds and the *ôCoriolis* effect. Gyres move clockwise in the northern hemisphere and anti-clockwise in the southern hemisphere.

gyroscope mechanical instrument, used as a stabilizing device and consisting, in its simplest form, of a heavy wheel mounted on an axis fixed in a ring that can be rotated about another axis, which is also fixed in a ring capable of rotation about a third axis.

Applications of the gyroscope principle include the gyrocompass, the gyropilot for automatic steering, and gyro-directed torpedoes.

The components of the gyroscope are arranged so that the three axes of rotation in any position pass through the wheel's centre of gravity. The wheel is thus capable of rotation about three mutually perpendicular axes, and its axis may take up any direction. If the axis of the spinning wheel is displaced, a restoring movement develops, returning it to its initial direction.

GZip in computing, compression software, properly called **GNU Zip**, commonly used on the Internet. Files compressed using GZip can be recognized by the file extension '.GZ'. The software is published by the **Free Software Foundation** and was originally developed for UNIX, although a DOS version is readily available.

H

ha symbol for hectare.

Haber process or **Haber-Bosch process** industrial process by which ammonia is manufactured by direct combination of its elements, nitrogen and hydrogen. The reaction is carried out at 400–500°C/752–932°F and at 200 atmospheres pressure. The two gases, in the proportions of 1:3 by volume, are passed over a catalyst of finely divided iron.

Around 10% of the reactants combine, and the unused gases are recycled. The ammonia is separated either by being dissolved in water or by being cooled to liquid form.

habitat localized environment in which an organism lives, and which provides for all (or almost all) of its needs. The diversity of habitats found within the Earth's ecosystem is enormous, and they are changing all the time. Many can be considered inorganic or physical; for example, the Arctic ice cap, a cave, or a cliff face. Others are more complex; for instance, a woodland or a forest floor. Some habitats are so precise that they are called **microhabitats**, such as the area under a stone where a particular type of insect lives. Most habitats provide a home for many species.

hacking unauthorized access to a computer, either for fun or for malicious or fraudulent purposes. Hackers generally use microcomputers and telephone lines to obtain access. In computing, the term is used in a wider sense to mean using software for enjoyment or self-education, not necessarily involving unauthorized access. The most destructive form of hacking is the introduction of a computer virus.

Hacking can be divided into four main areas: viruses, phreaking, software piracy (stripping away the protective coding that should prevent the software being copied), and accessing operating systems.

A 1996 US survey co-sponsored by the FBI showed 41% of academic, corporate, and government organizations interviewed had had their computer systems hacked into during 1995.

haddock marine fish belonging to the cod family and found off the N Atlantic coastline. It is brown with silvery underparts and black markings above the pectoral fins. It can grow up to 1 m/3 ft in length. Haddock are important food fish; about 45 million kg/100 million lb are taken annually off the New England fishing banks alone. (Species *Melanogrammus aeglefinus*, family Gadidae.)

Hadrian's Wall Roman frontier system built AD 122–26 to mark England's northern boundary and abandoned about 383; its ruins run 185 km/115 mi from Wallsend on the river Tyne to Maryport, W Cumbria. In some parts, the wall was covered with a glistening, white coat of mortar. The fort at South Shields, Arbeia, built to defend the eastern end, has been under reconstruction.

hadron in physics, a subatomic particle that experiences the strong nuclear force. Each is made up of two or three indivisible particles called quarks. The hadrons are grouped into the baryons (protons, neutrons, and hyperons) and the mesons (particles with masses between those of electrons and protons).

Hadron-Electron Ring Accelerator (HERA) particle accelerator built under the streets of Hamburg, Germany, occupying a tunnel 6.3 km/3.9 mi in length. It is the world's most power-

Haber, Fritz (1868–1934)

German chemist whose conversion of atmospheric nitrogen to ammonia opened the way for the synthetic fertilizer industry. His study of the combustion of hydrocarbons led to the commercial 'cracking' or fractional distillation of natural oil (petroleum) into its components (for example, diesel, petrol, and paraffin). In electrochemistry, he was the first to demonstrate that oxidation and reduction take place at the electrodes; from this he developed a general electrochemical theory.

At the outbreak of World War I in 1914, Haber was asked to devise a method of producing nitric acid for making high explosives. Later he became one of the principals in the German chemical-warfare effort, devising weapons and gas masks, which led to protests against his Nobel prize in 1918.

ful collider of protons and electrons, designed to accelerate protons to energies of 820 GeV (billion electron volts), and electrons to 30 GeV. HERA began operating 1992.

HERA can propel electrons into the proton interior, where they interact with the proton's constituent particles: three quarks and a number of gluons.

haematology medical speciality concerned with disorders of the blood.

haemoglobin protein used by all vertebrates and some invertebrates for oxygen transport because the two substances combine reversibly. In vertebrates it occurs in red blood cells (erythrocytes), giving them their colour.

In the lungs or gills where the concentration of oxygen is high, oxygen attaches to haemoglobin to form oxyhaemoglobin. This process effectively increases the amount of oxygen that can be carried in the bloodstream. The oxygen is later released in the body tissues where it is at a low concentration, and the deoxygenated blood returned to the lungs or gills. Haemoglobin will combine also with carbon monoxide to form carboxyhaemoglobin, but in this case the reaction is irreversible.

haemolymph circulatory fluid of those molluscs and insects that have an 'open' circulatory system. Haemolymph contains water, amino acids, sugars, salts, and white cells like those of blood. Circulated by a pulsating heart, its main functions are to transport digestive and excretory products around the body. In molluscs, it also transports oxygen and carbon dioxide.

haemolysis destruction of red blood cells. Aged cells are constantly being lysed (broken down), but increased wastage of red cells is seen in some infections and blood disorders. It may result in jaundice (through the release of too much haemoglobin) and in anaemia.

haemophilia any of several inherited diseases in which normal blood clotting is impaired. The sufferer experiences prolonged bleeding from the slightest wound, as well as painful internal bleeding without apparent cause.

Haemophilias are nearly always sex-linked, transmitted through the female line only to male infants; they have afflicted a number

of European royal households. Males affected by the most common form cannot synthesize Factor VIII, a protein involved in the clotting of blood. Treatment is primarily with Factor VIII (now mass-produced by recombinant techniques), but the haemophilic remains at risk from the slightest incident of bleeding. The disease is a painful one that causes deformities of joints.

haemorrhage loss of blood from the circulatory system. It is 'manifest' when the blood can be seen, as when it flows from a wound, and 'occult' when the bleeding is internal, as from an ulcer or internal injury.

Rapid, profuse haemorrhage causes shock and may prove fatal if the circulating volume cannot be replaced in time. Slow, sustained bleeding may lead to anaemia. Arterial bleeding is potentially more serious than blood lost from a vein. It may be stemmed by applying pressure directly to the wound.

haemorrhoids distended blood vessels (varicose veins) in the area of the anus, popularly called piles.

haemostasis natural or surgical stoppage of bleeding. In the natural mechanism, the damaged vessel contracts, restricting the flow, and blood platelets plug the opening, releasing chemicals essential to clotting.

hafnium Latin *Hafnia* 'Copenhagen' silvery, metallic element, symbol Hf, atomic number 72, relative atomic mass 178.49. It occurs in nature in ores of zirconium, the properties of which it resembles. Hafnium absorbs neutrons better than most metals, so it is used in the control rods of nuclear reactors; it is also used for light-bulb filaments.

It was named in 1923 by Dutch physicist Dirk Coster (1889-1950) and Hungarian chemist Georg von Hevesy after the city of Copenhagen, where the element was discovered.

hail precipitation in the form of pellets of ice (hailstones). It is caused by the circulation of moisture in strong convection currents, usually within cumulonimbus clouds.

Water droplets freeze as they are carried upwards. As the circulation continues, layers of ice are deposited around the droplets until they become too heavy to be supported by the currents and they fall as a hailstorm.

HAIL

Hailstones can kill. In the Gopalganj region of Bangladesh in 1988, 92 people died after being hit by huge hailstones weighing up to 1 kg/2.2 lb.

hair fine filament growing from mammalian skin. Each hair grows from a pit-shaped follicle embedded in the second layer of the skin, the dermis. It consists of dead cells impregnated with the protein keratin.

The average number of hairs on a human head varies from 98,000 (red-heads) to 120,000 (blondes). Each grows at the rate of 5-10 mm/0.2-0.4 in per month, lengthening for about three years before being replaced by a new one. A coat of hair helps to insulate land mammals by trapping air next to the body. The thickness of this layer can be varied at will by raising or flattening the coat. In some mammals a really heavy coat may be so effective that it must be shed in summer and a thinner one grown. Hair also aids camouflage, as in the zebra and the white winter coats of Arctic animals; and protection, as in the porcupine and hedgehog; bluffing enemies by apparently increasing the size, as in the cat; sexual display, as in humans and the male lion; and its colouring or erection may be used for communication. In 1990 scientists succeeded for the first time in growing human hair in vitro.

hairstreak any of a group of small butterflies, related to blues and coppers. Hairstreaks live in both temperate and tropical regions. Most of them are brownish or greyish-blue with hairlike tips streaked with white at the end of their hind wings. (Genera

Callophrys and other related genera, family Lycaenidae.)

hake any of various marine fishes belonging to the cod family, found in N European, African, and American waters. They have silvery elongated bodies and grow up to 1 m/3 ft in length. They have two dorsal fins and one long anal fin. The silver hake (*M. bilinearis*) is an important food fish. (Genera *Merluccius* and *Urophycis*, family Gadidae.)

hakea shrub or tree of the Australian genus *Hakea*, family Proteaceae, characterized by hard woody fruit with winged seeds.

half duplex in computing, a modem setting which controls whether or not characters echo to (appear on) the screen. See full duplex.

half-life during radioactive decay, the time in which the strength of a radioactive source decays to half its original value. In theory, the decay process is never complete and there is always some residual radioactivity. For this reason, the half-life of a radioactive isotope is measured, rather than the total decay time. It may vary from millions of a second to billions of years.

Radioactive substances decay exponentially; thus the time taken for the first 50% of the isotope to decay will be the same as the time taken by the next 25%, and by the 12.5% after that, and so on.

For example, carbon-14 takes about 5,730 years for half the material to decay; another 5,730 for half of the remaining half to decay; then 5,730 years for half of that remaining half to decay, and so on. Plutonium-239, one of the most toxic of all radioactive substances, has a half-life of about 24,000 years.

halftone in computing, term used in the publishing industry for a black-and-white photograph, indicating the many shades of grey that must be reproduced.

halftone process technique used in printing to reproduce the full range of tones in a photograph or other illustration. The intensity of the printed colour is varied from full strength to the lightest shades, even if one colour of ink is used. The picture to be reproduced is photographed through a screen ruled with a rectangular mesh of fine lines, which breaks up the tones of the original into areas of dots that vary in frequency according to the intensity of the tone. In the darker areas the dots run together; in the lighter areas they have more space between them.

halibut any of a group of large flatfishes found in the Atlantic and Pacific oceans. The largest of the flatfishes, they may grow up to 2 m/6 ft in length and weigh 90-135 kg/200-300 lb. They are a very dark mottled brown or green above and pure white on the underside. The Atlantic halibut (*H. hippoglossus*) is caught offshore at depths from 180 m/600 ft to 730 m/2,400 ft. (Genus *Hippoglossus*, family Pleuronectidae.)

halide any compound produced by the combination of a halogen, such as chlorine or iodine, with a less electronegative element (see electronegativity). Halides may be formed by ionic bonds or by covalent bonds.

halite mineral form of sodium chloride, NaCl. Common salt is the mineral halite. When pure it is colourless and transparent, but it is often pink, red, or yellow. It is soft and has a low density.

Halite occurs naturally in evaporite deposits that have precipitated on evaporation of bodies of salt water. As rock salt, it forms beds within a sedimentary sequence; it can also migrate upwards through surrounding rocks to form salt domes. It crystallizes in the cubic system.

Hall effect production of a voltage across a conductor or semiconductor carrying a current at a right angle to a surrounding magnetic field. It was discovered in 1897 by the US physicist Edwin Hall (1855-1938). It is used in the Hall probe for measuring the strengths of magnetic fields and in magnetic switches.

Halley's comet comet that orbits the Sun about every 76 years, named after Edmond Halley who calculated its orbit. It is the brightest and most conspicuous of the periodic comets. Recorded

Halley, Edmond (1656–1742)

English astronomer. He not only identified the comet that was later to be known by his name, but also compiled a star catalogue, detected the proper motion of stars, using historical records, and began a line of research that, after his death, resulted in a reasonably accurate calculation of the astronomical unit.

Halley calculated that the comet sightings reported in 1456, 1531, 1607, and 1682 all represented reappearances of the same comet. He reasoned that the comet would follow a parabolic path and announced in 1705 in his *Synopsis Astronomiae*

Cometae that it would reappear in 1758. When it did, public acclaim for the astronomer was such that his name was irrevocably attached to it.

He made many other notable contributions to astronomy, including the discovery of the proper motions of Aldebaran, Arcturus, and Sirius, and working out a method of obtaining the solar parallax by observations made during a transit of Venus. He was Astronomer Royal from 1720.

Mary Evans Picture Library

sightings go back over 2,000 years. It travels around the Sun in the opposite direction to the planets. Its orbit is inclined at almost 20° to the main plane of the Solar System and ranges between the orbits of Venus and Neptune. It will next reappear 2061.

The comet was studied by space probes at its last appearance in 1986. The European probe *Giotto* showed that the nucleus of Halley's comet is a tiny and irregularly shaped chunk of ice, measuring some 15 km/10 m long by 8 km/5 m wide, coated by a layer of very dark material, thought to be composed of carbon-rich compounds. This surface coating has a very low albedo, reflecting just 4% of the light it receives from the Sun. Although the comet is one of the darkest objects known, it has a glowing head and tail produced by jets of gas from fissures in the outer dust layer. These vents cover 10% of the total surface area and become active only when exposed to the Sun. The force of these jets affects the speed of the comet's travel in its orbit.

hallmark official mark stamped on British gold, silver, and (from 1913) platinum, instituted in 1327 (royal charter of London Goldsmiths) in order to prevent fraud. After 1363, personal marks of identification were added. Now tests of metal content are carried out at authorized assay offices in London, Birmingham, Sheffield, and Edinburgh; each assay office has its distinguishing mark, to which is added a maker's mark, date letter, and mark guaranteeing standard.

hallucinogen any substance that acts on the central nervous system to produce changes in perception and mood and often hallucinations. Hallucinogens include LSD, peyote, and mescaline. Their effects are unpredictable and they are illegal in most countries.

In some circumstances hallucinogens may produce panic or even suicidal feelings, which can recur without warning several days or months after taking the drug. In rare cases they produce an irreversible psychotic state mimicking schizophrenia. Spiritual or religious experiences are common, hence the ritual use of hallucinogens in some cultures. They work by chemical interference with the normal action of neurotransmitters in the brain.

Reality is not only more fantastic than we think, but also much more fantastic than we imagine.

halogen any of a group of five nonmetallic elements with similar chemical bonding properties: fluorine, chlorine, bromine, iodine, and astatine. They form a linked group in the periodic table of the elements, descending from fluorine, the most reactive, to astatine, the least reactive. They combine directly with most metals to form salts, such as common salt (NaCl). Each halogen has seven electrons in its valence shell, which accounts for the chemical similarities displayed by the group.

halon organic chemical compound containing one or two carbon atoms, together with bromine and other halogens. The most commonly used are halon 1211 (bromochlorodifluoromethane) and halon 1301 (bromotrifluoromethane). The halons are gases and are widely used in fire extinguishers. As destroyers of the ozone layer, they are up to ten times more effective than chlorofluorocarbons (CFCs), to which they are chemically related.

Levels in the atmosphere are rising by about 25% each year, mainly through the testing of fire-fighting equipment. The use of halons in fire extinguishers was banned in 1994.

halophyte plant adapted to live where there is a high concentration of salt in the soil, for example, in salt marshes and mud flats.

hamadryad or **king cobra** or **giant cobra** large and poisonous cobra found from India to China and the Philippines, sometimes reaching a length of 5 m/16 ft. It is one of the longest and most venomous of snakes, and is yellow with black crossbands.

classification The hamadryad *Ophiophagus hannah* is in family Elapidae, suborder Serpentes, order Squamata, class Reptilia.

hammerhead any of several species of shark found in tropical seas, characterized by having eyes at the ends of flattened hammerlike extensions of the skull. Hammerheads can grow to 4 m/13 ft in length. (Genus *Sphyrna*, family Sphyrnidae.)

hamster any of a group of burrowing rodents with a thickset body, short tail, and cheek pouches to carry food. Several genera are found across Asia and in SE Europe. Hamsters are often kept as pets. (Genera include *Cricetus* and *Mesocricetus*, family Cricetidae.)

Species include the European and Asian black-bellied or common hamster (*C. cricetus*), about 25 cm/10 in long, which can be a crop pest and stores up to 90 kg/200 lb of seeds in its burrow. The golden hamster (*M. auratus*) lives in W Asia and SE Europe. All golden hamsters now kept as pets originated from one female and 12 young captured in Syria 1930.

hand unit used in measuring the height of a horse from front hoof to shoulder (withers). One hand equals 10.2 cm/4 in.

handfish very rare Tasmanian fish *Brachionichthys hirsutus* that moves along the seafloor on handlike fins. It is about 10 cm/4 in long and is found only in the coastal waters of S Tasmania.

handle in computing, term used on Internet Relay Chat and other live chat services for a nickname.

A given user's handle may or may not be the same as his/her (user-ID); on many systems users are allowed to pick any name they like to use on chat systems as long as it is not already taken by another user.

Handles are also used on CB and ham radio, and hackers use handles, for cultural reasons as much as to disguise their real identities.

handshake in computing, an exchange of signals between two devices that establishes the communications channels and protocols necessary for the devices to send and receive data.

handwriting recognition in computing, ability of a computer to accept handwritten input and turn it into digital data that can be processed and displayed or stored as ASCII characters on the computer screen.

Handwriting recognition would free computer users from having to use the keyboard, but it is difficult to implement. A few machines, such as the Apple Newton, have the ability built in, but the technology is still at an early stage of development and such machines typically require users to train the machine by entering a sample alphabet. Technical limitations mean written input has to be printed in small boxes.

Hannover German fighter aircraft made by the *Hannoversche Waggonfabrik* from 1917. A two-seater biplane, the Hannover CLII. was also used for ground attack and as an escort for bombers. Improved as the CLII A, it became a major part of the German Air Force, over 550 being built in 1917-18.

Hansa-Brandenburg German seaplanes, the most popular float-planes with the German Navy in World War I. They continued in use after the war, and the chief designer, Ernst Heinkel, became famous as a manufacturer of warplanes during World War II.

haploid having a single set of chromosomes in each cell. Most higher organisms are diploid - that is, they have two sets - but their gametes (sex cells) are haploid. Some plants, such as mosses, liverworts, and many seaweeds, are haploid, and male honey bees are haploid because they develop from eggs that have not been fertilized. See also meiosis.

hard copy computer output printed on paper.

hard disc in computing, a storage device usually consisting of a rigid metal disc coated with a magnetic material. Data are read from and written to the disc by means of a disc drive. The hard disc may be permanently fixed into the drive or in the form of a disc pack that can be removed and exchanged with a different pack. Hard discs vary from large units with capacities of more than 3,000 megabytes, intended for use with mainframe computers, to small units with capacities as low as 20 megabytes, intended for use with microcomputers.

hardening of oils transformation of liquid oils to solid products by hydrogenation.

Vegetable oils contain double covalent carbon-to-carbon bonds and are therefore examples of unsaturated compounds. When hydrogen is added to these double bonds, the oils become saturated. The more saturated oils are waxlike solids.

hardness physical property of materials that governs their use. Methods of heat treatment can increase the hardness of metals. A scale of hardness was devised by German-Austrian mineralogist Friedrich Mohs in the 1800s, based upon the hardness of certain minerals from soft talc (Mohs' hardness 1) to diamond (10), the hardest of all materials.

hard-sectored disc floppy disc that is sold already formatted, so that disc formatting is not necessary. Usually sectors are marked by holes near the hub of the disc. This system is now obsolete.

hardware the mechanical, electrical, and electronic components of a computer system, as opposed to the various programs, which constitute software.

hard water water that does not lather easily with soap, and produces a deposit or 'scale' in kettles. It is caused by the presence of

certain salts of calcium and magnesium.

Temporary hardness is caused by the presence of dissolved hydrogencarbonates (bicarbonates); when the water is boiled, they are converted to insoluble carbonates that precipitate as 'scale'. **Permanent hardness** is caused by sulphates and silicates, which are not affected by boiling. Water can be softened by distillation, ion exchange (the principle underlying commercial water softeners), addition of sodium carbonate or of large amounts of soap, or boiling (to remove temporary hardness).

Hardy-Weinberg equilibrium in population genetics, the theoretical relative frequency of different alleles within a given population of a species, when the stable endpoint of evolution in an undisturbed environment is reached.

hare mammal closely related to the rabbit, similar in appearance but larger. Hares have very long black-tipped ears, long hind legs, and short upright tails. (Genus *Lepus*, family Leporidae, order Lagomorpha.)

Throughout the long breeding season (June-August) there are chases and 'boxing matches' among males and females; the expression 'mad as a March hare' arises from this behaviour.

harebell perennial plant of the bellflower family, with bell-shaped blue flowers, found on dry grassland and heaths. It is known in Scotland as the bluebell. (*Campanula rotundifolia*, family Campanulaceae.)

Hare's apparatus in physics, a specific kind of hydrometer used to compare the relative densities of two liquids, or to find the density of one if the other is known. It was invented by US chemist Robert Hare (1781-1858).

It consists of a vertical E-shaped glass tube, with the long limbs dipping into the two liquids and a tap on the short limb. With the tap open, air is removed from the tops of the tubes and the liquids are pushed up the tubes by atmospheric pressure. When the tap is closed, the heights of the liquids are inversely proportional to their relative densities.

Harrier the only truly successful vertical takeoff and landing fixed-wing aircraft, often called the **jump jet**. It was built in Britain and made its first flight 1966. It has a single jet engine and a set of swivelling nozzles. These deflect the jet exhaust vertically downwards for takeoff and landing, and to the rear for normal flight. Designed to fly from confined spaces with minimal ground support, it refuels in midair.

harrier any of a group of birds of prey. Harriers have long wings and legs, a small head with a short beak, an owl-like frill of thick-set feathers around the face, and soft plumage. They eat frogs, birds, snakes, and small mammals, and are found mainly in marshy areas throughout the world. (Genus *Circus*, family Accipitridae, order Falconiformes.)

harrier breed of hound, similar to a foxhound but smaller, used in packs for hare-hunting.

harrow agricultural implement used to break up the furrows left by the plough and reduce the soil to a fine consistency or tilth, and to cover the seeds after sowing. The traditional harrow consists of spikes set in a frame; modern harrows use sets of discs.

hartebeest large African antelope with lyre-shaped horns set close on top of the head in both sexes. It can grow to 1.5 m/5 ft tall at the rather humped shoulders and up to 2 m/6 ft long. Although they are clumsy-looking runners, hartebeest can reach speeds of 65 kph/40 mph. (Species *Alcelaphus buselaphus*, family Bovidae.)

hart's-tongue fern with straplike undivided fronds, up to 60 cm/24 in long, which have clearly visible brown spore-bearing organs on the undersides. The plant is native to Europe, Asia, and E North America, and is found on walls, in shady rocky places, and in woods. (*Phyllitis scolopendrium*, family Polypodiaceae.)

harvestman small animal (an arachnid) related to spiders with very long, thin legs and a small body. Harvestmen are different from true spiders in that they do not have a waist or narrow part

to the oval body. They feed on small insects and spiders, and lay their eggs in autumn, to hatch the following spring or early summer. They are found from the Arctic to the tropics. (Order Opiliones.)

harvest mite another name for the *ŕchigger*, a parasitic mite.

Harwell main research establishment of the United Kingdom Atomic Energy Authority, situated near the village of Harwell in Oxfordshire.

hash function in computing, an *ŕalgorithm* that calculates a value from the content of a message which can then be used to detect alterations to the original message.

Similar to a *ŕchecksum* but with greater security, hash functions play an important role in secure cryptographic systems (see *ŕcryptography*), where authentication is as important as hiding the data from third parties.

hashing in computing, the process used to convert a record, usually in a database, into a number that can be used to retrieve the record, or check its validity. The 'hashing algorithm', which may be based on manipulating the ASCII values of letters, will be devised so that different records give a useful range of results. Hashing is faster than storing things alphabetically, for example, where some areas may have lots of very similar records (for example, under c, s, or t) while others are little used (q, x, z).

hashish drug made from the resin contained in the female flowering tops of hemp (*ŕcannabis*).

hash total in computing, a *ŕvalidation* check in which an otherwise meaningless control total is calculated by adding together numbers (such as payroll or account numbers) associated with a set of records. The hash total is checked each time data are input, in order to ensure that no entry errors have been made.

hassium synthesized, radioactive element of the *ŕtransactinide* series, symbol Hs, atomic number 108, relative atomic mass 265. It was first synthesized in 1984 by the Laboratory for Heavy Ion Research in Darmstadt, Germany. Its temporary name was unillocium.

haustorium (plural *haustoria*) specialized organ produced by a parasitic plant or fungus that penetrates the cells of its host to absorb nutrients. It may be either an outgrowth of hyphae (see *ŕhypha*), as in the case of parasitic fungi, or of the stems of flowering parasitic plants, as in dodders (*ŕCuscuta*). The suckerlike haustoria of a dodder penetrate the vascular tissue of the host plant without killing the cells.

Havana cat breed of domestic shorthaired cat bred in Britain during the 1950s from a cross between two varieties of Siamese. It has a deep, rich-brown fur, wedge-shaped head, green eyes, long legs, and svelte build. In America, the Havana Brown is less Oriental in look than its British counterparts. It is sturdier with a medium-length body, rounder face, oval eyes, and longer fur. The name is derived from the colouring which resembles the Cuban cigar tobacco.

hawfinch European *ŕfinch*, about 18 cm/7 in long. It feeds on berries and seeds, and can crack cherry stones with its large, powerful beak. The male bird has brown plumage, a black throat and black wings with a bold white shoulder stripe, a short white-tipped tail, and a broad band of grey at the back of the neck. (Species *ŕCoccothraustes coccothraustes*, family *ŕFringillidae*, order *ŕPasseriformes*.)

Hawfinches spend most of their time in the treetops, where they eat the fruits of pine, hornbeam, plum, cherry, hawthorn, laurel, and holly trees. They build their nests of twigs and mosses in lichen-covered trees, 2–10 m/6.5–33 ft above the ground. They are abundant in southern Europe and are also found in the temperate parts of Asia.

hawk any of a group of small to medium-sized birds of prey, belonging to the same family as eagles, kites, ospreys, and vultures.

HAWK

Some hawks have evolved a unique way of hanging on to their prey. The African harrier hawk and the Central and South American crane hawk can bend their legs both backwards and forwards from the middle joint. Their prey (mostly frogs, lizards, and baby birds) thus has great difficulty eluding them in even the trickiest crevices.

Hawks have short, rounded wings and a long tail compared with *ŕfalcons*, and keen eyesight; the *ŕsparrow hawk* and *ŕgoshawk* are examples. (Especially genera *ŕAccipiter* and *ŕButeo*, family *ŕAccipitridae*.)

Hawking, Stephen (William) (1942–)

English physicist whose work in general relativity – particularly gravitational field theory – led to a search for a quantum theory of gravity to explain black holes and the Big Bang, singularities that classical relativity theory does not adequately explain. His book *A Brief History of Time* 1988 gives a popular account of cosmology and became an international bestseller. His latest book is *The Nature of Space and Time*, written with Roger Penrose.

Hawking's objective of producing an overall synthesis of quantum mechanics and relativity theory began around the time of the publication in 1973 of his seminal book *The Large Scale Structure of Space-Time*, written with G F R Ellis. His most remarkable result, published in 1974, was that black holes could in fact emit particles in the form of thermal radiation – the so-called Hawking radiation.

If we find why it is that we and the universe exist, it would be the ultimate triumph of human reason – for then we would know the mind of God.

STEPHEN HAWKING English physicist.

hawk moth any member of a family of *ŕmoths* with more than 1,000 species distributed throughout the world, but found mainly in tropical regions. Some South American hawk moths closely resemble hummingbirds. (Family *ŕSphingidae*.)

HAWK MOTH

The tongue of the Malagasy hawk moth is more than twice the length of its body. This enables it to feed from flowers without having to land on them, thus avoiding predators waiting in ambush.

hawthorn any of a group of shrubs or trees belonging to the rose family, growing abundantly in E North America, and also in Europe and Asia. All have alternate, toothed leaves and bear clusters of showy white, pink, or red flowers. Their small applelike fruits can be red, orange, blue, or black. Hawthorns are popular as ornamentals. (Genus *ŕCrataegus*, family *ŕRosaceae*.)

hay preserved grass used for winter livestock feed. The grass is cut and allowed to dry in the field before being removed for storage in a barn.

The optimum period for cutting is when the grass has just come into flower and contains most feed value. During the natural drying process, the moisture content is reduced from 70–80% down to a safe level of 20%. In normal weather conditions, this takes from two to five days, during which time the hay is turned by machine to ensure even drying. Hay is normally baled before removal from the field.

Hayashi track in astronomy, a path on the Hertzsprung–Russell diagram taken by protostars as they emerge from the clouds of dust and gas out of which they were born. A protostar appears on the right (cool) side of the Hertzsprung–Russell diagram and follows a Hayashi track until it arrives on the main sequence where hydrogen burning can start. It is named after the Japanese astrophysicist Chushiro Hayashi, who studied the theory of protostars in the 1960s.

hay fever allergic reaction to pollen, causing sneezing, with inflammation of the nasal membranes and conjunctiva of the eyes. Symptoms are due to the release of histamine. Treatment is by antihistamine drugs.

hazard label The internationally recognized symbols, warning of the potential dangers of handling certain substances.

hazardous waste waste substance, usually generated by industry, that represents a hazard to the environment or to people living or working nearby. Examples include radioactive wastes, acidic resins, arsenic residues, residual hardening salts, lead from car exhausts, mercury, nonferrous sludges, organic solvents, asbestos, chlorinated solvents, and pesticides. The cumulative effects of toxic waste can take some time to become apparent (anything from a

few hours to many years), and pose a serious threat to the ecological stability of the planet; its economic disposal or recycling is the subject of research.

haze factor unit of visibility in mist or fog. It is the ratio of the brightness of the mist compared with that of the object.

hazel any of a group of shrubs or trees that includes the European common hazel or cob (*C. avellana*), of which the filbert is the cultivated variety. North American species include the American hazel (*C. americana*). (Genus *Corylus*, family Corylaceae.)

headache pain felt within the skull. Most headaches are caused by stress or tension, but some may be symptoms of brain or systemic disease, including fever.

Chronic daily headache may be caused by painkiller misuse, according to the European Headache Foundation in 1996. People who take daily analgesics to treat chronic headaches may actually be causing the headaches by doing so. See also migraine.

header in computing, line or lines of text that appear at the beginning of each e-mail or USENET message sent across the Internet. The header includes important routing and identifying information, such as the sender's name, recipient's name (either a person or a newsgroup), date, time, and machine used when the message was composed, and the path by which the message arrived at its destination.

In the case of USENET postings, it also indicates if the message is intended for more than one group. The exact material is determined by RFC (requests for comments) and discussion.

head louse parasitic insect that lives in human hair. See louse.

health, world the health of people worldwide is monitored by the World Health Organization (WHO). Outside the industrialized world in particular, poverty and degraded environmental conditions mean that easily preventable diseases are widespread: WHO estimated in 1990 that 1 billion people, or 20% of the world's population, were diseased, in poor health, or malnourished. In North Africa and the Middle East, 25% of the population were ill.

vaccine-preventable diseases Every year, 46 million infants are not fully immunized; 2.8 million children die and 3 million are disabled due to vaccine-preventable diseases (polio, tetanus, diphtheria, whooping cough, tuberculosis, and measles).

diarrhoea Every year, there are 750 million cases in children, causing 4 million deaths. Oral rehydration therapy can correct dehydration and prevent 65% of deaths due to diarrhoeal disease. The basis of therapy is prepackaged sugar and salt. Treatment to cure the disease costs less than 20 cents, but fewer than one-third of children are treated in this way.

tuberculosis 1.6 billion people carry the bacteria, and there are 3 million deaths every year. Some 95% of all patients could be cured within six months using a specific antibiotic therapy which costs less than \$30 per person.

prevention and cure Increasing health spending in industrialized countries by only \$2 per head would enable immunization of all children to be performed, polio to be eradicated, and drugs provided to cure all cases of diarrhoeal disease, acute respiratory infection, tuberculosis, malaria, schistosomiasis, and most sexually transmitted diseases.

hearing aid any device to improve the hearing of partially deaf people. Hearing aids usually consist of a battery-powered transistorized microphone/amplifier unit and earpiece. Some miniaturized aids are compact enough to fit in the ear or be concealed in the frame of eyeglasses.

heart The structure of the human heart. During an average lifetime, the human heart beats more than 2,000 million times and pumps 500 million l/110 million gal of blood. The average pulse rate is 70–72 beats per minute at rest for adult males, and 78–82 beats per minute for adult females.

heart muscular organ that rhythmically contracts to force blood around the body of an animal with a circulatory system. Annelid worms and some other invertebrates have simple hearts consisting of thickened sections of main blood vessels that pulse regularly. An earthworm has ten such hearts. Vertebrates have one heart. A fish heart has two chambers – the thin-walled **atrium** (once called the auricle) that expands to receive blood, and the thick-walled **ventricle** that pumps it out. Amphibians and most reptiles have two atria and one ventricle; birds and mammals have two atria and two ventricles. The beating of the heart is controlled by the autonomic nervous system and an internal control centre or pacemaker, the **sinoatrial node**.

the cardiac cycle The cardiac cycle is the sequence of events during one complete cycle of a heart beat. This consists of the simultaneous contraction of the two atria, a short pause, then the simultaneous contraction of the two ventricles, followed by a longer pause while the entire heart relaxes. The contraction phase is called 'systole' and the relaxation phase which follows is called 'diastole'. The whole cycle is repeated 70–80 times a minute under resting conditions.

When the atria contract, the blood in them enters the two relaxing ventricles, completely filling them. The mitral and tricuspid valves, which were open, now begin to shut and as they do so, they create vibrations in the heart walls and tendons, causing the first heart sound. The ventricles on contraction push open the pulmonary and aortic valves and eject blood into the respective vessels. The closed mitral and tricuspid valves prevent return of blood into the atria during this phase. As the ventricles start to relax, the aortic and pulmonary valves close to prevent backward flow of blood, and their

closure causes the second heart sound. By now, the atria have filled once again and are ready to start contracting to begin the next cardiac cycle.

heart attack or **myocardial infarction** sudden onset of gripping central chest pain, often accompanied by sweating and vomiting, caused by death of a portion of the heart muscle following obstruction of a coronary artery by thrombosis (formation of a blood clot). Half of all heart attacks result in death within the first two hours, but in the remainder survival has improved following the widespread use of thrombolytic (clot-buster) drugs.

After a heart attack, most people remain in hospital for seven to ten days, and may make a gradual return to normal activity over the following months. How soon a patient is able to return to work depends on the physical and mental demands of their job. Despite widespread fears to the contrary, it is safe to return to normal sexual activity within about a month of the attack.

Home page of the American Heart Association offers a risk assessment test, information about healthy living, including the effects of diet, and access to resources for both patients and carers.

heartbeat the regular contraction and relaxation of the heart, and the accompanying sounds. As blood passes through the heart a double beat is heard. The first is produced by the sudden closure of the valves between the atria and the ventricles. The second, slightly delayed sound, is caused by the closure of the valves found at the entrance to the major arteries leaving the heart. Diseased valves may make unusual sounds, known as heart murmurs.

heartburn burning sensation behind the breastbone (sternum). It results from irritation of the lower oesophagus (gullet) by excessively acid stomach contents, as sometimes happens during pregnancy and in cases of duodenal ulcer or obesity. It is often due to a weak valve at the entrance to the stomach that allows its contents to well up into the oesophagus.

heart-lung machine apparatus used during heart surgery to take over the functions of the heart and the lungs temporarily. It has a pump to circulate the blood around the body and is able to add oxygen to the blood and remove carbon dioxide from it. A heart-lung machine was first used for open-heart surgery in the USA in 1953.

heat form of energy possessed by a substance by virtue of the vibrating movement (kinetic energy) of its molecules or atoms. Heat energy is transferred by conduction, convection, and radiation. It always flows from a region of higher temperature (heat intensity) to one of lower temperature. Its effect on a substance may be simply to raise its temperature, or to cause it to expand, melt (if a solid), vaporize (if a liquid), or increase its pressure (if a confined gas).

measurement Quantities of heat are usually measured in units of energy, such as joules (J) or calories (cal). The specific heat of a substance is the ratio of the quantity of heat required to raise the temperature of a given mass of the substance through a given range of temperature to the heat required to raise the temperature of an equal mass of water through the same range. It is measured by a calorimeter.

conduction, convection, and radiation Conduction is the passing of heat along a medium to neighbouring parts with no visible motion accompanying the transfer of heat – for example, when the whole length of a metal rod is heated when one end is held in a fire. Convection is the transmission of heat through a fluid (liquid or gas) in currents – for example, when the air in a room is warmed by a fire or radiator. Radiation is heat transfer by infrared rays. It can pass through a vacuum, travels at the same speed as light, can be reflected and refracted, and does not affect the medium through which it passes. For example, heat reaches the Earth from the Sun by radiation.

For the transformation of heat, see *thermodynamics*.

heat capacity in physics, the quantity of heat required to raise the temperature of an object by one degree. The specific heat capacity of a substance is the heat capacity per unit mass, measured in joules per kilogram per kelvin ($\text{J kg}^{-1} \text{K}^{-1}$).

heat death in cosmology, a possible fate of the universe in which it continues expanding indefinitely while all the stars burn out and no new ones are formed. See *cosmological density*.

heath in botany, any of a group of woody, mostly evergreen shrubs, including *heather*, many of which have bell-shaped pendant flowers. They are native to Europe, Africa, and North America. (Common Old World genera *Erica* and *Calluna*, family Ericaceae.)

heather low-growing evergreen shrub of the *heath* family, common on sandy or acid soil. The common heather (*Calluna vulgaris*) is a carpet-forming shrub, growing up to 60 cm/24 in high and bearing pale pink-purple flowers. It is found over much of Europe and has been introduced to North America.

heat of reaction alternative term for *energy of reaction*.

heat pump machine, run by electricity or another power source, that cools the interior of a building by removing heat from interior air and pumping it out or, conversely, heats the inside by extracting energy from the atmosphere or from a hot-water source and pumping it in.

heat shield any heat-protecting coating or system, especially the coating (for example, tiles) used in spacecraft to protect the astronauts and equipment inside from the heat of re-entry when returning to Earth. Air friction can generate temperatures of up to $1,500^{\circ}\text{C}/2,700^{\circ}\text{F}$ on re-entry into the atmosphere.

heat storage any means of storing heat for release later. It is usually achieved by using materials that undergo phase changes, for example, Glauber's salt and sodium pyrophosphate, which melts at $70^{\circ}\text{C}/158^{\circ}\text{F}$. The latter is used to store off-peak heat in the home: the salt is liquefied by cheap heat during the night and then freezes to give off heat during the day.

Other developments include the use of plastic crystals, which change their structure rather than melting when they are heated. They could be incorporated in curtains or clothing.

heatstroke or sunstroke rise in body temperature caused by excessive exposure to heat.

Mild heatstroke is experienced as feverish lassitude, sometimes with slight fainting; recovery is prompt following rest and replenishment of salt lost in sweat. Severe heatstroke causes collapse akin to that seen in acute shock, and is potentially lethal without prompt treatment, including cooling the body carefully and giving fluids to relieve dehydration.

heat treatment in industry, the subjection of metals and alloys to controlled heating and cooling after fabrication to relieve internal stresses and improve their physical properties. Methods include *annealing*, *quenching*, and *tempering*.

Heaviside's dolphin or benguela dolphin *Cephalorhynchus heavisidii* one of the least-known dolphins, confined to the coastal waters of Namibia. It is thought that about 100 a year are killed in purse seine nets from fishing boats, which could endanger this apparently rare species.

heavy horse powerful horse specially bred for hauling wagons and heavy agricultural implements. After a decline following the introduction of the tractor, they are again being bred in increasing numbers and used for specialized work.

heavy industry industry that processes large amounts of bulky raw materials. Examples are the iron and steel industry, shipbuilding, and aluminium smelting. Heavy industries are often tied to locations close to their supplies of raw materials.

heavy water or deuterium oxide D_2O water containing the isotope deuterium instead of hydrogen (relative molecular mass 20 as opposed to 18 for ordinary water).

Its chemical properties are identical with those of ordinary water, but its physical properties differ slightly. It occurs in ordinary water in the ratio of about one part by mass of deuterium to 5,000 parts by mass of hydrogen, and can be concentrated by electrolysis, the ordinary water being more readily decomposed by this means than the heavy water. It has been used in the nuclear industry because it can slow down fast neutrons, thereby controlling the chain reaction.

hectare metric unit of area equal to 100 ares or 10,000 square metres (2.47 acres), symbol ha.

Trafalgar Square, London's only metric square, was laid out as one hectare.

hedge or hedgerow row of closely planted shrubs or low trees, generally acting as a land division and windbreak. Hedges also serve as a source of food and as a refuge for wildlife, and provide a habitat not unlike the understorey of a natural forest.

hedgehog insectivorous mammal native to Europe, Asia, and Africa. The body, including the tail, is 30 cm/1 ft long. It is greyish brown in colour, has a piglike snout, and its back and sides are covered with sharp spines. When threatened it rolls itself into a ball bristling with spines. Hedgehogs feed on insects, slugs, mice, frogs, young birds, and carrion. Long-eared hedgehogs and desert hedgehogs are placed in different genera. (Genus *Erinaceus*, order Insectivora, family Erinacidae.)

Hedgehogs normally shelter by day and go out at night. They find food more by smell and sound than by sight. The young are born in the late spring or early summer, and are blind, helpless, and covered with soft spines. For about a month they feed on their mother's milk, after which she teaches them to find their own food. In the autumn, hedgehogs make a nest of leaves and moss in the roots of a tree or in a hole in the ground and hibernate until spring.

hedge sparrow another name for the *chuncock*, a small European bird.

height of a plane figure or solid, the perpendicular distance from the vertex to the base; see *altitude*.

Heisenberg, Werner (Karl) (1901–1976)

German physicist who developed quantum theory and formulated the uncertainty principle, which concerns matter, radiation, and their reactions, and places absolute limits on the achievable accuracy of measurement. He was awarded a Nobel prize in 1932 for work he carried out when only 24.

Heisenberg was concerned not to try to picture what happens inside the atom but to find a mathematical system that explained it. His starting point was the spectral lines given by hydrogen, the simplest atom. Assisted by Max Born, Heisenberg presented his ideas in 1925 as a system called *matrix mechanics*. He obtained the frequencies of the lines in the hydrogen spectrum by mathematical treatment of values within matrices or arrays. His work was the first precise mathematical description of the workings of the atom and with it Heisenberg is regarded as founding quantum mechanics, which seeks to explain atomic structure in mathematical terms.

Heisenberg also was able to predict from studies of the hydrogen spectrum that hydrogen exists in two allotropes – ortho-hydrogen and para-hydrogen – in which the two nuclei of the atoms in a hydrogen molecule spin in the same or opposite directions respectively. The allotropes were discovered in 1929 (see *allotropy*).

In 1927, Heisenberg made the discovery of the *uncertainty principle*, for which he is best known. The uncertainty principle states that there is a theoretical limit to the precision with which a particle's position and momentum can be measured. In other words, it is impossible to specify precisely both the position and the simultaneous momentum (mass multiplied by velocity) of a particle. There is always a degree of uncertainty in either, and as one is determined with greater precision, the other can only be found less exactly. Heisenberg also formulated that multiplying the degrees of uncertainty of the position and momentum yields a value approximately equal to Planck's constant. The idea that the result of an action can be expressed only in terms of the probability of a certain effect was revolutionary, and it discomforted even Albert Einstein (1879–1955), but has remained valid.

In 1927, Heisenberg used the Pauli exclusion principle, which states that no two electrons can have all four quantum numbers the same, to show that ferromagnetism (the ability of some materials to acquire magnetism in the presence of an external magnetic field) is caused by electrostatic interaction between the electrons.

Helicobacter pylori spiral-shaped swimming bacterium that causes gastritis and stomach ulcers when it colonizes the stomach lining. Without antibiotic treatment, infection can be permanent. *H. pylori* may also contribute towards stomach cancer.

Approximately 60% of 60-year-olds in the USA and western Europe are infected with *H. pylori*; the infection is rarely found in children. In developing countries 60–70% of children under 10 exhibit infection.

In 1997 scientists completed a full genetic blueprint (or genome) of *H. pylori*.

HELISPOT

<http://www.helispot.com/>

Helicopters of all shapes, sizes, and purposes are shown in photographs on this Web site. Police, military, news, and rescue helicopters are all featured in the hundreds of photographs listed. In addition there is an e-mail forum and many links to other helicopter resources

helicopter powered aircraft that achieves both lift and propulsion by means of a rotary wing, or rotor, on top of the fuselage. It can take off and land vertically, move in any direction, or remain stationary in the air. It can be powered by piston or jet engine. The *autogiro* was a precursor.

The rotor of a helicopter has two or more blades of aerofoil cross-section like an aeroplane's wings. Lift and propulsion are achieved by angling the blades as they rotate. Experiments using the concept of helicopter flight date from the early 1900s, with the first successful lift-off and short flight in 1907. Ukrainian-US engineer Igor Sikorsky built the first practical single-rotor craft in the USA in 1939.

A single-rotor helicopter must also have a small tail rotor to counter the torque, or tendency of the body to spin in the opposite direction to the main rotor. Twin-rotor helicopters, like the Boeing Chinook, have their rotors turning in opposite directions to prevent the body from spinning. Helicopters are now widely used in passenger service, rescue missions on land and sea, police pursuits and traffic control, fire-fighting, and agriculture. In war they carry troops and equipment into difficult terrain, make aerial reconnaissance and attacks, and carry the wounded to aid stations. A fire-fighting helicopter was tested in Japan 1996, designed to reach skyscrapers beyond the reach of fire-engine ladders.

heliography old method of signalling, used by armies in the late 19th century, which employed sunlight reflected from a mirror to pass messages in Morse code. On a clear day, a heliograph could send over distances in excess of 50 km/30 mi.

Also, an early photographic process by which a permanent image was formed on a glass plate.

helioseismology study of the Sun's structure by analysing vibrations and monitoring effects on the Sun's surface. Compare with *seismology*.

heliosphere region of space through which the solar wind flows outwards from the Sun. The *heliopause* is the boundary of this region, believed to lie about 100 astronomical units from the Sun, where the flow of the solar wind merges with the interstellar gas.

heliotrope decorative plant belonging to the borage family, with distinctive spikes of blue, lilac, or white flowers, including the Peruvian or cherry pie heliotrope (*H. peruvianum*). (Genus *Heliotropium*, family Boraginaceae.)

helium Greek *helios* 'Sun' colourless, odourless, gaseous, non-metallic element, symbol He, atomic number 2, relative atomic mass 4.0026. It is grouped with the inert gases, is nonreactive, and forms no compounds. It is the second-most abundant element (after hydrogen) in the universe, and has the lowest boiling (–268.9°C/–452°F) and melting points (–272.2°C/–458°F) of all the elements. It is present in small quantities in the Earth's atmosphere from gases issuing from radioactive elements (from α decay) in the Earth's crust; after hydrogen it is the second lightest element.

Helium is a component of most stars, including the Sun, where the nuclear-fusion process converts hydrogen into helium with the

helicopter The helicopter is controlled by varying the rotor pitch (the angle of the rotor blade as it moves through the air). For backwards flight, the blades in front of the machine have greater pitch than those behind the craft. This means that the front blades produce more lift and a backwards thrust. For forwards flight, the situation is reversed. In level flight, the blades have unchanging pitch.

production of heat and light. It is obtained by compression and fractionation of naturally occurring gases. It is used for inflating balloons and as a dilutant for oxygen in deep-sea breathing systems. Liquid helium is used extensively in low-temperature physics (cryogenics).

helix in mathematics, a three-dimensional curve resembling a spring, corkscrew, or screw thread. It is generated by a line that encircles a cylinder or cone at a constant angle.

hellebore poisonous European ϕ herbaceous plant belonging to the buttercup family. The stinking hellebore (*H. foetidus*) has greenish flowers early in the spring. (Genus *Helleborus*, family Ranunculaceae.)

helleborine one of several temperate Old World orchids, including the marsh helleborine (*E. palustris*) and the hellebore orchid (*E. helleborine*) introduced to North America. (Genera *Epipactis* and *Cephalanthera*, family Orchidaceae.)

helminth in medicine, collective name used to describe parasitic worms. There are several classes of helminth that can cause infections in humans, including ascariids (ascaridiasis), ϕ tapeworms, and ϕ threadworms.

helper application in computing, in Web ϕ browsers, an external application that adds the ability to display certain types of files. Common helper applications include ϕ RealAudio, which allows browsers to play live sound tracks such as radio broadcasts or recorded lectures; ϕ Acrobat; and mIRC, which allows access to ϕ Internet Relay Chat via the World Wide Web.

hematite principal ore of iron, consisting mainly of iron(III) oxide, Fe_2O_3 . It occurs as specular hematite (dark, metallic lustre), kidney ore (reddish radiating fibres terminating in smooth, rounded surfaces), and a red earthy deposit.

Hemiptera large insect order consisting of the ϕ bugs and containing about 55,000 species.

classification Hemiptera is in class Insecta, phylum Arthropoda.

The order is divided into two suborders.

suborder Homoptera These are the plant bugs. They are small to moderate-sized (from 3 mm/0.1 in to several centimetres/nearly an inch) insects with two pairs of wings usually present, held sloping over the body at rest. The forewings are usually evenly thickened with chitin; wingless forms are frequent. This suborder contains a large number of agricultural pests, some of which are vectors of plant viruses.

The important groups include the families Aleyrodidae, whiteflies; the Aphididae, greenflies; Cicadidae, cicadas; the Cicadellidae, leafhoppers; and the Psyllidae, plant lice. The superfamily Coccoidea, mealy bugs and scale insects, contains a further 16 families, many of which are important, including the lac insects from which shellac is obtained.

The plant bugs attack and destroy a wide range of plant life including grains, cereals, vegetables, fruit trees, and other trees. The aphids, one of the most important groups, transmit over 50 plant diseases.

suborder Heteroptera This suborder, characterized by having forewings unevenly thickened with chitin, is separated into two divisions: *Gymnocerata* have antennae that are usually longer than the head. They are terrestrial or water-skating forms. There are

over 40 families, a few containing pests of agricultural importance. The Pyrrhocoridae, the cotton-stainers cause the most damage; the Coreidae, Pentastomidae, and Tingidae are of lesser importance. Most of the other families are predaceous, feeding on other insects. Three families: Cimicidae, bedbugs; Polytentidae; and Reduviidae, assassin bugs, are active bloodsuckers of mammals and birds. (Polytentidae attacks only bats.)

suborder Cryptocerata Members of this suborder have antennae that are shorter than the head and are usually concealed. These bugs are usually predaceous, and are truly aquatic, being adapted for swimming. This division includes the families Belostomatidae, giant water bugs; Corixidae, water boatmen; Nepidae, water-scorpions; and Notonectidae, backswimmers.

hemlock plant belonging to the carrot family, native to Europe, W Asia, and N Africa. It grows up to 2 m/6 ft high and produces delicate clusters of small white flowers. The whole plant, especially the root and fruit, is poisonous, causing paralysis of the nervous system. The name 'hemlock' is also given to some North American and Asiatic conifers (genus *Tsuga*) belonging to the pine family. (*Conium maculatum*, family Umbelliferae.)

hemp annual plant originally from Asia, now cultivated in most temperate countries for the fibres produced in the outer layer of the stem, which are used in ropes, twines, and, occasionally, in a type of linen or lace. The drug *Cannabis* is obtained from certain varieties of hemp. (*Cannabis sativa*, family Cannabaceae.)

The name 'hemp' is also given to other similar types of fibre: sisal hemp and henequen obtained from the leaves of *Agave* species native to Yucatán and cultivated in many tropical countries, and manila hemp obtained from *Musa textilis*, a plant native to the Philippines and the Maluku Islands, Indonesia.

henbane poisonous plant belonging to the nightshade family, found on waste ground throughout most of Europe and W Asia. It is a branching plant, up to 80 cm/31 in high, with hairy leaves and a sickening smell. The yellow flowers are bell-shaped. Henbane is used in medicine as a source of the drugs hyoscyamine and scopolamine. (*Hyoscyamus niger*, family Solanaceae.)

henna small shrub belonging to the loosestrife family, found in Iran, India, Egypt, and N Africa. The leaves and young twigs are ground to a powder, mixed to a paste with hot water, and applied to the fingernails and hair to give an orange-red hue. The colour may then be changed to black by applying a preparation of indigo. (*Lawsonia inermis*, family Lythraceae.)

Henna can also be used to dye both natural and synthetic textiles.

henry SI unit (symbol H) of inductance (the reaction of an electric current against the magnetic field that surrounds it). One henry is the inductance of a circuit that produces an opposing voltage of one volt when the current changes at one ampere per second.

It is named after the US physicist Joseph Henry.

hepatitis any inflammatory disease of the liver, usually caused by a virus. Other causes include alcohol, drugs, gallstones, *Clonus erythematous*, and amoebic dysentery. Symptoms include weakness, nausea, and jaundice.

Five different hepatitis viruses have been identified: A, B, C, D, and E. The hepatitis A virus (HAV) is the commonest cause of viral hepatitis, responsible for up to 40% of cases worldwide. It is spread by contaminated food. Hepatitis B, or serum hepatitis, is a highly contagious disease spread by blood products or in body fluids. It often culminates in liver failure, and is also associated with liver cancer, although only 5% of those infected suffer chronic liver damage. During 1995, 1.1 million people died of hepatitis B. Around 300 million people are carriers. Vaccines are available against hepatitis A and B.

Hepatitis C is mostly seen in people needing frequent transfusions. Hepatitis D, which only occurs in association with hepatitis B, is common in the Mediterranean region. Hepatitis E is endemic in India and South America.

herb any plant (usually a flowering plant) tasting sweet, bitter, aromatic, or pungent, used in cooking, medicine, or perfumery;

HERB

The herb Catnip (*Nepeta cataria*) has a remarkable effect on cats. Members of the cat family roll over, extend their claws and twist in excitement when they smell the pungent odour of catnip. This reaction is believed to be caused by a chemical called trans-nepetalactone, which is similar to a substance found in the female cat's urine.

technically, a herb is any plant in which the aerial parts do not remain above ground at the end of the growing season.

herbaceous plant plant with very little or no wood, dying back at the end of every summer. The herbaceous perennials survive winters as underground storage organs such as bulbs and tubers.

herbalism in alternative medicine, the prescription and use of plants and their derivatives for medication. Herbal products are favoured by alternative practitioners as 'natural medicine', as opposed to modern synthesized medicines and drugs, which are regarded with suspicion because of the dangers of side effects and dependence.

Many herbal remedies are of proven efficacy both in preventing and curing illness. Medical herbalists claim to be able to prescribe for virtually any condition, except those so advanced that surgery is the only option.

herbarium collection of dried, pressed plants used as an aid to identification of unknown plants and by taxonomists in the classification of plants. The plant specimens are accompanied by information, such as the date and place of collection, by whom collected, details of habitat, flower colour, and local names.

Herbaria range from small collections containing plants of a limited region, to the large university and national herbaria (some at botanical gardens) containing millions of specimens from all parts of the world.

herbicide any chemical used to destroy plants or check their growth; see *weedkiller*.

herbivore animal that feeds on green plants (or photosynthetic single-celled organisms) or their products, including seeds, fruit, and nectar. The most numerous type of herbivore is thought to be the zooplankton, tiny invertebrates in the surface waters of the oceans that feed on small photosynthetic algae. Herbivores are more numerous than other animals because their food is the most abundant. They form a vital link in the food chain between plants and carnivores.

herb Robert wild *Geranium* found throughout Europe and central Asia and naturalized in North America. About 30 cm/12 in high, it has hairy leaves and small pinkish to purplish flowers. (*Geranium robertianum*, family Geraniaceae.)

Herculaneum ancient city of Italy between Naples and Pompeii. Along with Pompeii, it was buried when Vesuvius erupted AD 79. It was excavated from the 18th century onwards.

Hercules in astronomy, the fifth-largest constellation, lying in the northern hemisphere. Despite its size it contains no prominent stars. Its most important feature is the best example in the northern hemisphere of a globular cluster of stars 22,500 light years from Earth, which lies between Eta and Zeta Herculis.

Hercules beetle largest beetle in the world: males measure up to 17 cm/6.6 in in length; females are smaller. Hercules beetles are found mainly in the tropical and subtropical regions.

They are black, nocturnal, and exhibit extreme forms of sexual dimorphism (marked visual differences between males and females). Males have a dark-coloured, slender, curved horn of up to 10 mm/3.9 in long, on their heads.

classification Hercules beetles *Dynastes hercules* belong to the subfamily Dynastinae, family Scarabaeidae, order Coleoptera, class Insecta, phylum Arthropoda.

heredity in biology, the transmission of traits from parent to offspring. See also genetics.

hermaphrodite organism that has both male and female sex organs. Hermaphroditism is the norm in such species as earthworms and snails, and is common in flowering plants. Cross-fertilization is the rule among hermaphrodites, with the parents functioning as male and female simultaneously, or as one or the other sex at different stages in their development. Human hermaphrodites are extremely rare.

hermit crab type of crab.

hernia or **rupture** protrusion of part of an internal organ through a weakness in the surrounding muscular wall, usually in the groin. The appearance is that of a rounded soft lump or swelling.

heroin or **diamorphine** powerful opiate analgesic, an acetyl derivative of morphine. It is more addictive than morphine but causes less nausea. It has an important place in the control of severe pain in terminal illness, severe injuries, and heart attacks, but is widely used illegally.

Heroin was discovered in Germany in 1898. The major regions of opium production, for conversion to heroin, are the 'Golden Crescent' of Afghanistan, Iran, and Pakistan, and the 'Golden Triangle' across parts of Myanmar (Burma), Laos, and Thailand.

In 1971 there were 3,000 registered heroin addicts in the UK; in 1989 there were over 100,000.

heron large to medium-sized wading bird belonging to the same family as bitterns, egrets, night herons, and boatbills. Herons have sharp bills, broad wings, long legs, slender bodies, and soft plumage. They are found mostly in tropical and subtropical regions, but also in temperate zones, on lakes, fens, and mudflats, where they wade searching for prey. (Genera include *Ardea*, *Butorides*, and *Nycticorax*; family Ardeidae, order Ciconiiformes.)

They capture small animals, such as fish, molluscs, and worms, by spearing them with their long bills. Herons nest in trees or bushes, on ivy-covered rocks, or in reedbeds, making a loose fabric of sticks lined with grass or leaves; they lay greenish or drab-coloured eggs, varying in number from two to seven according to the different species.

herpes any of several infectious diseases caused by viruses of the herpes group. **Herpes simplex I** is the causative agent of a common inflammation, the cold sore. **Herpes simplex II** is responsible for genital herpes, a highly contagious, sexually transmitted disease characterized by painful blisters in the genital area. It can be transmitted in the birth canal from mother to newborn. **Herpes zoster** causes shingles; another herpes virus causes chickenpox.

A number of antivirals treat these infections, which are particularly troublesome in patients whose immune systems have been suppressed medically; for example, after a transplant operation. The drug acyclovir, originally introduced for the treatment of genital herpes, has now been shown to modify the course of chickenpox and the related condition shingles, by reducing the duration of the illness.

herpetology the scientific study of reptiles, including their classification, anatomy, physiology, behaviour, and ecology.

herring any of various marine fishes belonging to the herring family, but especially the important food fish *Clupea harengus*. A silvery greenish blue, it swims close to the surface, and may be 25–40 cm/10–16 in long. Herring travel in schools several kilometres long and wide. They are found in large quantities off the east coast of North America, and the shores of NE Europe. Overfishing and pollution have reduced their numbers. (Family Clupeidae.)

HERRING

The wolf herring *Clupea pallasii* is the largest fish in the herring order. It grows up to 3.7 m/12 ft long.

Herschel, (Frederick) William (1738–1822)

German-born English astronomer. He was a skilled telescope-maker, and pioneered the study of binary stars and nebulae. He discovered the planet Uranus in 1781 and infrared solar rays in 1801. He catalogued over 800 double stars, and found over 2,500 nebulae, catalogued by his sister Caroline Herschel; this work was continued by his son John Herschel. By studying the distribution of stars, William established the basic form of our Galaxy, the Milky Way.

Herschel discovered the motion of binary stars around one another, and recorded it in his *Motion of the Solar System in Space* 1783. In 1789 he built, in Slough, Berkshire, a 1.2-m/4-ft telescope of 12 m/40 ft focal length (the largest in the world at the time), but he made most use of a more satisfactory 46-cm/18-in instrument. He discovered two satellites of Uranus and two of Saturn.

hertz SI unit (symbol Hz) of frequency (the number of repetitions of a regular occurrence in one second). Radio waves are often measured in megahertz (MHz), millions of hertz, and the clock rate of a computer is usually measured in megahertz. The unit is named after Heinrich Hertz.

Hertz, Heinrich Rudolf (1857–1894)

German physicist who studied electromagnetic waves, showing that their behaviour resembles that of light and heat waves.

Hertz confirmed James Clerk Maxwell's theory of electromagnetic waves. In 1888, he realized that electric waves could be produced and would travel through air, and he confirmed this experimentally. He went on to determine the velocity of these waves (which were later called radio waves) and, on showing that it was the same as that of light, devised experiments to show that the waves could be reflected, refracted, and diffracted.

Hertzsprung–Russell diagram in astronomy, a graph on which the surface temperatures of stars are plotted against their luminosities. Most stars, including the Sun, fall into a narrow band called the main sequence. When a star grows old it moves from the main sequence to the upper right part of the graph, into the

Hertzsprung-Russell diagram The Hertzsprung-Russell diagram relates the brightness (or luminosity) of a star to its temperature. Most stars fall within a narrow diagonal band called the main sequence. A star moves off the main sequence when it grows old. The Hertzsprung-Russell diagram is one of the most important diagrams in astrophysics.

Hertzsprung, Ejnar (1873-1967)

Danish astronomer and physicist. He introduced the concept of the absolute magnitude (brightness) of a star, and described the relationship between the absolute magnitude and the temperature of a star, formulating his results in the form of a diagram, known as the Hertzsprung-Russell diagram, that has become a standard reference.

His astronomical interests were very wide, but his observations were mainly of variable stars, double stars, and clusters.

area of the giants and supergiants. At the end of its life, as the star shrinks to become a white dwarf, it moves again, to the bottom left area. It is named after the Dane Ejnar Hertzsprung (1873-1967) and the American Henry Norris Russell (1877-1957), who independently devised it in the years 1911-13.

hessian fly or **barley midge** tiny black fly, a species of *Ogall* midge that feeds on wheat and is considered a serious pest of winter wheat in the USA and New Zealand.

classification The hessian fly *Mayetiola destructor* belongs to the family Cecidomyiidae (suborder Nematocera) of order Diptera, class Insecta, phylum Arthropoda.

Hessian flies lay their eggs on the top surface of leaves of young wheat. The larvae feed on the leaf sheaths and also suck the plant sap. Wheat infested during the autumn appears stunted and the leaves are dark bluish-green. Intensely parasitized plants die during the winter.

The use of resistant wheat varieties in combination with delayed planting in the autumn (observing 'fly-safe' dates) has greatly reduced the damage caused by hessian flies in most wheat-producing areas of the USA.

Other allied pests include the sorghum midge *Contarinia sorghicola*, and the clover seed midge, *Dasyneura leguminicola*. The sorghum midge is a serious pest in the southern USA and the more humid areas of the Gulf States.

heterogeneous reaction in chemistry, a reaction where there is an interface between the different components or reactants. Examples of heterogeneous reactions are those between a gas and a solid, a gas and a liquid, two immiscible liquids, or two different solids.

heterosis or **hybrid vigour** improvement in physical capacities that sometimes occurs in the hybrid produced by mating two genetically different parents.

heterostyly Heterostyly, in which lengths of the stamens and stigma differ in flowers of different plants of the same species. This is a device to ensure cross-pollination by visiting insects.

The parents may be of different strains or varieties within a species, or of different species, as in the mule, which is stronger and has a longer life span than either of its parents (donkey and horse). Heterosis is also exploited in hybrid varieties of maize, tomatoes, and other crops.

heterostyly in botany, having σ styles of different lengths.

Certain flowers, such as primroses (*Primula vulgaris*), have different-sized σ anthers and styles to ensure cross-fertilization (through ϕ pollination) by visiting insects.

heterotroph any living organism that obtains its energy from organic substances produced by other organisms. All animals and fungi are heterotrophs, and they include herbivores, carnivores, and saprotrophs (those that feed on dead animal and plant material).

heterozygous in a living organism, having two different alleles for a given trait. In ϕ homozygous organisms, by contrast, both chromosomes carry the same allele. In an outbreeding population an individual organism will generally be heterozygous for some genes but homozygous for others.

For example, in humans, alleles for both blue and brown-pigmented eyes exist, but the 'blue' allele is ϕ recessive to the dominant 'brown' allele.

Only individuals with blue eyes are predictably homozygous for this trait; brown-eyed people can be either homozygous or heterozygous.

heuristics in computing, a process by which a program attempts to improve its performance by learning from its own experience.

The separate branches of natural knowledge have a real and intimate connection.

Hewlett-Packard (often abbreviated to **HP**) major manufacturer of computer and telecommunications hardware, founded 1939 by William Hewlett and David Packard and based in Palo Alto, California, USA. In 1996 the company was manufacturing more than 24,000 products, including medical equipment, analytical instruments, calculators, PCs, printers, workstations, and palmtops.

HP's sales grew dramatically from \$13.2 billion in 1990 to \$38.4 billion in 1996.

hexachlorophene (C_6HCl_6O) white, odourless bactericide, used in minute quantities in soaps and surgical disinfectants.

Trichlorophenol is used in its preparation, and, without precise temperature control, the highly toxic TCDD (tetrachlorodibenzo-dioxin; see ϕ dioxin) may form as a by-product.

hexadecimal number system or **hex** number system to the base 16, used in computing. In hex the decimal numbers 0-15 are

represented by the characters 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F.

Hexadecimal numbers are easy to convert to the computer's internal ϕ binary code and are more compact than binary numbers.

Each place in a number increases in value by a power of 16 going from right to left; for instance, 8F is equal to $15 + (8 \times 16) = 143$ in decimal. Hexadecimal numbers are often preferred by programmers writing in low-level languages because they are more easily converted to the computer's internal binary (base-two) code than are decimal numbers, and because they are more compact than binary numbers and therefore more easily keyed, checked, and memorized.

hexagon six-sided ϕ polygon.

HF in physics, abbreviation for high ϕ frequency. HF radio waves have frequencies in the range 3-30 MHz.

HGV abbreviation for **heavy goods vehicle**.

hibernation state of dormancy in which certain animals spend the winter. It is associated with a dramatic reduction in all metabolic processes, including body temperature, breathing, and heart rate. It is a fallacy that animals sleep throughout the winter.

The body temperature of the Arctic ground squirrel falls to below 0°C/32°F during hibernation. Hibernating bats may breathe only once every 45 minutes, and can go for up to 2 hours without taking a breath.

hibiscus any of a group of plants belonging to the mallow family. Hibiscuses range from large ϕ herbaceous plants to trees. Popular as ornamental plants because of their brilliantly coloured, red to white, bell-shaped flowers, they include *H. syriacus* and *H. rosa-sinensis* of Asia and the rose mallow (*H. palustris*) of North America. (Genus *Hibiscus*, family Malvaceae.)

hickory tree belonging to the walnut family, native to North America and Asia. It provides a valuable timber, and all species produce nuts, though some are inedible. The pecan (*C. illinoensis*) is widely cultivated in the southern USA, and the shagbark (*C. orata*) in the northern USA. (Genus *Carya*, family Juglandaceae.)

hidden file computer file in an ϕ MS-DOS system that is not normally displayed when the directory listing command is given. Hidden files include certain system files, principally so that there is less chance of modifying or deleting them by accident, but any file can be made hidden if required.

hide or **hyde** Anglo-Saxon unit of measurement used to measure the extent of arable land; it varied from about 296 ha/120 acres in the east of England to as little as 99 ha/40 acres in Wessex. One hide was regarded as sufficient to support a peasant and his household; it was the area that could be ploughed in a season by one plough and one team of oxen.

The hide was the basic unit of assessment for taxation and military service; under Norman rule it became the basis for the feudal tax of hidage.

hierarchy in computing, on USENET, the structure for naming ϕ newsgroups. All newsgroups on USENET are assigned to a major

group. The ♢Big Seven hierarchies were the first to be set up, and setting up a new newsgroup in these involved following more or less formal procedures. The ♢alt hierarchy was set up to allow more flexibility. The biz hierarchy was set up 1994, after the first incidence of ♢spamming, to give advertising its own place.

A number of other hierarchies are available, set up for specific countries (de is Germany, dk is Denmark, uk is Britain); for Internet Service Providers (Demon, CompuServe, and AOL all have their own local groups); or for individual companies.

hi-fi (abbreviation for *high-fidelity*) faithful reproduction of sound from a machine that plays recorded music or speech. A typical hi-fi system includes a turntable for playing vinyl records, a cassette tape deck to play magnetic tape recordings, a tuner to pick up radio broadcasts, an amplifier to serve all the equipment, possibly a compact-disc player, and two or more loudspeakers.

Advances in mechanical equipment and electronics, such as digital recording techniques and compact discs, have made it possible to eliminate many distortions in sound-reproduction processes.

Higgs boson or *Higgs particle* postulated elementary particle whose existence would explain why particles have mass. The current theory of elementary particles, called the ♢standard model, cannot explain how mass arises. To overcome this difficulty, Peter Higgs (1929–) of the University of Edinburgh and Thomas Kibble (1932–) of Imperial College, London proposed in 1964 a new particle that binds to other particles and gives them their mass. The Higgs boson has not yet been detected experimentally.

high-definition television (HDTV) ♢television system offering a significantly greater number of scanning lines, and therefore a clearer picture, than that provided by conventional systems. Typically, HDTV has about twice the horizontal and vertical resolution of current 525-line (such as the American standard, NTSC) or 625-line standards (such as the British standard, PAL); a frame rate of at least 24 Hz; and a picture aspect ratio of 9:16 instead of the current 3:4. HDTV systems have been in development since the mid-1970s.

The Japanese HDTV system, or HiVision as it is trade-named in Japan, uses 1,125 scanning lines and an aspect ratio of 16:9 instead of the squarish 4:3 that conventional television uses. A European HDTV system, called HD-MAC, using 1,250 lines, is under development. In the USA, a standard incorporating digital techniques is being discussed.

highest common factor (HCF) in a set of numbers, the highest number that will divide every member of the set without leaving a remainder. For example, 6 is the highest common factor of 36, 48 and 72.

high-level language in computing, a programming language designed to suit the requirements of the programmer; it is independent of the internal machine code of any particular computer. High-level languages are used to solve problems and are often described as *problem-oriented languages* – for example, ♢BASIC was designed to be easily learnt by first-time programmers; ♢COBOL is used to write programs solving business problems; and ♢FORTRAN is used for programs solving scientific and mathematical problems. In contrast, low-level languages, such as ♢assembly languages, closely reflect the machine codes of specific computers, and are therefore described as *machine-oriented languages*.

Unlike low-level languages, high-level languages are relatively easy to learn because the instructions bear a close resemblance to everyday language, and because the programmer does not require a detailed knowledge of the internal workings of the computer. Each instruction in a high-level language is equivalent to several machine-code instructions. High-level programs are therefore more compact than equivalent low-level programs. However, each high-level instruction must be translated into machine code – by either a ♢compiler or an ♢interpreter program – before it can be executed by a computer. High-level languages are designed to be *portable* – programs written in a high-level language can be run on any computer that has a compiler or interpreter for that particular language.

high memory in computing, the first 64 kilobytes in the ♢extended memory of an ♢MS-DOS system. The operating system

itself is usually installed in this area to allow more conventional memory (below 640 kilobytes) for applications.

High-Sierra format in computing, standard format for writing CD-ROM discs; see ♢ISO 9660.

high-tech industry any industry that makes use of advanced technology. The largest high-tech group is the fast-growing electronics industry and especially the manufacture of computers, microchips, and telecommunications equipment.

The products of these industries have low bulk but high value, as do their components. Silicon Valley in the USA and Silicon Glen in Scotland are two areas with high concentrations of such firms.

highway in Britain, any road over which there is a right of way. In the USA, any public road, especially a main road.

high-yield variety crop that has been specially bred or selected to produce more than the natural varieties of the same species. During the 1950s and 1960s, new strains of wheat and maize were developed to reduce the food shortages in poor countries (the ♢Green Revolution). Later, IR8, a new variety of rice that increased yields by up to six times, was developed in the Philippines. Strains of crops resistant to drought and disease were also developed. High-yield varieties require large amounts of expensive artificial fertilizers and sometimes pesticides for best results.

HII region in astronomy, a region of extremely hot ionized hydrogen, surrounding one or more hot stars, visible as a bright patch or emission ♢nebula in the sky. The gas is ionized by the intense ultraviolet radiation from the stars within it. HII regions are often associated with interstellar clouds in which new stars are being born. An example is the ♢Orion Nebula. It takes its name from a spectroscopic notation in which HI represents neutral hydrogen (H) and HII represents ionized hydrogen (H⁺).

hill figure in Britain, any of a number of figures, usually of animals, cut from the turf to reveal the underlying chalk. Their origins are variously attributed to Celts, Romans, Saxons, Druids, or Benedictine monks, although most are of modern rather than ancient construction.

hillfort European Iron Age site with massive banks and ditches for defence, used as both a military camp and a permanent settlement. Examples found across Europe, in particular France, central Germany, and the British Isles, include Heuneberg near Sigmaringen, Germany, Spinaans Hill in County Wicklow, Ireland, and Maiden Castle, Dorset, England.

Iron Age Germanic peoples spread the tradition of forts with massive defences, timberwork reinforcements, and sometimes elaborately defended gateways with guardrooms, the whole being overlooked from a rampart walk. The ramparts usually follow the natural line of a hilltop and are laid out to avoid areas of dead ground.

hinge joint in vertebrates, a joint where movement occurs in one plane only. Examples are the elbow and knee, which are controlled by pairs of muscles, the ♢flexors and ♢extensors.

hinterland area that is served by a port or settlement (the central place) and included in its sphere of influence. The city of Rotterdam, the Netherlands, is the hinterland of a port.

hinting in computing, a method of reducing the effects of ♢aliasing in the appearance of ♢outline fonts. Hinting makes use of a series of priorities so that noticeable distortions, such as uneven stem weight, are corrected. ♢PostScript Type 1 and ♢TrueType fonts are hinted.

Hipparchos (acronym for *high precision parallax collecting satellite*) satellite launched by the European Space Agency in 1989. Named after the Greek astronomer Hipparchus, it is the world's first ♢astrometry satellite and is providing precise positions, distances, colours, brightnesses, and apparent motions for over 100,000 stars.

hippopotamus Greek '*river horse*' large herbivorous, short-legged, even-toed hoofed mammal. The common *hippopotamus* (*Hippopotamus amphibius*) is found in Africa. It weighs up to 3,200 kg/7,040 lb, stands about 1.6 m/5.25 ft tall, and has a

Hippocrates (c. 460–c. 377 BC)

Greek physician, often called the founder of medicine. Important Hippocratic ideas include cleanliness (for patients and physicians), moderation in eating and drinking, letting nature take its course, and living where the air is good. He believed that health was the result of the 'humours' of the body being in balance; imbalance caused disease. These ideas were later adopted by Galen.

He was born and practised on the island of Kos, where he founded a medical school. He travelled throughout Greece and

Asia Minor, and died in Larisa, Thessaly. He is known to have discovered aspirin in willow bark. The *Corpus Hippocraticum*/Hippocratic Collection, a group of some 70 works, is attributed to him but was probably not written by him, although the works outline his approach to medicine. They include *Aphorisms* and the Hippocratic Oath, which embodies the essence of medical ethics.

brown or slate-grey skin. It is an endangered species. (Family Hippopotamidae.)

Hippopotamuses are social animals and live in groups. Because they dehydrate rapidly (at least twice as quickly as humans), they must stay close to water. When underwater, adults need to breathe every 2–5 minutes and calves every 30 seconds. When out of water, their skin exudes an oily red fluid that protects them against the Sun's ultraviolet rays. The hippopotamus spends the day wallowing in rivers or waterholes, only emerging at night to graze. It can eat up to 25–40 kg/55–88 lb of grass each night. The pygmy hippopotamus (*Choeropsis liberiensis*) lives in West Africa.

There are an estimated 157,000 hippos in Africa (1993 figure), but they are under threat from hunters because of the value of their meat, hides, and large canine teeth (up to 0.5 m/1.6 ft long), which are used as a substitute for ivory.

histamine inflammatory substance normally released in damaged tissues, which also accounts for many of the symptoms of allergy. It is an amine, $C_5H_9N_3$. Substances that neutralize its activity are known as antihistamines. Histamine was first described in 1911 by British physiologist Henry Dale (1875–1968).

histogram in statistics, a graph showing frequency of data, in which the horizontal axis details discrete units or class boundaries, and the vertical axis represents the frequency. Blocks are drawn such that their areas (rather than their height as in a bar chart) are proportional to the frequencies within a class or across several class boundaries. There are no spaces between blocks.

histology study of plant and animal tissue by visual examination, usually with a microscope.

Stains are often used to highlight structural characteristics such as the presence of starch or distribution of fats.

histology in medicine, the laboratory study of cells and tissues.

history in computing, a list of sites visited by a Web browser during the current session. The history is usually stored as a list of page titles and is accessed via the browser's menu system. The purpose is to make it easy for users to go back to a recently visited site.

hit in computing, request sent to a file server.

Sites on the World Wide Web often measure their popularity in numbers of hits. However, this is misleading, as a single Web page may be made up of many files, each of which counts as a hit when a user downloads the whole page. Counting individual visits is a better indication of a site's success.

HIV (abbreviation for *human immunodeficiency virus*) the infectious agent that is believed to cause AIDS. It was first discovered in 1983 by Luc Montagnier of the Pasteur Institute in Paris, who called it lymphocyte-associated virus (LAV). Independently, US scientist Robert Gallo of the National Cancer Institute in Bethesda, Maryland, claimed its discovery in 1984 and named it human T-lymphocytotropic virus 3 (HTLV-III).

transmission Worldwide, heterosexual activity accounts for three-quarters of all HIV infections. In addition to heterosexual men and women, high-risk groups are homosexual and bisexual men, prostitutes, intravenous drug-users sharing needles, and haemophiliacs and other patients treated with contaminated blood products. The virus has a short life outside the body, which makes transmission of the infection by methods other than sexual contact, blood transfusion, and shared syringes extremely unlikely.

US researchers in 1995 developed an explanation of why HIV is transmitted mainly by heterosexual sex in Africa and Asia, and by homosexual sex and intravenous drug use in Europe and the USA. They found that the HIV variant subtype B – responsible for 90% of European and US cases – did not grow well in reproductive tract cells, whereas subtype E – common in developing countries – did grow well. If subtype E becomes more prevalent in Europe and the USA, infection patterns will probably change. The first case of subtype E in Britain was documented in May 1996.

the development of HIV Many people who have HIV in their blood are not ill; in fact, it was initially thought that during the delay between infection with HIV and the development of AIDS the virus lay dormant. However, US researchers estimated in 1995 that HIV reproduces at a rate of a billion viruses a day, even in individuals with no symptoms, but is held at bay by the immune system producing enough white blood cells (CD4 cells) to destroy them. Gradually, the virus mutates so much that the immune system is unable to continue to counteract; people with advanced AIDS have virtually no CD4 cells remaining. These results indicate the importance of treating HIV-positive individuals before symptoms develop, rather than delaying treatment until the onset of AIDS.

About 15% of babies born to HIV-positive mothers are themselves HIV-positive. A very small number of these babies (less than 3%) test negative for the virus some months later, a phenomenon yet to be explained.

HIV statistics In 1997 there were an estimated just under 30 million (1% of the world's adult population) HIV infections in the world. In Sub-Saharan Africa there were an estimated 20 million HIV sufferers, in S and SE Asia 6 million, in South America 1.3 million, in North America 860,000, and Western Europe 150,000 (figures released by the United Nations AIDS programme, UNAIDS).

hoatzin tropical bird found only in the Amazon, resembling a small pheasant in size and appearance. The beak is thick and the facial skin blue. Adults are olive-coloured with white markings above and red-brown below. The hoatzin is the only bird in its family. (Species *Opisthocomus hoatzin*, family Opisthocomidae, order Galliformes.)

The young are hatched naked, with claws on their wings, which they use to crawl reptile-fashion about the tree; these claws later fall off. They fly only reluctantly and prefer to climb among branches using their wings – they cannot grip with their feet. Hoatzin are chiefly arboreal, nesting on low trees or shrubs, and feeding on leaves and fruit.

hobby small falcon found across Europe and N Asia. It is about 30 cm/1 ft long, with a grey-blue back, streaked front, and chestnut thighs. It is found in open woods and heaths, and feeds on insects and small birds. (Species *Falco subbuteo*.)

Hodgkin's disease or **lymphadenoma** rare form of cancer mainly affecting the lymph nodes and spleen. It undermines the immune system, leaving the sufferer susceptible to infection.

However, it responds well to radiotherapy and cytotoxic drugs, and long-term survival is usual.

Hoffman, Albert

Swiss-born, US physician who, in 1943, accidentally discovered lysergic acid diethylamide (LSD), the most potent psychoactive drug ever known. LSD causes hallucinatory effects, paranoia, and depression, and is illegal except for research purposes.

Hoffman, together with Swiss chemist Arthur Stoll, produced lysergic acid diethylamide (LSD) in 1938 while trying to synthesize a new drug for the treatment of headaches. Since the new drug appeared to have no analgesic (pain-relieving) effect on laboratory animals, it remained untouched on a shelf for five years. Hoffman decided to perform further tests on LSD in 1943, during which he accidentally ingested an unknown amount of the drug. He described his first experience of LSD intoxication as 'a kind of drunkenness which was not unpleasant and which was characterized by extreme activity of the imagination'. LSD was later shown to block or inhibit the action of the neurotransmitter serotonin in the brain.

Hoffman's voltameter in chemistry, an apparatus for collecting gases produced by the electrolysis of a liquid.

It consists of a vertical E-shaped glass tube with taps at the upper ends of the outer limbs and a reservoir at the top of the central limb. Platinum electrodes fused into the lower ends of the outer limbs are connected to a source of direct current. At the beginning of an experiment, the outer limbs are completely filled with electrolyte by opening the taps. The taps are then closed and the current switched on. Gases evolved at the electrodes bubble up the outer limbs and collect at the top, where they can be measured.

hog any member of the pig family. The river hog (*Potamochoerus porcus*) lives in Africa, south of the Sahara. Reddish or black, up to 1.3 m/4 ft long plus tail, and 90 cm/3 ft at the shoulder, this gregarious animal roots for food in many types of habitat. The giant forest hog (*Hylochoerus meinertzhageni*) lives in thick forests of central Africa and grows up to 1.9 m/6 ft long. The dwarf hog is another African wild pig. The pygmy hog *Sus salvanus*, the smallest of the pig family, is about 65 cm long (25 cm at the shoulder) and weighs 8–9 kg.

hogsnore North American colubrine, nonvenomous snake with a flattened head and a projecting snout for burrowing.

classification The hogsnore is in genus *Heterodon*, family Elapidae, suborder Serpentes, order Squamata, class Reptilia.

hogweed any of a group of plants belonging to the carrot family. The giant hogweed (*H. mantegazzianum*) grows over 3 m/9 ft high. (Genus *Heracleum*, family Umbelliferae.)

holdfast organ found at the base of many seaweeds, attaching them to the sea bed. It may be a flattened, suckerlike structure, or dissected and fingerlike, growing into rock crevices and firmly anchoring the plant.

holism in philosophy, the concept that the whole is greater than the sum of its parts.

holistic medicine umbrella term for an approach that virtually all alternative therapies profess, which considers the overall health and lifestyle profile of a patient, and treats specific ailments not primarily as conditions to be alleviated but rather as symptoms of more fundamental disease.

A physician is obligated to consider more than a diseased organ, more even than the whole man – he must view the man in his world.

holly any of a group of trees or shrubs that includes the English Christmas holly (*I. aquifolium*), an evergreen with spiny, glossy leaves, small white flowers, and poisonous scarlet berries on the female tree. Leaves of the Brazilian holly (*I. paraguayensis*) are used to make the tea yerba maté. (Genus *Ilex*, family Aquifoliaceae.)

hollyhock tall flowering plant belonging to the mallow family. *A. rosea*, originally a native of Asia, produces spikes of large white, yellow, pink, or red flowers, 3 m/10 ft high when cultivated as a biennial; it is a popular cottage garden plant. (Genus *Althaea*, family Malvaceae.)

holmium Latin *Holmia* 'Stockholm' silvery, metallic element of the lanthanide series, symbol Ho, atomic number 67, relative atomic mass 164.93. It occurs in combination with other rare-earth metals and in various minerals such as gadolinite. Its compounds are highly magnetic.

The element was discovered in 1878, spectroscopically, by the Swiss chemists J. L. Soret and Delafontaine, and independently in 1879 by Swedish chemist Per Cleve (1840–1905), who named it after Stockholm, near which it was found.

Holocene epoch of geological time that began 10,000 years ago, the second and current epoch of the Quaternary period. During this

epoch the glaciers retreated, the climate became warmer, and humans developed significantly.

hologram three-dimensional image produced by holography. Small, inexpensive holograms appear on credit cards and software licences to guarantee their authenticity.

holography method of producing three-dimensional (3-D) images, called holograms, by means of laser light. Holography uses a photographic technique (involving the splitting of a laser beam into two beams) to produce a picture, or hologram, that contains 3-D information about the object photographed. Some holograms show meaningless patterns in ordinary light and produce a 3-D image only when laser light is projected through them, but reflection holograms produce images when ordinary light is reflected from them (as found on credit cards).

Although the possibility of holography was suggested as early as 1947 (by Hungarian-born British physicist Dennis Gabor), it could not be demonstrated until a pure coherent light source, the laser, became available in 1963. The first laser-recorded holograms were created by Emmett Leith and Juris Upatnieks at the University of Michigan, USA, and Yuri Denisyuk in the Soviet Union.

The technique of holography is also applicable to sound, and bats may navigate by ultrasonic holography. Holographic techniques also have applications in storing dental records, detecting stresses and strains in construction and in retail goods, detecting forged paintings and documents, and producing three-dimensional body scans. The technique of detecting strains is of widespread application. It involves making two different holograms of an object on one plate, the object being stressed between exposures. If the object has distorted during stressing, the hologram will be greatly changed, and the distortion readily apparent.

Using holography, digital data can be recorded page by page in a crystal. In 1993 10,000 pages (100 megabytes) of digital data were stored in an iron-doped lithium niobate crystal measuring 1 cm³.

holography Recording a transmission hologram. Light from a laser is divided into two beams. One beam goes directly to the photographic plate. The other beam reflects off the object before hitting the photographic plate. The two beams combine to produce a pattern on the plate which contains information about the 3-D shape of the object. If the exposed and developed plate is illuminated by laser light, the pattern can be seen as a 3-D picture of the object.

homeopathy alternative spelling of *homoeopathy*.

homeostasis maintenance of a constant internal state in an organism, particularly with regard to pH, salt concentration, temperature, and blood sugar levels. Stable conditions are important for the efficient functioning of the enzyme reactions within the cells, which affect the performance of the entire organism.

homeothermy maintenance of a constant body temperature in endothermic (warm-blooded) animals, by the use of chemical processes to compensate for heat loss or gain when external temperatures change. Such processes include generation of heat by the breakdown of food and the contraction of muscles, and loss of heat by sweating, panting, and other means.

Mammals and birds are homeotherms, whereas invertebrates, fish, amphibians, and reptiles are cold-blooded or poikilotherms. Homeotherms generally have a layer of insulating material to retain heat, such as fur, feathers, or fat (see *blubber*). Their metabolism functions more efficiently due to homeothermy, enabling them to remain active under most climatic conditions.

home page in computing, opening page on a particular site on the World Wide Web. The term is also used for the page which loads automatically when a user opens a Web browser, and for a user's own personal Web pages.

Many Internet Service Providers provide free space to allow all their users to create and maintain their own home pages.

homoeopathy or **homeopathy** system of alternative medicine based on the principle that symptoms of disease are part of the body's self-healing processes, and on the practice of administering extremely diluted doses of natural substances found to produce in a healthy person the symptoms manifest in the illness being treated. Developed by German physician Samuel Hahnemann (1755–1843), the system is widely practised today as an alternative to allopathic (orthodox) medicine, and many controlled tests and

achieved cures testify its efficacy.

In 1992, the German health authority, the *Bundesgesundheitsamt*, banned 50 herbal and homeopathic remedies containing alkaloids because they are toxic, and set dose limits on 550 other natural remedies.

homogeneous reaction in chemistry, a reaction where there is no interface between the components. The term applies to all reactions where only gases are involved or where all the components are in solution.

homologous in biology, a term describing an organ or structure possessed by members of different taxonomic groups (for example, species, genera, families, orders) that originally derived from the same structure in a common ancestor. The wing of a bat, the arm of a monkey, and the flipper of a seal are homologous because they all derive from the forelimb of an ancestral mammal.

homologous series any of a number of series of organic chemicals with similar chemical properties in which members differ by a constant relative molecular mass.

Alkanes (paraffins), alkenes (olefins), and alkynes (acetylenes) form such series in which members differ in mass by 14, 12, and 10 atomic mass units respectively. For example, the alkane homologous series begins with methane (CH_4), ethane (C_2H_6), propane (C_3H_8), butane (C_4H_{10}), and pentane (C_5H_{12}), each member differing from the previous one by a CH_2 group (or 14 atomic mass units).

homozygous in a living organism, having two identical alleles for a given trait. Individuals homozygous for a trait always breed true; that is, they produce offspring that resemble them in appearance when bred with a genetically similar individual; inbred varieties or species are homozygous for almost all traits.

Recessive alleles are only expressed in the homozygous condition. See also *heterozygous*.

honey sweet syrup produced by honey bees from the nectar of flowers. It is stored in honeycombs and made in excess of their needs as food for the winter. Honey comprises various sugars,

mainly laevulose and dextrose, with enzymes, colouring matter, acids, and pollen grains. It has antibacterial properties and was widely used in ancient Egypt, Greece, and Rome as a wound salve. It is still popular for sore throats, in hot drinks or in lozenges.

honeycomb moth another name for the *ox* moth.

honeycomb worm colonial marine worm *Sabellaria alveolata* named after the hexagonal tubes made of cemented sand and shell fragments in which it lives low down on rocky sandy beaches. It feeds on organic material suspended in the water. It spends its larval stage as plankton.

honeyeater or **honey-sucker** any of a group of small, brightly coloured birds with long, curved beaks and long tails, native to Australia. They have a long tongue divided into four at the end to form a brush for collecting nectar from flowers. (Family Meliphagidae.)

Larger honeyeaters, such as the **blue-faced honeyeater** (*Entomyza cyanotis*) of NE Australia, which is 30 cm/12 in long, also eat insects and fruit. The blood-bird is a honeyeater.

Honeyeaters from Australasia colonized Hawaii, where four distinct species evolved of which only one, the *Kauai*, survives; it too was thought to be extinct but was rediscovered in 1960.

honey guide in botany, line or spot on the petals of a flower that indicate to pollinating insects the position of the nectaries (see *nectar*) within the flower. The orange dot on the lower lip of the toadflax flower (*Linaria vulgaris*) is an example. Sometimes the markings reflect only ultraviolet light, which can be seen by many insects although it is not visible to the human eye.

honey possum or **honey mouse** or **noobenger** tiny marsupial that is native of western Australia. It lives in trees, and feeds on insects and honey, which it extracts from flowers with its long extensible tongue.

classification The honey possum *Tarsipes spenserae* is the only member of the family Tarsipedidae, order Marsupialia, class Mammalia.

honeysuckle vine or shrub found in temperate regions of the world. The common honeysuckle or woodbine (*L. periclymenum*) of Europe is a climbing plant with sweet-scented flowers, reddish and yellow-tinted outside and creamy white inside; it now grows in the northeastern USA. (Genus *Lonicera*, family Caprifoliaceae.)

The North American trumpet honeysuckle (*L. sempervirens*) has unusual vaselike flowers and includes scarlet and yellow varieties.

hoof horny covering that protects the sensitive parts of the foot of an animal. The possession of hooves is characteristic of the orders Artiodactyla (even-toed ungulates such as deer and cattle), and Perissodactyla (horses, tapirs, and rhinoceroses).

The flexibility of the hoof is promoted by a fluid secreted by the keratogenous (horn-producing) membrane. The cloven hoof of the Artiodactyla has been evolved for walking and climbing on irregular surfaces by the formation of a separate hoof on each digit of the foot. Horses walk on the third digit of the foot, while cattle walk on the third and fourth.

Hooke, Robert (1635–1703)

English scientist and inventor, originator of Hooke's law, and considered the foremost mechanic of his time. His inventions included a telegraph system, the spirit level, marine barometer, and sea gauge. He coined the term 'cell' in biology.

He studied elasticity, furthered the sciences of mechanics and microscopy, invented the hairspring regulator in timepieces, perfected the air pump, and helped improve such scientific instruments as microscopes, telescopes, and barometers. His work on gravitation and in optics contributed to the achievements of his contemporary Isaac Newton.

Hooke's law law stating that the deformation of a body is proportional to the magnitude of the deforming force, provided that the body's elastic limit (see *Elasticity*) is not exceeded. If the elastic limit is not reached, the body will return to its original size once the force is removed. The law was discovered by Robert Hooke 1676.

For example, if a spring is stretched by 2 cm by a weight of 1 N, it will be stretched by 4 cm by a weight of 2 N, and so on; however, once the load exceeds the elastic limit for the spring, Hooke's law will no longer be obeyed and each successive increase in weight will result in a greater extension until finally the spring breaks.

hookworm parasitic roundworm (see *Worm*) with hooks around its mouth. It lives mainly in tropical and subtropical regions, but also in humid areas in temperate climates. The eggs are hatched in damp soil, and the larvae bore into the host's skin, usually through the soles of the feet. They make their way to the small intestine, where they live by sucking blood. The eggs are expelled with faeces, and the cycle starts again. The human hookworm causes anaemia, weakness, and abdominal pain. It is common in areas where defecation occurs outdoors. (Genus *Necator*.)

hoopoe bird slightly larger than a thrush, with a long, thin, slightly downward-curving bill and a bright pinkish-buff crest tipped with black that expands into a fan shape on top of the head. The wings and tail are banded with black and white, and the rest of the plumage is buff-coloured. The hoopoe is found throughout southern Europe and Asia down to southern Africa, India, Malaysia. (Species *Upupa epops*, family Upupidae, order Coraciiformes.)

hoop pine softwood timber tree *Araucaria cunninghamii* of NE New South Wales and Queensland in Australia, and Papua New Guinea.

Hoover Dam highest concrete dam in the USA, 221 m/726 ft, on the Colorado River at the Arizona-Nevada border. It was built 1931–36. Known as Boulder Dam 1933–47, its name was restored by President Truman as the reputation of the former president, Herbert Hoover, was revived. It impounds Lake Mead, and has a hydroelectric power capacity of 1,300 megawatts.

hop in computing, on the Internet, an intermediate stage of the journey taken by a message travelling from one site to another.

Internet messages must travel through many machines to get to their destinations. The exact route is recorded in the *hop* path.

Hoppe's apparatus in physics, an apparatus used to demonstrate the temperature at which water has its maximum density. It is named after Thomas Charles Hoppe (1766–1844).

It consists of a vertical cylindrical vessel fitted with horizontal thermometers through its sides near the top and bottom, and surrounded at the centre by a ledge that holds a freezing mixture (ice

hops A female hop plant showing the fruits which, in cultivated varieties, are used in brewing. The genus *Humulus* is a small one, with *H. lupulus* coming from Europe and W Asia and one species each from North America and E Asia. Premaphotos Wildlife

and salt). When the cylinder is filled with water, this gradually cools, the denser water sinking to the bottom; eventually the upper thermometer records 0°C/32°F (the freezing point of water) and the lower one has a constant reading of 4°C/39°F (the temperature at which water is most dense).

hops female fruit heads of the hop plant *Humulus lupulus*, family Cannabaceae; these are dried and used as a tonic and in flavouring beer. In designated areas in Europe, no male hops may be grown, since seedless hops produced by the unspooned female plant contain a greater proportion of the alpha acid that gives beer its bitter taste.

horehound any of a group of plants belonging to the mint family. The white horehound (*M. vulgare*), found in Europe, N Africa, and W Asia and naturalized in North America, has a thick hairy stem and clusters of dull white flowers; it has medicinal uses. (Genus *Marrubium*, family Labiatae.)

horizon in astronomy, the great circle dividing the visible part of the sky from the part hidden by the Earth.

horizon the limit to which one can see across the surface of the sea or a level plain, that is, about 5 km/3 mi at 1.5 m/5 ft above sea level, and about 65 km/40 mi at 300 m/1,000 ft.

hormone Greek 'arousing' secretion of the endocrine glands, concerned with control of body functions. The major glands are the thyroid, parathyroid, pituitary, adrenal, pancreas, ovary, and testis. Hormones bring about changes in the functions of various organs according to the body's requirements. The hypothalamus, which adjoins the pituitary gland, at the base of the brain, is a control centre for overall coordination of hormone secretion; the thyroid hormones determine the rate of general body chemistry; the adrenal hormones prepare the organism during stress for 'fight or flight'; and the sexual hormones such as oestrogen govern reproductive functions.

There are also hormone-secreting cells in the kidney, liver, gastrointestinal tract, thymus (in the neck), pineal (in the brain), and placenta. Many diseases due to hormone deficiency can be relieved with hormone preparations.

hormone-replacement therapy (HRT) use of oestrogen and progesterone to help limit the unpleasant effects of the menopause in women. The treatment was first used in the 1970s.

At the menopause, the ovaries cease to secrete natural oestrogen. This results in a number of symptoms, including hot flushes, anxiety, and a change in the pattern of menstrual bleeding. It is also associated with osteoporosis, or a thinning of bones, leading to an increased incidence of fractures, frequently of the hip, in older women. Oestrogen preparations, taken to replace the decline in natural hormone levels, combined with regular exercise can help to maintain bone strength in women. In order to improve bone density, however, HRT must be taken for five years, during which time the woman will continue to menstruate. Many women do not find this acceptable.

horn broad term for a hardened processes on the heads of some members of order Artiodactyla: deer, antelopes, cattle, goats, and sheep; and the rhinoceroses in order Perissodactyla. They are used usually for sparring rather than serious fighting, often between members of the same species rather than against predators.

The structure of horn shows immense variation, some being primarily made of bone, as in the antlers of deer; others of the substance called horn, as in cattle or antelopes; and others of compressed hair, as in rhinoceroses. Antlers are usually shed and regrown every year, while true horns are grown for life.

In most horned species they are possessed by both sexes, but in some species horns are limited to males.

hornbeam any of a group of trees belonging to the birch family. They have oval leaves with toothed edges and hanging clusters of flowers, each with a nutlike seed attached to the base. The trunk is usually twisted, with smooth grey bark. (Genus *Carpinus*, family Betulaceae.)

hornbill any of a group of omnivorous birds found in Africa, India, and Malaysia. They are about 1 m/3 ft long, and have powerful down-curved beaks, usually surmounted by a bony growth or casque. During the breeding season, the female walls herself into a hole in a tree and does not emerge until the young are hatched. There are about 45 species. (Family Bucerotidae, order Coraciiformes.)

Hornbills feed chiefly on the ground, their food consisting of insects, small mammals, and reptiles. The great hornbill (*Buceros bicornis*) of SE Asia can reach up to 1.3 m/4.3 ft in length.

The southern ground hornbill lives in groups of about three to five birds (though sometimes as many as ten) with only one breeding pair, and the rest acting as helpers. On average, only one chick is reared successfully every nine years. Lifespan can be 40 years or more.

hornblende green or black rock-forming mineral, one of the amphiboles. It is a hydrous silicate composed mainly of calcium, iron, magnesium, and aluminium in addition to the silicon and oxygen that are common to all silicates. Hornblende is found in both igneous and metamorphic rocks and can be recognized by its colour and prismatic shape.

horned toad or **horned lizard** common name for several species of lizard. Horned toads have large spines or horns on their heads and pointed scales, vary from 7–12 cm/3–5 in long, and are found in arid areas of North and Central America. An example is the desert-dwelling spiny molech.

When attacked, horned toads inflate the body with air, gape, hiss, and bite.

classification Horned toads are in the genus *Phrynosoma*, family Iguanidae, suborder Sauria, order Squamata, class Reptilia.

horned viper northeast African snake. It is remarkable for the possession of a large spiky scale above each eye.

classification The horned viper *Cerastes cornutus* belongs to the family Viperidae, suborder Serpentes, order Squamata, class Reptilia.

hornet type of wasp.

hornfels metamorphic rock formed by rocks heated by contact with a hot igneous body. It is fine-grained, brittle, and lacks foliation (a planar structure).

Hornfels may contain minerals only formed under conditions of great heat, such as andalusite, Al_2SiO_5 , and cordierite, $(Mg,Fe)Al_2SiO_5$. This rock, originating from sedimentary rock strata, is found in contact with large igneous intrusions where it represents the heat-altered equivalent of the surrounding clay. Its hardness makes it suitable for road building and railway ballast.

horn fly small fly that is a pest of cattle and other animals.

classification Horn flies are in the family Muscidae, class Insecta, phylum Arthropoda.

hornwort nonvascular plant (with no 'veins' to carry water and food), related to the liverworts and mosses. Hornworts are found in warm climates, growing on moist shaded soil. (Class Anthocerotae, order Bryophyta.)

The name is also given to a group of aquatic flowering plants which are found in slow-moving water. They have whorls of finely divided leaves and may grow up to 2 m/7 ft long. (Genus *Ceratophyllum*, family Ceratophyllaceae.)

Like liverworts and mosses, the bryophyte hornworts exist in two different reproductive forms, sexual and asexual, which appear alternately (see alternation of generations). A leafy plant body, or gametophyte, produces gametes, or sex cells, and a small horned form, or sporophyte, which grows upwards from the gametophyte, produces spores. Unlike the sporophytes of mosses and liverworts, the hornwort sporophyte survives after the gametophyte has died.

horse hoofed, odd-toed, grazing mammal belonging to the same family as zebras and asses. The many breeds of domestic horse of Euro-Asian origin range in colour from white to grey, brown, and black. The yellow-brown Mongolian wild horse, or Przewalski's horse (*Equus przewalskii*), named after its Polish 'discoverer' about 1880, is the only surviving species of wild horse. (Species *Equus caballus*, family Equidae.)

Przewalski's horse became extinct in the wild because of hunting and competition with domestic animals for food, about 800 survive in captivity. However, in the late 1990s 55 Przewalski's horses were successfully reintroduced to the wild in Mongolia.

horse chestnut any of a group of trees, especially *A. hippocastanum*, originally from SE Europe but widely planted elsewhere. Horse chestnuts have large palmate (five-lobed) leaves, showy upright spikes of white, pink, or red flowers, and large, shiny, inedible seeds (conkers) in prickly green capsules. The horse chestnut is not related to the true chestnut. In North America it is called buckeye. (Genus *Aesculus*, family Hippocastanaceae.)

horsefly any of over 2,500 species of fly. The females suck blood from horses, cattle, and humans; the males live on plants and suck nectar. The larvae are carnivorous. (Family Tabanidae.)

horsefly A female horsefly, or cleg, *Ematopota pluvialis* feeding on human blood. The bite of these insects is painful and in humans often produces a large swelling that can take a long time to heal. *Premaphotos Wildlife*

HORSEFLY

There is a fly larva that eats toads. The horsefly larva *Tabanus punctifer* lives in the soft mud at the edges of ponds. It kills tiny, newly metamorphosed spadefoot toads by injecting them with venom, and then sucks out their body fluids.

horsepower imperial unit (abbreviation hp) of power, now replaced by the *owatt*. It was first used by the engineer James *Watt*, who employed it to compare the power of steam engines with that of horses.

horseradish hardy perennial plant, native to SE Europe but naturalized elsewhere. The thick cream-coloured root is strong-tasting and is often made into a savoury sauce to accompany food. (*Armoracia rusticana*, family Cruciferae.)

horsetail plant related to ferns and club mosses; some species are also called *scouring rush*. There are about 35 living species, bearing their spores on cones at the stem tip. The upright stems are ribbed and often have spaced whorls of branches. Today they are of modest size, but hundreds of millions of years ago giant tree-like forms existed. (Genus *Equisetum*, order Equisetales.)

horticulture art and science of growing flowers, fruit, and vegetables. Horticulture is practised in gardens and orchards, along with millions of acres of land devoted to vegetable farming. Some areas, like California, have specialized in horticulture because they have the mild climate and light fertile soil most suited to these crops.

host in biology, an organism that is parasitized by another. In *commensalism*, the partner that does not benefit may also be called the host.

hot key in computing, a key stroke (or sequence of key strokes) that triggers a memory-resident program. Such programs are called *terminate and stay resident*. Hot keys should be chosen so that they do not conflict with key sequences in commonly used applications.

hotlist in computing, stored list of favourite sites which allows users to move quickly to frequently used resources. See also *bookmark*.

HOTOL (acronym for *horizontal takeoff and landing*) reusable hypersonic spaceplane invented by British engineer Alan Bond in 1983 but never put into production.

HOTOL was to be a single-stage vehicle that could take off and land on a runway. It featured a revolutionary dual-purpose engine that enabled it to carry far less oxygen than a conventional spaceplane: it functioned as a jet engine during the initial stage of flight, taking in oxygen from the surrounding air; when the air became too thin, it was converted into a rocket, burning oxygen from an onboard supply. The project was developed by British Aerospace and Rolls-Royce but foundered for lack of capital in 1988.

hot spot in geology, isolated rising plume of molten mantle material that may rise to the surface of the Earth's crust creating features such as volcanoes, chains of ocean islands, seamounts, and rifts in continents. Hot spots occur beneath the interiors of tectonic plates and so differ from areas of volcanic activity at plate margins (see *plate tectonics*). Examples of features made by hot spots are Iceland in the Atlantic Ocean, and in the Pacific Ocean the Hawaiian Islands and Emperor Seamount chain, and the Galápagos Islands.

Hot spots are responsible for large amounts of volcanic activity within tectonic plates rather than at plate margins. Volcanism from a hot spot formed the unique features of Yellowstone National Park, Wyoming, USA. The same hot spot that built Iceland atop the mid-Atlantic ridge in the North Atlantic Ocean also produced the voluminous volcanic rocks of the Isle of Skye, Scotland, at a time before these regions were rifted apart by the opening of the Atlantic Ocean.

Chains of volcanic seamounts trace the movements of tectonic plates as they pass over hot spots. Immediately above a hot spot on oceanic crust a volcano will form. This volcano is then carried away by plate tectonic movement, and becomes extinct. A new volcano forms beside it, again above the hot spot. The result is an active volcano and a chain of increasingly old and eroded extinct volcanoes stretching away along the line traced by the plate movement. The chain of volcanoes comprising the Hawaiian Islands and Emperor Seamounts formed in this way.

hot-swapping in computing, a technique that allows a user to exchange components without having to shut down the entire system.

The most common example of hot-swapping is *PCMCIA* (personal computer memory card interface adapter) components: a user with only one PCMCIA slot can exchange a modem for a network card or hard disc while the machine is running. Special software recognizes the components and allows their immediate use.

hour period of time comprising 60 minutes; 24 hours make one calendar day.

housefly fly found in and around human dwellings, especially *M. domestica*, a common worldwide species. Houseflies are grey and have mouthparts adapted for drinking liquids and sucking moisture from food and manure. (Genus *Musca*.)

HOUSEFLY

In nine months, a housefly could lay enough eggs to produce a layer of flies that would cover all of Germany to a depth of 14 m/47 ft.

hovercraft vehicle that rides on a cushion of high-pressure air, free from all contact with the surface beneath, invented by British engineer Christopher Cockerell in 1959. Hovercraft need a smooth terrain when operating overland and are best adapted to use on waterways. They are useful in places where harbours have not been established.

Large hovercraft (SR-N4) operate a swift car-ferry service across the English Channel, taking only about 35 minutes between Dover and Calais. They are fitted with a flexible 'skirt' that helps maintain the air cushion.

A military version made of fibreglass, the M-10, is tough manoeuvrable, and less noisy. See *illustration on page 377*.

hoverfly brightly coloured winged insect. Hoverflies usually have spots, stripes, or bands of yellow or brown against a dark-coloured background, sometimes with dense hair covering the body surface. Many resemble bees, bumble bees, and wasps (displaying Batesian mimicry) and most adults feed on nectar and pollen.

classification Hoverflies are members of the large family *Syrphidae* (numbering over 2,500 species), suborder *Cyclorhapha*, order *Diptera*, class *Insecta*, phylum *Arthropoda*.

One of the most characteristic features of hoverflies is the presence of a longitudinal false vein in the wing.

larva The larvae show remarkable variations in appearance and feeding habits. They may feed externally on plants or they may be internal feeders, attacking the bulbs; for example the narcissus fly, *Meredon equestris*. Many are carnivorous, feeding on *scale* insects, greenfly (*aphids*), and other insects that harm commercial crops.

The larvae may also feed on rotting wood or the decaying organic matter in stagnant pools; for example the rat-tailed maggot, larva of the drone fly *Eristalis tenax* is found in polluted pools. They breathe by extending their tail breathing tubes to reach the surface of the water.

howler monkey widely distributed large Central and South American monkey. Howler monkeys are tree-dwelling and feed on fruit and leaves. They have a prominent, hairless face and deep jaw, and the tail is long and prehensile.

Howler monkeys howl at dawn to demarcate territory. The howling is produced by the unusually developed egg-shaped hyoid bone at the upper end of the wind-pipe, in a swelling beneath the chin; the whole forms a hollow, resonant soundbox.

classification Howler monkeys are in genus *Alouatta*, family Cebidae, order Primates.

HP in computing, abbreviation for ϕ Hewlett-Packard.

hp abbreviation for ϕ horsepower.

HPGL (abbreviation for *Hewlett Packard Graphics Language*) file format used in ϕ vector graphics. HPGL is often generated by ϕ CAD systems.

href in computing, a tag in HTML (hypertext markup language) that indicates that the following text is a link either to another portion of the same document or to an external document on the same or a remote site.

ht abbreviation for height.

HTML (abbreviation for *Hypertext Markup Language*) standard for structuring and describing a document on the ϕ World Wide Web. The HTML standard provides labels for constituent parts of a document (for example headings and paragraphs) and permits the inclusion of images, sounds, and 'hyperlinks' to other documents. A ϕ browser program is then used to convert this information into a graphical document on-screen. The specifications for HTML version 4, called Dynamic HTML, were adopted at the end of 1997.

HTML is a specific example of ϕ SGML (the international standard for text encoding). As such it is not a rigid standard but is constantly being improved to incorporate new features and allow greater freedom of design.

HTML extension in computing, any proprietary addition to the standard specification of HTML (hypertext markup language).

Both Microsoft and Netscape, publishers of the two leading Web ϕ browsers, have built in such extensions, which are controversial as they clash with the basic ideal that the Net should operate on open standards which allow interoperability. In general, any browser should be able to log on to any site and be able to access most of its information, but the features implemented with proprietary extensions will only display correctly with a browser that supports those extensions.

HTTP (abbreviation for *Hypertext Transfer Protocol*) in computing, the protocol used for communications between client (the Web ϕ browser) and ϕ server on the World Wide Web.

hub in computing, central distribution point in a computer ϕ network.

Hubble classification in astronomy, a scheme for classifying ϕ galaxies according to their shapes, originally devised by the US astronomer Edwin Hubble in the 1920s.

Elliptical galaxies are classed from type E0 to E7, where the figure denotes the degree of ellipticity. An E0 galaxy appears circular to an observer, while an E7 is highly elliptical (this is based on the apparent shape; the true shape, distorted by foreshortening, may be quite different.) Spiral galaxies are classed as type Sa, Sb, or Sc, where Sa is a tightly wound spiral with a large central bulge and Sc is loosely wound with a small bulge. Intermediate types are denoted by Sab or Sbc. Barred spiral galaxies, which have a prominent bar across their centres, are similarly classed as type SBa, SBb, or SBc with intermediates SBab or SBbc. Lenticular galaxies, which have no spiral arms, are classed as type S0. Irregular galaxies, type Irr, can be subdivided into Irr I, which resemble poorly formed spirals, and Irr II which are otherwise

The Hubble classification was once believed to reveal an evolutionary sequence (from ellipticals to spirals) but this is now known not to be the case. Our own Milky Way Galaxy is classified as type Sb or Sc, but may have a bar.

hovercraft There are several alternative ways of containing the cushion of air beneath the hull of a hovercraft. The passenger-carrying hovercraft that sails across the English Channel has a flexible skirt; other systems are the open plenum and the peripheral jet.

Hubble's constant in astronomy, a measure of the rate at which the universe is expanding, named after Edwin Hubble. Observations suggest that galaxies are moving apart at a rate of 50–100 kps/30–60 mps for every million parsecs of distance. This means that the universe, which began at one point according to the Big Bang theory, is between 10 billion and 20 billion years old (probably closer to 20). Observations by the Hubble Space Telescope in 1996 produced a revised constant of 73 kps/45 mps.

Hubble's law the law that relates a galaxy's distance from us to its speed of recession as the universe expands, announced in 1929 by Edwin Hubble. He found that galaxies are moving apart at speeds that increase in direct proportion to their distance apart. The rate of expansion is known as Hubble's constant.

Hubble Space Telescope (HST) space-based astronomical observing facility, orbiting the Earth at an altitude of 610 km/380 mi. It consists of a 2.4 m/94 in telescope and four complementary scientific instruments, is roughly cylindrical, 13 m/43 ft long, and 4 m/13 ft in diameter, with two large solar panels. HST produces a wealth of scientific data, and allows astronomers to observe the birth of stars, find planets around neighbouring stars, follow the expanding remnants of exploding stars, and search for black holes in the centre of galaxies. HST is a cooperative programme between the European Space Agency (ESA) and the US agency NASA, and is the first spacecraft specifically designed to be serviced in orbit as a permanent space-based observatory. It was launched in 1990.

By having a large telescope above Earth's atmosphere, astronomers are able to look at the universe with unprecedented clarity. Celestial observations by HST are unhampered by clouds and other atmospheric phenomena that distort and attenuate starlight. In particular, the apparent twinkling of starlight caused by density fluctuations in the atmosphere limits the clarity of ground-based telescopes. HST performs at least ten times better than such telescopes and can see almost back to the edge of the universe and to the beginning of time (see Big Bang).

Before HST could reach its full potential, a flaw in the shape of its main mirror, discovered two months after the launch, had to be corrected. In 1993, as part of a planned servicing and instrument upgrade mission, NASA astronauts aboard the space shuttle *Endeavour* installed a set of corrective lenses to compensate for the error in the mirror figure. COSTAR (corrective optics space telescope axial replacement), a device containing ten coin-sized mirrors, now feeds a corrected image from the main mirror to three of the HST's four scientific instruments. HST is also being used to detail the distribution of dust and stars in nearby galaxies, watch the collisions of galaxies in detail, infer the evolution of galaxies, and measure the age of the universe.

In December 1995 HST was trained on an 'empty' area of sky near the Plough, now termed the Hubble Deep Field. Around 1,500 galaxies, mostly new discoveries, were photographed.

Two new instruments were added in February 1997. The Near Infrared Camera and Multi-Object Spectrometer (NICMOS) will enable Hubble to see things even further away (and therefore older) than ever before. The Space Telescope Imaging Spectrograph will work 30 times faster than its predecessor as it can gather information about different stars at the same time. Three new cameras had to be fitted shortly afterwards as one of the original ones was found to be faulty.

In May 1997, three months after astronauts installed new equipment, US scientists reported that Hubble had made an extraordinary finding. Within 20 minutes of searching, it discovered evidence of a black hole 300 million times the mass of the Sun. It is located in the middle of galaxy M84 about 50 million light-years from Earth. Further findings in December 1997 concerned different shapes of dying stars. Previously, astronomers had thought that most stars die with a round shell of burning gas expanding into space. The photographs taken by the HST show shapes such as pinwheels and jet exhaust. This may be indicative of how the Sun will die.

huckleberry berry-bearing bush closely related to the blueberry in the USA and bilberry in Britain. Huckleberry bushes have edible dark-blue berries. (Genus *Gaylussacia*, family Ericaceae.)

A human being: an ingenious assembly of portable plumbing.

CHRISTOPHER MORLEY US editor, poet, and essayist.
Human Being

human body the physical structure of the human being. It develops from the single cell of the fertilized ovum, is born at 40 weeks, and usually reaches sexual maturity between 11 and 18 years of age. The bony framework (skeleton) consists of more than 200 bones, over half of which are in the hands and feet. Bones are held together by joints, some of which allow movement. The circulatory system supplies muscles and organs with blood, which provides oxygen and food and removes carbon dioxide and other waste products. Body functions are controlled by the nervous system and hormones. In the upper part of the trunk is the thorax, which contains the lungs and heart. Below this is the abdomen, containing the digestive system (stomach and intestines); the liver, spleen, and pancreas; the urinary system (kidneys, ureters, and bladder); and, in women, the reproductive organs (ovaries, uterus, and vagina). In men, the prostate gland and seminal vesicles only of the reproductive system are situated in the abdomen, the testes being in the scrotum, which, with the penis, is suspended in front of and below the abdomen. The bladder empties through a small channel (urethra); in the female this opens in the upper end of the vulval cleft, which also contains the opening of the vagina, or birth canal; in the male, the urethra is continued into the penis. In both sexes, the lower bowel terminates in the anus, a ring of strong muscle situated between the buttocks.

skeleton The skull is mounted on the spinal column, or spine, a chain of 24 vertebrae. The ribs, 12 on each side, are articulated to the spinal column behind, and the upper seven meet the breastbone (sternum) in front. The lower end of the spine rests on the pelvic girdle, composed of the triangular sacrum, to which are attached the hipbones (ilia), which are fused in front. Below the sacrum is the tailbone (coccyx). The shoulder blades (scapulae) are held in place behind the upper ribs by muscles, and connected in front to the breastbone by the two collarbones (clavicles).

Each shoulder blade carries a cup (glenoid cavity) into which fits the upper end of the arm bone (humerus). This articulates below with the two forearm bones (radius and ulna). These are articulated at the wrist (carpals) to the bones of the hand (metacarpals and phalanges). The upper end of each thigh bone (femur) fits into a depression (acetabulum) in the hipbone; its lower end is articulated at the knee to the shinbone (tibia) and calf bone (fibula), which are articulated at the ankle (tarsals) to the bones of the foot (metatarsals and phalanges). At a moving joint, the end of each bone is formed of tough, smooth cartilage, lubricated by synovial fluid. Points of special stress are reinforced by bands of fibrous tissue (ligaments).

Muscles are bundles of fibres wrapped in thin, tough layers of connective tissue (fascia); these are usually prolonged at the ends into strong, white cords (tendons, sinews) or sheets (aponeuroses), which connect the muscles to bones and organs, and by way of which the muscles do their work. Membranes of connective tissue also enfold the organs and line the interior cavities of the body. The thorax has a stout muscular floor, the diaphragm, which expands and contracts the lungs in the act of breathing.

The blood vessels of the circulatory system, branching into multitudes of very fine tubes (capillaries), supply all parts of the muscles and organs with blood, which carries oxygen and food necessary for life. The food passes out of the blood to the cells in a clear fluid (lymph); this is returned with waste matter through a system of lymphatic vessels that converge into collecting ducts that drain into large veins in the region of the lower neck. Capillaries join together to form veins which return blood, depleted of oxygen, to the heart.

A finely branching nervous system regulates the function of the muscles and organs, and makes their needs known to the controlling centres in the central nervous system, which consists of the brain and spinal cord. The inner spaces of the brain and the cord contain cerebrospinal fluid. The body processes are regulated both by the nervous system and by hormones secreted by the endocrine

human body The adult human body has approximately 650 muscles, 100 joints, 100,000 km/60,000 mi of blood vessels and 13,000 nerve cells. There are 206 bones in the adult body, nearly half of them in the hands and feet.

glands. Cavities of the body that open onto the surface are coated with mucous membranes, which secrete a lubricating fluid (mucus).

The exterior surface of the body is covered with **skin**. Within the skin are the sebaceous glands, which secrete sebum, an oily fluid that makes the skin soft and pliable, and the sweat glands, which secrete water and various salts. From the skin grow hairs, chiefly on the head, in the armpits, and around the sexual organs; and nails shielding the tips of the fingers and toes; both hair and nails are modifications of skin tissue. The skin also contains nerve receptors for sensations of touch, pain, heat, and cold.

The human **digestive system** is nonspecialized and can break down a wide variety of foodstuffs. Food is mixed with saliva in the mouth by chewing and is swallowed. It enters the stomach, where it is gently churned for some time and mixed with acidic gastric juice. It then passes into the small intestine. In the first part of this, the duodenum, it is broken down further by the juice of the pancreas and duodenal glands, and mixed with bile from the liver, which splits up the fat. The jejunum and ileum continue the work

of digestion and absorb most of the nutritive substances from the food. The large intestine completes the process, reabsorbing water into the body, and ejecting the useless residue as faeces.

The body, to be healthy, must maintain water and various salts in the right proportions; the process is called **osmoregulation**. The blood is filtered in the two kidneys, which remove excess water, salts, and metabolic wastes. Together these form urine, which has

Human Genome Project research scheme, begun in 1988, to map the complete nucleotide (see nucleic acid) sequence of human DNA. There are approximately 80,000 different genes in the human genome, and one gene may contain more than 2 million nucleotides. The programme aims to collect 10–15,000 genetic specimens from 722 ethnic groups whose genetic make-up is to be preserved for future use and study. The knowledge gained is expected to help prevent or treat many crippling and lethal diseases, but there are potential ethical problems associated with knowledge of an individual's genetic make-up, and fears that it will lead to genetic discrimination. Many indigenous people have condemned the project as 'bio-prospecting' – taking genetic material and exploiting it for economic gain – after attempts were made to patent Human T-Lymphotropic Virus Type 2 taken from a Guayami woman with leukaemia, in 1993.

The Human Genome Organization (HUGO) coordinating the project expects to spend \$1 billion over the first five years, making this the largest research project ever undertaken in the life sciences. Work is being carried out in more than 20 centres around the world. By the beginning of 1991, about 2,000 genes had been mapped. By late 1994 a genetic map of the complete genome had been completed.

Concern that, for example, knowledge of an individual's genes may make that person an unacceptable insurance risk has led to planned legislation on genome privacy in the USA, and 3% of HUGO's funds have been set aside for researching and reporting on the ethical implications of the project.

Each strand of DNA carries a sequence of chemical building blocks, the nucleotides. There are only four different types, but the number of possible combinations is immense. The different combinations of nucleotides produce different proteins in the cell, and thus determine the structure of the body and its individual variations. To establish the nucleotide sequence, DNA strands are broken into fragments, which are duplicated (by being introduced into cells of yeast or the bacterium *Escherichia coli*) and distributed to the research centres.

Genes account for only a small amount of the DNA sequence. Over 90% of DNA appears not to have any function, although it is perfectly replicated each time the cell divides, and handed on to the next generation. Many higher organisms have large amounts of redundant DNA and it may be that this is an advantage, in that there is a pool of DNA available to form new genes if an old one is lost by mutation.

instead of 46, so that on fertilization the resulting cell has the correct genetic complement. Fertilization is internal, which increases the chances of conception; unusually for mammals, copulation and pregnancy can occur at any time of the year. Human beings are also remarkable for the length of childhood and for the highly complex systems of parental care found in society. The use of contraception and the development of laboratory methods of insemination and fertilization are issues that make human reproduction more than a merely biological phenomenon.

human species, origins of evolution of humans from ancestral primates. The African apes (gorilla and chimpanzee) are shown by anatomical and molecular comparisons to be the closest living relatives of humans. The oldest known hominids (of the human group), the australopithecines, found in Africa, date from 3.5–4.4 million years ago. The first to use tools came 2 million years later, and the first humanoids to use fire and move out of Africa appeared 1.7 million years ago. Neanderthals were not direct ancestors of the human species. Modern humans are all believed to descend from one African female of 200,000 years ago, although there is a rival theory that humans evolved in different parts of the world simultaneously.

Miocene apes Genetic studies indicate that the last common ancestor between chimpanzees and humans lived 5 to 10 million years ago. There are only fragmentary remains of ape and hominid fossils from this period. Dispute continues over the hominid status of *Ramapithecus*, the jaws and teeth of which have been found in India and Kenya in late Miocene deposits, dated between 14 and 10 million years. The lower jaw of a fossil ape found in the Otavi Mountains, Namibia, comes from deposits dated between 10 and 15 million years ago, and is similar to finds from E Africa and Turkey. It is thought to be close to the initial divergence of the great apes and humans.

Australopithecines Bones of the earliest known human ancestor, a hominid named *Australopithecus ramidus* 1994, were found in Ethiopia and dated as 4.4 million years old. *A. afarensis*, found in Ethiopia and Kenya, date from 3.9 to 4.4 million years ago. These hominids walked upright and they were either direct ancestors or an offshoot of the line that led to modern humans. They may have been the ancestors of *Homo habilis* (considered by some to be a species of *Australopithecus*), who appeared about 2 million years later, had slightly larger bodies and brains, and were probably the first to use stone tools. Also living in Africa at the same time was *A. africanus*, a gracile hominid thought to be a meat-eater, and *A. robustus*, a hominid with robust bones, large teeth, heavy jaws, and thought to be a vegetarian. They are not generally considered to be our ancestors.

Homo erectus Over 1.7 million years ago, *Homo erectus*, believed by some to be descended from *H. habilis*, appeared in Africa. *H. erectus* had prominent brow ridges, a flattened cranium, with the widest part of the skull low down, and jaws with a rounded tooth row, but the chin, characteristic of modern humans, is lacking. They also had much larger brains (900–1,200 cu cm), and were probably the first to use fire and the first to move out of Africa. Their remains are found as far afield as China, W Asia, Spain, and S Britain. Modern human *H. sapiens sapiens* and the Neanderthals *H. sapiens neanderthalensis* are probably descended from *H. erectus*.

Neanderthals Neanderthals were large-brained and heavily built, probably adapted to the cold conditions of the ice ages. They lived in Europe and the Middle East, and disappeared about 40,000 years ago, leaving *H. sapiens sapiens* as the only remaining species of the hominid group. Possible intermediate forms between Neanderthals and *H. sapiens sapiens* have been found at Mount Carmel in Israel and at Broken Hill in Zambia, but it seems that *H. sapiens sapiens* appeared in Europe quite rapidly and either wiped out the Neanderthals or interbred with them.

modern humans There are currently two major views of human evolution: the 'out of Africa' model, according to which *H. sapiens* emerged from *H. erectus*, or a descendant species, in Africa and then spread throughout the world; and the **multiregional model**, according to which selection pressures led to the emergence of similar advanced types of *H. sapiens* from *H. erectus* in different parts of the world at around the same time. Evolution: Out of Africa and the Eve Hypothesis

BY CHRIS STRINGER

Introduction

Most palaeoanthropologists recognize the existence of two human species during the last million years – *Homo erectus*, now extinct, and *Homo sapiens*, the species which includes recent or 'modern' humans. In general, they believe that *Homo erectus* was the ancestor of *Homo sapiens*. How did the transition occur?

The multiregional model

There are two opposing views. The multiregional model says that *Homo erectus* gave rise to *Homo sapiens* across its whole range, which, about 700,000 years ago, included Africa, China, Java (Indonesia), and, probably, Europe. *Homo erectus*, following an African origin about 1.7 million years ago, dispersed around the Old World, developing the regional variation that lies at the roots of modern 'racial' variation. Particular features in a given region persisted in the local descendant populations of today.

For example, Chinese *Homo erectus* specimens had the same flat faces, with prominent cheekbones, as modern Oriental populations. Javanese *Homo erectus* had robustly built cheekbones and faces that jutted out from the braincase, characteristics found in modern Australian Aborigines. No definite representatives of *Homo erectus* have yet been discovered in Europe. Here, the fossil record does not extend back as far as those of Africa and eastern Asia, although a possible *Homo erectus* jawbone more than a million years old was recently excavated in Georgia.

Nevertheless, the multiregional model claims that European *Homo erectus* did exist, and evolved into a primitive form of *Homo sapiens*. Evolution in turn produced the Neanderthals: the ancestors of modern Europeans. Features of continuity in this European lineage include prominent noses and midfaces.

Genetic continuity

The multiregional model was first described in detail by Franz Weidenreich, a German palaeoanthropologist. It was developed further by the American Carleton Coon, who tended to regard the regional lineages as genetically separate. Most recently, the model has become associated with such researchers as Milford Wolpoff (USA) and Alan Thorne (Australia), who have re-emphasized the importance of gene flow between the regional lines. In fact, they regard the continuity in time and space between the various forms of *Homo erectus* and their regional descendants to be so complete that they should be regarded as representing only one species – *Homo sapiens*.

The opposing view

The opposing view is that *Homo sapiens* had a restricted origin in time and space. This is an old idea. Early in the 20th century,

workers such as Marcellin Boule (France) and Arthur Keith (UK) believed that the lineage of *Homo sapiens* was very ancient, having developed in parallel with that of *Homo erectus* and the Neanderthals. However, much of the fossil evidence used to support their ideas has been re-evaluated, and few workers now accept the idea of a very ancient and separate origin for modern *Homo sapiens*.

The Garden of Eden

Modern proponents of this approach focus on a recent and restricted origin for modern *Homo sapiens*. This was dubbed the 'Garden of Eden' or 'Noah's Ark' model by the US anthropologist William Hovells in 1976 because of the idea that all modern human variation had a localized origin from one centre. Hovells did not specify the centre of origin, but research since 1976 points to Africa as especially important in modern human origins.

The consequent 'Out of Africa' model claims that *Homo erectus* evolved into modern *Homo sapiens* in Africa about 100,000–150,000 years ago. Part of the African stock of early modern humans spread from the continent into adjoining regions and eventually reached Australia, Europe, and the Americas (probably by 45,000, 40,000, and 15,000 years ago respectively). Regional ('racial') variation only developed during and after the dispersal, so that there is no continuity of regional features between *Homo erectus* and present counterparts in the same regions.

Like the multiregional model, this view accepts that *Homo erectus* evolved into new forms of human in inhabited regions outside Africa, but argues that these non-African lineages became extinct without evolving into modern humans. Some, such as the Neanderthals, were displaced and then replaced by the spread of modern humans into their regions.

... and an African Eve?

In 1987, research on the genetic material called mitochondrial DNA (mtDNA) in living humans led to the reconstruction of a hypothetical female ancestor for all present-day humanity. This 'Eve' was believed to have lived in Africa about 200,000 years ago. Recent re-examination of the 'Eve' research has cast doubt on this hypothesis, but further support for an 'Out of Africa' model has come from genetic studies of nuclear DNA, which also point to a relatively recent African origin for present-day *Homo sapiens*.

Studies of fossil material of the last 50,000 years also seem to indicate that many 'racial' features in the human skeleton have developed only over the last 30,000 years, in line with the 'Out of Africa' model, and at odds with the million-year timespan one would expect from the multiregional model.

recent human populations suggests that *H. sapiens* originated about 200,000 years ago in Africa from a single female ancestor, 'Eve'. The oldest known fossils of *H. sapiens* also come from Africa, dating from 150,000–100,000 years ago. Separation of human populations would have occurred later, with separation of Asian, European, and Australian populations taking place between 100,000 and 50,000 years ago.

humidity the quantity of water vapour in a given volume of the atmosphere (absolute humidity), or the ratio of the amount of water vapour in the atmosphere to the saturation value at the same temperature (relative humidity). At (dew point the relative humidity is 100% and the air is said to be saturated. Condensation (the conversion of vapour to liquid) may then occur. Relative humidity is measured by various types of hygrometer.

hummingbird any of various small, brilliantly coloured birds found in the Americas. The name comes from the sound produced by the rapid vibration of their wings when hovering near flowers to feed. Hummingbirds have long, needlelike bills and tongues to obtain nectar from flowers and capture insects. They are the only birds able to fly backwards. The Cuban bee hummingbird (*Mellisuga helenae*), the world's smallest bird, is 5.5 cm/2 in long and weighs less than 2.5 g/0.1 oz. There are over 300 species. (Family Trochilidae, order Apodiformes.)

The long cleft tongue of a hummingbird is in the form of a double tube, which can be extended a considerable distance beyond the bill and withdrawn again very rapidly; the sternum (breastbone) is greatly developed, forming a suitable base for the wing muscles; the plumage has a metallic lustre.

humours, theory of theory prevalent in the West in classical and medieval times that the human body was composed of four kinds of fluid: phlegm, blood, choler or yellow bile, and melancholy or black bile. Physical and mental characteristics were explained by different proportions of humours in individuals.

An excess of phlegm produced a 'phlegmatic', or calm, temperament; of blood a 'sanguine', or passionate, one; of yellow bile a 'choleric', or irascible, temperament; and of black bile a 'melancholy', or depressive, one. The Greek physician Galen connected the theory to that of the four elements (see *elements*, the four); the phlegmatic was associated with water, the sanguine with air, the choleric with fire, and the melancholic with earth. An imbalance of the humours could supposedly be treated by diet.

hunting dog or *painted dog* wild dog that once roamed over virtually the whole of sub-Saharan Africa. A pack might have a range of almost 4,000 km/2,500 mi, hunting zebra, antelope, and other game. Individuals can run at 50 kph/30 mph for up to 5 km/3 mi, with short bursts of even higher speeds. The number of hunting dogs that survive has been reduced to a fraction of the original population. According to a 1997 International Union for the Conservation of Nature (IUCN) report, there were fewer than 3,000 hunting dogs remaining in the wild, with many existing populations too small to be viable. (Species *Lycan pictus*, family Canidae.)

The maximum pack size found today is usually eight to ten, whereas in the past several hundred might have hunted together. Habitat destruction and the decline of large game herds have played a part in its decline, but the hunting dog has also suffered badly from the effects of distemper, a disease which was introduced into E Africa early in the 20th century.

Huntington's chorea rare hereditary disease of the nervous system that mostly begins in middle age. It is characterized by involuntary movements (*chorea*), emotional disturbances, and rapid mental degeneration progressing to *dementia*. There is no known cure but the genetic mutation giving rise to the disease was located 1993, making it easier to test individuals for the disease and increasing the chances of developing a cure.

hurricane revolving storm in tropical regions, called *typhoon* in the N Pacific. It originates at latitudes between 5° and 20° N or S of

the Equator, when the surface temperature of the ocean is above 27°C/80°F. A central calm area, called the eye, is surrounded by inwardly spiralling winds (anticlockwise in the northern hemisphere) of up to 320 kph/200 mph. A hurricane is accompanied by lightning and torrential rain, and can cause extensive damage. In meteorology, a hurricane is a wind of force 12 or more on the *Beaufort* scale.

During 1995 the Atlantic Ocean region suffered 19 tropical storms, 11 of them hurricanes. This was the third-worst season since 1871, causing 137 deaths. The most intense hurricane recorded in the Caribbean/Atlantic sector was Hurricane Gilbert in 1988, with sustained winds of 280 kph/175 mph and gusts of over 320 kph/200 mph.

Hutton, James (1726–1797)

Scottish geologist, known as the 'founder of geology', who formulated the concept of uniformitarianism. In 1785 he developed a theory of the igneous origin of many rocks.

His *Theory of the Earth* 1788 proposed that the Earth was incalculably old. Uniformitarianism suggests that past events could be explained in terms of processes that work today. For example, the kind of river current that produces a certain settling pattern in a bed of sand today must have been operating many millions of years ago, if that same pattern is visible in ancient sandstones.

Huygens, Christiaan (1629–1695)

or Huyghens Dutch mathematical physicist and astronomer. He proposed the wave theory of light, developed the pendulum clock in 1657, discovered polarization, and observed Saturn's rings. He made important advances in pure mathematics, applied mathematics, and mechanics, which he virtually founded. His work in astronomy was an impressive defence of the Copernican view of the Solar System.

mechanics Huygens' first studies in applied mathematics dealt with mechanics, the branch of physics pertaining to motions and forces. Working on impact and collision, Huygens used the idea of relative frames of reference, considering the motion of one body relative to the other. He anticipated the law of conservation of momentum stating that in a system of bodies under impact the centre of gravity is conserved. In *De Motu Corporum* 1656, he was also able to show that the quantity $\frac{1}{2}mv^2$ is conserved in an elastic collision.

Huygens also studied centrifugal force and showed, in 1659, its similarity to gravitational force, although he lacked the Newtonian concept of acceleration. He considered projectiles and gravity, developing the mathematically primitive ideas of Galileo. He found an accurate experimental value for the distance covered by a falling body in one second. In fact, his gravitational theories successfully deal with several difficult points that Newton carefully avoided. In the 1670s, Huygens studied motion in resisting media, becoming convinced by experiment that the resistance in such media as air is proportional to the square of the velocity.

the pendulum clock In 1657, Huygens developed a clock regulated by a pendulum, an idea that he published and patented. By 1658, major towns in Holland had pendulum tower clocks.

hydatode specialized pore, or less commonly, a hair, through which water is secreted by hydrostatic pressure from the interior of a plant leaf onto the surface. Hydatodes are found on many different plants and are usually situated around the leaf margin at vein endings. Each pore is surrounded by two crescent-shaped cells and resembles an open stoma, but the size of the opening cannot be varied as in a stoma. The process of water secretion through hydatodes is known as *guttation*.

Huygens worked at the theory first of the simple pendulum and then of harmonically oscillating systems throughout the rest of his life, publishing the *Horologium Oscillatorium* 1673. He derived the relationship between the period of a simple pendulum and its length.

the theory of light The *Traité de la Lumière/Treatise on Light* 1678 contained Huygens' famous wave or pulse theory of light. Two years earlier, Huygens had been able to use his principle of secondary wave fronts to explain reflection and refraction, showing that refraction is related to differing velocities of light in media. He theorized that light is transmitted as a pulse moving through a medium, or ether, by setting up a whole train of vibrations in the ether in a serial displacement. His publication was partly a counter to Newton's particle theory of light. The thoroughness of Huygens' analysis of this model is impressive, but although he observed the effects due to polarization, he could not yet use his ideas to explain this phenomenon.

astronomy and the telescope Huygens' comprehensive study of geometric optics led to the invention of a telescope eyepiece that reduced chromatic aberration. It consisted of two thin plano-convex lenses, rather than one fat lens, with the field lens having a focal length three times greater than that of the eyepiece lens. Its main disadvantage was that cross-wires could not be fitted to measure the size of an image. Huygens then developed a micrometer to measure the angular diameter of celestial objects.

With a home-made telescope, he discovered Titan, one of Saturn's moons, in 1655. Later that year he observed that Titan's period of revolution was about 16 days and that it moved in the same plane as the so-called 'arms' of Saturn. This phenomenon had been somewhat of an enigma to many earlier astronomers, but because of Huygens' superior 7-m telescope, he partially unravelled the detail of Saturn's rings. In 1659, he published a Latin anagram that, when interpreted, read 'It (Saturn) is surrounded by a thin flat ring, nowhere touching and inclined to the ecliptic'. The theory behind Huygens' hypothesis followed later in *Systema Saturnium* 1659, which included observations on the planets, their satellites, the Orion nebula and the determination of the period of Mars, and provided further evidence for the Copernican view of the Solar System.

hydra in zoology, any of a group of freshwater polyps, belonging among the *Coeleenterata*. The body is a double-layered tube (with six to ten hollow tentacles around the mouth), 1.25 cm/0.5 in long when extended, but capable of contracting to a small knob. Usually fixed to waterweed, hydras feed on minute animals that are caught and paralysed by stinging cells on the tentacles. (Genus *Hydra*, family *Hydridae*, phylum *Coeleenterata*, subphylum *Cnidaria*.)

Hydras reproduce asexually in the summer and sexually in the winter. They have no specialized organs except those of reproduction.

hydrangea any of a group of flowering shrubs belonging to the *saxifrage* family, native to Japan. Cultivated varieties of *H. macrophylla* normally produce round heads of pink flowers, but these may be blue if there are certain chemicals in the soil, such as alum or iron. The name comes from the Greek for 'water vessel', after the cuplike seed capsules. (Genus *Hydrangea*, family *Hydrangeaceae*.)

hydrate chemical compound that has discrete water molecules combined with it. The water is known as *water of crystallization* and the number of water molecules associated with one molecule

of the compound is denoted in both its name and chemical formula: for example, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ is copper(II) sulphate pentahydrate.

hydration in chemistry, the combination of water and another substance to produce a single product. It is the opposite of dehydration.

hydraulic radius measure of a river's channel efficiency (its ability to discharge water), used by water engineers to assess the likelihood of flooding. The hydraulic radius of a channel is defined as the ratio of its cross-sectional area to its wetted perimeter (the part of the cross-section that is in contact with the water).

The greater the hydraulic radius, the greater the efficiency of the channel and the less likely the river is to flood. The highest values occur when channels are deep, narrow, and semi-circular in shape.

hydraulics field of study concerned with utilizing the properties of water and other liquids, in particular the way they flow and transmit pressure, and with the application of these properties in engineering. It applies the principles of hydrostatics and hydrodynamics. The oldest type of hydraulic machine is the **hydraulic press**, invented by Joseph Bramah in England in 1795. The hydraulic principle of pressurized liquid increasing a force is commonly used on vehicle braking systems, the forging press, and the hydraulic systems of aircraft and excavators.

A hydraulic press consists of two liquid-connected pistons in cylinders, one of narrow bore, one of large bore. A force applied to the narrow piston applies a certain pressure (force per unit area) to the liquid, which is transmitted to the larger piston. Because the area of this piston is larger, the force exerted on it is larger. Thus the original force has been magnified, although the smaller piston must move a great distance to move the larger piston only a little.

hydraulics The hydraulic jack transmits the pressure on a small piston to a larger one. A larger total force is developed by the larger piston but it moves a smaller distance than the small piston.

hydride chemical compound containing hydrogen and one other element, and in which the hydrogen is the more electronegative element (see electronegativity).

Hydrides of the more reactive metals may be ionic compounds containing a hydride anion (H^-).

hydrocarbon any of a class of chemical compounds containing only hydrogen and carbon (for example, the alkanes and alkenes). Hydrocarbons are obtained industrially principally from petroleum and coal tar.

hydrocephalus potentially serious increase in the volume of cerebrospinal fluid (CSF) within the ventricles of the brain. In infants, since their skull plates have not fused, it causes enlargement of the head, and there is a risk of brain damage from CSF pressure on the developing brain.

Hydrocephalus may be due to mechanical obstruction of the outflow of CSF from the ventricles or to faulty reabsorption. Treatment usually involves surgical placement of a shunt system to drain the fluid into the abdominal cavity. In infants, the condition is often seen in association with spina bifida. Hydrocephalus may occur as a consequence of brain injury or disease.

hydrochloric acid HCl solution of hydrogen chloride (a colourless, acidic gas) in water. The concentrated acid is about 35% hydrogen chloride and is corrosive. The acid is a typical strong, monobasic acid forming only one series of salts, the chlorides. It has many industrial uses, including recovery of zinc from galvanized scrap iron and the production of chlorine. It is also produced in the stomachs of animals for the purposes of digestion.

hydrocyanic acid or **prussic acid** solution of hydrogen cyanide gas (HCN) in water. It is a colourless, highly poisonous, volatile liquid, smelling of bitter almonds.

hydrodynamics branch of physics dealing with fluids (liquids and gases) in motion.

hydroelectric power electricity generated by moving water. In a typical scheme, water stored in a reservoir, often created by damming a river, is piped into water turbines, coupled to electricity generators. In pumped storage plants, water flowing through the turbines is recycled. A tidal power station exploits the rise and fall of the tides. About one-fifth of the world's electricity comes from hydroelectric power.

Hydroelectric plants have prodigious generating capacities. The Grand Coulee plant in Washington State, USA, has a power output of around 10,000 megawatts. The Itaipu power station on the Paraná River (Brazil/Paraguay) has a potential capacity of 12,000 megawatts.

Work on the world's largest hydroelectric project, the Three Gorges Dam on the Chang Jiang, was officially inaugurated in 1994. By 1996, around 600,000 sq km/231,660 sq mi of land had been flooded worldwide for hydroelectric reservoirs.

hydrofoil wing that develops lift in the water in much the same way that an aeroplane wing develops lift in the air. A hydrofoil boat is one whose hull rises out of the water owing to the lift, and the boat skims along on the hydrofoils. The first hydrofoil was fitted to a boat 1906. The first commercial hydrofoil went into operation 1956. One of the most advanced hydrofoil boats is the Boeing Oriskany. Hydrofoils are now widely used for fast island ferries in calm seas.

hydrogen Greek *hydro* + *gen* 'water generator' colourless, odourless, gaseous, nonmetallic element, symbol H, atomic number 1, relative atomic mass 1.00797. It is the lightest of all the elements and occurs on Earth chiefly in combination with oxygen as water. Hydrogen is the most abundant element in the universe, where it accounts for 93% of the total number of atoms and 76% of the total mass. It is a component of most stars, including the Sun, whose heat and light are produced through the nuclear-fusion process that converts hydrogen into helium. When subjected to a pressure 500,000 times greater than that of the Earth's atmosphere, hydrogen becomes a solid with metallic properties, as in one of the inner zones of Jupiter. Hydrogen's common and industrial uses include the hardening of oils and fats by hydrogenation, the creation of high-temperature flames for welding, and as rocket fuel. It has been proposed as a fuel for road vehicles.

TO REMEMBER THE FOUR ELEMENTS THAT MAKE LIFE'S BUILDING BLOCKS:

HONC IF YOU LIKE LIFE!

HYDROGEN, OXYGEN, NITROGEN, CARBON

Its isotopes δ deuterium and δ tritium (half-life 12.5 years) are used in nuclear weapons, and deuterons (deuterium nuclei) are used in synthesizing elements. The element's name refers to the generation of water by the combustion of hydrogen, and was coined in 1787 by French chemist Louis Gayton de Morveau (1737–1816).

hydrogenation addition of hydrogen to an unsaturated organic molecule (one that contains δ double bonds or δ triple bonds). It is widely used in the manufacture of margarine and low-fat spreads by the addition of hydrogen to vegetable oils.

Vegetable oils contain double carbon-to-carbon bonds and are therefore examples of unsaturated compounds. When hydrogen is added to these double bonds, the oils become saturated and more solid in consistency.

hydrogen bomb bomb that works on the principle of nuclear δ fusion. Large-scale explosion results from the thermonuclear release of energy when hydrogen nuclei are fused to form helium nuclei. The first hydrogen bomb was exploded at Eniwetok Atoll in the Pacific Ocean by the USA in 1952.

In some sort of crude sense ... the physicists have known sin; and this is a knowledge which they cannot lose.

J ROBERT OPPENHEIMER US physicist.

hydrogen burning in astronomy, any of several processes by which hydrogen is converted to δ helium by δ nuclear fusion in the core of a star. In the Sun, the main process is the proton-proton chain, while in heavier stars the carbon cycle is more important. In both processes, four protons are converted to a helium nucleus with the emission of δ positrons, δ neutrinos, and gamma δ rays. The temperature must exceed several million K for hydrogen burning to start and the least massive stars (δ brown dwarfs) never become hot enough.

hydrogen carbonate or **bicarbonate** compound containing the ion HCO_3^- , an acid salt of carbonic acid (solution of carbon dioxide in water). When heated or treated with dilute acids, it gives off carbon dioxide. The most important compounds are δ sodium hydrogen carbonate (bicarbonate of soda), and δ calcium hydrogen carbonate.

hydrogen cyanide HCN poisonous gas formed by the reaction of sodium cyanide with dilute sulphuric acid; it is used for fumigation.

The salts formed from it are cyanides – for example sodium cyanide, used in hardening steel and extracting gold and silver from their ores. If dissolved in water, hydrogen cyanide gives hydrocyanic acid.

hydrogen peroxide H_2O_2 in medicine, a liquid used, in diluted form, as an antiseptic. Oxygen is released when hydrogen peroxide is added to water and the froth helps to discharge dead tissue from wounds and ulcers. It is also used as a mouthwash and as a bleach.

hydrogen sulphate HSO_4^- compound containing the hydrogen sulphate ion. Hydrogen sulphates are δ acid salts.

hydrogen sulphide H_2S poisonous gas with the smell of rotten eggs. It is found in certain types of crude oil where it is formed by decomposition of sulphur compounds. It is removed from the oil at the refinery and converted to elemental sulphur.

hydrogen trioxide H_2O_3 relatively stable compound of hydrogen and oxygen present in the atmosphere and possibly also in living tissue. It was first synthesized in 1994; previously it had been assumed to be too unstable.

It is produced in a reaction similar to that used for the commercial production of hydrogen peroxide (H_2O_2) but ozone (O_3) is used instead of oxygen. Hydrogen trioxide is stable at low temperatures but begins to decompose slowly at -40°C forming the high energy form of oxygen, singlet oxygen.

hydrograph graph showing how the discharge of a river varies with time. By studying hydrographs, water engineers can predict when flooding is likely and take action to prevent its taking place.

A hydrograph shows the time lag, or delay, between peak rainfall and the resultant peak in discharge, and the length of time taken for that discharge to peak. The shorter the time lag and the higher the peak, the more likely it is that flooding will occur. Factors likely to give short time lags and high peaks include heavy rainstorms, steep slopes, deforestation, poor soil quality, and the covering of surfaces with impermeable substances such as tarmac and concrete. Actions taken by water engineers to increase time lags and lower peaks include planting trees in the drainage basin of a river.

hydrography study and charting of Earth's surface waters in seas, lakes, and rivers.

hydrological cycle alternative name for the δ water cycle, by which water is circulated between the Earth's surface and its atmosphere.

hydrology study of the location and movement of inland water, both frozen and liquid, above and below ground. It is applied to major civil engineering projects such as irrigation schemes, dams, and hydroelectric power, and in planning water supply.

hydrolysis chemical reaction in which the action of water or its ions breaks down a substance into smaller molecules. Hydrolysis occurs in certain inorganic salts in solution, in nearly all nonmetallic chlorides, in esters, and in other organic substances. It is one of the mechanisms for the breakdown of food by the body, as in the conversion of starch to glucose.

hydrometer in physics, an instrument used to measure the relative density of liquids (the density compared with that of water). A hydrometer consists of a thin glass tube ending in a sphere that leads into a smaller sphere, the latter being weighted so that the hydrometer floats upright, sinking deeper into less dense liquids than into denser liquids. Hydrometers are used in brewing and to test the strength of acid in car batteries.

The hydrometer is based on δ Archimedes' principle.

hydrophilic Greek 'water-loving' in chemistry, a term describing functional groups with a strong affinity for water, such as the carboxyl group ($-\text{COOH}$).

If a molecule contains both a hydrophilic and a hydrophobic group (a group that repels water), it may have an affinity for both aqueous and nonaqueous molecules. Such compounds are used to stabilize δ emulsions or as δ detergents.

hydrophily type of δ pollination where the pollen is transported by water. Water-pollinated plants occur in 31 genera in 11 different families. They are found in habitats as diverse as rainforests and seasonal desert pools. Pollen is either dispersed underwater or on the water's surface.

Pollen may be released directly onto the water's surface, as in the sea grass *Halodule pinifolia*, forming pollen rafts, or as in the freshwater plant *Valisneria*, the pollen may be released within floating male flowers. In Caribbean turtle grass, *Thalassia testudinum*, pollen is released underwater embedded in strands of mucilage. Denser than water, it is carried by the current.

hydrophobia another name for the disease δ rabies.

hydrophobic Greek 'water-hating' in chemistry, a term describing functional groups that repel water (the opposite of hydrophilic).

hydrophone underwater δ microphone and ancillary equipment capable of picking up waterborne sounds. It was originally developed to detect enemy submarines but is now also used, for example, for listening to the sounds made by whales.

hydrophyte plant adapted to live in water, or in waterlogged soil.

Hydrophytes may have leaves with a very reduced or absent cuticle and no δ stomata (since there is no need to conserve water), a reduced root and water-conducting system, and less supporting tissue since water buoys plants up. There are often numerous spaces

between the cells in their stems and roots to make O_2 exchange with all parts of the plant body possible. Many have highly divided leaves, which lessens resistance to flowing water; an example is spiked water milfoil *Myriophyllum spicatum*.

hydroplane on a submarine, a movable horizontal fin angled downwards or upwards when the vessel is descending or ascending. It is also a highly manoeuvrable motorboat with its bottom rising in steps to the stern, or a ϕ hydrofoil boat that skims over the surface of the water when driven at high speed.

hydroponics cultivation of plants without soil, using specially prepared solutions of mineral salts. Beginning in the 1930s, large crops were grown by hydroponic methods, at first in California but since then in many other parts of the world.

Julius von Sachs (1832–1897), in 1860, and W Knop, in 1865, developed a system of plant culture in water whereby the relation of mineral salts to plant growth could be determined, but it was not until about 1930 that large crops could be grown. The term was first coined by US scientist W F Gericke.

hydrosphere the water component of the Earth, usually encompassing the oceans, seas, rivers, streams, swamps, lakes, groundwater, and atmospheric water vapour.

hydrostatics in physics, the branch of ϕ statics dealing with fluids in equilibrium – that is, in a static condition. Practical applications include shipbuilding and dam design.

hydroxide any inorganic chemical compound containing one or more hydroxyl (OH) groups and generally combined with a metal. Hydroxides include sodium hydroxide (caustic soda, NaOH), potassium hydroxide (caustic potash, KOH), and calcium hydroxide (slaked lime, $\text{Ca}(\text{OH})_2$).

hydroxyl group an atom of hydrogen and an atom of oxygen bonded together and covalently bonded to an organic molecule. Common compounds containing hydroxyl groups are alcohols and phenols.

In chemical reactions, the hydroxyl group ($-\text{OH}$) frequently behaves as a single entity.

hydroxypropanoic acid technical name for lactic acid.

HYENA

The female spotted hyena has a higher level of the male sex hormone testosterone than the male. She is also up to 12% heavier than the male.

hyena any of three species of carnivorous doglike mammals living in Africa and Asia. Hyenas have extremely powerful jaws. They are scavengers, feeding on the remains of animals killed by predators such as lions, although they will also attack and kill live prey. (Genera *Hyaena* and *Crocuta*, family Hyaenidae, order Carnivora.)

The species are the striped hyena (*H. hyaena*) found from Asia Minor to India; the brown hyena (*H. brunnea*), found in S Africa; and the spotted or laughing hyena (*C. crocuta*), common south of the Sahara. The ϕ ardwolf also belongs to the hyena family.

Facts about hyenas illustrated by a number of photos. There is also a highly informative 'Frequently Asked Questions' section dealing with questions such as 'Do they really laugh?' and 'Will they eat people?', as well as a folklore section dealing with the depiction of hyenas through history.

hygrometer The most common hygrometer, or instrument for measuring the humidity of a gas, is the wet and dry bulb hygrometer. The wet bulb records a lower temperature because water evaporates from the muslin, taking heat from the wet bulb. The degree of evaporation and hence cooling depends upon the humidity of the surrounding air or other gas.

hygrometer in physics, any instrument for measuring the humidity, or water vapour content, of a gas (usually air). A wet and dry bulb hygrometer consists of two vertical thermometers, with one of the bulbs covered in absorbent cloth dipped into water. As the water evaporates, the bulb cools, producing a temperature difference between the two thermometers. The amount of evaporation, and hence cooling of the wet bulb, depends on the relative humidity of the air.

Other hygrometers work on the basis of a length of natural fibre, such as hair or a fine strand of gut, changing with variations in humidity. In a ϕ dew-point hygrometer, a polished metal mirror gradually cools until a fine mist of water (dew) forms on it. This gives a measure of the dew point, from which the air's relative humidity can be calculated.

hyoscine or *scopolamine* drug that acts on the autonomic nervous system and prevents muscle spasm. It is frequently included in premedication to dry up lung secretions and as a postoperative sedative. It is also used to treat ulcers, to relax the womb in labour, for travel sickness, and to dilate the pupils before an eye examination. It is an alkaloid, $\text{C}_{17}\text{H}_{21}\text{NO}_2$, obtained from various plants of the nightshade family (such as ϕ belladonna).

hyperactivity condition of excessive activity in young children, combined with restlessness, inability to concentrate, and difficulty in learning. There are various causes, ranging from temperamental predisposition to brain disease. In some cases food additives have come under suspicion; in such instances modification of the diet may help. Mostly there is improvement at puberty, but symptoms may persist in the small proportion diagnosed as having ϕ attention-deficit hyperactivity disorder.

hyperbola in geometry, a curve formed by cutting a right circular cone with a plane so that the angle between the plane and the base is greater than the angle between the base and the side of the cone. All hyperbolae are bounded by two asymptotes (straight

hyperbola The hyperbola is produced when a cone is cut by a plane. It is one of a family of curves called conic sections: the circle, ellipse, and parabola. These curves are produced when the plane cuts the cone at different angles and positions.

lines which the hyperbola moves closer and closer to but never reaches).

A hyperbola is a member of the family of curves known as conic sections.

A hyperbola can also be defined as a path traced by a point that moves such that the ratio of its distance from a fixed point (focus) and a fixed straight line (directrix) is a constant and greater than 1; that is, it has an eccentricity greater than 1.

Hypercard computer application developed for the Apple Macintosh, in which data are stored as if on cards in a card-index system. A group of cards forms a stack. Additional features include the ability to link cards in different ways and, by the use of software buttons (icons that can be clicked or double clicked with a mouse), to access other data. Hypercard is very similar to hypertext, although it does not conform to the rigorous definition of hypertext.

hypercharge in physics, a property of certain elementary particles, analogous to electric charge, that accounts for the absence of some expected behaviour (such as decay).

hyperlink link from one document to another or, within the same document, from one place to another. It can be activated by clicking on the link with a mouse. The link is usually highlighted in some way, for example by the inclusion of a small graphic. Documents linked in this way are described as hypertext. Examples of programs that use hypertext and hyperlinks are Windows help files, Acrobat, and Mosaic.

hypermedia in computing, system that uses links to lead users to related graphics, audio, animation, or video files in the same way that hypertext systems link related pieces of text. The World Wide Web is an example of a hypermedia system, as is HyperCard.

hyperon in physics, any of a group of highly unstable elementary particles that includes all the baryons with the exception of protons and neutrons. They are all composed of three quarks. The lambda, xi, sigma, and omega particles are hyperons.

hypertension abnormally high blood pressure due to a variety of causes, leading to excessive contraction of the smooth muscle cells of the walls of the arteries. It increases the risk of kidney disease, stroke, and heart attack.

Hypertension is one of the major public health problems of the developed world, affecting 15–20% of adults in industrialized countries (1996). It may be of unknown cause (essential hypertension), or it may occur in association with some other condition, such as kidney disease (secondary or symptomatic hypertension). It is controlled with a low-salt diet and drugs.

hypertext system for viewing information (both text and pictures) on a computer screen in such a way that related items of information can easily be reached. For example, the program might display a map of a country; if the user clicks (with a mouse) on a particular city, the program will display information about that city.

hyperthyroidism or **thyrotoxicosis** overactivity of the thyroid gland due to enlargement or tumour. Symptoms include accelerated heart rate, sweating, anxiety, tremor, and weight loss. Treatment is by drugs or surgery.

hypha (plural **hyphae**) delicate, usually branching filament, many of which collectively form the mycelium and fruiting bodies of a fungus. Food molecules and other substances are transported along hyphae by the movement of the cytoplasm, known as 'cytoplasmic streaming'.

Typically hyphae grow by increasing in length from the tips and by the formation of side branches. Hyphae of the higher fungi (the ascomycetes and basidiomycetes) are divided by cross walls or septa at intervals, whereas those of lower fungi (for example, bread mould) are undivided. However, even the higher fungi are not truly cellular, as each septum is pierced by a central pore, through which cytoplasm, and even nuclei, can flow. The hyphal walls contain chitin, a polysaccharide.

hypnosis artificially induced state of relaxation or altered attention characterized by heightened suggestibility. There is evidence that, with susceptible persons, the sense of pain may be diminished, memory of past events enhanced, and illusions or hallucinations experienced. Posthypnotic amnesia (forgetting what happened during hypnosis) and posthypnotic suggestion (performing an action after hypnosis that had been suggested during it) have also been demonstrated.

Hypnosis has a number of uses in medicine. Hypnotically induced sleep, for example, may assist the healing process, and hypnotic suggestion (hypnotherapy) may help in dealing with the symptoms of emotional and psychosomatic disorders. The Austrian physician Friedrich Anton Mesmer is said to be the discoverer of hypnosis, but he called it 'animal magnetism', believing it to be a physical force or fluid. The term 'hypnosis' was coined by James Braid (1795–1860), a British physician and surgeon who was the first to regard it as a psychological phenomenon. The Scottish surgeon James Esdaile (1805–1859), working in India, performed hundreds of operations in which he used hypnosis to induce analgesia (insensitivity to pain) or general anaesthesia (total insensitivity).

hypnotic any substance (such as barbiturate, benzodiazepine, alcohol) that depresses brain function, inducing sleep. Prolonged use may lead to physical or psychological addiction.

hypo in photography, a term for sodium thiosulphate, discovered 1819 by John Herschel, and used as a fixative for photographic images since 1837.

hypocycloid in geometry, a cusped curve traced by a point on the circumference of a circle that rolls around the inside of another larger circle. (Compare epicycloid.)

hypodermic syringe instrument used for injecting fluids beneath the skin into either muscles or blood vessels. It consists of a small graduated tube with a close-fitting piston and a nozzle onto which a hollow needle can be fitted.

hypogeal term used to describe seed germination in which the cotyledons remain below ground. It can refer to fruits that develop underground, such as peanuts *Arachis hypogaea*.

hypoglycaemia condition of abnormally low level of sugar (glucose) in the blood (below 60 g/100 ml), which starves the brain. It causes weakness, sweating, and mental confusion, sometimes fainting.

Hypoglycaemia is most often seen in diabetes. Low blood sugar occurs when the diabetic has taken too much insulin. It is treated by administering glucose.

hypotenuse the longest side of a right-angled triangle, opposite the right angle. It is of particular application in Pythagoras' theo-

rem (the square of the hypotenuse equals the sum of the squares of the other two sides), and in trigonometry where the ratios ϕ sine and ϕ cosine are defined as the ratios opposite/hypotenuse and adjacent/hypotenuse respectively.

hypothalamus region of the brain below the ϕ cerebrum which regulates rhythmic activity and physiological stability within the body, including water balance and temperature. It regulates the production of the pituitary gland's hormones and controls that part of the ϕ nervous system governing the involuntary muscles.

hypothermia condition in which the deep (core) temperature of the body falls below 35°C. If it is not discovered, coma and death ensue. Most at risk are the aged and babies (particularly if premature).

hypothesis in science, an idea concerning an event and its possible explanation. The term is one favoured by the followers of the philosopher Karl Popper, who argue that the merit of a scientific hypothesis lies in its ability to make testable predictions.

Historians will have to face the fact that natural selection determined the evolution of cultures in the same manner as it did that of species.

KONRAD LORENZ Austrian zoologist.
On Aggression 1966

hypothyroidism or **myxoedema** deficient functioning of the thyroid gland, causing slowed mental and physical performance, weight gain, sensitivity to cold, and susceptibility to infection.

This may be due to lack of iodine in the diet or a defect of the thyroid gland, both being productive of ϕ goitre; or to the pituitary gland providing insufficient stimulus to the thyroid gland. Treatment of thyroid deficiency is by the hormone thyroxine. When present from birth, hypothyroidism can lead to cretinism if untreated.

hypsoneter Greek *hypsos* 'height' instrument for testing the accuracy of a thermometer at the boiling point of water. It was originally used for determining altitude by comparing changes in the boiling point with changes in atmospheric pressure.

Hyracotherium extinct mammal belonging to the order Perissodactyla and considered to be an ancestor of the horse. It occurs in Eocene strata in Europe and was a small animal about 1 m/3.3 ft in length, with complete dentition, four digits on the

forelimbs, and three on the hind-limbs, and orbits not enclosed by bone.

hyrax any of a group of small, rodentlike, herbivorous mammals that live among rocks in desert areas, and in forests in Africa, Arabia, and Syria. They are about the size of a rabbit, with a plump body, short legs, short ears, brownish fur, and long, curved front teeth. (Family Procaviidae, order Hyracoidea.)

They have four toes on the front limbs, and three on the hind limbs, each of which has a tiny hoof. There are nine species of hyrax. They are related to elephants.

hyssop aromatic herb belonging to the mint family, found in Asia, S Europe, and around the Mediterranean. It has blue flowers, oblong leaves, and stems that are woody near the ground but herbaceous (fleshy) above. (*Hyssopus officinalis*, family Labiatae.)

hysterectomy surgical removal of all or part of the uterus (womb). The operation is performed to treat fibroids (benign tumours growing in the uterus) or cancer; also to relieve heavy menstrual bleeding. A woman who has had a hysterectomy will no longer menstruate and cannot bear children.

hysteresis phenomenon seen in the elastic and electromagnetic behaviour of materials, in which a lag occurs between the application or removal of a force or field and its effect.

If the magnetic field applied to a magnetic material is increased and then decreased back to its original value, the magnetic field inside the material does not return to its original value. The internal field 'lags' behind the external field. This behaviour results in a loss of energy, called the hysteresis loss, when a sample is repeatedly magnetized and demagnetized. Hence the materials used in transformer cores and electromagnets should have a low hysteresis loss. Similar behaviour is seen in some materials when varying electric fields are applied (electric hysteresis). Elastic hysteresis occurs when a varying force repeatedly deforms an elastic material. The deformation produced does not completely disappear when the force is removed, and this results in energy loss on repeated deformations.

Hytnet (contraction of *hypertext browser for Telnets-accessible sites on the Internet*) in computing, program developed in 1990 which indexes Telnets-accessible sites on the Internet so that users can quickly look up the necessary access information.

Versions of Hytnet exist for PCs, DEC VAXes, and UNIX machines. Hytnet is distributed as ϕ shareware; it is updated via the HYTEL-L electronic mailing list.

H ϕ in physics, the symbol for ϕ ertzt.

ANTARCTICA

The ice that covers Antarctica is 4,776 m/15,669 ft

IAB in computing, abbreviation for *Internet Architecture Board*.

IAEA abbreviation for *International Atomic Energy Agency*.

ibex any of various wild goats found in mountainous areas of Europe, NE Africa, and Central Asia. They grow to 100 cm/3.5 ft, and have brown or grey coats and heavy horns. They are herbivorous and live in small groups.

ibis any of various wading birds, about 60 cm/2 ft tall, belonging to the same family as spoonbills. Ibises have long legs and necks, and long, downward-curved beaks, rather blunt at the end; the upper part is grooved. Their plumage is generally black and white. Various species occur in the warmer regions of the world. (Family Threskiornidae, order Ciconiiformes.)

The scarlet ibis (*Guara ruber*), a South American species, is brilliant scarlet with a few black patches. The scarlet colour is caused by an accumulation of pigment from the aquatic invertebrates that it feeds on.

IBM (abbreviation for *International Business Machines*) multinational company, the largest manufacturer of computers in the world. The company is a descendant of the Tabulating Machine Company, formed 1896 by US inventor Herman Hollerith to exploit his punched-card machines. It adopted its present name in 1924. By 1991 it had an annual turnover of \$64.8 billion and employed about 345,000 people, but in 1992 and 1993 it made considerable losses. The company acquired Lotus Development Corporation in 1995. By 1997 IBM had, under new management, recovered financially, with an annual turnover of \$76 billion, which means it is still a dominant industry player.

Its acquisition of the Lotus Development Corporation gave IBM access to its wide range of innovative software, including the 1-2-3 spreadsheet and Notes, a market leader in groupware.

IBM-compatible in computing, a clone of an IBM PC; synonymous with PC-compatible.

Although there were successful personal computers before the PC, IBM set the most common standard for these machines when it launched the PC in 1981. It created a clone industry by using readily available parts in the IBM PC, instead of developing proprietary parts itself. The success of the PC established Intel processors and Microsoft software as industry standards.

IC abbreviation for *integrated circuit*.

Icarus in astronomy, an α Apollo asteroid 1.5 km/1 mi in diameter, discovered 1949. It orbits the Sun every 409 days at a distance of 28-300 million km/18-186 million mi (0.19-2.0 astronomical units). It was the first asteroid known to approach the Sun closer than does the planet Mercury. In 1968 it passed 6 million km/4 million mi from the Earth.

ice solid formed by water when it freezes. It is colourless and its crystals are hexagonal. The water molecules are held together by hydrogen bonds.

The freezing point of ice, used as a standard for temperature, is 0° for the Celsius and Réaumur scales and 32° for the Fahrenheit. Ice expands in the act of freezing (hence burst pipes), becoming less dense than water (0.9175 at 5°C/41°F).

ice form of methamphetamine that is smoked for its stimulating effect; its use has been illegal in the USA since 1989. Its use may be followed by a period of depression and psychosis.

ice age any period of glaciation occurring in the Earth's history, but particularly that in the Pleistocene epoch, immediately preceding historic times. On the North American continent, glaciers reached as far south as the Great Lakes, and an ice sheet spread over N Europe, leaving its remains as far south as Switzerland.

There were several glacial advances separated by interglacial stages during which the ice melted and temperatures were higher than today.

Formerly there were thought to have been only three or four glacial advances, but recent research has shown about 20 major incidences. For example, ocean-bed cores record the absence or presence in their various layers of such cold-loving small marine animals as radiolaria, which indicate a fall in ocean temperature at regular intervals. Other ice ages have occurred throughout geological time: there were four in the Precambrian era, one in the Ordovician, and one at the end of the Carboniferous and beginning of the Permian. The occurrence of an ice age is governed by a combination of factors (the Milankovitch hypothesis): (1) the Earth's change of attitude in relation to the Sun, that is, the way it tilts in a 41,000-year cycle and at the same time wobbles on its axis in a 22,000-year cycle, making the time of its closest approach to the Sun come at different seasons; and (2) the 92,000-year cycle of eccentricity in its orbit round the Sun, changing it from an elliptical to a near circular orbit, the severest period of an ice age coinciding with the approach to circularity. There is a possibility that the Pleistocene ice age is not yet over. It may reach another maximum in another 60,000 years.

iceberg floating mass of ice, about 80% of which is submerged, rising sometimes to 100 m/300 ft above sea level. Glaciers that reach the coast become extended into a broad foot; as this enters the sea, masses break off and drift towards temperate latitudes, becoming a danger to shipping.

iceman nickname given to the preserved body of a prehistoric man discovered in a glacier on the Austrian-Italian border 1991. On the basis of the clothing and associated artefacts, the body was at first believed to be 4,000 years old, from the Bronze Age. Carbon dating established its age at about 5,300 years. The discovery led to a reappraisal of the boundary between the Bronze and the Stone Age.

ichneumon fly any of a large group of parasitic wasps. There are several thousand species in Europe, North America, and other regions. They have slender bodies, and the females have unusually long, curved ovipositors (egg-laying instruments) that can pierce several inches of wood. The eggs are laid in the eggs, larvae, or pupae of other insects, usually butterflies or moths. (Family Ichneumonidae.)

ichthyology the scientific study of fish, including their classification, general biology, behaviour, ecology, and research into commercial fisheries.

ICHTHYOLOGY RESOURCES

<http://muse.bio.cornell.edu/cgi-bin/hl?fish>

Everything anyone should need for studying fish, including historical information about development, as well as up-to-date listings of currently endangered species. There is also a gallery of fish images and paintings for the less scientifically inclined.

icon in computing, a small picture on the computer screen, or \odot VDU, representing an object or function that the user may

manipulate or otherwise use. It is a feature of graphical user interface (GUI) systems. Icons make computers easier to use by allowing the user to point to and click with a mouse on pictures, rather than type commands.

icosahedron (plural *icosahedra*) regular solid with 20 equilateral (equal-sided) triangular faces. It is one of the five regular polyhedra, or Platonic solids.

id in Freudian psychology, the mass of motivational and instinctual elements of the human mind, whose activity is largely governed by the arousal of specific needs. It is regarded as the unconscious element of the human psyche, and is said to be in conflict with the ego and the superego.

IDEA (acronym for *International Data Encryption Algorithm*) in computing, an encryption algorithm, developed in 1990 in Zürich, Switzerland. For reasons of speed, it is used in the encryption program Pretty Good Privacy (PGP) along with RSA.

identity in mathematics, a number or operation that leaves others unchanged when combined with them. Zero is the identity for addition; one is the identity for multiplication. For example:

$$\begin{aligned}7 + 0 &= 7 \\7 \times 1 &= 7\end{aligned}$$

id Software computer software company that publishes popular games such as *Doom* and *Quake*, based in Texas, USA. An entire subculture has built up around id's games because of its habit of releasing source code to enable fans to write their own additional game levels using settings of their own choice.

The company's first major product was the 1992 game *Wolfenstein 3-D*, in which players move around a series of complicated mazes retrieving treasure and shooting Nazi troops and guard dogs. *Quake*, released in 1996, uses complex, carefully styled 3-D graphics, adds vertical movement and underwater caves, and includes a gruesome collection of fierce aliens. Both *Doom* and *Quake* can be played competitively over networks, including the Internet.

IEEE abbreviation for *Institute of Electrical and Electronic Engineers*, US institute which sets technical standards for electrical equipment and computer data exchange.

IETF in computing, abbreviation for Internet Engineering Task Force.

igneous rock rock formed from cooling magma or lava, and solidifying from a molten state. Igneous rocks are largely composed of silica (SiO₂) and they are classified according to their crystal size, texture, method of formation, or chemical composition, for example by the proportions of light and dark minerals.

ignis fatuus another name for will-o'-the-wisp.

ignition coil transformer that is an essential part of a petrol engine's ignition system. It consists of two wire coils wound around an iron core. The primary coil, which is connected to the car battery, has only a few turns. The secondary coil, connected via the distributor to the spark plugs, has many turns. The coil takes in a low voltage (usually 12 volts) from the battery and transforms it to a high voltage (about 15,000–20,000 volts) to ignite the engine.

When the engine is running, the battery current is periodically interrupted by means of the contact breaker in the distributor. The collapsing current in the primary coil induces a current in the secondary coil, a phenomenon known as electromagnetic induction. The induced current in the secondary coil is at very high voltage, typically about 15,000–20,000 volts. This passes to the spark plugs to create sparks.

ignition temperature or **fire point** minimum temperature to which a substance must be heated before it will spontaneously burn independently of the source of heat; for example, ethanol has an ignition temperature of 425°C/798°F and a flash point of 12°C/54°F.

iguana any of about 700 species of lizard, chiefly found in the Americas. The common iguana (*I. iguana*) of Central and South

America is a vegetarian and may reach 2 m/6 ft in length. (Especially genus *Iguana*, family Iguanidae.)

iguanodon plant-eating dinosaur whose remains are found in deposits of the Lower Cretaceous age, together with the remains of other dinosaurs of the same order (ornithischians) such as stegosaurus and triceratops. It was 5–10 m/16–32 ft long and, when standing upright, 4 m/13 ft tall. It walked on its hind legs, using its long tail to balance its body. (Order *Ornithischia*.)

ileum part of the small intestine of the digestive system, between the duodenum and the colon, that absorbs digested food.

Its wall is muscular so that waves of contraction (peristalsis) can mix the food and push it forward. Numerous fingerlike projections, or villi, point inwards from the wall, increasing the surface area available for absorption. The ileum has an excellent blood supply, which receives the food molecules passing through the wall and transports them to the liver via the hepatic portal vein.

i.Link in computing, Sony Corporation's branded name for the IEEE 1394 serial port and bus. Sony has licensed the name and logo to other companies including Hitachi, Matsushita, Sharp, and Victor of Japan (JVC).

illumination or illuminance the brightness or intensity of light falling on a surface. It depends upon the brightness, distance, and angle of any nearby light sources. The SI unit is the lux.

ILS abbreviation for instrument landing system, an automatic system for assisting aircraft landing at airports.

IMA in computing, abbreviation for *Interactive Multimedia Association*.

image in mathematics, a point or number that is produced as the result of a transformation or mapping.

image picture or appearance of a real object, formed by light that passes through a lens or is reflected from a mirror. If rays of light actually pass through an image, it is called a **real image**. Real images, such as those produced by a camera or projector lens, can be projected onto a screen. An image that cannot be projected onto a screen, such as that seen in a flat mirror, is known as a **virtual image**.

image compression in computing, one of a number of methods used to reduce the amount of information required to represent an image, so that it takes up less computer memory and can be transmitted more rapidly and economically via telecommunications systems. It plays a major role in fax transmission and in videophone and multimedia systems.

image intensifier electronic device that brightens a dark image. Image intensifiers are used for seeing at night; for example, in military situations.

The intensifier first forms an image on a photocathode, which emits electrons in proportion to the intensity of the light falling on it. The electron flow is increased by one or more amplifiers. Finally, a fluorescent screen converts the electrons back into visible light, now bright enough to see.

image map in computing, on the World Wide Web, a large image with multiple hot spots on which users click to navigate around the site.

image processing technique for cleaning up and digitally retouching photographs.

A lot of the fundamental work involved in developing image processing techniques was done at the Jet Propulsion Laboratory in Pasadena, California, USA, which manages unmanned space flight for NASA. Pictures taken in-flight of planets have drop-out areas where data is missing due to static or other interference. These pictures are also often taken using parts of the spectrum which the human eye cannot see. Accordingly, computer algorithms had to be developed to fill in the missing data and compute the correct colours. The images produced in this way are made available publicly and often appear in the media.

imaginary number term often used to describe the non-real element of a complex number. For the complex number $(a + ib)$, i is the imaginary number where $i = \sqrt{-1}$, and b any real number.

The imaginary number is a fine and wonderful recourse of the divine spirit, almost an amphibian between being and not being.

GOTTFRIED WILHELM LEIBNIZ German mathematician and philosopher.

imago sexually mature stage of an insect.

immediate access memory in computing, memory provided in the central processing unit to store the programs and data in current use.

immersive in virtual reality, term describing the sense that the user is completely surrounded by and immersed in the virtual world.

immiscible describing liquids that will not mix with each other, such as oil and water. When two immiscible liquids are shaken together, a turbid mixture is produced. This normally forms separate layers on being left to stand.

immunity the protection that organisms have against foreign microorganisms, such as bacteria and viruses, and against cancerous cells (see cancer). The cells that provide this protection are called white blood cells, or leucocytes, and make up the immune system. They include neutrophils and macrophages, which can engulf invading organisms and other unwanted material, and natural killer cells that destroy cells infected by viruses and cancerous cells. Some of the most important immune cells are the B cells and T cells. Immune cells coordinate their activities by means of chemical messengers or lymphokines, including the antiviral messenger interferon. The lymph nodes play a major role in organizing the immune response.

Immunity is also provided by a range of physical barriers such as the skin, tear fluid, acid in the stomach, and mucus in the airways. AIDS is one of many viral diseases in which the immune system is affected.

immunization conferring immunity to infectious disease by artificial methods. The most widely used technique is vaccination.

Immunization is an important public health measure. If most of the population has been immunized against a particular disease, it is impossible for an epidemic to take hold.

Vaccination against smallpox was developed by Edward Jenner in 1796. In the late 19th century Louis Pasteur developed vaccines against cholera, typhoid, typhus, plague, and yellow fever. In 1991, the WHO and UNICEF announced that four out of five children around the world are now immunized against six killer diseases: measles, tetanus, polio, diphtheria, whooping cough, and tuberculosis. Ten years ago this figure was only one in five children.

When meditating over a disease, I never think of finding a remedy for it, but, instead, a means of preventing it.

LOUIS PASTEUR French chemist and microbiologist.
Address to the Fraternal Association of Former Students of the Ecole Centrale des Arts et Manufactures, Paris, 15 May 1884

immunocompromised lacking a fully effective immune system. The term is most often used in connection with infections such as AIDS where the virus interferes with the immune response (see immunity).

Other factors that can impair the immune response are pregnancy, diabetes, old age, malnutrition and extreme stress, making someone susceptible to infections by microorganisms (such as bacteria) that do not affect normal, healthy people. Some people are immunodeficient; others could be on immunosuppressive drugs.

immunodeficient lacking one or more elements of a working immune system. Immune deficiency is the term generally used for patients who are born with such a defect, while those who acquire such a deficiency later in life are referred to as immunocompromised or immunosuppressed.

A serious impairment of the immune system is sometimes known as SCID, or Severe Combined Immune Deficiency. At one time children born with this condition would have died in infancy. They can now be kept alive in a germ-free environment, then treated with a bone-marrow transplant from a relative, to replace the missing immune cells. At present, the success rate for this type of treatment is still fairly low. See also gene therapy.

immunoglobulin human globulin protein that can be separated from blood and administered to confer immediate immunity on the recipient. It participates in the immune reaction as the antibody for a specific antigen (disease-causing agent).

Normal immunoglobulin (gamma globulin) is the fraction of the blood serum that, in general, contains the most antibodies, and is obtained from plasma pooled from about a thousand donors. It is given for short-term (two to three months) protection when a person is at risk, mainly from hepatitis A (infectious hepatitis), or when a pregnant woman, not immunized against German measles, is exposed to the rubella virus.

Specific immunoglobulins are injected when a susceptible (non-immunized) person is at risk of infection from a potentially fatal disease, such as hepatitis B (serum hepatitis), rabies, or tetanus. These immunoglobulins are prepared from blood pooled from donors convalescing from the disease.

immunosuppressive any drug that suppresses the body's normal immune responses to infection or foreign tissue. It is used in the treatment of autoimmune disease (see autoimmunity); as part of chemotherapy for leukaemias, lymphomas, and other cancers; and to help prevent rejection following organ transplantation.

Immunosuppressed patients are at greatly increased risk of infection.

impact printer computer printer that creates characters by striking an inked ribbon against the paper beneath. Examples of impact printers are dot-matrix printers, daisywheel printers, and most types of line printer.

Impact printers are noisier and slower than nonimpact printers, such as ink-jet and laser printers, but can be used to produce carbon copies.

impala African antelope found from Kenya to South Africa in savannas and open woodland. The body is sandy brown. Males have lyre-shaped horns up to 75 cm/2.5 ft long. Impalas grow up to 1.5 m/5 ft long and 90 cm/3 ft tall. They live in herds and spring high in the air when alarmed. (Species *Aepyceros melampus*, family Bovidae.)

impedance the total opposition of a circuit to the passage of alternating electric current. It has the symbol Z . For an alternating current (AC) it includes the resistance R and the reactance X (caused by capacitance or inductance); the impedance can then be found using the equation $Z^2 = R^2 + X^2$.

Imperial College of Science, Technology, and Medicine (formerly *Imperial College of Science and Technology*) institution established in South Kensington, London, 1907, for advanced scientific training and research, applied especially to industry. Part of the University of London, it comprises three separate colleges, the City and Guilds College (engineering faculty), the Royal College of Science (pure science), and the Royal School of Mines (mining). St Mary's Hospital Medical School was added in 1988, resulting in the change of name.

imperial system traditional system of units developed in the UK, based largely on the foot, pound, and second (f.p.s.) system.

implantation in mammals, the process by which the developing embryo attaches itself to the wall of the mother's uterus and stimulates the development of the placenta. In humans it occurs 6-8 days after ovulation.

Immunization: Vaccines in Foods

BY J M DUNWELL

Vaccines

Vaccines are ϕ roteins that stimulate the immune response of animals, and help protect against infectious diseases caused by ϕ iruses and ϕ bacteria. More than 75 such diseases can now be prevented in this way and millions of deaths are prevented annually by the use of these products.

Oral immunization

Many infectious diseases are spread by contaminated water or food, and enter the body through the membranes of the ϕ digestive system. Stimulating the immune system of the cells lining the digestive system best combats such diseases. Most people are familiar with the ϕ polio vaccine provided on sugar cubes. This is probably the best example of vaccination provided by mouth (oral immunization) rather than by injection. The most obvious advantage of the oral route is that it does not require the use of sterile needles.

Need for new production methods

Like many pharmaceutical products, vaccines are relatively expensive to produce. Recently, it has been suggested that plants may be a useful new production system because large amounts of ϕ antigen (the active protein component of the vaccine) could be produced at low cost, using agricultural methods rather than ϕ cell culture-based systems that are expensive and complex. This would be particularly valuable for developing countries which often lack capital-intensive infrastructure, and where, for example, the problem of ϕ diarrhoeal diseases of children is especially acute.

Transgenic plants as a production system

There are two potential methods for producing vaccines in plants. In the first, the ϕ DNA fragment encoding the antigen could be introduced directly into the nuclear ϕ chromosome of the plant, using any of the methods developed for the production of ϕ transgenic plants. The transgenic plants containing the antigen would then be used directly as an oral vaccine, or the antigen could be purified and then consumed. Alternatively, the DNA could be incorporated into a specific virus that only infects plants; this virus could be multiplied within the plant chosen for production. The plant virus particles containing the antigen would then be purified prior to their being used as a vaccine.

Both methods have already been shown to be effective in primary studies, including some conducted on animals. Crops used for animal feed, such as ϕ alfalfa, ϕ cereals, and ϕ legumes are obvious choices for animal vaccines. For humans, plants chosen for production include ϕ potato and ϕ banana; the latter species may be preferred for tropical countries since it would permit vaccine production in the regions of greatest need. It would also allow inexpensive storage of vaccine material without the need for costly refrigeration facilities.

Future prospects

In the next stage of development, the promising results must be confirmed in a wider range of animal and human studies, before such production systems can be approved for widespread use. Remaining challenges include maximizing the level of production of the antigenic protein, stabilizing this protein during post-harvest storage of plant material, and enhancing its immunogenic capacity. In addition, it will be necessary to determine whether 'edible vaccines' should be provided as a specific medical (or veterinary) product or as a routine food source.

In some species, such as seals and bats, implantation is delayed for several months, during which time the embryo does not grow; thus the interval between mating and birth may be longer than the ϕ gestation period.

import file in computing, a file that can be read by a program even though it was produced as an ϕ export file by a different program or made of computer.

imprinting in ϕ ethology, the process whereby a young animal learns to recognize both specific individuals (for example, its mother) and its own species.

Imprinting is characteristically an automatic response to specific stimuli at a time when the animal is especially sensitive to those stimuli (the sensitive period). Thus, goslings learn to recognize their mother by following the first moving object they see after hatching; as a result, they can easily become imprinted on other species, or even inanimate objects, if these happen to move near them at this time. In chicks, imprinting occurs only between 10 and 20 hours after hatching. In mammals, the mother's attachment to her infant may be a form of imprinting made possible by a sensitive period; this period may be as short as the first hour after giving birth.

improper fraction ϕ fraction whose numerator is larger than its denominator.

impulse in mechanics, the product of a force and the time over which it acts. An impulse applied to a body causes its ϕ momentum to change and is equal to that change in momentum. It is measured in newton seconds (N s).

For example, the impulse J given to a football when it is kicked is given by:

$$J = Ft$$

where F is the kick force in newtons and t is the time in seconds for which the boot is in contact with the ball.

in abbreviation for ϕ inch, a measure of distance.

inbreeding in ϕ genetics, the mating of closely related individuals. It is considered undesirable because it increases the risk that offspring will inherit copies of rare deleterious ϕ recessive alleles (genes) from both parents and so suffer from disabilities.

incandescence emission of light from a substance in consequence of its high temperature. The colour of the emitted light from liquids or solids depends on their temperature, and for solids generally the higher the temperature the whiter the light. Gases may become incandescent through ϕ ionizing radiation, as in the glowing vacuum ϕ discharge tube.

The oxides of cerium and thorium are highly incandescent and for this reason are used in gas mantles. The light from an electric filament lamp is due to the incandescence of the filament, rendered white-hot when a current passes through it.

inch imperial unit of linear measure, a twelfth of a foot, equal to 2.54 centimetres.

It was defined in statute by Edward II of England as the length of three barley grains laid end to end.

incisor sharp tooth at the front of the mammalian mouth. Incisors are used for biting or nibbling, as when a rabbit or a sheep eats grass. Rodents, such as rats and squirrels, have large continually-growing incisors, adapted for gnawing. The elephant tusk is a greatly enlarged incisor. In humans, the incisors are the four teeth at the front centre of each jaw.

inclination angle between the ϕ ecliptic and the plane of the orbit of a planet, asteroid, or comet. In the case of satellites orbiting a planet, it is the angle between the plane of orbit of the satellite and the equator of the planet.

inclusive fitness in ϕ genetics, the success with which a given variant (or allele) of a ϕ gene is passed on to future generations by a particular individual, after additional copies of the allele in the individual's relatives and their offspring have been taken into account.

The concept was formulated by W D Hamilton as a way of explaining the evolution of altruism in terms of natural selection. See also fitness and kin selection.

incontinence failure or inability to control evacuation of the bladder or bowel (or both in the case of double incontinence). It may arise as a result of injury, childbirth, disease, or senility.

incremental backup in computing, a backup copy of only those files that have been modified or created since the last incremental or full backup.

Independent Television Commission (ITC) (formerly the Independent Broadcasting Authority) public body responsible for licensing and regulating commercial television services in the UK, including ITV, Channel Four, and Channel Five, as well as Teletext and a number of cable and satellite services. It is not responsible for licensing S4C, the fourth Welsh channel. Its duties include implementing a code of practice, ensuring adequate quality of services, reporting on complaints, and ensuring competition. It is funded by payments from its licensees; it was paid £315 million in 1995. Members of the Commission are appointed by the Government.

indeterminacy principle alternative name for uncertainty principle.

In effect, we have redefined the task of science to be the discovery of laws that will enable us to predict events up to the limits set by the uncertainty principle.

STEPHEN HAWKING English physicist.

index (plural *indices*) Latin 'sign, indicator' in mathematics, another term for exponent, the number that indicates the power to which a term should be raised.

indexed sequential file in computing, a type of file access in which an index is used to obtain the address of the block containing the required record.

indexing in computing, computerized service on the Internet that automatically scans servers and compiles lists of the information they hold to make it easier for users to find what they are looking for.

Indexing servers for FTP (File Transfer Protocol) are called Archie servers. On the World Wide Web, the best-known indexing service is Yahoo, which organizes sites by categories and subcategories, and also allows free-form searching.

Indian corn another name for maize.

indicator in chemistry, a compound that changes its structure and colour in response to its environment. The commonest chemical indicators detect changes in pH (for example, litmus), or in the oxidation state of a system (redox indicators).

indicator species plant or animal whose presence or absence in an area indicates certain environmental conditions, such as soil type, high levels of pollution, or, in rivers, low levels of dissolved oxygen. Many plants show a preference for either alkaline or acid soil conditions, while certain trees require aluminium, and are found only in soils where it is present. Some lichens are sensitive to sulphur dioxide in the air, and absence of these species indicates atmospheric pollution.

indigo violet-blue vegetable dye obtained from various tropical plants such as the anil, but now replaced by a synthetic product. It was once a major export crop of India. (Plant genus *Indigofera*, family Leguminosae.)

indium Latin *indicum* 'indigo' soft, ductile, silver-white, metallic element, symbol In, atomic number 49, relative atomic mass 114.82. It occurs in nature in some zinc ores, is resistant to abrasion, and is used as a coating on metal parts. It was discovered in 1863 by German metallurgists Ferdinand Reich (1799–1882) and Hieronymus Richter (1824–1898), who named it after the two indigo lines of its spectrum.

indri largest living lemur of Madagascar. It is black and white, almost tailless, with long arms and legs, and grows to 70 cm/2.3 ft long. It lives in the trees and is active by day. Its howl is doglike or human in tone. Like all lemurs, its survival is threatened by the widespread deforestation of Madagascar. (Species *Indri indri*, family Indridae.)

induced current electric current that appears in a closed circuit when there is relative movement of its conductor in a magnetic field. The effect is known as the **dynamo effect**, and is used in all dynamos and generators to produce electricity. See **electromagnetic induction**.

There is no battery or other source of power in a circuit in which an induced current appears: the energy supply is provided by the relative motion of the conductor and the magnetic field. The magnitude of the induced current depends upon the rate at which the magnetic flux is cut by the conductor, and its direction is given by Fleming's right-hand rule (see **Fleming's rules**).

induced current

inductance in physics, the phenomenon where a changing current in a circuit builds up a magnetic field which induces an electromotive force either in the same circuit and opposing the current (self-inductance) or in another circuit (mutual inductance). The SI unit of inductance is the henry (symbol H).

A component designed to introduce inductance into a circuit is called an inductor (sometimes inductance) and is usually in the form of a coil of wire. The energy stored in the magnetic field of the coil is proportional to its inductance and the current flowing through it. See **electromagnetic induction**.

induction in obstetrics, deliberate intervention to initiate labour before it starts naturally; then it usually proceeds normally.

Induction involves rupture of the fetal membranes (amniotomy) and the use of the hormone oxytocin to stimulate contractions of the womb. In biology, induction is a term used for various processes, including the production of an enzyme in response to a particular chemical in the cell, and the differentiation of cells in an embryo in response to the presence of neighbouring tissues.

In obstetrics, induction is recommended as a medical necessity where there is risk to the mother or baby in waiting for labour to begin of its own accord.

induction in physics, an alteration in the physical properties of a body that is brought about by the influence of a field. See **electromagnetic induction** and **magnetic induction**.

induction coil type of electrical transformer, similar to an ignition coil, that produces an intermittent high-voltage alternat-

ing current from a low-voltage direct current supply.

It has a primary coil consisting of a few turns of thick wire wound around an iron core and passing a low voltage (usually from a battery). Wound on top of this is a secondary coil made up of many turns of thin wire. An iron armature and make-and-break mechanism (similar to that in an electric bell) repeatedly interrupts the current to the primary coil, producing a high, rapidly alternating current in the secondary circuit.

inductor device included in an electrical circuit because of its inductance.

Industrial Light & Magic (ILM) company that creates special effects for films and which has broken new ground in computer animation techniques (see animation, computer). ILM was set up in 1975 by US director George Lucas to create special effects for his *Star Wars* films, and is based in San Rafael, California, USA.

The company's best-known computer-generated effects include the sea creature in *The Abyss* 1990, the liquid-metal man in *Terminator 2* 1991, and the dinosaurs in *Jurassic Park* 1993.

industry the extraction and conversion of raw materials, the manufacture of goods, and the provision of services. Industry can be either low technology, unspecialized, and labour-intensive, as in countries with a large unskilled labour force, or highly automated, mechanized, and specialized, using advanced technology, as in the industrialized countries. Major recent trends in industrial activity have been the growth of electronic, robotic, and microelectronic technologies, the expansion of the offshore oil industry, and the prominence of Japan and other Pacific-region countries in manufacturing and distributing electronics, computers, and motor vehicles.

Indus Valley civilization one of the four earliest ancient civilizations of the Old World (the other three being the Sumerian civilization 3500 BC; Egypt 3000 BC; and China 2200 BC), developing in the NW of the Indian subcontinent about 2500 BC.

Mohenjo Daro and Harappa were the two main city complexes, but many more existed along the Indus Valley, now in Pakistan. Remains include grid-planned streets with municipal drainage, public and private buildings, baths, temples, and a standardized system of weights and measures – all of which testify to centralized political control. Evidence exists for trade with Sumer and Akkad. The Aryan invasion of about 1500 BC probably led to its downfall.

inequality in mathematics, a statement that one quantity is larger or smaller than another, employing the symbols $<$ and $>$. Inequalities may be solved by finding sets of numbers that satisfy them. For example, the solution set to the inequality $2x + 5 < 19$ consists of all values of x less than 7. Inequality relationships involving variables are sometimes called **inequations**.

inert gas or **noble gas** any of a group of six elements (helium, neon, argon, krypton, xenon, and radon), so named because they were originally thought not to enter into any chemical reactions. This is now known to be incorrect: in 1962, xenon was made to combine with fluorine, and since then, compounds of argon, krypton, and radon with fluorine and/or oxygen have been described.

The extreme unreactivity of the inert gases is due to the stability of their electronic structure. All the electron shells (energy levels) of inert gas atoms are full and, except for helium, they all have eight electrons in their outermost (valency) shell. The apparent stability of this electronic arrangement led to the formulation of the octet rule to explain the different types of chemical bond found in simple compounds.

inertia in physics, the tendency of an object to remain in a state of rest or uniform motion until an external force is applied, as described by Isaac Newton's first law of motion (see *Newton's laws of motion*).

inertial navigation navigation system that makes use of gyroscopes and accelerometers to monitor and measure a vehicle's movements. A computer calculates the vehicle's position relative to its starting position using the information supplied by the sensors. Inertial navigation is used in aircraft, submarines, spacecraft, and guided missiles.

infant mortality rate measure of the number of infants dying under one year of age, usually expressed as the number of deaths per 1,000 live births. Improved sanitation, nutrition, and medical care have considerably lowered figures throughout much of the world; for example in the 18th century in the USA and UK infant mortality was about 500 per thousand, compared with under 10 per thousand in 1989. The lowest infant mortality rate is in Japan, at 4.5 per 1,000 live births. In much of the Third World, however, the infant mortality rate remains high.

infection invasion of the body by disease-causing organisms (pathogens, or germs) that become established, multiply, and produce symptoms. Bacteria and viruses cause most diseases, but diseases are also caused by other microorganisms, protozoans, and other parasites.

Most pathogens enter and leave the body through the digestive or respiratory tracts. Polio, dysentery, and typhoid are examples of diseases contracted by ingestion of contaminated foods or fluids. Organisms present in the saliva or nasal mucus are spread by airborne or droplet infection; fine droplets or dried particles are inhaled by others when the affected individual talks, coughs, or sneezes. Diseases such as measles, mumps, and tuberculosis are passed on in this way.

A less common route of entry is through the skin, either by contamination of an open wound (as in tetanus) or by penetration of the intact skin surface, as in a bite from a malaria-carrying mosquito. Relatively few diseases are transmissible by skin-to-skin contact. Glandular fever and herpes simplex (cold sore) may be passed on by kissing, and the group now officially bracketed as sexually transmitted diseases (STDs) are mostly spread by intimate contact.

inferiority complex in psychology, a complex or cluster of repressed fears, described by Alfred Adler, based on physical inferiority. The term is popularly used to describe general feelings of inferiority and the overcompensation that often ensues.

inferior planet planet (Mercury or Venus) whose orbit lies within that of the Earth, best observed when at its greatest elongation from the Sun, either at eastern elongation in the evening (setting after the Sun) or at western elongation in the morning (rising before the Sun).

inferno in astrophysics, a unit for describing the temperature inside a star. One inferno is 1 billion K, or approximately 1 billion °C.

infertility in medicine, inability to reproduce. In women, this may be due to blockage in the Fallopian tubes, failure of ovulation, a deficiency in sex hormones, or general ill health. In men, impotence, an insufficient number of sperm or abnormal sperm may be the cause of infertility. Clinical investigation will reveal the cause of the infertility in about 75% of couples and assisted conception may then be appropriate.

infinite series in mathematics, a series of numbers consisting of a denumerably infinite sequence of terms. The sequence n, n^2, n^3, \dots gives the series $n + n^2 + n^3 + \dots$. For example, $1 + 2 + 3 + \dots$ is a divergent infinite arithmetic series, and $8 + 4 + 2 + 1 + \frac{1}{2} + \dots$ is a convergent infinite geometric series that has a sum to infinity of 16.

infinitesimal mathematical quantity that is larger than any fixed assignable quantity; symbol ϵ . By convention, the result of dividing any number by zero is regarded as infinity.

inflammation defensive reaction of the body tissues to disease or damage, including redness, swelling, and heat. Denoted by the suffix *-itis* (as in appendicitis), it may be acute or chronic, and may be accompanied by the formation of pus. This is an essential part of the healing process.

Inflammation occurs when damaged cells release a substance (histamine) that causes blood vessels to widen and leak into the surrounding tissues. This phenomenon accounts for the redness, swelling, and heat. Pain is due partly to the pressure of swelling and also to irritation of nerve endings. Defensive white blood cells congregate within an area of inflammation to engulf and remove foreign matter and dead tissue.

inflation in cosmology, a phase of extremely fast expansion thought to have occurred within 10–32 seconds of the Big Bang and in which almost all the matter and energy in the universe was created. The inflationary model based on this concept accounts for the density of the universe being very close to the critical density, the smoothness of the cosmic background radiation, and the homogeneous distribution of matter in the universe. Inflation was proposed by US astronomer Alan Guth in the early 1980s.

inflorescence in plants, a branch, or system of branches, bearing two or more individual flowers. Inflorescences can be divided into two main types: cymose (or definite) and racemose (or indefinite). In a cymose inflorescence, the tip of the main axis produces a single flower and subsequent flowers arise on lower side branches, as in forget-me-not *Myosotis* and chickweed *Stellaria*; the oldest flowers are, therefore, found at the tip. A racemose inflorescence has an active growing region at the tip of its main axis, and bears flowers along its length, as in hyacinth *Hyacinthus*; the oldest flowers are found near the base or, in cases where the inflorescence is flattened, towards the outside.

The stalk of the inflorescence is called a peduncle; the stalk of each individual flower is called a pedicel.

Types of racemose inflorescence include the raceme, a spike of similar, stalked flowers, as seen in lupin *Lupinus*. A corymb, seen in candytuft *Iberis amara*, is rounded or flat-topped because the pedicels of the flowers vary in length, the outer pedicels being longer than the inner ones. A panicle is a branched inflorescence made up of a number of racemes; such inflorescences are seen in many grasses, for example, the oat *Avena*. The pedicels of an umbel, seen in members of the carrot family (Umbelliferae), all arise from the same point on the main axis, like the spokes of an umbrella. Other types of racemose inflorescence include the catkin, a pendulous inflorescence, made up of many small stalkless flowers; the spadix, in which tiny flowers are borne on a fleshy axis; and the capitulum, in which the axis is flattened or rounded, bears many small flowers, and is surrounded by large petal-like bracts.

influenza any of various viral infections primarily affecting the air passages, accompanied by systemic effects such as fever, chills, headache, joint and muscle pains, and lassitude. Treatment is with bed rest and analgesic drugs such as aspirin or paracetamol.

Depending on the virus strain, influenza varies in virulence and duration, and there is always the risk of secondary (bacterial) infection of the lungs (pneumonia). Vaccines are effective against known strains but will not give protection against newly evolving viruses. The 1918–19 influenza pandemic (see *epidemic*) killed about 20 million people worldwide.

infobahn (from German autobahn 'motorway') in computing, short name for information superhighway.

information service in computing, commercial online service which offers access to (usually high-price) periodical databases and other information sources. The two major services are America Online (AOL) and CompuServe.

information superhighway popular collective name for the Internet and other related large-scale computer networks. The term was first used in 1993 by US vice president Al Gore in a speech outlining plans to build a high-speed national data communications network.

information technology (IT) collective term for the various technologies involved in processing and transmitting information. They include computing, telecommunications, and microelectronics.

Word processing, databases, and spreadsheets are just some of the computing (software) packages that have revolutionized work in the office environment. Not only can work be done more quickly than before, but IT has given decisionmakers the opportunity to consider far more data when making decisions.

infotainment (contraction of *information* and *entertainment*) term applied to software that seeks to inform and entertain simultaneously. Many non-fiction CD-ROM titles are classified as infotainment, such as multimedia encyclopedias or reference discs. Compare *edutainment*.

infrared absorption spectrometry technique used to determine the mineral or chemical composition of artefacts and organic substances, particularly amber. A sample is bombarded by infrared radiation, which causes the atoms in it to vibrate at frequencies characteristic of the substance present, and absorb energy at those frequencies from the infrared spectrum, thus forming the basis for identification.

infrared astronomy study of infrared radiation produced by relatively cool gas and dust in space, as in the areas around forming stars. In 1983, the Infra-Red Astronomy Satellite (IRAS) surveyed the entire sky at infrared wavelengths. It found five new comets, thousands of galaxies undergoing bursts of star formation, and the possibility of planetary systems forming around several dozen stars.

Planets and gas clouds emit their light in the far and mid-infrared region of the spectrum. The Infrared Space Observatory (ISO), launched in 1995, observes a broad wavelength (3–200 micrometres) in this region. It is 10,000 times more sensitive than IRAS, and will search for brown dwarfs (cool masses of gas smaller than the Sun).

infrared radiation invisible electromagnetic radiation of wavelength between about 0.75 micrometres and 1 millimetre – that is, between the limit of the red end of the visible spectrum and the shortest microwaves. All bodies above the absolute zero of temperature absorb and radiate infrared radiation. Infrared radiation is used in medical photography and treatment, and in industry, astronomy, and criminology.

Infrared absorption spectra are used in chemical analysis, particularly for organic compounds. Objects that radiate infrared radiation can be photographed or made visible in the dark on specially sensitized emulsions. This is important for military purposes and in detecting people buried under rubble. The strong absorption by many substances of infrared radiation is a useful method of applying heat.

Infrared Space Observatory (ISO) orbiting telescope with a 60-cm/24-in diameter mirror. It was launched in November 1995 by the European Space Agency and will spend 18 months in an elongated orbit giving it a range from the Earth of 1,000–70,500 km/620–43,800 mi and keeping it as much as possible outside the radiation belts that would swamp its detectors.

Since its launch, ISO has made the first-ever discovery of water vapour from a source beyond the Solar System (in planetary nebula NGC 2027); has traced the spiral arms of the Whirlpool Galaxy and detected sites of star formation there; and obtained the first comprehensive spectrum of Saturn's atmosphere.

infrared telescope in astronomy, a telescope designed to receive electromagnetic waves in the infrared part of the spectrum. Infrared telescopes are always reflectors (glass lenses are opaque to infrared waves) and are normally of the Cassegrain telescope type.

Since all objects at normal temperatures emit strongly in the infrared, careful design is required to ensure that the weak signals from the sky are not swamped by radiation from the telescope itself. Infrared telescopes are sited at high mountain observatories above the obscuring effects of water vapour in the atmosphere. Modern large telescopes are often designed to work equally well in both visible and infrared light.

infrastructure on the Internet, the underlying structure of telephone links, leased lines, and computer programs that makes communication possible.

ingestion process of taking food into the mouth. The method of food capture varies but may involve biting, sucking, or filtering. Many single-celled organisms have a region of their cell wall that acts as a mouth. In these cases surrounding tiny hairs (cilia) sweep food particles together, ready for ingestion.

inhibition, neural in biology, the process in which activity in one nerve cell suppresses activity in another. Neural inhibition in networks of nerve cells leading from sensory organs, or to muscles, plays an important role in allowing an animal to make fine sensory discriminations and to exercise fine control over movements.

ink-jet printer computer printer that creates characters and graphics by spraying very fine jets of quick-drying ink onto paper. Ink-jet printers range in size from small machines designed to work with microcomputers to very large machines designed for high-volume commercial printing.

Because they produce very high-quality printing and are virtually silent, small ink-jet printers (along with laser printers) are replacing impact printers, such as dot-matrix and daisy-wheel printers, for use with microcomputers.

in-line graphics on the World Wide Web, images included in Web pages which can be downloaded and viewed on the fly. Web browsers display these graphics automatically without any action required by the user. Those with slow connections, however, may choose to turn these off in the interests of speed and just view the text.

in-line video in computing, on the World Wide Web, video files included in Web pages which can be played back on the fly. Web browsers typically require a helper application or plug-in to be installed to play these files. Most sites which include in-line video have links to the necessary software for users who are not already equipped.

inoculation injection into the body of dead or weakened disease-carrying organisms or their toxins (vaccine) to produce immunity by inducing a mild form of a disease.

inorganic chemistry branch of chemistry dealing with the chemical properties of the elements and their compounds, excluding the more complex covalent compounds of carbon, which are considered in organic chemistry.

The origins of inorganic chemistry lay in observing the characteristics and experimenting with the uses of the substances (compounds and elements) that could be extracted from mineral ores. These could be classified according to their chemical properties: elements could be classified as metals or nonmetals; compounds as acids or bases, oxidizing or reducing agents, ionic compounds (such as salts), or covalent compounds (such as gases). The arrangement of elements into groups possessing similar properties led to Mendeleev's periodic table of the elements, which prompted chemists to predict the properties of undiscovered elements that might occupy gaps in the table. This, in turn, led to the discovery of new elements, including a number of highly radioactive elements that do not occur naturally.

inorganic compound compound found in organisms that are not typically biological.

Water, sodium chloride, and potassium are inorganic compounds because they are widely found outside living cells. The term is also applied to those compounds that do not contain carbon and that are not manufactured by organisms. However, carbon dioxide is considered inorganic, contains carbon, and is manufactured by organisms during respiration. See organic compound.

input device device for entering information into a computer. Input devices include keyboards, joysticks, mice, light pens, touch-sensitive screens, scanners, graphics tablets, speech-recognition devices, and vision systems. Compare output device.

types of input device Keyboards, the most frequently used input devices, are used to enter instructions and data via keys. There are many variations on the layout and labelling of keys. Extra numeric keys may be added, as may special-purpose function keys, whose effects can be defined by programs in the computer.

The **graphics tablet** is an input device in which a stylus or cursor is moved, by hand, over a flat surface. The computer can keep track of the position of the stylus, enabling the operator to input drawings or diagrams into the computer. The joystick signals to a computer the direction and extent of displacement of a hand-held lever.

Light pens resemble ordinary pens and are used to indicate locations on a computer screen. With certain computer-aided design (CAD) programs, the light pen can be used to instruct the computer to change the shape, size, position, and colours of sections of a screen image.

Scanners produce a digital image of a document for input and storage in a computer, using technology similar to that of a

photocopier. Small scanners can be passed over the document surface by hand; larger versions have a flat bed, like that of a photocopier, on which the input document is placed and scanned.

Input devices that are used commercially – for example, by banks, postal services, and supermarkets – must be able to read and capture large volumes of data very rapidly. Such devices include document readers for magnetic-ink character recognition (MICR), optical character recognition (OCR), and optical mark recognition (OMR); mark-sense readers; bar-code scanners; magnetic-strip readers; and point-of-sale (POS) terminals. Punched-card and paper-tape readers were used in earlier commercial applications but are now obsolete.

insanity in medicine and law, any mental disorder in which the patient cannot be held responsible for their actions. The term is no longer used to refer to psychosis.

INSECT

The world's smallest winged insect is smaller than the eye of a house fly. It is the Tanzanian parasitic wasp, which has a wingspan of 0.2 mm/0.008 in.

insect any of a vast group of small invertebrate animals with hard, segmented bodies, three pairs of jointed legs, and, usually, two pairs of wings; they belong among the arthropods and are distributed throughout the world. An insect's body is divided into three segments: head, thorax, and abdomen. On the head is a pair of feelers, or antennae. The legs and wings are attached to the thorax, or middle segment of the body. The abdomen, or end segment of the body, is where food is digested and excreted and where the reproductive organs are located.

Insects vary in size from 0.02 cm/0.007 in to 35 cm/13.5 in in length. The world's smallest insect is believed to be a 'fairy fly' wasp in the family Mymaridae, with a wingspan of 0.2 mm/0.008 in. (Class Insecta.)

Many insects hatch out of their eggs as larvae (an immature stage, usually in the form of a caterpillar, grub, or maggot) and have to pass through further major physical changes (metamorphosis) before reaching adulthood. An insect about to go through metamorphosis hides itself or makes a cocoon in which to hide, then rests while the changes take place; at this stage the insect is called a pupa, or a chrysalis if it is a butterfly or moth. When the changes are complete, the adult insect emerges.

The classification of insects is largely based upon characteristics of the mouthparts, wings, and metamorphosis. Insects are divided into two subclasses (one with two divisions) and 29 orders. More than 1 million species are known, and several thousand new ones are discovered each year.

The study of insects is called entomology.

INSECT CONTROL FAQ

<http://res.agr.ca/lond/pmr/faq/insect.html>

Table of frequently asked questions about all kinds of insect control, including the Colorado potato beetle and aphids. The questions answered on this site include 'what are the most common insect pests?' and 'what alternatives are there to insecticides to control insects?'

insect Body plan of an insect. The general features of the insect body include a segmented body divided into head, thorax, and abdomen, jointed legs, feelers or antennae, and usually two pairs of wings. Insects often have compound eyes with a large field of vision.

insecticide any chemical pesticide used to kill insects. Among the most effective insecticides are synthetic organic chemicals such as DDT and dieldrin, which are chlorinated hydrocarbons. These chemicals, however, have proved persistent in the environment and are also poisonous to all animal life, including humans, and are consequently banned in many countries. Other synthetic insecticides include organic phosphorus compounds such as malathion. Insecticides prepared from plants, such as derris and pyrethrum, are safer to use but need to be applied frequently and carefully.

insectivore any animal whose diet is made up largely or exclusively of insects. In particular, the name is applied to mammals of the order Insectivora, which includes the shrews, hedgehogs, moles, and tenrecs.

According to the Red List of endangered species published by the World Conservation Union (IUCN) for 1996, 36% of insectivore species are threatened with extinction.

insectivorous plant plant that can capture and digest live prey (normally insects), to obtain nitrogen compounds that are lacking in its usual marshy habitat. Some are passive traps, for example, the pitcher plants *Nepenthes* and *Sarracenia*. One pitcher-plant species has container-traps holding 1.6 l/3.5 pt of the liquid that 'digests' its food, mostly insects but occasionally even rodents. Others, for example, sundews *Drosera*, butterworts *Pinguicula*, and Venus flytraps *Dionaea muscipula*, have an active trapping mechanism. Insectivorous plants have adapted to grow in poor soil conditions where the number of microorganisms recycling nitrogen compounds is very much reduced. In these circumstances other plants cannot gain enough nitrates to grow. See also *cleaf*.

Near-carnivorous plants are unable to digest insects, but still trap them on their sticky coated leaves. The insects die and decay naturally, with the nutrients eventually becoming washed into the soil where they finally benefit the plant.

inselberg or *kopje* German 'island mountain' prominent steep-sided hill of resistant solid rock, such as granite, rising out of a plain, usually in a tropical area. Its rounded appearance is caused

by so-called onion-skin *weathering*, in which the surface is eroded in successive layers.

The Sugar Loaf in Rio de Janeiro harbour in Brazil, and Ayers Rock in Northern Territory, Australia, are famous examples.

insemination, artificial see *artificial insemination*.

instinct in *ethology*, behaviour found in all equivalent members of a given species (for example, all the males, or all the females with young) that is presumed to be genetically determined.

Examples include a male robin's tendency to attack other male robins intruding on its territory and the tendency of many female mammals to care for their offspring. Instincts differ from *reflexes* in that they involve very much more complex actions, and learning often plays an important part in their development.

instruction register in computing, a special memory location used to hold the instruction that the computer is currently processing. It is located in the control unit of the *central processing unit*, and receives instructions individually from the immediate-access memory during the fetch phase of the *fetch-execute cycle*.

instruction set in computing, the complete set of machine-code instructions that a computer's *central processing unit* can obey.

instrument landing system (ILS) landing aid for aircraft that uses *radio beacons* on the ground and instruments on the flight deck. One beacon (*localizer*) sends out a vertical radio beam along the centre line of the runway. Another beacon (*glide slope*) transmits a beam in the plane at right angles to the localizer beam at the ideal approach-path angle. The pilot can tell from the instruments how to manoeuvre to attain the correct approach path.

insulation process or material that prevents or reduces the flow of electricity, heat or sound from one place to another.

Electrical insulation makes use of materials such as rubber, PVC, and porcelain, which do not conduct electricity, to prevent a current from leaking from one conductor to another or down to the ground. Insulation is a vital safety measure that prevents electric

currents from being conducted through people and causing electric shock.

Double insulation is a method of constructing electrical appliances that provides extra protection from electric shock, and renders the use of an earth wire unnecessary. In addition to the usual cable insulation, an appliance that meets the double insulation standard is totally enclosed in an insulating plastic body or structure so that there is no direct connection between any external metal parts and the internal electrical components.

Thermal or heat insulation makes use of insulating materials such as fiberglass to reduce the loss of heat through the roof and walls of buildings. The U-value of an insulating layer is a measure of its ability to conduct heat – a material chosen as an insulator should therefore have a low U-value. Air trapped between the fibres of clothes acts as a thermal insulator, preventing loss of body warmth.

insulator any poor conductor of heat, sound, or electricity. Most substances lacking free (mobile) electrons, such as non-metals, are electrical or thermal insulators. Usually, devices of glass or porcelain, called insulators, are used for insulating and supporting overhead wires.

insulin protein hormone, produced by specialized cells in the islets of Langerhans in the pancreas, that regulates the metabolism (rate of activity) of glucose, fats, and proteins. Insulin was discovered by Canadian physician Frederick Banting and Canadian physiologist Charles Best, who pioneered its use in treating diabetes.

Normally, insulin is secreted in response to rising blood sugar levels (after a meal, for example), stimulating the body's cells to store the excess. Failure of this regulatory mechanism in diabetes mellitus requires treatment with insulin injections or capsules taken by mouth. Types vary from pig and beef insulins to synthetic and bioengineered ones. They may be combined with other substances to make them longer- or shorter-acting. Implanted, battery-powered insulin pumps deliver the hormone at a preset rate, to eliminate the unnatural rises and falls that result from conventional, subcutaneous (under the skin) delivery. Human insulin has now been produced from bacteria by genetic engineering techniques, but may increase the chance of sudden, unpredictable hypoglycaemia, or low blood sugar. In 1990 the Medical College of Ohio developed gelatin capsules and an aspirinlike drug which helps the insulin pass into the bloodstream.

TO REMEMBER THE ROLE OF INSULIN:

REMEMBER THAT INSULIN GETS SUGAR INTO CELLS. WITHOUT INSULIN, A PERSON CAN HAVE EXCESS SUGAR IN HIS BLOOD YET DIE OF LACK OF SUGAR.

integer any whole number. Integers may be positive or negative; 0 is an integer, and is often considered positive. Formally, integers are members of the set $Z = \{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}$. Fractions, such as $\frac{1}{2}$ and 0.35, are known as non-integral numbers ('not integers').

lions of components and yet measure only 5 mm/0.2 in square and 1 mm/0.04 in thick. The IC is encapsulated within a plastic or ceramic case, and linked via gold wires to metal pins with which it is connected to a printed circuit board and the other components that make up such electronic devices as computers and calculators.

Integrated Services Digital Network (ISDN) internationally developed telecommunications system for sending signals in digital format. It involves converting the 'local loop' – the link between the user's telephone for private automatic branch exchange) and the digital telephone exchange – from an analogue system into a digital system, thereby greatly increasing the amount of information that can be carried. The first large-scale use of ISDN began in Japan in 1988.

ISDN has advantages in higher voice quality, better quality faxes, and the possibility of data transfer between computers faster than current modems. With ISDN's Basic Rate Access, a multiplexer divides one voice telephone line into three channels: two B bands and a D band. Each B band offers 64 kilobits per second and can carry one voice conversation or 50 simultaneous data calls at 1,200 bits per second. The D band is a data-signalling channel operating at 16 kilobits per second. With Primary Rate Access, ISDN provides 30 B channels.

integrated steelworks modern industrial complex where all the steelmaking processes – such as iron smelting and steel shaping – take place on the same site.

integration in mathematics, a method in calculus of determining the solutions of definite or indefinite integrals.

An example of a definite integral can be thought of as finding the area under a curve (as represented by an algebraic expression or function) between particular values of the function's variable. In practice, integral calculus provides scientists with a powerful tool for doing calculations that involve a continually varying quantity (such as determining the position at any given instant of a space rocket that is accelerating away from Earth). Its basic principles were discovered in the late 1660s independently by the German philosopher Leibniz and the British scientist Newton.

integument in seed-producing plants, the protective coat surrounding the ovule. In flowering plants there are two, in gymnosperms only one. A small hole at one end, the micropyle, allows a pollen tube to penetrate through to the egg during fertilization.

Intel manufacturer of the microprocessors that form the basis of the IBM PC range and its clones. Intel developed the first microprocessor, the 4004, in 1971, and has largely retained compatibility throughout the x86 range from the 8086 to the 80486 and the Pentium or 586 released in 1993. Intel's current strategy is to promote the use of the Pentium II processor, introduced in 1997, while it is developing its next-generation chip, code-named Merced, in conjunction with Hewlett-Packard.

History of Insulin

BY PAULETTE PRATT

The term 'diabetes' (from the Ionian Greek 'to pass through'), together with a succinct clinical description of this once-fatal disease, was bequeathed to us by Aretaeus of Cappadocia. In the 2nd century AD he wrote: 'Diabetes is a dreadful affliction, not very frequent among men, being a melting down of the flesh and limbs into urine. The patients never stop making water and the flow is incessant, like the opening of aqueducts. Life is short, unpleasant and painful, thirst unquenchable, drinking excessive...'

'One cannot stop them either from drinking or making water. If for a while they abstain from drinking, their mouths become parched and their bodies dry; the viscera seem scorched up, the patients are affected by nausea, restlessness and a burning thirst, and within a short time they expire.'

Although Eastern physicians had noted the sweet taste of the urine in diabetes a thousand years earlier, in Europe the connection between sugar in the urine and diabetes was only made in 1670 by an English physician, Thomas Willis. In 1776, Liverpool physician Matthew Dobson showed that the blood serum of diabetic patients also contains a sweet-tasting substance. He proved that this is sugar and deduced that it is formed in the serum rather than in the kidneys. This was the first indication that diabetes is a systemic disease (pervading the whole body) rather than a specific kidney problem as some people had thought.

Soon after, another English physician, John Rollo, was among the first to attach the adjective 'mellitus' (from the Greek and Latin roots for 'honey') to distinguish diabetes from other conditions where there is copious urine output. The next major observation, published in the *London Medical Journal* in 1788, was that diabetes may ensue from damage to the pancreas. In Strasbourg a century later, Oskar Minkowski and Josef von Mering were able to produce experimental diabetes in a dog by removing its pancreas.

This firm association of diabetes with pancreatic deficiency prompted researchers to begin looking for the actual substance involved in order to develop a treatment. In 1893, a Frenchman, Edouard Laguesse, suggested that the pancreatic 'islets of Langerhans' might be implicated. He named these after the distinguished German pathologist, Paul Langerhans, who, at the age of 22, had been the first person to describe them (1869).

A Belgian physician, Jean de Meyer, gave the name *insuline* (from the Latin *insula*, meaning island) to the as yet hypothetical blood sugar-lowering substance in 1909. The British physiologist Edward Sharpey Schafer, who argued that the islets must secrete a substance which governs carbohydrate metabolism, used the word 'insulin' for this notional substance in 1916, but the term did not immediately become current: Banting and Best and their collaborators, who discovered insulin in 1921, at first called it 'isletin'.

By the early years of this century then, it was known that diabetes mellitus arises from a lack of this unknown substance. Meanwhile, people developing the disease lived brief, wretched

lives. Those who sought treatment were put on starvation diets. The effect of this was to lower blood glucose and produce emaciation; the extension it won to the patient's life was at best a few months.

At this time a number of scientists were on the track of insulin and an unknown Canadian doctor, 29-year-old Frederick Grant Banting, also developed an interest in the hormone. He approached J J R Macleod, then Professor of Physiology at the University of Toronto (and an expert on sugar metabolism), for facilities to conduct experiments in a bid to isolate insulin. Macleod made available laboratory space and experimental dogs for Banting's use; he also offered one of his students as an assistant, Charles H Best (who had won the opportunity to work alongside Banting on the toss of a coin). But it was the addition of biochemist James B. Collip which would ensure their success.

The first trial of the team's pancreatic extract was on 14-year-old Leonard Thompson, who was dying of diabetes in Toronto General Hospital, on January 1, 1922. This failed to relieve his symptoms and, moreover, caused an abscess to form at the injection site. However, a further extract, injected on January 23, brought the boy's blood sugar down to normal. In May, when the group reported the outcome of this modest trial to a meeting of the Association of American Physicians in Washington DC, they received a standing ovation.

From October 1923, once a commercially viable extraction process had been developed, insulin became widely available throughout North America and Europe. Now, for diabetic patients who would otherwise have been doomed, the issue was no longer one of survival but of quality of life on insulin treatment.

Among the people who witnessed the introduction of the life-saving extract into clinical use was a Portuguese doctor, Ernesto Roma, who was on a visit to Boston. Returning to Lisbon in 1926, he set up the World's first diabetic organisation, the Portuguese Association for the Protection of Poor Diabetics, which provided insulin free of charge. The British Diabetic Association was founded in 1934 by a doctor whose life had been saved by insulin, Robin Lawrence, and the writer H G Wells, who also had the disease.

Contrroversially, only Banting and Macleod received the Nobel prize for the discovery of insulin, in 1923 (in what was one of the Nobel committee's quickest ever recognitions). Despite the acrimony which had arisen within the group, the two men shared the award money with their collaborators. Frederick Banting, whose vision had driven the project, became a World hero and received a knighthood and a generous annuity from the Canadian government. He died in an air crash in Newfoundland in 1941.

Leonard Thompson, the original insulin 'guinea pig', survived until 1935 and at least two of the children who had been treated in Toronto in the trial period outlived all four of the men who had worked on the discovery of insulin. One of these, Ted Ryder, lived until 1993, reaching the age of 76.

Intel is thought to supply the processors for almost 90% of the world's personal computers.

intellectual property material such as computer software, magazine articles, songs, novels, or recordings which can be described as the expression of ideas fixed in a tangible form.

Generally, intellectual property is protected by copyright law, and distribution, sale, and copying of such material is restricted so that the creators can be paid for their work. On the Internet, intellectual property may include the words, graphics, audio files, and other material which comprise pages on the World Wide Web, as well as the words written by individuals in e-mail or on USENET.

intellectual property rights the right of control over the copying, distribution, and sale of intellectual property which is codified in the copyright laws.

The future of intellectual property rights is unclear, as the Internet makes mass distribution and copying quick and easy. In the mid-1990s, many schemes were being considered for using encryption to mark computer files or prevent copying in an effort to safeguard these rights.

intelligence in psychology, a general concept that summarizes the abilities of an individual in reasoning and problem solving, particularly in novel situations. These consist of a wide range of verbal and nonverbal skills and therefore some psychologists dispute a unitary concept of intelligence.

Intelligence is quickness to apprehend as distinct from ability, which is capacity to act wisely on the thing apprehended.

intelligence test test that attempts to measure innate intellectual ability, rather than acquired ability.

It is now generally believed that a child's ability in an intelligence test can be affected by his or her environment, cultural background, and teaching. There is scepticism about the accuracy of intelligence tests, but they are still widely used as a diagnostic tool when children display learning difficulties. 'Sight and sound' intelligence tests, developed by Christopher Brand in 1981, avoid cultural bias and the pitfalls of improvement by practice. Subjects are shown a series of lines being flashed on a screen at increasing speed, and are asked to identify in each case the shorter of a pair; and when two notes are relayed over headphones, they are asked to identify which is the higher. There is a close correlation between these results and other intelligence test scores.

intelligent agent in computing, another name for *agent*.

intelligent terminal in computing, a terminal with its own processor which can take some of the processing load away from the main computer.

Intelsat (acronym for *International Telecommunications Satellite Organization*) organization established in 1964 to operate a worldwide system of communications satellites. In 1994 it had 134 member nations and 22 satellites in orbit. Its headquarters are in Washington DC. Intelsat satellites are stationed in geostationary orbit (maintaining their positions relative to the Earth) over the Atlantic, Pacific, and Indian Oceans. The first Intelsat satellite was *Early Bird*, launched in 1965.

intensity in physics, the power (or energy per second) per unit area carried by a form of radiation or wave motion. It is an indication of the concentration of energy present and, if measured at varying distances from the source, of the effect of distance on this. For example, the intensity of light is a measure of its brightness, and may be shown to diminish with distance from its source in accordance with the inverse square law (its intensity is inversely proportional to the square of the distance).

interactive describing a computer system that will respond directly to data or commands entered by the user. For example, most popular programs, such as word processors and spreadsheet applications, are interactive. Multimedia programs are usually highly interactive, allowing users to decide what type of information to display (text, graphics, video, or audio) and enabling them (by means of *hypertext*) to choose an individual route through the information.

interactive computing in computing, a system for processing data in which the operator is in direct communication with the computer, receiving immediate responses to input data. In *batch* processing, by contrast, the necessary data and instructions are prepared in advance and processed by the computer with little or no intervention from the operator.

interactive digital video service alternative term for *video-on-demand*.

interactive media in computing, new technology such as *CD-ROM* and online systems which allow users to interact with other users or to choose their own path through the material.

The newest attempts to create interactive media are books published on the World Wide Web which allow readers to use *hyperlinks* to move around the material at will in the order they choose. Other interactive media include plans for films and other projects which allow viewers to choose how to follow the story, which characters to focus on, or which plot threads to follow.

Interactive Multimedia Association (IMA) organization founded in 1987 to promote the growth of the multimedia industry.

Based in Annapolis, Maryland, USA, the IMA runs special interest groups, summit meetings, conferences, and trade shows for its member companies.

interactive video (IV) computer-mediated system that enables the user to interact with and control information (including text, recorded speech, or moving images) stored on video disc. IV is most commonly used for training purposes, using analogue video discs, but has wider applications with digital video systems such as *CD-I* (Compact Disc Interactive, from Philips and Sony) which are based on the *CD-ROM* format derived from audio compact discs.

intercast in computing, *Intel* device that adds TV reception capability to a PC and uses blank lines to deliver data.

A number of leading PC manufacturers expect to bundle Intericast TV tuner boards with new computer systems.

intercostal in biology, the nerves, blood vessels, and muscles that lie between the ribs.

interface in computing, the point of contact between two programs or pieces of equipment. The term is most often used for the physical connection between the computer and a peripheral device, which is used to compensate for differences in such operating characteristics as speed, data coding, voltage, and power consumption. For example, a printer interface is the cabling and circuitry used to transfer data from a computer to a printer, and to compensate for differences in speed and coding.

Common standard interfaces include the *Centronics interface*, used to connect parallel devices, and the *RS232 interface*, used to connect serial devices. For example, in many microcomputer systems, an RS232 interface is used to connect the microcomputer to a modem, and a Centronics device is used to connect it to a printer.

interference in physics, the phenomenon of two or more wave motions interacting and combining to produce a resultant wave of larger or smaller amplitude (depending on whether the combining waves are in or out of phase with each other).

Interference of white light (multiwavelength) results in spectral coloured fringes; for example, the iridescent colours of oil films seen on water or soap bubbles (demonstrated by *Newton's rings*). Interference of sound waves of similar frequency produces the phenomenon of beats, often used by musicians when tuning an instrument. With monochromatic light (of a single wavelength), interference produces patterns of light and dark bands. This is the basis of *holography*, for example. Interferometry can also be applied to radio waves, and is a powerful tool in modern astronomy.

interferometer in physics, a device that splits a beam of light into two parts, the parts being recombined after travelling different paths to form an interference pattern of light and dark bands.

Interferometers are used in many branches of science and industry where accurate measurements of distances and angles are needed.

In the Michelson interferometer, a light beam is split into two by a semisilvered mirror. The two beams are then reflected off fully silvered mirrors and recombined. The pattern of dark and light bands is sensitive to small alterations in the placing of the mirrors, so the interferometer can detect changes in their position to within one ten-millionth of a metre. Using lasers, compact devices of this kind can be built to measure distances, for example to check the accuracy of machine tools.

In radio astronomy, interferometers consist of separate radio telescopes, each observing the same distant object, such as a galaxy, in the sky. The signal received by each telescope is fed into a computer. Because the telescopes are in different places, the distance travelled by the signal to reach each differs and the overall signal is akin to the interference pattern in the Michelson interferometer. Computer analysis of the overall signal can build up a detailed picture of the source of the radio waves.

In space technology, interferometers are used in radio and radar systems. These include space-vehicle guidance systems, in which the position of the spacecraft is determined by combining the signals received by two precisely spaced antennae mounted on it.

interferometry in astronomy, any of several techniques used in astronomy to obtain high-resolution images of astronomical

objects. See ϕ speckle interferometry and ϕ VBLI (very long baseline interferometry).

interferon naturally occurring cellular protein that makes up part of the body's defences against viral disease. Three types (alpha, beta, and gamma) are produced by infected cells and enter the bloodstream and uninfected cells, making them immune to virus attack.

Interferon was discovered in 1957 by Scottish virologist Alick Isaacs. Interferons are cytokines, small molecules that carry signals from one cell to another. They can be divided into two main types: **type I** (alpha, beta, tau, and omega) interferons are more effective at bolstering cells' ability to resist infection; **type II** (gamma) interferon is more important to the normal functioning of the immune system. Alpha interferon may be used to treat some cancers; interferon beta 1b has been found useful in the treatment of multiple sclerosis.

interior angle one of the four internal angles formed when a transversal cuts two or more (usually parallel) lines. Also, one of the angles inside a polygon.

interlacing technique for increasing resolution on computer graphic displays. The electron beam traces alternate lines on each pass, providing twice the number of lines of a non-interlaced screen. However, screen refresh is slower and screen flicker may be increased over that seen on an equivalent non-interlaced screen.

intermediate technology application of mechanics, electrical engineering, and other technologies, based on inventions and designs developed in scientifically sophisticated cultures, but utilizing materials, assembly, and maintenance methods found in technologically less advanced regions (known as the Third World).

Intermediate technologies aim to allow developing countries to benefit from new techniques and inventions of the 'First World', without the burdens of costly maintenance and supply of fuels and spare parts that in the Third World would represent an enormous and probably uneconomic overhead. intermediate vector boson alternative name for **weakon**, the elementary particle responsible for carrying the ϕ weak nuclear force.

intermolecular force or *van der Waals' force* force of attraction between molecules. Intermolecular forces are relatively weak; hence simple molecular compounds are gases, liquids, or low-melt-point solids.

internal-combustion engine heat engine in which fuel is burned inside the engine, contrasting with an external-combustion engine (such as the steam engine) in which fuel is burned in a separate unit. The ϕ diesel engine and ϕ petrol engine are both internal-combustion engines. Gas (turbines and ϕ jet) and ϕ rocket engines

are also considered to be internal-combustion engines because they burn their fuel inside their combustion chambers.

internal modem in computing, a ϕ modem that fits into a slot inside a personal computer. On older PCs, an internal modem may prove a better choice for high-speed data communications than an external modem, as it may have built-in features which make up for features missing in older computers. Internal modems are generally also cheaper, except for the small-sized ϕ PCMCIA types.

The disadvantages are that an internal modem cannot easily be swapped from one computer to another, require greater skill to install (again except for PCMCIA), and have no external displays of lights to give users feedback.

internal resistance or **source resistance** the resistance inside a power supply, such as a battery of cells, that limits the current that it can supply to a circuit.

International Atomic Energy Agency (IAEA) agency of the United Nations established in 1957 to advise and assist member countries in the development and peaceful application of nuclear power, and to guard against its misuse. It has its headquarters in Vienna, and is responsible for research centres in Austria and Monaco, and the International Centre for Theoretical Physics, Trieste, Italy, established in 1964. It conducts inspections of nuclear installations in countries suspected of developing nuclear weapons, for example Iraq and North Korea.

international biological standards drugs (such as penicillin and insulin) of which the activity for a specific mass (called the international unit, or IU), prepared and stored under specific conditions, serves as a standard for measuring doses. For penicillin, one IU is the activity of 0.0006 mg of the sodium salt of penicillin, so a dose of a million units would be 0.6 g.

International Organization for Standardization (ISO) international organization founded in 1947 to standardize technical terms, specifications, units, and so on. Its headquarters are in Geneva.

International Telecommunication Union body belonging to the Economic and Social Council of the United Nations. It aims to extend international cooperation by improving telecommunications of all kinds.

International Telecommunications Union (ITU) international organization, based in Geneva, Switzerland, which manages telecommunications standards such as ϕ modem speeds and ϕ protocols. ITU activities include the coordination, development, regulation, and standardization of telecommunications.

The ITU has two permanent standards-making committees, the International Telegraph and Telephone Consultative Committee (CCITT) and the International Radio Consultative Committee (CCIR).

The Internal Combustion Engine

BY PETER LAFFERTY

The steam engine was the first reliable source of power. By the early 1800s, the steam engine had developed to the point where it could propel carriages along the road at reasonable speeds, and undertake long journeys. But the quest was on for a lighter, more powerful engine.

The idea of an internal combustion engine seems to have occurred around 1800 to French inventor Philippe Lebon. He argued that an engine that burnt fuel inside a cylinder would waste less heat and be more efficient than an engine, like the steam engine, which had a separate furnace in which the fuel was burnt. He proposed an engine in which a compressed mixture of gas and air was burnt in a cylinder, the heated gas driving a piston. Unfortunately, Lebon met an untimely end before he could build the engine. He was attacked and stabbed on the Champs Elysées in Paris and died of his wounds.

After Lebon, several inventors tried to build internal combustion engines but failed, mainly because of difficulties with ignition of the fuel-air mixture inside the cylinder.

In 1807 Swiss inventor Isaac de Rivas built an engine which he used to move a trolley. However, the engine was too inefficient to be of any use. In 1829, the Reverend William Cecil read a paper at Cambridge University about his experiments, and William Barnett in 1839 also laid claims to the invention. In 1853 Italians Eugenio Barsanti and Felice Matteucci patented a design, but they never built a working engine. It was not until 1860 that an efficient engine was built by Belgian engineer Etienne Lenoir.

Lenoir's engine consisted of a single cylinder with a storage battery for electrical ignition of the fuel-air mixture. It was a two-stroke engine, producing its power in two strokes, or movements, of the piston. It was fuelled by coal gas, as used then for domestic purposes and street lighting. The engine developed a feeble two horsepower. This was just enough power to drive a road vehicle and in 1863 Lenoir took a 10 km/6 mi journey in the first car powered by an internal combustion engine. The trip took 3 h to complete. The real value of the Lenoir engine was for powering small machines, and by 1865 more than 400 were in use in Paris, driving printing presses, lathes and water pumps. However, technical weaknesses, especially low compression, limited the

potential of the Lenoir engine.

The next step forward was taken by German engineer Nikolaus Otto. In 1876, Otto patented the four-stroke engine, which produced its power using four movements of the piston. It used only half the fuel consumed by the Lenoir engine and was more powerful. The Otto engine was an immediate success; more than 35,000 were made in a few years. They were large engines and developed over 450 kW/600 hp.

Unfortunately for him, Otto's patent was invalidated in 1886 when his competitors dug up an earlier patent taken out by French inventor Alphonse Beau de Rochas in 1862. Rochas had described the four-stroke cycle in his patent. A court battle ensued, lasting two years, after which Otto's patent was declared invalid. This gave the go-ahead to other inventors to use the basic ideas without hindrance. German Karl Benz refined the Lenoir engine and introduced the use of liquid fuel, such as alcohol or petrol. He fitted his engine into a three-wheeled vehicle and in July 1886 at Mannheim the first petrol-driven motor car took to the roads. The trip covered about 1.6 km/1 mi at a speed of 14.5 kph/9 mph. Meanwhile, just 100 km/60 mi away in Cannstadt, Gottlieb Daimler was building his four-wheeled petrol-driven motor car. He completed a successful test run in August 1886.

A different type of internal combustion engine was invented by German engineer Karl Diesel in 1892. In the diesel engine, the compression used in the piston is much higher than in the petrol engine. This compression raises the temperature of air in the cylinder so high that electric ignition is not needed – the fuel ignites spontaneously when injected into the cylinder. This arrangement avoided the problems associated with electrical ignition and produced a simpler engine.

Working with such high pressures, Diesel was lucky to escape being killed when the cylinder head blew off one of his prototype engines. Undeterred he carried on to perfect the engine, and in 1899 he set up a factory to manufacture the engines. The factory flourished despite Diesel having little business sense. In 1913, at the height of his success, he vanished from the decks of a steamer crossing from Antwerp to England. His body was never found.

International Traffic in Arms Regulations US laws which prohibit the export of strong encryption by classifying it as a munition. Non-US users of common products such as Netscape and Lotus Notes are affected by these laws, as outside the USA American software suppliers must weaken the encryption built in to protect sensitive data.

In the mid-1990s several bills were introduced into the US Congress attempting to change these laws.

International Union for the Conservation of Nature (IUCN) organization established by the United Nations to promote the conservation of wildlife and habitats as part of the national policies of member states.

It has formulated guidelines and established research programmes (for example, International Biological Programme, IBP) and set up advisory bodies (such as Survival Commissions, SSC). In 1980, it launched the World Conservation Strategy to highlight particular problems, designating a small number of areas as World Heritage Sites to ensure their survival as unspoiled habitats (for example, Yosemite National Park in the USA, and the Simen Mountains in Ethiopia). It also compiles the Red Data List of Threatened Animals, classifying species according to their vulnerability to extinction.

According to its list of endangered species published in 1996, 25% of all mammal species (including 36% of insectivores and 33% of pigs and antelopes) and 11% of all bird species are threatened with extinction.

Internet global computer network connecting governments, companies, universities, and many other networks and users. Electronic mail, conferencing, and chat services are all supported across the network, as is the ability to access remote computers and send and retrieve files. In 1997 around 55 million adults had access to the Internet in the USA alone.

The technical underpinnings of the Internet were developed as a project funded by the Advanced Research Project Agency (ARPA) to research how to build a network that would withstand bomb damage. The Internet itself began in 1984 with funding from the US National Science Foundation as a means to allow US universities to share the resources of five regional supercomputing centres. The number of users grew quickly, and in the early 1990s access became cheap enough for domestic users to have their own links on home personal computers. As the amount of information available via the Internet grew, indexing and search services such as Gopher, Archie, Veronica, and WAIS were created by Internet users to help both themselves and others. The newer World Wide Web allows seamless browsing across the Internet via hypertext.

Internet Architecture Board (IAB) in computing, committee that coordinates the development of Internet standards. Set up 1983, the IAB is a technical advisory group of the Internet Society. Its responsibilities include architectural oversight for the protocols and procedures used by the Internet, standards process oversight and appeal, editorial management and publication of RFC (request for comments) documents, and advising the Internet

Internet The Internet is accessed by users via a modem to the service provider's hub, which handles all connection requests. Once connected, the user can access a whole range of information from many different sources, including the World Wide Web.

Society concerning technical, architectural, procedural, and some policy matters.

Internet-enabled in computing, facility that allows desktop applications to exchange information directly across the Internet. The most common Internet facility to build in is e-mail. Also popular is integrated Web access, so that a user can click on a *URL* (uniform resource locator) from inside an application such as a word processor or personal information manager and be taken directly to that page on the World Wide Web.

Internet Engineering Task Force (IETF) in computing, international group which supervises the development of RFC (requests for comments), *protocols*, and other engineering design for the Internet, reporting to the *Internet Architecture Board*. It was formed 1986 and is based in Reston, Virginia, USA.

Internet Explorer in computing, Web *browser* created by Microsoft 1995 to compete with *Netscape Navigator*. Internet Explorer is given away free by Microsoft and bundled with its Windows 95 program. The US Justice Department sued Microsoft 1997 to prevent it from denying firms access to Windows 95 if they chose not to include Internet Explorer.

Internet Hunt in computing, monthly game played to test contestants' skills at finding information on the Internet.

Internet mail in computing, e-mail sent across the Internet. The distinction is primarily made on closed or commercial systems,

where Internet mail comes from outside via a *gateway*. Systems such as *CompuServe* used to charge extra for receiving or sending Internet mail, but such charges have been phased out.

Internet phone in computing, technology allowing users of the World Wide Web to talk to each other in more or less real time, via microphones and headsets. Network delays mean such connections are not as good quality as traditional telephone connections, but they are much cheaper for long-distance calls since users pay only for their local telephone connection to the Internet.

The earliest products were limited in that they only allowed users to talk to each other if both were logged on to the *Vocaltec* Web site at the same time. More recent products make it possible for a person using the Internet to dial any telephone in the world.

Internet Relay Chat (IRC) in computing, service that allows users connected to the Internet to chat with each other over many channels. There are probably hundreds of IRC channels active at any one time, covering a variety of topics. Many abbreviations are used to cut down on typing.

Internet Service Provider (ISP) in computing, any company that sells dial-up access to the Internet. Several types of company provide Internet access, including online information services such as *CompuServe* and *America Online (AOL)*, electronic conferencing systems such as the *OWELL* and *CompuLink Information eXchange*, and local bulletin board systems (BBSs). Most recently founded ISPs, such as *Demon Internet* and *PIPEX*, offer only

direct access to the Internet without the burden of running services of their own just for their members.

Such companies typically work out cheaper for their users, as they charge a low, flat rate for unlimited usage. By contrast, commercial online services typically charge by the hour or minute.

Internet Society (ISOC) global volunteer group that works to coordinate and develop the Internet and its underlying technology. It was founded 1992 and is based in Reston, Virginia, USA; the president (1996) is Vinton Cerf. Members include individuals, companies, nonprofit-making organizations, and government agencies.

Internet Talk Radio (also known as the *Internet multicasting service*) service that broadcasts radio programmes of interest to the technical community, such as *Geek of the Week*. Based in Washington DC, USA, the service broadcasts via *CBONE*.

Internet worm in computing, a virus; see *worm*.

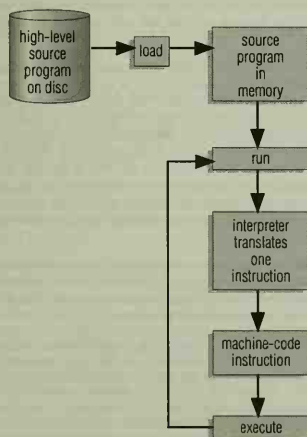

InterNIC in computing, service that administers domain names and maintains a number of Internet user directories. Users interested in registering a particular domain name can use the InterNIC's resources to check if the domain name or a similar one is already in use.

interplanetary matter gas and dust thinly spread through the Solar System. The gas flows outwards from the Sun as the solar wind.

Fine dust lies in the plane of the Solar System, scattering sunlight to cause the zodiacal light. Swarms of dust shed by comets enter the Earth's atmosphere to cause meteor showers.

interpolation mathematical technique for using two values to calculate intermediate values. It is used in computer graphics to create smooth shadings.

interpreter computer program that translates and executes a program written in a high-level language. Unlike a compiler, which produces a complete machine-code translation of the high-level program in one operation, an interpreter translates the source program, instruction by instruction, each time that program is run.

interpreter The sequence of events when running an interpreter on a high-level language program. Instructions are translated one at a time, making the process a slow one; however, interpreted programs do not need to be compiled and may be executed immediately.

Man is the interpreter of nature, science the right interpretation.

interquartile range in statistics, a measure of dispersion in a frequency distribution, equalling the difference in value between the upper and lower quartiles.

interrupt in computing, a signal received by the computer's central processing unit that causes a temporary halt in the execution of a program while some other task is performed. Interrupts may be generated by the computer's internal electronic clock (clock interrupt), by an input or output device, or by a software routine. After the computer has completed the task to which it was diverted, control returns to the original program.

For example, many computers, while printing a long document, allow the user to carry on with other work. When the printer is ready for more data, it sends an interrupt signal that causes the computer to halt work on the user's program and transmit more data to the printer.

intersection on a graph, the point where two lines or curves meet. The intersections of graphs provide the graphical solutions of equations.

intersection in set theory, the set of elements that belong to both set A and set B.

intersex individual that is intermediate between a normal male and a normal female in its appearance (for example, a genetic male that lacks external genitalia and so resembles a female).

interstellar cirrus in astronomy, wispy cloud-like structures discovered in the mid-1980s by the Infrared Astronomy Satellite (*IRAS*) and believed to be the remains of dust shells blown into space from cool giant or supergiant stars.

interstitial in biology, undifferentiated tissue that is interspersed with the characteristic tissue of an organ. It is often formed of fibrous tissue and supports the organ. Interstitial fluid refers to the fluid present in small amounts in the tissues of an organ.

intestine in vertebrates, the digestive tract from the stomach outlet to the anus. The human small intestine is 6 m/20 ft long, 4 cm/1.5 in in diameter, and consists of the duodenum, jejunum, and ileum; the large intestine is 1.5 m/5 ft long, 6 cm/2.5 in in diameter, and includes the caecum, colon, and rectum. Both are muscular tubes comprising an inner lining that secretes alkaline digestive juice, a submucous coat containing fine blood vessels and nerves, a muscular coat, and a serous coat covering all, supported by a strong peritoneum, which carries the blood and lymph vessels, and the nerves. The contents are passed along slowly by peristalsis (waves of involuntary muscular action). The term intestine is also applied to the lower digestive tract of invertebrates.

intranet in computing, the use of software and other technology developed for the Internet on internal company networks.

Many company networks (and those of other organizations) use the same protocols as the Internet, namely TCP/IP. Therefore the same technology that enables the World Wide Web can be used on an internal network to build an organization-wide web of internal documents that is familiar, easy to use, and comparatively inexpensive.

intrauterine device (IUD) or coil, a contraceptive device that is inserted into the womb (uterus). It is a tiny plastic object, sometimes containing copper. By causing a mild inflammation of the lining of the uterus it prevents fertilized eggs from becoming implanted.

IUDs are not usually given to women who have not had children. They are generally very reliable, as long as they stay in place, with a success rate of about 98%. Some women experience heavier and more painful periods, and there is a very slight risk of a pelvic infection leading to infertility.

intron or *junk DNA* in genetics, a sequence of bases in ϕ DNA that carries no genetic information. Introns, discovered in 1977, make up 98% of DNA (the rest is made up of ϕ exons). Their function is unknown.

10% of the human genome is made up of one base sequence, *Alu*, that occurs in about 1 million separate locations. It is made up of 283 nucleotides, has no determinable function (though some do have an effect on nearby genes), and is a ϕ transposon ('jumping gene').

introversion in psychology, preoccupation with the self, generally coupled with a lack of sociability. The opposite of introversion is ϕ extroversion.

The term was introduced by the Swiss psychiatrist Carl Jung 1924 in his description of ϕ schizophrenia, where he noted that 'interest does not move towards the object but recedes towards the subject'. The term is also used within psychoanalysis to refer to the turning of the instinctual drives towards objects of fantasy rather than the pursuit of real objects. Another term for this sense is fantasy cathexis.

intrusion mass of ϕ igneous rock that has formed by 'injection' of molten rock, or magma, into existing cracks beneath the surface of the Earth, as distinct from a volcanic rock mass which has erupted from the surface. Intrusion features include vertical cylindrical structures such as stocks, pipes, and necks; sheet structures such as dykes that cut across the strata and sills that push between them; lacoliths, which are blisters that push up the overlying rock; and batholiths, which represent chambers of solidified magma and contain vast volumes of rock.

intrusive rock ϕ igneous rock formed beneath the Earth's surface. Magma, or molten rock, cools slowly at these depths to form coarse-grained rocks, such as granite, with large crystals. (ϕ extrusive rocks, which are formed on the surface, are usually fine-grained.) A mass of intrusive rock is called an intrusion.

intuitionism in mathematics, the theory that propositions can be built up only from intuitive concepts that we all recognize easily, such as unity or plurality. The concept of ϕ infinity, of which we have no intuitive experience, is thus not allowed.

There are children playing in the street who could solve some of my top problems in physics, because they have modes of sensory perception that I lost long ago.

Invar trademark for an alloy of iron containing 36% nickel, which expands or contracts very little when the temperature changes.

It is used to make precision instruments (such as pendulums and tuning forks) whose dimensions must not alter.

inverse function ϕ unction that exactly reverses the transformation produced by a function f ; it is usually written as f^{-1} . For example $3x + 2$ and $(x - 2)/3$ are mutually inverse functions. Multiplication and division are inverse operations (see ϕ reciprocals).

An inverse function is clearly demonstrated on a calculator by entering any number, pressing x^2 , then pressing \sqrt{x} to get the inverse. The functions on a scientific calculator can be inverted in a similar way.

inverse multiplexing in computing, technique for combining individual low-bandwidth channels into a single high-bandwidth channel. It is used to create high-speed telephone links for applications such as ϕ videconferencing which require the transmission of huge quantities of data.

inverse square law in physics, the statement that the magnitude of an effect (usually a force) at a point is inversely proportional to the square of the distance between that point and the object exerting the force.

Light, sound, electrostatic force (Coulomb's law), gravitational force (Newton's law) all obey the inverse square law.

inverse video or *reverse video* in computing, a display mode in which images on a display screen are presented as a negative of their normal appearance.

For example, if the computer screen normally displays dark images on a light background, inverse video will change all or part of the screen to a light image on a dark background.

Inverse video is commonly used to highlight parts of a display or to mark out text and pictures that the user wishes the computer to change in some way. For example, the user of a word-processing program might use a pointing device such as a mouse to mark in inverse video a paragraph of text that is to be deleted from the document.

invertebrate animal without a backbone. The invertebrates comprise over 95% of the million or so existing animal species and include sponges, coelenterates, flatworms, nematodes, annelid worms, arthropods, molluscs, echinoderms, and primitive aquatic chordates, such as sea squirts and lancelets.

INVERTEBRATE

Every year, at least two species of British invertebrates become extinct.

inverted file in computing, a file that reorganizes the structure of an existing data file to enable a rapid search to be made for all records having one field falling within set limits.

For example, a file used by an estate agent might store records on each house for sale, using a reference number as the key field for ϕ sorting. One field in each record would be the asking price of the house. To speed up the process of drawing up lists of houses falling within certain price ranges, an inverted file might be created in which the records are rearranged according to price. Each record would consist of an asking price, followed by the reference numbers of all the houses offered for sale at this approximate price.

in vitro fertilization (IVF; '*fertilization in glass*') allowing eggs and sperm to unite in a laboratory to form embryos. The embryos (properly called pre-embryos in their two- to eight-celled state) are stored by cooling to the temperature of liquid air (cryopreservation) until they are implanted into the womb of the otherwise infertile mother (an extension of ϕ artificial insemination). The first baby to be produced by this method was born in 1978 in the UK. In cases where the Fallopian tubes are blocked, fertilization may be carried out by *intra-vaginal culture*, in which egg and sperm are incubated (in a plastic tube) in the mother's vagina, then transferred surgically into the uterus.

in vitro process biological experiment or technique carried out in a laboratory, outside the body of a living organism (literally 'in glass', for example in a test tube). By contrast, an *in vivo* process takes place within the body of an organism.

in vivo process biological experiment or technique carried out within a living organism; by contrast, an *in vitro* process takes place outside the organism, in an artificial environment such as a laboratory.

involuntary action behaviour not under conscious control, for example the contractions of the gut during peristalsis or the secretion of adrenaline by the adrenal glands. Breathing and urination reflexes are involuntary, although both can be controlled voluntarily to some extent. These processes are regulated by the ϕ autonomic nervous system.

involute Latin '*rolled in*' in geometry, ϕ spiral that can be thought of as being traced by a point at the end of a taut nonelastic thread being wound onto or unwound from a spool.

I/O (abbreviation for *input/output*) see *input devices* and *output devices*. The term is also used to describe transfer to and from disc – that is, *data I/O*.

Io in astronomy, the third-largest moon of the planet Jupiter, 3,630 km/2,260 mi in diameter, orbiting in 1.77 days at a distance of 422,000 km/262,000 mi. It is the most volcanically active body in the Solar System, covered by hundreds of vents that erupt not lava but sulphur, giving Io an orange-coloured surface.

In July 1995 the Hubble Space Telescope revealed the appearance of a 320-km/200-mi yellow spot on the surface of Io, located on the volcano Ra Patera. Though clearly volcanic in origin, astronomers are unclear as to the exact cause of the new spot.

Using data gathered by the spacecraft *Galileo*, US astronomers concluded in 1996 that Io has a large metallic core. The *Galileo* space probe also detected a 10-megawatt beam of electrons flowing between Jupiter and Io.

In 1997 instruments aboard the spacecraft *Galileo* measured the temperature of Io's volcanoes and detected a minimum temperature of 1,800 K (in comparison, Earth's hottest volcanoes only reach about 1,600 K).

iodide compound formed between iodine and another element in which the iodine is the more electronegative element (see *electronegativity*, *halide*).

iodine *Greek iodes 'violet'* greyish-black nonmetallic element, symbol I, atomic number 53, relative atomic mass 126.9044. It is a member of the halogen group. Its crystals give off, when heated, a violet vapour with an irritating odour resembling that of chlorine. It only occurs in combination with other elements. Its salts are known as iodides, which are found in sea water. As a mineral nutrient it is vital to the proper functioning of the thyroid gland, where it occurs in trace amounts as part of the hormone thyroxine. Absence of iodine from the diet leads to *goitre*. Iodine is used in photography, in medicine as an antiseptic, and in making dyes.

Its radioactive isotope ^{131}I (half-life of eight days) is a dangerous fission product from nuclear explosions and from the nuclear reactors in power plants, since, if ingested, it can be taken up by the thyroid and damage it. It was discovered in 1811 by French chemist B Courtois (1777–1838).

iodoform (chemical name *triiodomethane*) CHI_3 , an antiseptic that crystallizes into yellow hexagonal plates. It is soluble in ether, alcohol, and chloroform, but not in water.

lomega in computing, leading manufacturer of removable storage and back-up devices, in direct competition with *QSyquest*. Based in Roy, Utah, in the USA, lomega's two most popular products are the Zip drive, which uses inexpensive 100Mb discs, and the Jaz drive, which uses 1Gb discs.

ion atom, or group of atoms, that is either positively charged (cation) or negatively charged (anion), as a result of the loss or gain of electrons during chemical reactions or exposure to certain forms of radiation.

ion engine rocket engine that uses ions (charged particles) rather than hot gas for propulsion. Ion engines have been successfully tested in space, where they will eventually be used for gradual rather than sudden velocity changes. In an ion engine, atoms of mercury, for example, are ionized (given an electric charge by an electric field) and then accelerated at high speed by a more powerful electric field.

ion exchange process whereby an ion in one compound is replaced by a different ion, of the same charge, from another compound. It is the basis of a type of chromatography in which the components of a mixture of ions in solution are separated according to the ease with which they will replace the ions on the polymer matrix through which they flow. The exchange of positively charged ions is called cation exchange; that of negatively charged ions is called anion exchange.

Ion-exchange is used in commercial water softeners to exchange the dissolved responsible for the water's hardness with others that do not have this effect. For example, when hard water is passed

over an ion-exchange resin, the dissolved calcium and magnesium ions are replaced by either sodium or hydrogen ions, so the hardness is removed.

ion half equation equation that describes the reactions occurring at the electrodes of a chemical cell or in electrolysis. It indicates which ion is losing electrons (oxidation) or gaining electrons (reduction).

Examples are given from the electrolysis of dilute hydrochloric acid (HCl).

ionic bond or **electrovalent bond** bond produced when atoms of one element donate electrons to atoms of another element, forming positively and negatively charged ions respectively. The attraction between the oppositely charged ions constitutes the bond. Sodium chloride (Na^+Cl^-) is a typical ionic compound.

Each ion has the electronic structure of an inert gas (see *ionable gas structure*). The maximum number of electrons that can be gained is usually two.

ionic bond The formation of an ionic bond between a sodium atom and a chlorine atom to form a molecule of sodium chloride. The sodium atom transfers an electron from its outer electron shell (becoming the positive ion Na^+) to the chlorine atom (which becomes the negative chloride ion Cl^-). The opposite charges mean that the ions are strongly attracted to each other. The formation of the bond means that each atom becomes more stable, having a full quota of electrons in its outer shell.

ionic compound substance composed of oppositely charged ions. All salts, most bases, and some acids are examples of ionic compounds. They possess the following general properties: they are crystalline solids with a high melting point; are soluble in water and insoluble in organic solvents; and always conduct electricity when molten or in aqueous solution. A typical ionic compound is sodium chloride (Na^+Cl^-).

ionic equation equation showing only those ions in a chemical reaction that actually undergo a change, either by combining together to form an insoluble salt or by combining together to form one or more molecular compounds. Examples are the precipitation of insoluble barium sulphate when barium and sulphate ions are combined in solution, and the production of ammonia and water from ammonium hydroxide.

The other ions in the mixtures do not take part and are called *spectator ions*.

ionization process of ion formation. It can be achieved in two ways. The first way is by the loss or gain of electrons by atoms to form positive or negative ions.

In the second mechanism, ions are formed when a covalent bond breaks, as when hydrogen chloride gas is dissolved in water. One portion of the molecule retains both electrons, forming a negative ion, and the other portion becomes positively charged. This bond-fission process is sometimes called *dissociation*.

ionization chamber device for measuring ionizing radiation. The radiation ionizes the gas in the chamber and the ions formed are collected and measured as an electric charge. Ionization chambers are used for determining the intensity of X-rays or the disintegration rate of radioactive materials.

ionization potential measure of the energy required to remove an electron from an atom. Elements with a low ionization potential readily lose electrons to form cations.

ionization therapy enhancement of the atmosphere of an environment by instrumentally boosting the negative ion content of the air.

Fumes, dust, cigarette smoke, and central heating cause negative ion deficiency, which particularly affects sufferers from respiratory disorders such as bronchitis, asthma, and sinusitis. Symptoms are alleviated by the use of ionizers in the home or workplace. In severe cases, ionization therapy is used as an adjunct to conventional treatment.

ionizing radiation radiation that knocks electrons from atoms during its passage, thereby leaving ions in its path. Alpha and beta particles are far more ionizing in their effect than are neutrons or gamma radiation.

ionosphere ionized layer of Earth's outer atmosphere (60–1,000 km/38–620 mi) that contains sufficient free electrons to modify the way in which radio waves are propagated, for instance by reflecting them back to Earth. The ionosphere is thought to be produced by absorption of the Sun's ultraviolet radiation.

ion plating method of applying corrosion-resistant metal coatings. The article is placed in argon gas, together with some coating metal, which vaporizes on heating and becomes ionized (acquires charged atoms) as it diffuses through the gas to form the coating. It has important applications in the aerospace industry.

IP address (abbreviation for *Internet protocol address*) in computing, numbered address assigned to an Internet host. Traditionally, IP addresses are 32-bit, which means that numbered addresses have four sections separated by dots, each a decimal number between 0 and 255.

ipeacacuanha or **ipeaca** South American plant belonging to the madder family, the dried roots of which are used in medicine as an emetic (to cause vomiting) and to treat amoebic dysentery (infection of the intestine with amoebae). (*Psychotria ipeacacuanha*, family Rubiaceae.)

IR or **ir** in physics, abbreviation for *infrared*.

IRAS acronym for *Infrared Astronomy Satellite* joint US-UK-Dutch satellite launched in 1983 to survey the sky at infrared wavelengths, studying areas of star formation, distant galaxies, possible embryo planetary systems around other stars, and discovering five new comets in our own Solar System. It operated for 10 months.

IRC in computing, abbreviation for *Internet Relay Chat*.

iridium Latin *iridis* 'rainbow' hard, brittle, silver-white, metallic

element, symbol Ir, atomic number 77, relative atomic mass 192.2. It is resistant to tarnish and corrosion. Iridium is one of the so-called platinum group of metals; it occurs in platinum ores and as a free metal (native metal) with osmium in osmiridium, a natural alloy that includes platinum, ruthenium, and rhodium.

It is alloyed with platinum for jewellery and used for watch bearings and in scientific instruments. It was named in 1804 by English chemist Smithson Tennant (1761–1815) for its iridescence in solution.

iridium anomaly unusually high concentrations of the element iridium found world-wide in sediments which were deposited at the Cretaceous-Tertiary boundary (C-T boundary) 65 million years ago. Since iridium is more abundant in extraterrestrial material, its presence is thought to be evidence for a large meteor impact which may have caused the extinction of the dinosaurs.

iris in anatomy, the coloured muscular diaphragm that controls the size of the pupil in the vertebrate eye. It contains radial muscle that increases the pupil diameter and circular muscle that constricts the pupil diameter. Both types of muscle respond involuntarily to light intensity.

iris in botany, any of a group of perennial northern temperate flowering plants belonging to the iris family. The leaves are usually sword-shaped; the purple, white, or yellow flowers have three upright inner petals and three outward- and downward-curving sepals. The wild yellow iris is called a flag. (Genus *Iris*, family Iridaceae.)

Irish terrier breed of large terrier from the region of Cork and Ballymena. It has a thick, rough coat in reddish and wheaten hues and an athletic build. It stands about 45 cm/18 in at the shoulder.

Irish water spaniel breed of medium-sized Gundog with a dark brown, thickly curling coat, used especially for hunting and retrieving waterfowl. It grows to 58.5 cm/23 in and is an ancestor of the smaller (up to 46 cm/18 in), but very similar, American water spaniel.

Irish wolfhound breed of hound used in Ireland for many centuries to hunt wolves and other large game. Of massive size (80 cm/32 in upwards) and powerful build, the wolfhound has a shaggy coat in a range of colours – wheaten, grey, brindle, black, red, or white.

In the 19th century the breed was revived when nearly extinct by crossing it with the deerhound.

iron hard, malleable and ductile, silver-grey, metallic element, symbol Fe (from Latin *ferrum*), atomic number 26, relative atomic mass 55.847. It is the fourth most abundant element (the second most abundant metal, after aluminium) in the Earth's crust. Iron occurs in concentrated deposits as the ores hematite (Fe_2O_3), sphatite ore (FeCO_3), and magnetite (Fe_3O_4). It sometimes occurs as a free metal, occasionally as fragments of iron or iron-nickel meteorites.

Iron is the most common and most useful of all metals; it is strongly magnetic and is the basis for steel, an alloy with carbon and other elements (see also cast iron). In electrical equipment it is used in all permanent magnets and electromagnets, and forms the cores of transformers and magnetic amplifiers. In the human body, iron is an essential component of haemoglobin, the molecule in red blood cells that transports oxygen to all parts of the body. A deficiency in the diet causes a form of anaemia.

Iron Age developmental stage of human technology when weapons and tools were made from iron. Preceded by the Stone and Bronze ages, it is the last technological stage in the Three Age System framework for prehistory. Iron was produced in Thailand about 1600 BC, but was considered inferior in strength to bronze until about 1000 BC, when metallurgical techniques improved, and the alloy steel was produced by adding carbon during the smelting process.

Ironworking was introduced into different regions over a wide time span, appearing in Thailand about 1600 BC, Asia Minor about 1200 BC, central Europe about 900 BC, China about 600 BC, and in remoter areas during exploration and colonization by the Old

World. It reached the Fiji Islands with an expedition in the late 19th century.

Iron Age cultures include Hallstatt (named after a site in Austria) and La Tène (named after a site in Switzerland).

ironbark any species of *Eucalyptus* tree with hard, tough bark.

iron ore any mineral from which iron is extracted. The chief iron ores are δ magnetite, a black oxide; hematite, or kidney ore, a reddish oxide; limonite, brown, impure oxyhydroxides of iron; and siderite, a brownish carbonate.

Iron ores are found in a number of different forms, including distinct layers in igneous intrusions, as components of contact metamorphic rocks, and as sedimentary beds. Much of the world's iron is extracted in Russia, Kazakhstan, and the Ukraine. Other important producers are the USA, Australia, France, Brazil, and Canada; over 40 countries produce significant quantities of ore.

iron pyrites or **pyrite** FeS_2 , common iron ore. Brassy yellow, and occurring in cubic crystals, it is often called 'fool's gold', since only those who have never seen gold would mistake it.

irradiation subjecting anything to radiation, including cancer tumours. See also δ food irradiation.

irrational number a number that cannot be expressed as an exact fraction. Irrational numbers include some square roots (for example, $\sqrt{2}$, $\sqrt{3}$, and $\sqrt{5}$ are irrational) and numbers such as π (the ratio of the circumference of a circle to its diameter, which is approximately equal to 3.14159) and e (the base of natural logarithms, approximately 2.71828).

irregular galaxy in astronomy, a class of galaxy with little structure, which does not conform to any of the standard shapes in the Hubble classification. The two satellite galaxies of the δ Milky Way, the δ Magellanic Clouds, are both irregulars. Some galaxies previously classified as irregulars are now known to be normal galaxies distorted by tidal effects or undergoing bursts of star formation (see δ starburst galaxy).

irrigation artificial water supply for dry agricultural areas by means of dams and channels. Drawbacks are that it tends to concentrate salts at the surface, ultimately causing soil infertility, and that rich river silt is retained at dams, to the impoverishment of the land and fisheries below them.

Irrigation has been practised for thousands of years, in Eurasia as well as the Americas. An example is the channelling of the annual Nile flood in Egypt, which has been done from earliest times to its present control by the Aswan High Dam.

ISA bus (abbreviation for **industry standard architecture bus**) in computing, 16-bit data bus introduced in 1984 with the IBM PC AT and still in common use in PCs, alongside the superior δ PCI bus. PC hardware and software manufacturers would like to get rid of the ISA bus as it is not compatible with δ Plug and Play.

ISBN (abbreviation for **International Standard Book Number**) code number used for ordering or classifying book titles. Every book printed now has a number on its back cover or jacket, preceded by the letters ISBN. It is a code to the country of origin and the publisher. The number is unique to the book, and will identify it anywhere in the world.

The final digit in each ISBN number is a check digit, which can be used by a computer program to validate the number each time it is input (see δ validation).

ischaemic heart disease (IHD) disorder caused by reduced perfusion of the coronary arteries due to δ atherosclerosis. It is the commonest cause of death in the Western world, leading to more than a million deaths each year in the USA and about 160,000 in the UK. See also δ coronary artery disease.

Early symptoms of IHD include angina or palpitations, but sometimes a heart attack is the first indication that a person is affected.

ISDN abbreviation for **Integrated Services Digital Network**, a telecommunications system.

island area of land surrounded entirely by water. Australia is classed as a continent rather than an island, because of its size.

Islands can be formed in many ways. **Continental islands** were once part of the mainland, but became isolated by tectonic movement, erosion, or a rise in sea level, for example. **Volcanic islands**, such as Japan, were formed by the explosion of underwater volcanoes. **Coral islands** consist mainly of coral, built up over many years. An atoll is a circular coral reef surrounding a lagoon; atolls were formed when a coral reef grew up around a volcanic island that subsequently sank or was submerged by a rise in sea level. **Barrier islands** are found by the shore in shallow water, and are formed by the deposition of sediment eroded from the shoreline.

island arc curved chain of islands produced by volcanic activity at a destructive margin (where one tectonic plate slides beneath another). Island arcs are common in the Pacific where they ring the ocean on both sides; the Aleutian Islands off Alaska are an example.

Such island arcs are often later incorporated into continental margins during mountain-building episodes.

islets of Langerhans groups of cells within the pancreas responsible for the secretion of the hormone insulin. They are sensitive to the blood sugar, producing more hormone when glucose levels rise.

ISO abbreviation for **International Organization for Standardization**.

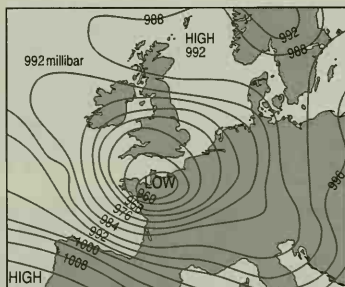

ISO in photography, a numbering system for rating the speed of films, devised by the International Standards Organization.

ISO 9660 in computing, standard file format for δ CD-ROM discs, synonymous with High Sierra format. This format is compatible with most systems, so the same disc can contain both Apple Macintosh and PC versions.

isobar line drawn on maps and weather charts linking all places with the same atmospheric pressure (usually measured in millibars).

When used in weather forecasting, the distance between the isobars is an indication of the barometric gradient (the rate of change in pressure).

Where the isobars are close together, cyclonic weather is indicated, bringing strong winds and a depression, and where far apart anticyclonic, bringing calmer, settled conditions.

isobar The isobars around a low-pressure area or depression. In the northern hemisphere, winds blow anticlockwise around lows, approximately parallel to the isobars, and clockwise around highs. In the southern hemisphere, the winds blow in the opposite directions.

ISOC in computing, abbreviation for **Internet Society**.

isomer chemical compound having the same molecular composition and mass as another, but with different physical or chemical properties owing to the different structural arrangement of its constituent atoms. For example, the organic compounds butane ($\text{CH}_3(\text{CH}_2)_2\text{CH}_3$) and methyl propane ($\text{CH}_3\text{CH}(\text{CH}_3)\text{CH}_3$) are isomers, each possessing four carbon atoms and ten hydrogen atoms but differing in the way that these are arranged with respect to each other.

butane $\text{CH}_3(\text{CH}_2)_2\text{CH}_3$ methyl propane $\text{CH}_3\text{CH}(\text{CH}_3)\text{CH}_3$ 

isomer The chemicals butane and methyl propane are isomers. Each has the molecular formula $\text{CH}_3\text{CH}(\text{CH}_3)\text{CH}_3$, but with different spatial arrangements of atoms in their molecules.

Structural isomers have obviously different constructions, but geometrical and optical isomers must be drawn or modelled in order to appreciate the difference in their three-dimensional arrangement. Geometrical isomers have a plane of symmetry and arise because of the restricted rotation of atoms around a bond; optical isomers are mirror images of each other. For instance, 1,1-dichloroethene ($\text{CH}_2=\text{CCl}_2$) and 1,2-dichloroethene ($\text{CHCl}=\text{CHCl}$) are structural isomers, but there are two possible geometric isomers of the latter (depending on whether the chlorine atoms are on the same side or on opposite sides of the plane of the carbon-carbon double bond).

isometric transformation a η transformation in which length is preserved.

isomorphism the existence of substances of different chemical composition but with similar crystalline form.

isoprene $\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2$ (technical name *methylbutadiene*) colourless, volatile fluid obtained from petroleum and coal, used to make synthetic rubber.

isosceles triangle a η triangle with two sides equal, hence its base angles are also equal. The triangle has an axis of symmetry which is an altitude of the triangle.

isostasy the theoretical balance in buoyancy of all parts of the Earth's crust, as though they were floating on a denser layer beneath. There are two theories of the mechanism of isostasy, the Airy hypothesis and the Pratt hypothesis, both of which have validity. In the Airy hypothesis crustal blocks have the same density but different depths: like ice cubes floating in water, higher mountains have deeper roots. In the Pratt hypothesis, crustal blocks have different densities allowing the depth of crustal material to be the same.

There appears to be more geological evidence to support the Airy hypothesis of isostasy. During an η ice age the weight of the ice sheet pushes that continent into the Earth's mantle; once the ice has melted, the continent rises again. This accounts for shoreline features being found some way inland in regions that were heavily glaciated during the Pleistocene period.

isotope one of two or more atoms that have the same atomic number (same number of protons), but which contain a different number of neutrons, thus differing in their atomic masses. They may be stable or radioactive, naturally occurring or synthesized. The term was coined by English chemist Frederick Soddy, pioneer researcher in atomic disintegration.

ISP in computing, abbreviation for η Internet Service Provider.

iteration in computing, a method of solving a problem by performing the same steps repeatedly until a certain condition is satisfied. For example, in one method of η sorting, adjacent items are repeatedly exchanged until the data are in the required sequence.

iteration in mathematics, method of solving η equations by a series of approximations which approach the exact solution more and more closely. For example, to find the square root of N , start with a guess n_1 ; calculate $N/n_1 = x_1$; calculate $(n_1 + x_1)/2 = n_2$; calculate $N/n_2 = x_2$; calculate $(n_2 + x_2)/2 = n_3$. The sequence n_1, n_2, n_3 approaches the exact square root of N .

N . Iterative methods are particularly suitable for work with computers and programmable calculators.

iteroparity in biology, the repeated production of offspring at intervals throughout the life cycle. It is usually contrasted with η semelparity, where each individual reproduces only once during its life.

ITU abbreviation for η International Telecommunications Union, the standards-setting body for the communications industry.

IUE (acronym for *International Ultraviolet Explorer*) joint NASA-ESA (US and European Space Agency) orbiting ultraviolet telescope with a 45-cm/18-in mirror, launched in 1978. It was switched off in September 1996.

IUPAC abbreviation for *International Union of Pure and Applied Chemistry*, organization that recommends the nomenclature to be used for naming substances, the units to be used, and which conventions are to be adopted when describing particular changes.

IVF abbreviation for η in vitro fertilization.

ivory hard white substance of which the teeth and tusks of certain mammals are made. Among the most valuable are elephants' tusks, which are of unusual hardness and density. Ivory is used in carving and other decorative work, and is so valuable that poachers continue to illegally destroy the remaining wild elephant herds in Africa to obtain it.

Poaching for ivory has led to the decline of the African elephant population from 2 million to approximately 600,000, with the species virtually extinct in some countries. Trade in ivory was halted by Kenya in 1989, but Zimbabwe continued its policy of controlled culling to enable the elephant population to thrive and to release ivory for export. China and Hong Kong have refused to obey an international ban on ivory trading. In 1997, the 138 member nations of the Convention on International Trade in Endangered Species (η CITES) voted in Harare, amidst much controversy, to remove the ban on trade in ivory in Botswana, Namibia, and Zimbabwe. These three countries would be allowed to sell a limited amount of ivory to Japan, and the money must be channelled into elephant conservation projects. Trade is scheduled to resume in 1999 and would only be allowed from the existing stockpiles of ivory.

Vegetable ivory is used for buttons, toys, and cheap ivory goods. It consists of the hard albumen of the seeds of a tropical palm (*Phytelphas macrocarpa*), and is imported from Colombia.

ivy any of an Old World group of woody climbing, trailing, or creeping evergreen plants. English or European ivy (*H. helix*) has shiny five-lobed leaves and clusters of small, yellowish-green flowers followed by black berries. It climbs by means of rootlike suckers put out from its stem, and causes damage to trees. (Genus *Hedera*, family Araliaceae.)

Ground ivy (*Glechoma hederacea*) is a small, originally European creeping plant belonging to the mint family; the North American poison ivy (*Rhus radicans*) belongs to the cashew family.

J

J in physics, the symbol for **joule**, the SI unit of energy.

jabiru stork found in Central and South America. It is 1.5 m/5 ft tall with white plumage. The head is black and red with a massive, slightly upturned bill. The neck is bare of feathers and can be puffed out, a manoeuvre which is probably used in social rituals. (Species *Jabiru mycteria*, family Ciconiidae, order Ciconiiformes.)

laborandi plant belonging to the rue family, native to South America. It is the source of **pilocarpine**, used in medicine to contract the pupil of the eye. (*Pilocarpus microphyllus*, family Rutaceae.)

jacamar insect-eating bird related to the woodpeckers, found in dense tropical forest in Central and South America. It has a long, straight, sharply-pointed bill, a long tail, and paired toes. The plumage is golden-bronze with a steely lustre. Jacamars are usually seen sitting motionless on trees from which they fly out to catch insects on the wing, then return to crack them on a branch before eating them. The largest species is *Jacamerops aurea*, which is nearly 30 cm/12 in long. (Family Galbulidae, order Piciformes.)

jacana or **lily-trotter** wading bird with very long toes and claws enabling it to walk on the floating leaves of water plants. There are seven species. Jacanas are found in Mexico, Central America, South America, Africa, S Asia, and Australia, usually in marshy areas. (Family Jacanidae, order Charadriiformes.)

The **Australian jacana** (*Irediparra gallinacea*) is so well adapted to life on water that the eggs are laid on floating vegetation and can themselves float.

jacaranda any of a group of tropical American trees belonging to the bignonia family, with fragrant wood and showy blue or violet flowers, commonly cultivated in the southern USA. (Genus *Jacaranda*, family Bignoniaceae.)

jack in computing, small plug allowing users to connect peripherals to CPUs (central processing units).

jack tool or machine for lifting, hoisting, or moving heavy weights, such as motor vehicles. A **screw jack** uses the principle of the screw to magnify an applied effort; in a car jack, for example, turning the handle many times causes the lifting screw to rise slightly, and the effort is magnified to lift heavy weights. A **hydraulic jack** uses a succession of piston strokes to increase pressure in a liquid and force up a lifting ram.

jackal any of several wild dogs found in S Asia, S Europe, and N Africa. Jackals can grow to 80 cm/2.7 ft long, and have greyish-brown fur and a bushy tail. (Genus *Canis*.)

The **golden jackal** (*C. aureus*) of S Asia, S Europe, and N Africa is 45 cm/1.5 ft high and 60 cm/2 ft long. It is greyish-yellow, and darker on the back. A nocturnal animal, it preys on smaller mammals and poultry, although packs will attack larger animals; it will also scavenge. The **side-striped jackal** (*C. adustus*) is found over much of Africa; the **black-backed jackal** (*C. mesomelas*) occurs only in the south of Africa.

jackdaw bird belonging to the crow family, native to Europe and Asia. It is mainly black, but greyish on the sides and back of the head, and about 33 cm/1.1 ft long. It nests in tree holes or on buildings. Usually it lays five bluish-white eggs, mottled with tiny dark brown spots. Jackdaws feed on a wide range of insects, molluscs,

spiders, worms, birds' eggs, fruit, and berries. (Species *Corvus monedula*, family Corvidae, order Passeriformes.)

Jack Russell terrier or **Parson Jack Russell terrier** breed of small, short-legged, smooth-haired terrier, which takes its name from its originator, the English clergyman and fox-hunting enthusiast John Russell (1795–1883). It was recognized by the UK Kennel Club 1990 as a distinct variant of the fox terrier, which it resembles in having a mainly white coat with brown patches.

jade semiprecious stone consisting of either jadeite, $\text{NaAlSi}_3\text{O}_6$ (a pyroxene), or nephrite, $\text{Ca}_2(\text{Mg,Fe})_5\text{Si}_8\text{O}_{22}(\text{OH,F})_2$ (an amphibole), ranging from colourless through shades of green to black according to the iron content. Jade ranks 5.5–6.5 on the Mohs' scale of hardness.

The early Chinese civilization discovered jade, bringing it from E Turkestan, and carried the art of jade-carving to its peak. The Olmecs, Aztecs, Maya, and the Maori have also used jade for ornaments, ceremony, and utensils.

jaggies in computing, 'stepped' appearance of curved or diagonal lines in computer graphics caused by aliasing.

jaguar largest species of cat in the Americas, formerly ranging from the southwestern USA to southern South America, but now extinct in most of North America. It can grow up to 2.5 m/8 ft long including the tail. The background colour of the fur varies from creamy white to brown or black, and is covered with black spots. The jaguar is usually solitary. (Species *Panthera onca*, family Felidae.)

jaguarundi wild cat found in forests in Central and South America. Up to 1.1 m/3.5 ft long, it is very slim with rather short legs and short rounded ears. It is uniformly coloured dark brown or chestnut. A good climber, it feeds on birds and small mammals and, unusually for a cat, has been reported to eat fruit. (Species *Felis yagouaroundi*, family Felidae.)

jansky unit of radiation received from outer space, used in radio astronomy. It is equal to 10^{-26} watts per square metre per hertz, and is named after US engineer Karl Jansky.

Jansky, Karl Guthe (1905–1950)

US radio engineer who in 1932 discovered that the Milky Way galaxy emanates radio waves; he did not follow up his discovery, but it marked the birth of radioastronomy.

jackal The black-backed jackal *Canis mesomelas* is a common sight on the savannas of S Africa. It hunts singly for small animals and in packs for larger prey, often scavenging on carcasses left by larger predators such as lions. Premaphotos Wildlife

Japan Current or *Kuroshio* warm ocean current flowing from Japan to North America.

Japanese spaniel or **Japanese chin** ancient breed of toy dog introduced into Japan from China. Daintily built, it stands about 30 cm/12 in tall, and, like the pekingese, has a rounded head, drooping ears, and tail curved over its back. Its long, soft coat is always white, with either black or red markings.

jarrah type of *Eucalyptus* tree of W Australia, with durable timber.

Jarvik 7 the first successful artificial heart intended for permanent implantation in a human being. Made from polyurethane plastic and aluminium, it is powered by compressed air. Barney Clark became the first person to receive a Jarvik 7, in Salt Lake City, Utah, USA, 1982; it kept him alive for 112 days.

jasmine any of a group of subtropical plants with white or yellow flowers. The common jasmine (*J. officinale*) has fragrant pure white flowers that yield jasmine oil, used in perfumes; the Chinese winter jasmine (*J. nudiflorum*) has bright yellow flowers that appear before the leaves. (Genus *Jasminum*, family Oleaceae.)

jaundice yellow discoloration of the skin and whites of the eyes caused by an excess of bile pigment in the bloodstream. Approximately 60% of newborn babies exhibit some degree of jaundice, which is treated by bathing in white, blue, or green light that converts the bile pigment bilirubin into a water-soluble compound that can be excreted in urine. A serious form of jaundice occurs in rhesus disease (see *rhesus factor*).

Bile pigment is normally produced by the liver from the breakdown of red blood cells, then excreted into the intestines. A build-up in the blood is due to abnormal destruction of red cells (as in some cases of *anaemia*), impaired liver function (as in *hepatitis*), or blockage in the excretory channels (as in *gallstones* or *cirrhosis*). The jaundice gradually recedes following treatment of the underlying cause.

Java in computing, programming language much like C developed by James Gosling at Sun Microsystems 1995. Java has been adopted as a multipurpose, cross-platform lingua franca for network computing, including the World Wide Web. When users connect to a server that uses Java, they download a small program called an applet onto their computers. The applet then runs on the computer's own processor via a Java Virtual Machine program or JVM.

Java Virtual Machine (JVM) in computing, a program that sits on top of a computer's usual operating system and runs Java applets.

Different computers require different JVMs but they should run the same Java code. This means that servers only need to provide one version of each applet, instead of different 'native code' versions for PCs, Apple Macintoshes, and UNIX workstations, as is the case with other plug-ins.

A JVM is commonly supplied as part of a Web browser but may be included as part of the operating system.

jaw one of two bony structures that form the framework of the mouth in all vertebrates except lampreys and hagfishes (the agnathous or jawless vertebrates). They consist of the upper jawbone (maxilla), which is fused to the skull, and the lower jawbone (mandible), which is hinged at each side to the bones of the temple by ligaments.

jay any of several birds belonging to the crow family, generally brightly coloured and native to Europe, Asia, and the Americas. In the Eurasian common jay (*Garrulus glandarius*), the body is fawn with patches of white, blue, and black on the wings and tail. (Family Corvidae, order Passeriformes.)

Jays are shy and retiring in their habits, but have a screeching cry with the power to vary it by mimicking other birds. They feed chiefly on snails, insects, worms, and nuts, particularly acorns. They hide their nests in trees with thick foliage and lay about five or six eggs at a time.

The blue jay (*Cyanocitta cristata*), of the eastern and central USA, has a crest and is very noisy and bold.

Jeans mass in astronomy, the mass that a cloud (or part of a cloud) of interstellar gas must have before it can contract under its

own weight to form a protostar. The Jeans mass is an expression of the Jeans criterion, which says that a cloud will contract when the gravitational force tending to draw material towards its centre is greater than the opposing force due to gas pressure. It is named after English mathematician James Hopwood Jeans whose work focussed on the kinetic theory of gases and the origins of the cosmos.

jellyfish marine invertebrate, belonging among the *coelenterates*, with an umbrella-shaped body made of a semi-transparent jellylike substance, often tinted with blue, red, or orange colours, and stinging tentacles that trail in the water. Most adult jellyfish move freely, but during parts of their life cycle many are polyp-like and attached to rocks, the seabed, or another underwater surface. They feed on small animals that are paralysed by stinging cells in the jellyfish tentacles. (Phylum *Coelenterata*, subphylum *Cnidaria*.)

Most jellyfish cause no more discomfort to humans than a nettle sting, but contact with the tentacles of the subtropical Portuguese man-of-war (*Physalia physalis*) or the Australian box jellyfish (*Chironex fleckeri*) can be life-threatening.

Jenner, Edward (1749–1823)

English physician who pioneered vaccination. In Jenner's day, smallpox was a major killer. His discovery in 1796 that inoculation with cowpox gives immunity to smallpox was a great medical breakthrough.

Jenner observed that people who worked with cattle and contracted cowpox from them never subsequently caught smallpox. In 1798 he published his findings that a child inoculated with cowpox, then two months later with smallpox, did not get smallpox. He coined the word 'vaccination' from the Latin word for cowpox, *vaccina*.

Jentink's duiker small, shy antelope that plunges into bushes when startled. It is acutely threatened by deforestation in its remaining habitat in W Africa, where it is also hunted. One captive breeding colony exists in Texas, USA, and there are hopes of establishing others as the immediate future for this species in the wild appears to be bleak. (Species *Cephalophus jentinki*, family Bovidae.)

jerboa any of a group of small nocturnal rodents with long and powerful hind legs developed for leaping. There are about 25 species of jerboa, native to desert areas of N Africa and SW Asia. (Family Dipodidae.)

The common N African jerboa (*Jaculus orientalis*) is a typical species. Its body is about 15 cm/6 in long and the tail is 25 cm/10 in long with a tuft at the tip. At speed it moves in a series of long jumps with its forefeet held close to its body.

Jerusalem artichoke a variety of artichoke.

JET (abbreviation for *Joint European Torus*) research facility at Culham, near Abingdon, Oxfordshire, UK, that conducts experiments on nuclear fusion. It is the focus of the European effort to produce a safe and environmentally sound fusion-power reactor. On 9 November 1991 the JET tokamak, operating with a mixture of deuterium and tritium, produced a 1.7 megawatt pulse of power

in an experiment that lasted two seconds. In 1997 isotopes of deuterium and tritium were fused to produce a record 21 megajoule of nuclear fusion power. JET has tested the first large-scale plant of the type needed to process and supply tritium in a future fusion power station.

jet in astronomy, a narrow luminous feature seen protruding from a star or galaxy, and representing a rapid outflow of material. See *active galaxy*.

jet hard, black variety of lignite, a type of coal. It is cut and polished for use in jewellery and ornaments. Articles made of jet have been found in Bronze Age tombs.

jetfoil advanced type of hydrofoil boat built by Boeing, propelled by water jets. It features horizontal, fully submerged hydrofoils fore and aft and has a sophisticated computerized control system to maintain its stability in all waters.

Jetfoils have been in service worldwide since 1975. A jetfoil service operates across the English Channel between Dover and Ostend, Belgium, with a passage time of about 1.5 hours. Cruising speed of the jetfoil is about 80 kph/50 mph.

jet lag the effect of a sudden switch of time zones in air travel, resulting in tiredness and feeling 'out of step' with day and night. In 1989 it was suggested that use of the hormone melatonin helped to lessen the effect of jet lag by resetting the body clock. See also *circadian rhythm*.

jet propulsion method of propulsion in which an object is propelled in one direction by a jet, or stream of gases, moving in the other. This follows from Isaac Newton's third law of motion: 'To every action, there is an equal and opposite reaction.' The most widespread application of the jet principle is in the jet engine, the most common kind of aircraft engine.

Jet Propulsion Laboratory NASA installation at Pasadena, California, operated by the California Institute of Technology. It is the command centre for NASA's deep-space probes such as the *Voyager*, *Magellan*, and *Galileo* missions, with which it communicates via the Deep Space Network of radio telescopes at Goldstone, California; Madrid, Spain; and Canberra, Australia.

jet stream narrow band of very fast wind (velocities of over 150 kph/95 mph) found at altitudes of 10–16 km/6–10 mi in the upper troposphere or lower stratosphere. Jet streams usually occur about the latitudes of the Westerlies (35°–60°).

The jet stream may be used by high flying aircraft to speed their journeys. Their discovery of the existence of the jet stream allowed the Japanese to send gas-filled balloons carrying bombs to the northwestern US during World War II.

jigger or **sandflea** flea found in tropical and subtropical countries. The males of the species are free-living and measure about 1 mm/0.03 in in length. The females, which are slightly bigger, are parasites of humans and other animals.

Jiggers burrow into the skin, particularly the soft skin between the toes, and soon become enveloped within a skin fold. As they feed they become enlarged and distended and their legs degenerate; eventually a stage is reached when only the last two segments at the abdomen protrude from the skin fold. The eggs are then voided and fall on the soil or sand.

Apart from their presence within the host skin, which causes acute pain and the formation of ulcers, the fleas may be responsible for secondary infections. Preventive measures include ridding the host of the parasite, and destroying breeding places.

classification The jigger *Tunga penetrans* is in order Siphonaptera, class Insecta, phylum Arthropoda.

Jobs, Steven Paul (1955–)

US computer entrepreneur. He cofounded Apple Computer Inc with Steve Wozniak 1976, and founded NeXT Technology Inc in 1985. In 1986 he bought Pixar Animation Studios, the computer animation studio spun off from George Lucas's Lucasfilm.

Jobs has been involved with the creation of three different types of computer: the Apple II personal computer 1977, the Apple Macintosh 1984 – marketed as 'the computer for the rest of us' – and the NeXT workstation 1988.

The NeXT was technically the most sophisticated and powerful design, but it was a commercial disaster, and in 1993 NeXT abandoned hardware manufacturing to concentrate on its highly-regarded UNIX-based object-oriented operating system, NextStep. Apple Computer bought NeXT at the end of 1996 to obtain NextStep, and Jobs returned to Apple in an advisory capacity. However, he soon took over as acting chief executive officer of the struggling firm 1997.

Jodrell Bank site in Cheshire, England, of the Nuffield Radio Astronomy Laboratories of the University of Manchester. Its largest instrument is the 76 m/250 ft radio dish (the Lovell Telescope), completed 1957 and modified 1970. A 38 x 25 m/125 x 82 ft elliptical radio dish was introduced 1964, capable of working at shorter wave lengths.

These radio telescopes are used in conjunction with six smaller dishes up to 230 km/143 mi apart in an array called MERLIN (multi-element radio-linked interferometer network) to produce detailed maps of radio sources.

joint in any animal with a skeleton, a point of movement or articulation. In vertebrates, it is the point where two bones meet. Some joints allow no motion (the sutures of the skull), others allow a very small motion (the sacroiliac joints in the lower back), but most allow a relatively free motion. Of these, some allow a gliding motion (one vertebra of the spine on another), some have a hinge action (elbow and knee), and others allow motion in all directions (hip and shoulder joints) by means of a ball-and-socket arrangement. The ends of the bones at a moving joint are covered with cartilage for greater elasticity and smoothness, and enclosed in an envelope (capsule) of tough white fibrous tissue lined with a membrane which secretes a lubricating and cushioning (synovial) fluid. The joint is further strengthened by ligaments. In invertebrates with an exoskeleton, the joints are places where the exoskeleton is replaced by a more flexible outer covering, the arthrodial membrane, which allows the limb (or other body part) to bend at that point.

jojoba desert shrub *Simmondsia chinensis* of southwest North America and Mexico, that grows to a height of around 6 m/20 ft. Its seeds are used as a source of jojoba oil, used as a substitute for sperm whale oil, and as a fragrance. It is increasingly grown as a commercial crop.

jonquil species of small daffodil, with yellow flowers. It is native to Spain and Portugal, and is cultivated in other countries. (*Narcissus jonquilla*, family Amaryllidaceae.)

Josephson junction device used in 'superchips' (large and complex integrated circuits) to speed the passage of signals by a phenomenon called 'electron tunnelling'. Although these superchips respond a thousand times faster than the silicon chip, they have the disadvantage that the components of the Josephson junctions operate only at temperatures close to absolute zero. They are named after English theoretical physicist Brian Josephson.

joule SI unit (symbol J) of work and energy, replacing the calorie (one joule equals 4.2 calories)

Joule, James Prescott (1818-1889)

English physicist. His work on the relations between electrical, mechanical, and chemical effects led to the discovery of the first law of thermodynamics.

He determined the mechanical equivalent of heat (Joule's equivalent) in 1843, and the SI unit of energy, the joule, is named after him. He also discovered Joule's law, which defines the relation between heat and electricity; and with Irish physicist Lord Kelvin in 1852 the Joule-Kelvin (or Joule-Thomson) effect.

Mary Evans Picture Library

Joule-Kelvin effect or **Joule-Thomson effect** in physics, the fall in temperature of a gas as it expands adiabatically (without loss or gain of heat to the system) through a narrow jet. It can be felt

when, for example, compressed air escapes through the valve of an inflated bicycle tyre. It is the basic principle of most refrigerators.

joystick in computing, an input device that signals to a computer the direction and extent of displacement of a hand-held lever. It is similar to the joystick used to control the flight of an aircraft.

Joysticks are sometimes used to control the movement of a cursor (marker) across a display screen, but are much more frequently used to provide fast and direct input for moving the characters and symbols that feature in computer games. Unlike a mouse, which can move a pointer in any direction, simple games joysticks are often capable only of moving an object in one of eight different directions.

JPEG (abbreviation for *Joint Photographic Experts Group*) used to describe a compression standard set up by that group and now widely accepted for the storage and transmission of colour images. The JPEG compression standard reduces the size of image files considerably.

Jughead (acronym for *Jonzy's Universal Gopher Hierarchy Excavation and Display*) in computing, a search engine enabling users of the Internet server Gopher to find keywords in Gopherspace directories.

jugular vein one of two veins in the necks of vertebrates; they return blood from the head to the superior (or anterior) vena cava and thence to the heart.

jujube any of a group of trees belonging to the buckthorn family, with berrylike fruits. The common jujube (*Z. jujuba*) of Asia, Africa, and Australia, cultivated in S Europe and California, has fruit the size of small plums, known as Chinese dates when preserved in syrup. See also lotus. (Genus *Zizyphus*, familyhamnaceae.)

Julian date in astronomy, a measure of time used in astronomy in which days are numbered consecutively from noon GMT on 1 January 4713 BC. It is useful where astronomers wish to compare observations made over long time intervals. The Julian date (JD) at noon on 1 January 2000 will be 2451545.0. The modified Julian date (MJD), defined as MJD = JD - 2400000.5, is more commonly used since the date starts at midnight GMT and the smaller numbers are more convenient.

jumbo jet popular name for a generation of huge wide-bodied airliners including the Boeing 747, which is 71 m/232 ft long, has a wingspan of 60 m/196 ft, a maximum takeoff weight of nearly 400 tonnes, and can carry more than 400 passengers.

jump in computing, a programming instruction that causes the computer to branch to a different part of a program, rather than execute the next instruction in the program sequence. Unconditional jumps are always executed; conditional jumps are only executed if a particular condition is satisfied.

juniper in computing, rectangular plug used to make connections on a circuit board. By pushing a juniper onto a particular set of pins on the board, or removing another, users can adjust the configuration of their computer's circuitry. Most home users, however, prefer to leave the insides of their machines with all the factory settings intact.

jumping hare or *springhare* either of two African species of long-eared rodents. The springhare (*P. capensis*) is about 40 cm/16 in long and resembles a small kangaroo with a bushy tail. It inhabits dry sandy country in E central Africa. (Genus *Pedetes*, family Pedetidae.)

Jung, Carl Gustav (1875–1961)

Swiss psychiatrist. He collaborated with Sigmund Freud from 1907 until their disagreement 1914 over the importance of sexuality in causing psychological problems. Jung studied myth, religion, and dream symbolism, saw the unconscious as a source of spiritual insight, and distinguished between introversion and extroversion.

Jung devised the word-association test in the early 1900s as a technique for penetrating a subject's unconscious mind. He also developed his theory concerning emotional, partly repressed ideas which he termed 'complexes'. In place of Freud's emphasis on infantile sexuality, Jung introduced the idea of a 'collective unconscious' which is made up of many archetypes or 'congenital conditions of intuition'.

jungle popular name for rainforest.

juniper any of a group of aromatic evergreen trees or shrubs of the cypress family, found throughout temperate regions. Its berries are used to flavour gin. Some junipers are mistakenly called cedars. (Genus *Juniperus*, family Cupressaceae.)

junk DNA another name for intron, a region of DNA that contains no genetic information.

Jupiter the fifth planet from the Sun, and the largest in the Solar System, with a mass equal to 70% of all the other planets combined, 318 times that of Earth's. It is largely composed of hydrogen and helium, liquefied by pressure in its interior, and probably with a rocky core larger than Earth. Its main feature is the Great Red Spot, a cloud of rising gases, 14,000 km/8,500 mi wide and 30,000 km/20,000 mi long, revolving anticlockwise.

mean distance from the Sun 778 million km/484 million mi

equatorial diameter 142,800 km/88,700 mi

rotation period 9 hr 51 min

year (complete orbit) 11.86 Earth years

atmosphere consists of clouds of white ammonia crystals, drawn out into belts by the planet's high speed of rotation (the fastest of any planet). Darker orange and brown clouds at lower levels may contain sulphur, as well as simple organic compounds. Further down still, temperatures are warm, a result of heat left over from Jupiter's formation, and it is this heat that drives the turbulent weather patterns of the planet.

surface although largely composed of hydrogen and helium, Jupiter probably has a rocky core larger than Earth.

In 1995, the *Galileo* probe revealed Jupiter's atmosphere to consist of 0.2% water, less than previously estimated.

satellites Jupiter has 16 moons. The four largest moons, Io, Europa (which is the size of our Moon), Ganymede, and Callisto, are the Galilean satellites, discovered 1610 by Galileo (Ganymede, which is about the size of Mercury, is the largest moon in the Solar System). Three small moons were discovered 1979 by the Voyager space probes, as was a faint ring of dust around Jupiter's equator 55,000 km/34,000 mi above the cloud tops.

The Great Red Spot was first observed in 1664. Its top is higher than the surrounding clouds; its colour is thought to be due to red phosphorus. Jupiter's strong magnetic field gives rise to a large surrounding magnetic 'shell', or magnetosphere, from which bursts of radio waves are detected. The Southern Equatorial Belt in which the Great Red Spot occurs is subject to unexplained fluctuation. In 1989 it sustained a dramatic and sudden fading.

Comet Shoemaker-Levy 9 crashed into Jupiter July 1994. Impact zones were visible but are not likely to remain.

Jurassic period of geological time 208–146 million years ago; the middle period of the Mesozoic era. Climates worldwide were equable, creating forests of conifers and ferns; dinosaurs were abundant, birds evolved, and limestones and iron ores were deposited.

The name comes from the Jura Mountains in France and Switzerland, where the rocks formed during this period were first studied.

jute fibre obtained from two plants of the linden family: *C. capsularis* and *C. olitorius*. Jute is used for sacks and sacking, upholstery, webbing (woven strips used to support upholstery), string, and stage canvas. (Genus *Corchorus*, family Tiliaceae.)

In the production of bulk packaging and tufted carpet backing, jute is now often replaced by synthetic polypropylene. The world's largest producer of jute is Bangladesh.

K

k symbol for kilo-, as in kg (kilogram) and km (kilometre).

K abbreviation for thousand, as in a salary of £30K.

K symbol for kelvin, a scale of temperature.

KA9Q in computing, TCP/IP protocol named after the call sign of Philip Karn, the radio ham who wrote it for packet radio. The system proved also to be useable on telephone connections, and so was adopted to several other computer platforms. It formed the basis of connections to the Demon Internet for many years.

Kagoshima Space Centre headquarters of Japan's Institute of Space and Astronautical Science (ISAS), situated in S Kyushu Island.

ISAS is responsible for the development of satellites for scientific research; other aspects of the space programme fall under the National Space Development Agency which runs the Tanegashima Space Centre. Japan's first satellite was launched from Kagoshima 1970. By 1988 ISAS had launched 17 satellites and space probes.

kagu crested bird found in New Caledonia in the S Pacific. About 50 cm/1.6 ft long, it is virtually flightless and nests on the ground. The introduction of cats and dogs has endangered its survival. (Species *Rhynchoceros jubatus*, order Gruiformes.)

kakapo nocturnal flightless parrot that lives in burrows in New Zealand. It is green, yellow, and brown with a disc of brown feathers round its eyes, like an owl. It weighs up to 3.5 kg/7.5 lb. When in danger, its main defence is to remain perfectly still. Because of the introduction of predators such as dogs, cats, rats, and ferrets, it is in danger of extinction; in 1997 there were only about 40 birds left. (Species *Strigops habroptilus*, order Psittaciformes.)

kale type of cabbage.

kaleidoscope optical toy invented by the British physicist David Brewster in 1816. It usually consists of a pair of long mirrors at an angle to each other, and arranged inside a triangular tube containing pieces of coloured glass, paper, or plastic. An axially symmetrical (hexagonal) pattern is seen by looking along the tube, which can be varied infinitely by rotating or shaking the tube.

kangaroo any of a group of marsupials (mammals that carry their young in pouches) found in Australia, Tasmania, and New Guinea. Kangaroos are plant-eaters and most live in groups. They are adapted to hopping, the vast majority of species having very large, powerful back legs and feet compared with the small forelimbs. The larger types can jump 9 m/30 ft in a single bound. Most are nocturnal. Species vary from small rat kangaroos, only 30 cm/1 ft long, through the medium-sized wallabies, to the large red and great grey kangaroos, which are the largest living marsupials.

KANGAROO

A fully grown kangaroo can jump 13 m/14 yd.

Mathematical calculations have shown that at speeds of over 29 kmph/18 mph, bouncing is a more energy-efficient way of moving for a kangaroo than running would be.

These may be 1.8 m/5.9 ft long with 1.1 m/3.5 ft tails. (Family Macropodidae.)

In New Guinea and N Queensland, tree kangaroos (genus *Dendrolagus*) occur. These have comparatively short hind limbs. The great grey kangaroo (*Macropus giganteus*) produces a single young ('joey') about 2 cm/1 in long after a very short gestation, usually in early summer. At birth the young kangaroo is too young even to suckle. It remains in its mother's pouch, attached to a nipple which squirts milk into its mouth at intervals. It stays in the pouch, with excursions as it matures, for about 280 days.

A new species of kangaroo was discovered 1994 in New Guinea. Local people know it as 'bondegezou'. It weighs 15 kg/33 lb and is 1.2 m/3.9 ft in height. As it shows traits of both arboreal and ground-dwelling species, it may be a 'missing link'.

kangaroo paw bulbous plant *Anigozanthos manglesii*, family Hamenioraceae, with a row of small white flowers emerging from velvety green tubes with red bases. It is the floral emblem of Western Australia.

kaolin group of clay minerals, such as kaolinite, $Al_2Si_2O_5(OH)_4$, derived from the alteration of aluminium silicate minerals, such as feldspars and mica. It is used in medicine to treat digestive upsets, and in poultices.

Kaolinite is economically important in the ceramic and paper industries. It is mined in the UK, the USA, France, and the Czech Republic.

kaolinite white or greyish clay mineral, hydrated aluminium silicate, $Al_2Si_2O_5(OH)_4$, formed mainly by the decomposition of feldspar in granite. China clay (kaolin) is derived from it. It is mined in France, the UK, Germany, China, and the USA.

kapok silky hairs that surround the seeds of certain trees, particularly the kapok tree (*Bombax ceiba*) of India and Malaysia and the silk-cotton tree (*Ceiba pentandra*) of tropical America. Kapok is used for stuffing cushions and mattresses and for sound insulation; oil obtained from the seeds is used in food and soap.

karabash breed of large guard dog developed by the shepherds of Anatolia to protect their flocks. It is strongly built, stands up to 75 cm/29 in, and has a short grey, beige, or brindle coat with black on its muzzle and ears.

Karelian bear dog breed of medium-sized dog, used to protect Russian settlements from bears. About 60 cm/2 ft high, the dog has a black or reddish-brown coat with white markings.

It was not exported until 1989, when some were sent to Yellowstone Park, USA, to keep bears away from tourists.

karri giant eucalyptus tree *Eucalyptus diversifolia*, found in the extreme SW of Australia. It may reach over 120 m/400 ft. Its exceptionally strong timber is used for girders.

karst landscape characterized by remarkable surface and underground forms, created as a result of the action of water on permeable limestone. The feature takes its name from the Karst region on the Adriatic coast in Slovenia and Croatia, but the name is applied to landscapes throughout the world, the most dramatic of which is found near the city of Guilin in the Guangxi province of China.

Limestone is soluble in the weak acid of rainwater. Erosion takes place most swiftly along cracks and joints in the limestone and these open up into gullies called grikes. The rounded blocks left unattended between them are called clints.

karyotype in biology, the set of chromosomes characteristic of a given species. It is described as the number, shape, and size of the chromosomes in a single cell of an organism. In humans for example, the karyotype consists of 46 chromosomes, in mice 40, crayfish 200, and in fruit flies 8.

The diagrammatic representation of a complete chromosome set is called a **karyogram**.

katydid or **bush cricket** or **longhorn grasshopper** one of over 4,000 insect species, most of which are tropical, related to grasshoppers.

Members of this family have very long antennae and they tend to be wingless. The tympanal organs ('ears') are on the forelegs. They may be either plant-eating or carnivorous.

Some species are winged and the left forewing generally overlaps the right one; stridulation is produced by rubbing the forewings together. The winged species are usually green and are found among herbage, bushes, and trees where they often simulate the colour and shape of a leaf. Wingless forms inhabit places at ground-level, such as in the soil or under stones.

classification Katydidids are in the family Tettigoniidae in order Orthoptera, class Insecta, phylum Arthropoda.

kauri pine New Zealand coniferous tree (see *conifer*). Its fossilized gum deposits are valued in varnishes; the wood is used for carving and handicrafts. (*Agathis australis*, family Araucariaceae.)

kava narcotic, intoxicating beverage prepared from the roots or leaves of a variety of pepper plant, *Piper methysticum*, found in the South Pacific islands.

kayser unit of wave number (number of waves in a unit length), used in spectroscopy. It is expressed as waves per centimetre, and is the reciprocal of the wavelength. A wavelength of 0.1 cm has a wave number of 10 kaysers.

kcal symbol for kilocalorie (see *calorie*).

kea hawklike greenish parrot found in New Zealand. It eats insects, fruits, and discarded sheep offal. The Maori name imitates its cry. (Species *Nestor notabilis*, family Psittacidae, order Psittaciformes.)

Keck Telescope world's largest optical telescope, situated on Mauna Kea, Hawaii. It has a primary mirror 10 m/33 ft in diameter, unique in that it consists of 36 hexagonal sections, each controlled and adjusted by a computer to generate single images of the objects observed. It received its first images in 1990.

An identical telescope next to it, named Keck II, became operational in 1996. It weighs 300 tonnes and has a 10-m/33-ft mirror comprised of 36 hexagons. Both telescopes are jointly owned by the California Institute of Technology and the University of California.

keeshond or **Dutch barge dog** sturdily built dog with erect ears and curled tail. It has a long grey top-coat, forming a mane around the neck, and a short, very thick undercoat, with darker 'spectacles' around the eyes. The ideal height is 46 cm/18 in for dogs; 43 cm/17 in for bitches.

keloid in medicine, overgrowth of fibrous tissue, usually produced at the site of a scar. Surgical removal is often unsuccessful, because the keloid returns.

kelp collective name for a group of large brown seaweeds. Kelp is also a term for the powdery ash of burned seaweeds, a source of iodine. (Typical families Fucaceae and Laminariaceae.)

The brown kelp (*Macrocystis pyrifera*), abundant in Antarctic and sub-Antarctic waters, is one of the fastest-growing living things, reaching lengths of up to 100 m/320 ft. It is farmed for the alginate industry, its rapid surface growth allowing cropping several times a year, but it is an unwanted pest in N Atlantic waters.

kelpie breed of small herding dog also known as the Australian sheepdog. Bred from imported collie stock crossed with *dingo*, it is much valued as a working dog. It has a coarse black or dark-coloured coat and is about 50 cm/20 in tall.

Do not imagine that mathematics is hard and crabbed, and repulsive to common sense. It is merely the etheralization of common sense.

WILLIAM KELVIN British physicist.
In S P Thomson *Life of Lord Kelvin* 1910

kelvin scale temperature scale used by scientists. It begins at (absolute zero (-273.15°C) and increases by the same degree intervals as the Celsius scale; that is, 0°C is the same as 273.15 K and 100°C is 373.15 K.

Kelvin, William Thomson, 1st Baron Kelvin (1824-1907)

Irish physicist who introduced the Kelvin scale, the absolute scale of temperature. His work on the conservation of energy in 1851 led to the second law of thermodynamics. Knighted 1866, Baron 1892.

Kelvin's knowledge of electrical theory was largely responsible for the first successful transatlantic telegraph cable. In 1847

he concluded that electrical and magnetic fields are distributed in a manner analogous to the transfer of energy through an elastic solid. From 1849 to 1859, Kelvin also developed the work of English scientist Michael Faraday into a full theory of magnetism, arriving at an expression for the total energy of a system of magnets.

Kepler's laws in astronomy, three laws of planetary motion formulated in 1609 and 1619 by the German mathematician and astronomer Johannes Kepler: (1) the orbit of each planet is an ellipse with the Sun at one of the foci; (2) the radius vector of each planet sweeps out equal areas in equal times; (3) the squares of the periods of the planets are proportional to the cubes of their mean distances from the Sun.

Kepler derived the laws after exhaustive analysis of numerous observations of the planets, especially Mars, made by Tycho *ø*Brahe without telescopic aid. Isaac *ø*Newton later showed that Kepler's Laws were a consequence of the theory of universal gravitation.

kermit in computing, a *ø*file-transfer protocol, originally developed at Columbia University and made available without charge. Kermit is available as part of most communications packages and

Kepler, Johannes (1571–1630)

German mathematician and astronomer. He formulated what are now called Kepler's laws of planetary motion: (1) the orbit of each planet is an ellipse with the Sun at one of the foci; (2) the radius vector of each planet sweeps out equal areas in equal times; (3) the squares of the periods of the planets are proportional to the cubes of their mean distances from the Sun. Kepler's laws are the basis of our understanding of the Solar System, and such scientists as Isaac Newton built on his ideas.

Kepler was one of the first advocates of Sun-centred cosmology, as put forward by Copernicus. Unlike Copernicus and Galileo, Kepler rejected the Greek and medieval belief that orbits must be circular in order to maintain the fabric of the cosmos in a state of perfection.

early work Kepler also produced a calendar of predictions for the year 1595 which proved uncanny in its accuracy. In 1596, he published his *Prodromus dissertationum cosmographicarum seu mysterium cosmographicum* in which he demonstrated that the five Platonic solids (the only five regular polyhedrons) could be fitted

alternately inside a series of spheres to form a 'nest'. The nest described quite accurately (within 5%) the distances of the planets from the Sun. Kepler regarded this discovery as a divine inspiration that revealed the secret of the Universe. Written in accordance with Copernican theories, it brought Kepler to the attention of all European astronomers.

In 1601, Kepler was bequeathed all of Tycho Brahe's data on planetary

motion. He had already made a bet that, given Tycho's unfinished tables, he could find an accurate planetary orbit within a week. It was five years before Kepler obtained his first planetary orbit, that of Mars. His analysis of these data led to the discovery of his three laws. In 1604, his attention was diverted from the planets by his observation of the appearance of a new star, 'Kepler's nova'. Kepler had observed the first supernova visible since the one discovered by Brahe in 1572.

Kepler's laws Kepler's first two laws of planetary motion were published in *Astronomia Nova* 1609. The first law stated that planets travel in elliptical rather than circular, or epicyclic, orbits and that the Sun occupies one of the two foci of the ellipses. The second law established the Sun as the main force governing the orbits of the planets. It stated that the line joining the Sun and a planet traverses equal areas of space in equal periods of time, so that the planets move more quickly when they are nearer the Sun. He also suggested that the Sun itself rotates, a theory that was confirmed using Galileo's observations of sunspots, and he postulated that this established some sort of 'magnetic' interaction between the planets and the Sun, driving them in orbit. This idea, although incorrect, was an important precursor of Newton's gravitational theory.

Kepler's third law was published in *De Harmonices Mundi*. It described in precise mathematical language the link between the distances of the planets from the Sun and their velocities – specifically, that the orbital velocity of a planet is inversely proportional to its distance from the Sun.

Rudolphine Tables and other work Kepler finally completed and published the *Rudolphine Tables* 1627 based on Brahe's observations. These were the first modern astronomical tables, enabling astronomers to calculate the positions of the planets at any time in the past, present or future. The publication also included other vital information, such as a map of the world, a catalogue of stars, and the latest aid to computation, logarithms.

kernel the inner, softer part of a nut, or of a seed within a hard shell.

kerosene thin oil obtained from the distillation of petroleum; a highly refined form is used in jet aircraft fuel. Kerosene is a mixture of hydrocarbons of the paraffin series.

Kerry blue terrier compact and sturdy dog, with a soft, full coat of bluish tone. It is 46 cm/18 in high and weighs 15–17 kg/33–37.4 lb. Its ears lie close to the head and it has a thin tail that is held erect.

kestrel or **windhover** small hawk that breeds in Europe, Asia, and Africa. About 30 cm/1 ft long, the male has a bluish grey head and tail and is light chestnut brown back with black spots on the back and pale with black spots underneath. The female is slightly larger and reddish brown above, with bars; she does not have the bluish grey head. The kestrel hunts mainly by hovering in midair while searching for prey. It feeds on small mammals, insects, frogs, and worms. (Species *Falco tinnunculus*, family Falconidae, order Falconiformes.)

It rarely builds its own nest, but uses those of other birds, such as crows and magpies, or scrapes a hole on a cliff-ledge. It is found all over Europe and Asia and most parts of Africa, and most birds migrate southwards in winter.

The lesser kestrel (*Falco naumanni*) is an inhabitant of southern Europe. The American kestrel or sparrowhawk (*F. sparverius*) is

somewhat smaller, and occurs in most of North America. It is russet, grey, and tan in colour, with the male having more grey on its wings.

ketone member of the group of organic compounds containing the carbonyl group (C=O) bonded to two atoms of carbon (instead of one carbon and one hydrogen as in aldehydes). Ketones are liquids or low-melting-point solids, slightly soluble in water.

An example is propanone (acetone, CH_3COCH_3), used as a solvent.

Kew Gardens popular name for the Royal Botanic Gardens, Kew, Surrey, England. They were founded 1759 by Augusta of Saxe-Coburg (1719–1772), the mother of King George III, as a small garden and passed to the nation by Queen Victoria 1840. By then they had expanded to almost their present size of 149 hectares/368 acres and since 1841 have been open daily to the public. They contain a collection of over 25,000 living plant species and many fine buildings. The gardens are also a centre for botanical research.

key in cryptography, the password needed to both encode and decipher a file. The key performs a sequence of operations on the original data. The recipient of the encoded file will need to apply another key in order to reverse all the operations in the correct order. Current encryption techniques such as Pretty Good Privacy (PGP) make use of a public key and a secret one.

keyboard in computing, an input device resembling a typewriter keyboard, used to enter instructions and data. There are many variations on the layout and labelling of keys. Extra numeric keys may be added, as may special-purpose function keys, whose effects can be defined by programs in the computer.

keyboard A standard 102-key keyboard. As well as providing a QWERTY typing keyboard, the function keys (labelled F1-F12) may be assigned tasks specific to a particular system.

key escrow in public key cryptography, requirement that users store copies of their private keys with the government or other authorities for release to law enforcement officials upon production of the necessary legal documents.

Key escrow was first proposed in the USA, where it was built into the controversial Clipper chip. In 1996, both the USA and the European Union were considering legislation requiring users of strong encryption to escrow their keys to protect law enforcement interests.

key field in computing, a selected field, or portion, of a record that is used to identify that record uniquely; in a file of records it is the field used as the basis for sorting the file. For example, in a file containing details of a bank's customers, the customer account number would probably be used as the key field.

key frame in animation, a frame which was drawn by the user rather than generated by the computer. Animators feed a sequence of key frames into the computer, allowing the program to draw the intervening stages in a process known as **tweening**.

keyhole limpet primitive mollusc with a conical shell resembling that of the common limpet.

The shell is either cleft, as in *Fissurella*, or has a hole at the tip of the shell, as in *Diodora* (the rough keyhole limpet). A siphon is developed from the mantle and projects through this opening as the exhalant exit. Water is drawn over the gills from the forward end.

classification Keyhole limpets are of the superfamily Fissurellacea in subclass Prosobranchia, class Gastropoda, phylum Mollusca.

key-to-disc system or **key-to-tape system** in computing, a system that enables large amounts of data to be entered at a keyboard and transferred directly onto computer-readable discs or tapes.

Such systems are used in batch processing, in which batches of data, prepared in advance, are processed by computer with little or no intervention from the user. The preparation of the data may be controlled by a minicomputer, freeing a larger, mainframe computer for the task of processing.

kg symbol for kilogram.

kiang type of Asiatic wild ass that lives in cold (below -40°C/-40°F in winter), high altitude (above 4,000 m/23,280 ft) deserts. Kiangs may be subspecies of the Asiatic wild ass *Equus hemionus*, or different species *E. kiang*. There are three varieties: southern, western, and eastern. All are endangered and until recently the southern kiang was believed to be extinct.

The southern kiang, found between Sikkim in N India and the Tsangpo River in Tibet, has a shoulder height of 104-114 cm/41-45 in. Only about 100 remain. The western population, which ranges across Pakistan, India, and China, numbers around 1,500 in India; the eastern population is more numerous, with 10,000-30,000 in the protected Arjin Mountain Nature Reserves in China.

kidney in vertebrates, one of a pair of organs responsible for fluid regulation, excretion of waste products, and maintaining the ionic composition of the blood. The kidneys are situated on the rear wall of the abdomen. Each one consists of a number of long tubules; the outer parts filter the aqueous components of blood, and the inner parts selectively reabsorb vital salts, leaving waste products in the remaining fluid (urine), which is passed through the ureter to the bladder.

The action of the kidneys is vital, although if one is removed, the other enlarges to take over its function. A patient with two defective kidneys may continue near-normal life with the aid of a kidney machine or continuous ambulatory peritoneal dialysis (CAPD); or a kidney transplant may be recommended.

kidney machine medical equipment used in dialysis.

killer application a program so good or so compelling to certain potential users that they buy the computer that the program runs on for no other reason than to be able to use that program.

Killer applications are very rare. The most successful was VisiCalc, the first spreadsheet to run on a personal computer (the original Apple II microcomputer). VisiCalc succeeded as a killer application because it provided a unique tool for accountants to manipulate numbers easily without the need for programming skills. Another clear example is PageMaker, the first desktop publishing program, which was responsible for selling the Apple Macintosh to the design and publishing community.

The World Wide Web is the killer application for the Internet: by bringing visual excitement and ease of use to the Internet, it inspired people to buy new computers capable of supporting Web browsers.

kidney Blood enters the kidney through the renal artery. The blood is filtered through the glomeruli to extract the nitrogenous waste products and excess water that make up urine. The urine flows through the ureter to the bladder; the cleaned blood then leaves the kidney via the renal vein.

KILLER WHALES

http://www.seaworld.org/killer_whale/killerwhales.html

Pictures and videos of this sea creature. There is also a lot of detailed biological information concerning, for example, the habitat, behaviour, and communication of killer whales. There are also plenty of activities and ideas to keep younger children entertained.

killer whale or *orca* toothed whale belonging to the dolphin family, found in all seas of the world. It is black on top, white below, and grows up to 9 m/30 ft long. It is the only whale that has been observed to prey on other whales, as well as on seals and seabirds. (Species *Orcinus orca*, family Delphinidae.)

killfile in computing, file specifying material that you do not wish to see when accessing a newsgroup. By entering names, subjects or phrases into a killfile, users can make USENET a more pleasant experience, filtering out tedious threads, offensive subject headings, spamming or contributions from other irritating subscribers.

kiln high-temperature furnace used commercially for drying timber, roasting metal ores, or for making cement, bricks, and pottery. Oil- or gas-fired kilns are used to bake ceramics at up to 1,760°C/3,200°F; electric kilns do not generally reach such high temperatures.

kilo- prefix denoting multiplication by 1,000, as in kilohertz, a unit of frequency equal to 1,000 hertz.

kilobyte (K or KB) in computing, a unit of memory equal to 1,024 bytes. It is sometimes used, less precisely, to mean 1,000 bytes.

In the metric system, the prefix 'kilo-' denotes multiplication by 1,000 (as in kilometre, a unit equal to 1,000 metres). However, computer memory size is based on the binary number system, and the most convenient binary equivalent of 1,000 is 2^{10} , or 1,024.

kilogram SI unit (symbol kg) of mass equal to 1,000 grams (2.24 lb). It is defined as a mass equal to that of the international prototype, a platinum-iridium cylinder held at the International Bureau of Weights and Measures in Sèvres, France.

kilometre unit of length (symbol km) equal to 1,000 metres, equivalent to 3,280.89 ft or 0.6214 (about $\frac{1}{2}$) of a mile.

kilowatt unit (symbol kW) of power equal to 1,000 watts or about 1.34 horsepower.

kilowatt-hour commercial unit of electrical energy (symbol kWh), defined as the work done by a power of 1,000 watts in one hour and equal to 3.6 megajoules. It is used to calculate the cost of electrical energy taken from the domestic supply.

Kimball tag stock-control device commonly used in clothes shops, consisting of a small punched card attached to each item offered for sale. The tag carries information about the item (such as its serial number, price, colour, and size), both in the form of printed details (which can be read by the customer) and as a pattern of small holes. When the item is sold, the tag (or a part of the tag) is removed and kept as a computer-readable record of sales.

kimberlite an igneous rock that is ultramafic (containing very little silica); a type of alkaline peridotite with a porphyritic texture (larger crystals in a fine-grained matrix), containing mica in addition to olivine and other minerals. Kimberlite represents the world's principal source of diamonds.

Kimberlite is found in carrot-shaped pipelike intrusions called **diatremes**, where mobile material from very deep in the Earth's crust has forced itself upwards, expanding in its ascent. The material, brought upwards from near the boundary between crust and mantle, often altered and fragmented, includes diamonds. Diatremes are found principally near Kimberley, South Africa, from which the name of the rock is derived, and in the Yakut area of Siberia, Russia.

kinesis (plural *kineses*) in biology, a nondirectional movement in response to a stimulus; for example, woodlice move faster in drier surroundings. Taxis is a similar pattern of behaviour, but there the response is directional.

kinetic energy the energy of a body resulting from motion. It is contrasted with potential energy.

kinetics the branch of chemistry that investigates the rates of chemical reactions.

kinetics branch of dynamics dealing with the action of forces producing or changing the motion of a body; **kinematics** deals with motion without reference to force or mass.

kinetic theory theory describing the physical properties of matter in terms of the behaviour – principally movement – of its component atoms or molecules. The temperature of a substance is dependent on the velocity of movement of its constituent particles, increased temperature being accompanied by increased movement. A gas consists of rapidly moving atoms or molecules and, according to kinetic theory, it is their continual impact on the walls of the containing vessel that accounts for the pressure of the gas. The slowing of molecular motion as temperature falls, according to kinetic theory, accounts for the physical properties of liquids and solids, culminating in the concept of no molecular motion at absolute zero (0K–273°C).

By making various assumptions about the nature of gas molecules, it is possible to derive from the kinetic theory the various gas laws (such as Δ Avogadro's hypothesis, Δ Boyle's law, and Δ Charles's law).

King Charles spaniel breed of toy dog favoured by King Charles I of England. It has a characteristic domed head and upturned muzzle. It normally weighs less than 6 kg/13 lb. Different varieties are distinguished by the colours of the coat: King Charles (black with red markings); Prince Charles (white and black with red markings); Ruby (chestnut); Blenheim (white with chestnut markings).

king crab or *horseshoe crab* marine arthropod found on the Atlantic coast of North America, and the coasts of Asia. The upper side of the body is entirely covered with a dark, rounded shell, and it has a long spinelike tail. It is up to 60 cm/2 ft long. It is unable to swim, and lays its eggs in the sand at the high-water mark. (Class Arachnida, subclass Xiphosura.)

There were approximately 500,000 *Paralithodes camtschatica* in the Barents Sea at the end of 1996. They were introduced by Russia as a potential food source. Norway claims they are unbalancing the marine ecosystem.

kingcup another name for Δ marsh marigold.

kingdom the primary division in biological classification. At one time, only two kingdoms were recognized: animals and plants. Today most biologists prefer a five-kingdom system, even though it still involves grouping together organisms that are probably unrelated. One widely accepted scheme is as follows: Kingdom Animalia (all multicellular animals); Kingdom Plantae (all plants, including seaweeds and other algae, except blue-green); Kingdom Fungi (all fungi, including the unicellular yeasts, but not slime moulds); Kingdom Protista or Protocista (protozoa, diatoms, dinoflagellates, slime moulds, and various other lower organisms with eukaryotic cells); and Kingdom Monera (all prokaryotes – the bacteria and cyanobacteria, or blue-green algae). The first four of these kingdoms make up the eukaryotes.

When only two kingdoms were recognized, any organism with a rigid cell wall was a plant, and so bacteria and fungi were considered plants, despite their many differences. Other organisms, such as the photosynthetic flagellates (euglenoids), were claimed by both kingdoms. The unsatisfactory nature of the two-kingdom system became evident during the 19th century, and the biologist Ernst Haeckel was among the first to try to reform it. High-power microscopes have revealed more about the structure of cells; it has become clear that there is a fundamental difference between cells without a nucleus (prokaryotes) and those with a nucleus (eukaryotes). However, these differences are larger than those between animals and higher plants, and are unsuitable for use as kingdoms. At present there is no agreement on how many kingdoms there are in the natural world.

Although the five-kingdom system is widely favoured, some schemes have as many as 20.

The idea of man as a dominant animal of the earth whose whole behaviour tends to be dominated by his own desire for dominance gripped me. It seemed to explain almost everything.

MACFARLANE BURNET Australian physician.
Dominant Man; 1911

kingfisher any of a group of heavy-billed birds found near streams, ponds, and coastal areas around the world. The head is exceptionally large, and the long, angular bill is keeled; the tail and wings are relatively short, and the legs very short, with short toes. Kingfishers plunge-dive for fish and aquatic insects. The nest is usually a burrow in a riverbank. (Family Alcedinidae, order Coraciiformes.)

There are 88 species of kingfisher, the largest being the Australian Δ kookaburra. The Alcedinidae are sometimes divided into the subfamilies Daceloninae, Alcedininae, and Cerylinae.

kinkajou Central and South American carnivorous mammal belonging to the raccoon family. Yellowish-brown, with a rounded face and slim body, the kinkajou grows to 55 cm/1.8 ft with a 50 cm/1.6 ft tail, and has short legs with sharp claws. It spends its time in trees and has a prehensile tail, which it uses as an extra limb when moving from branch to branch. It feeds largely on fruit. (Species *Potos flavus*, family Procyonidae.)

kin selection in biology, the idea that Δ truism shown to genetic relatives can be worthwhile, because those relatives share some genes with the individual that is behaving altruistically, and may continue to reproduce. See Δ inclusive fitness.

Alarm-calling in response to predators is an example of a behaviour that may have evolved through kin selection: relatives that are warned of danger can escape and continue to breed, even if the alarm caller is caught.

kiosk in computing, any computer that has been set up to act as an information centre in a public place. Users navigate the display using keyboards or Δ touch screens, but are never allowed to access the computer's operating system. A kiosk in a museum might show an interactive multimedia display, or one in a library might give readers access to catalogues.

Kirchhoff, Gustav Robert (1824–1887)

German physicist who with R W von Bunsen developed spectroscopic analysis in the 1850s and showed that all elements, heated to incandescence, have their individual spectra. In 1845 he derived the laws now known as Kirchhoff's laws that determine the value of the electric current and potential at any point in a network.

Mary Evans Picture Library

Kirchhoff's laws two laws governing electric circuits devised by the German physicist Gustav Kirchhoff. Kirchhoff's first law states that the total current entering any junction in a circuit is the same as the total current leaving it. This is an expression of the conservation of electric charge. Kirchhoff's second law states that the sum of the potential drops across each resistance in any closed loop in a circuit is equal to the total electromotive force acting in that loop. The laws are equally applicable to DC and AC circuits.

Kirkwood gaps in astronomy, regions of the Δ steroid belt, between Δ Mars, and Δ Jupiter, where there are relatively few asteroids.

The orbital periods of particles in the gaps correspond to simple fractions, especially $\frac{1}{3}$, $\frac{2}{5}$, and $\frac{1}{2}$, of the orbital period of Jupiter, indicating that they are caused by the gravitational influence of the larger planet. The gaps are named after Daniel Kirkwood, the 19th century US astronomer who first drew attention to them.

kiss of life (artificial ventilation) in first aid, another name for Δ artificial respiration.

kite any of a group of birds of prey found in all parts of the world. Kites have long, pointed wings and, usually, a forked tail. There are about 20 species. (Family Accipitridae, order Falconiformes.)

kite quadrilateral with two pairs of adjacent equal sides. The geometry of this figure follows from the fact that it has one axis of symmetry.

Kitt Peak National Observatory observatory in the Quinlan Mountains near Tucson, Arizona, USA, operated by AURA (Association of Universities for Research in Astronomy). Its main telescopes are the 4-m/158-in Mayall reflector, opened in 1973, and the McMath Solar Telescope, opened in 1962, the world's largest of its type.

Among numerous other telescopes on the site is a 2.3-m/90-in reflector owned by the Steward Observatory of the University of Arizona.

KITT PEAK NATIONAL OBSERVATORY

<http://www.noao.edu/kpno/kpno.html>

Comprehensive information on the range of research carried out at Kitt Peak. In addition to scientific information of interest mainly to professional astronomers, there are details of current weather conditions at Kitts Peak and information for visitors. Visible and infrared images from satellites in geostationary orbits can be accessed.

kiwi flightless bird found only in New Zealand. It has long hairlike brown plumage, minute wings and tail, and a very long beak with nostrils at the tip. It is nocturnal and insectivorous. It lays two white eggs, each weighing up to 450 g/15.75 oz. (Species *Apteryx australis*, family Apterygidae, order Apterygiformes.)

All kiwi species have declined since European settlement of New Zealand, and the little spotted kiwi is most at risk. It survives only on one small island reservation, which was stocked with birds from the mainland.

KIWI

The kiwi produces the largest egg, proportionally to size, of any bird. The female lays one or two eggs, each weighing a quarter of her body weight.

kiwi fruit or *Chinese gooseberry* fruit of a vinelike plant grown commercially on a large scale in New Zealand. Kiwi fruits are egg-sized, oval, and similar in flavour to gooseberries, though much sweeter, with a fuzzy brown skin. (*Actinidia chinensis*, family Actinidiaceae.)

kleptomania Greek *kleptēs* 'thief' behavioural disorder characterized by an overpowering desire to possess articles for which one has no need. In kleptomania, as opposed to ordinary theft, there is no obvious need or use for what is stolen and sometimes the sufferer has no memory of the theft.

kleptoparasitism habitual stealing of food from another organism. Skuas kleptoparasitize other seabirds, forcing them to relinquish their catches midflight. The Spanish slug *Deroceras hilbrandi* takes prey from the insect-eating plant *Pinguicula vulgaris* whilst leaving the edible plant unharmed. Many small spiders are kleptoparasites living on the webs of bigger spiders.

km symbol for kilometre.

knapweed any of several weedy plants belonging to the daisy family. In the common knapweed (*C. nigra*), also known as a hard-head, the hard, dark buds break open at the top into pale purple composite flowers. It is native to Europe and has been introduced to North America. (Genus *Centaurea*, family Compositae.)

knifefish any of a group of fishes in which the body is deep at the front and drawn to a narrow or pointed tail at the rear, the main fin being the well-developed long ventral (stomach) fin that completes the knife-like shape. The ventral fin is rippled for forward or backward movement. Knifefishes produce electrical fields, which they use for navigation. (Genus *Gymnotus* and other allied genera, family Gymnotidae.)

knocking in a spark-ignition petrol engine, a phenomenon that occurs when unburned fuel-air mixture explodes in the combustion chamber before being ignited by the spark. The resulting shock waves produce a metallic knocking sound. Loss of power occurs, which can be prevented by reducing the compression ratio, redesigning the geometry of the combustion chamber, or increasing the octane number of the petrol (usually by the use of tetraethyl lead anti-knock additives, or increasingly by MTBE - methyl tertiary butyl ether in unleaded petrol).

Knossos chief city of Minoan Crete, near present-day Iraklion, 6 km/4 mi SE of Candia. The archaeological site, excavated by Arthur Evans 1899-1935, dates from about 2000-1400 BC, and includes the palace throne room, the remains of frescoes, and construction on more than one level.

Excavation of the palace of the legendary King Minos showed that the story of Theseus' encounter with the Minotaur in a labyrinth was possibly derived from the ritual 'bull-leaping' by young people depicted in the palace frescoes and from the maze-like layout of the palace.

knot wading bird belonging to the sandpiper family. It is about 25 cm/10 in long, with a short bill, neck, and legs. In the winter, it is grey above and white below, but in the breeding season, it is brick-red on the head and chest and black on the wings and back. It feeds on insects and molluscs. (Species *Calidris canutus*, family Scolopacidae, order Charadriiformes.)

Breeding in North America, European, and Asian arctic regions, knots travel widely in winter, to be found as far south as South Africa, Australasia, and southern parts of South America.

knot in navigation, unit by which a ship's speed is measured, equivalent to one nautical mile per hour (one knot equals about 1.15 miles per hour). It is also sometimes used in aviation.

knotgrass annual plant belonging to the dock family. The bases of the small lance-shaped leaves enclose the slender stems, giving a superficial resemblance to grass. Small pinkish flowers are followed by seeds that are eaten by birds. Knotgrass grows worldwide except in the polar regions. (*Polygonum articulatum*, family Polygonaceae.)

knowbot in computing, a program that will search a system or a network, such as the Internet, seeking and retrieving information on behalf of a user and reporting back when it has found it. An example is the Knowbot Information Service, which can process users' queries by e-mail.

knowledge-based system (KBS) computer program that uses an encoding of human knowledge to help solve problems. It was discovered during research into artificial intelligence that adding heuristics (rules of thumb) enabled programs to tackle problems that were otherwise difficult to solve by the usual techniques of computer science.

Cheess-playing programs have been strengthened by including knowledge of what makes a good position, or of overall strategies, rather than relying solely on the computer's ability to calculate variations.

koala marsupial (mammal that carries its young in a pouch) found only in E Australia. It feeds almost entirely on eucalyptus shoots. It is about 60 cm/2 ft long, and resembles a bear (it is often incorrectly described as a 'koala bear'). The popularity of its greyish fur led to its almost complete extermination by hunters. Under protection since 1936, it rapidly increased in numbers, but recently numbers have fallen from 400,000 in 1985 to 40,000-80,000 in 1995. (Species *Phascolarctos cinereus*, family Phalangeridae.)

A three-year trial began in November 1996 in southern Australia, overpopulated by koalas, to bring their numbers under control by giving males vasectomies and females hormone implants preventing ovulation. In 1997, the programme of sterilization continued, and a relocation plan, following earlier trials, began.

KOALA

The fingerprints of koala bears are very similar to those of humans, with similar whorls, loop and arches. To avoid any confusion, Australian forensic scientists were warned, in 1996, to watch out for koalas at the scene of the crime.

Koch, (Heinrich Hermann) Robert (1843–1910)

German bacteriologist. Koch and his assistants devised the techniques for culturing bacteria outside the body, and formulated the rules for showing whether or not a bacterium is the cause of a disease. Nobel Prize for Physiology or Medicine 1905.

His techniques enabled him to identify the bacteria responsible for tuberculosis (1882), cholera (1883), and other diseases. He investigated anthrax bacteria in the 1870s and showed that they form spores which spread the infection.

Koch was a great teacher, and many of his pupils, such as Shibasaburo Kitasato, Paul Ehrlich, and Emil von Behring, became outstanding scientists.

kohlrabi variety of kale, which is itself a variety of cabbage; it is used for food and resembles a turnip. The leaves of kohlrabi shoot from a round swelling on the main stem. (*Brassica oleracea caulorapa* or *B. oleracea gongylodes*, family Cruciferae.)

kola alternative spelling of *cola*, any of a group of tropical trees.

komondor breed of large herding dog originating in Hungary. It has a long, heavy, all-white coat with a rough 'corded' texture. Larger than the rather similar *çpuli*, it stands about 80 cm/31.5 in tall.

Königsberg bridge problem long-standing puzzle that was solved by topology (the geometry of those properties of a figure which remain the same under distortion). In the city of Königsberg (now Kaliningrad in Russia), seven bridges connect the banks of the river Pregol'a and the islands in the river. For many years, people were challenged to cross each of the bridges in a single tour and return to their starting point. In 1736 Swiss mathematician Leonhard Euler converted the puzzle into a topological network, in which the islands and river banks were represented as nodes (junctions), and the connecting bridges as lines. By analysing this network he was able to show that it is not traversable – that is, it is impossible to cross each of the bridges once only and return to the point at which one started.

kookaburra or *laughing jackass* largest of the world's *çkingfishers*, found in Australia, with an extraordinary laughing call. It feeds on insects and other small creatures. The body and tail measure 45 cm/18 in, the head is greyish with a dark eye stripe, and the back and wings are flecked brown with grey underparts. It nests in shady forest regions, but will also frequent the vicinity of houses, and its cry is one of the most familiar sounds of the bush in E. Australia. (Species *Dacelo novaeguineae*, family Alcedinidae, order Coraciiformes.)

Koonalda Cave cave in SW South Australia below the Nullarbor Plain. Anthropologists in the 1950s and 1960s discovered evidence of flint-quarrying and human markings that have been dated as 20,000 years old.

Korat breed of domestic shorthaired cat. It derives its name from the NE province of Korat in Thailand where it originated. It has a blue-grey coat with a silvery sheen with very thick fur.

It has a heart-shaped face with green eyes, and a lithe body.

Imported into the USA 1959, the breed was recognized there 1966, and in the UK in 1975.

kouprey wild ox native to the forests of N Cambodia. Only known to science since 1937, it is in great danger of extinction. Koupreys have cylindrical, widely separated horns and grow to 1.9 m/6 ft in height. (Species *Bos sauveli*.)

Kourou second-largest town of French Guiana, NW of Cayenne, site of the Guiana Space Centre of the European Space Agency; population (1996) 20,000 (20% of the total population of French Guiana).

Kow Swamp area in N Victoria, Australia, W of the town of Echuca, where the remains of about 40 humans have been found, buried in shallow graves. These bones have mostly been dated as 9,000–14,000 years old and were accompanied by human artefacts and objects such as shells. They are of a larger and more robust group of humans than those found from an earlier period at Lake Mungo and are similar to other finds from widely scattered sites in Australia such as Talgai in Queensland.

kph or *km/h* symbol for kilometres per hour.

krait highly venomous Indian snake related to the *cobra*.

Krebs, Hans Adolf (1900–1981)

German-born British biochemist. He discovered the citric acid cycle, also known as the *çKrebs cycle*, the final pathway by which food molecules are converted into energy in living tissues. For this work he shared the 1953 Nobel Prize for Physiology or Medicine. Knighted 1958.

Krebs first became interested in the process by which the body degrades amino acids. He discovered that nitrogen atoms are the first to be removed (deamination) and are then excreted as urea in the urine. He then investigated the processes involved in the production of urea from the removed nitrogen atoms, and by 1932 he had worked out the basic steps in the urea cycle.

Krebs cycle The purpose of the Krebs (or citric acid) cycle is to complete the biochemical breakdown of food to produce energy-rich molecules, which the organism can use to fuel work. Acetyl coenzyme A (acetyl CoA) – produced by the breakdown of sugars, fatty acids, and some amino acids – reacts with oxaloacetic acid to produce citric acid, which is then converted in a series of enzyme-catalysed steps back to oxaloacetic acid. In the process, molecules of carbon dioxide and water are given off, and the precursors of the energy-rich molecules ATP are formed. (The numbers in the diagram indicate the number of carbon atoms in the principal compounds.)

Krebs cycle or *citric acid cycle* or *tricarboxylic acid cycle* final part of the chain of biochemical reactions by which organisms break down food using oxygen to release energy (respiration). It takes place within structures called mitochondria in the body's cells, and breaks down food molecules in a series of small steps, producing energy-rich molecules of Δ ATP.

krill any of several Antarctic crustaceans, the most common species being *Euphausia superba*. Similar to a shrimp, it is up to 5 cm/2 in long, with two antennae, five pairs of legs, seven pairs of light organs along the body, and is coloured orange above and green beneath. It is the most abundant animal, numbering perhaps 600 trillion (million million). (Order Euphausiacea.)

Moving in enormous swarms, krill constitute the chief food of the baleen whales, and have been used to produce a protein concentrate for human consumption, and meal for animal feed.

KRILL

Approximately 600 trillion krill thrive in the Southern Ocean. Together they weigh more than the world's entire human population. The schools of shrimplike krill (moving at a rapid 20 cm/7.9 in per sec) form the base of many food chains; whales alone consume 150 million tonnes a year.

krypton Greek *kryptos* 'hidden' colourless, odourless, gaseous, nonmetallic element, symbol Kr, atomic number 36, relative atomic mass 83.80. It is grouped with the inert gases and was long believed not to enter into reactions, but it is now known to combine with fluorine under certain conditions; it remains inert to all other

reagents. It is present in very small quantities in the air (about 114 parts per million). It is used chiefly in fluorescent lamps, lasers, and gas-filled electronic valves.

Krypton was discovered in 1898 in the residue from liquid air by British chemists William Ramsay and Morris Travers; the name refers to their difficulty in isolating it.

K-T boundary geologists' shorthand for the boundary between the rocks of the Cretaceous and the Tertiary periods 65 million years ago. It coincides with the end of the extinction of the dinosaurs and in many places is marked by a layer of clay or rock enriched in the element iridium. Extinction of the dinosaurs at the K-T boundary and deposition of the iridium layer are thought to be the result of either impact of a meteorite (or comet) that crashed into the Yucatán Peninsula (forming the Chicxulub crater) or the result of intense volcanism on the continent of India.

kudu either of two species of African antelope. The greater kudu (*T. strepsiceros*) is fawn-coloured with thin white vertical stripes, and stands 1.3 m/4.2 ft at the shoulder, with head and body 2.4 m/8 ft long. Males have long spiral horns. The greater kudu is found in bush country from Angola to Ethiopia. The similar lesser kudu (*T. imberbis*) lives in E Africa and is 1 m/3 ft at the shoulder. (Genus *Tragelaphus*, family Bovidae.)

kudzu Japanese creeper belonging to the legume family, which helps fix nitrogen (see nitrogen cycle) and can be used as a feed crop for animals, but became a pest in the southern USA when introduced to check soil erosion. (*Pueraria lobata*, family Leguminosae.)

Kuiper belt ring of small, icy bodies orbiting the Sun beyond the outermost planet. The Kuiper belt, named after US astronomer Gerard Kuiper who proposed its existence in 1951, is thought to be the source of comets that orbit the Sun with periods of less than 200 years. The first member of the Kuiper belt was seen in 1992. In 1995 the first comet-sized objects were discovered; previously the only objects found had diameters of at least 100 km/63 mi (comets generally have diameters of less than 10 km/6.3 mi).

Two new objects were discovered in the Kuiper belt in 1996. The first, 1996 TL66, is 500 km/300 mi in diameter and has an irregular orbit that takes it four-six times further from the Sun than Neptune. The second, 1996 RQ20, is slightly smaller, with an orbit that takes it about three times further from the Sun than Neptune. The orbits of both are at an angle of 20° to the plane of the Solar System.

kumquat small orange-yellow fruit of any of several evergreen trees native to E Asia and cultivated throughout the tropics. The trees grow 2.4–3.6 m/8–12 ft high and have dark green shiny leaves and white scented flowers. The fruit is eaten fresh (the skin is edible), preserved, or candied. The oval or Nagami kumquat is the most common variety. (Genus *Fortunella*, family Rutaceae.)

What killed the dinosaurs?

BY EDWARD YOUNG

Sixty-five million years ago dinosaurs disappeared. With them went 70% of all species of the time. This 'mass extinction', one of many such events throughout Earth's history, marks the end of the Cretaceous period and the beginning of the Tertiary period, an interval of geological time known as the K-T boundary (K for Kreide, German for Cretaceous). What killed the dinosaurs? Two rival hypotheses dominate. One is that a huge asteroid or comet collided with Earth during K-T time, the other, is that voluminous volcanism in what is now western India was responsible. Distinguishing between these two hypotheses has proven difficult. In either case, the possible link between these events and the demise of the dinosaurs is forcing scientists to reexamine the role of catastrophe in Earth's history.

From Catastrophism to Uniformitarianism

Geology arose as a modern scientific discipline in the early 19th century with the fall of catastrophism, the notion that the history of our planet was shaped by successive catastrophic events and the rise of uniformitarianism, which holds that every-day processes, operating however slowly, are sufficient to explain the principle features of Earth's history.

Naturalists of the late 18th century understood that fossil marine animals and the sedimentary rock in which they were found represented ancient sea floors. But the vast accumulations of fossil-bearing rock revealed in the sides of mountains posed a time problem. The Earth is just 6,000 years old, it was believed, and any casual observer of the oceans could see that sediment did not accumulate fast enough to yield kilometre thicknesses of marine sediment (later turned to rock) unless normal processes were somehow accelerated by cataclysmic events. The great flood described in the Old Testament of the Bible was one catastrophe commonly invoked. Catastrophic upheavals were also called upon to explain mountains.

Near the end of the 18th century a Scottish scientist named James Hutton reasoned that all of the Earth's geological features could be explained by the slow and unchanging forces operating all around us if the Earth was very much older than had been previously imagined. This new view, uniformitarianism, proved immensely successful in explaining geological observations, though not at first. Several decades later another Scot, Charles Lyell, refined and popularized Hutton's uniformitarianism. Lyell emphasized that human kind had existed for sufficient time as to bear witness to all kinds of processes that affect Earth history. Hutton and Lyell imagined Earth where the past looked much like the present, with no beginning nor an end. But it was their principle of uniformitarianism that allowed Charles Darwin to conceive of the evolution of species by natural selection and show that Earth's inhabitants at least, had changes irrevocably over geological time.

Without uniformitarianism there could have been no modern geology and no Darwinian theory of evolution and geologists have been understandably reluctant to dismiss the premise that 'the present is the key to the past'.

The new catastrophism

Was Lyell right? Have human beings actually witnessed all of the important agents of Earth change? Since the early years of uniformitarianism we have learned that Earth is 4.5 billion years old and that our Solar System formed from the collapse of a fragment of molecular interstellar cloud approximately 4.6 billion years ago. Human history spans a mere one tenth of one thousandth of this interval and we would have been fortunate indeed if our existence had coincided with all of the forces that periodically effect our planet over millions and even billions of years. Therefore the most likely answer to the question: was Lyell right? must be no. Meteorite impact or volcanism on a massive

scale may have killed off the dinosaurs. But both of these events, as it turns out, are normal in the course of the evolution of our planet. Should they be considered catastrophes in the context of Earth history?

In July of 1994 comet Shoemaker-Levy 9 collided with Jupiter. The impact was a catastrophe (for Jupiter) the like of which we have not seen before. Despite the fact that this event was unique in terms of human experiences, such colossal collisions are business-as-usual in astronomical terms. Numerous impact craters scar the rocky surfaces of most bodies in our solar system. These craters reveal that prior to 3.8 billion years ago, planets were routinely bombarded by meter to kilometre-sized objects. The collisions constituted the final stages of rocky accretion as the planets swept up the debris from which they were made. After 3.8 billion years accretion was essentially complete and impacts upon the planets became less frequent, but as Shoemaker-Levy 9 reminded us, they have not ceased entirely.

Impact structures dating back to the time of frequent bombardment have been destroyed on Earth by erosion and tectonic processes that constantly deform and make over the crust. Nonetheless, scientists have thus far managed to identify more than 100 younger impact craters on Earth. It is estimated that, on average, asteroids or comets measuring 5 to 10 kilometres in diameter impact our planet every 50 to 100 million years. Kilometre-sized bodies are thought to hit roughly every million years. Objects in the order of 50 meters in diameter strike about once every 1000 years. For comparison, Shoemaker-Levy 9 was composed of several objects ranging from one to several kilometres in size, their collision with Jupiter released more energy than all of the nuclear weapons on Earth combined.

At present 150 asteroids are known to pass within one Earth orbit of the Sun. They range in size from a few meters to 8 kilometres. A working group under the auspices of the United States National Aeronautics and Space Administration (NASA) suggests that there may be 2100 such bodies in all. The impact of a single asteroid of 2 or more kilometres would have enough energy to profoundly affect Earth's biosphere, hydrosphere, and atmosphere. Fortunately, the likelihood of a collision of severe consequence in the next few hundred years is remote.

Not all catastrophes arrive from space. In 1783, just as catastrophism was about to give way to uniformitarianism, the Laki volcano erupted on Iceland. Unusually harsh winter conditions ensued in North America and Europe. Sulphuric acid rain destroyed Iceland's crops and livestock. Several events of comparable magnitude have confirmed that volcanic eruptions can bring about changes in climate. Have human's experienced the full extent of the influence of volcanism on Earth history? The geological record suggests probably not.

The impact hypothesis

In 1980, physicist and Nobel Prize laureate Luis W. Alvarez and his colleagues Walter Alvarez, Frank Asaro and Helen V. Michel suggested that the K-T mass extinction resulted from the impact of an asteroid or comet (the term bolide describes an impactor of any sort). A bolide greater than 10 kilometres in diameter and travelling 10 kilometres per second, they submitted, would liberate enough energy to trigger environmental disaster across the globe. The Earth would be plunged into months of darkness as the dust propelled into the air by the collision blocked the Sun's rays.

Photosynthesis would cease and plant-eating animals would be deprived of food, touching off a breakdown in the food chain. Temperatures would fall and as the shroud of dust prevented the Sun from warming Earth's surface, a phenomenon referred to as 'impact winter'. While land-dwelling animals were fighting starvation and the cold, marine creatures would have to battle

acidification of the oceans; aerosols of debris and chemical reactions triggered by an atmospheric shock wave would result in nitric and sulphuric acid rain on a grand scale.

Alvarez and coworkers made their proposal on the basis of an unusual enrichment of the rare element iridium in a layer of clay marking the K-T boundary in Italy. Iridium, chemically similar to platinum and gold, is rare on Earth but much more abundant in primitive rocky meteorites. Since their original report, the 'iridium anomaly', as it has come to be known, has since been found in rocks and sediments deposited at the K-T boundary around the world. There is other evidence supportive of an impact. Ratios of the isotope of the element osmium, a platinum-group element like iridium, from some K-T samples are similar to primitive meteorites. Large amounts of soot in K-T boundary clay is thought to have come from large-scale burning of vegetation ignited by debris ejected from the atmosphere that fell back to earth like a hail of red-hot meteors. Quartz grains shocked by pressures exceeding one hundred thousand atmospheres have been found in K-T deposits. Previously, shocked quartz had only been found at impact craters (Arizona's Meteor Crater for example) or sites where underground nuclear weapons were tested.

In 1991 a circular impact structure of K-T age was found buried beneath one kilometre of Tertiary carbonate rock in Mexico's Yucatan peninsula. The structure is referred to as the Chicxulub crater after the nearby town of Chicxulub Puerto. Experts agree that Chicxulub is the most spectacular crater on Earth and is the best candidate for the K-T impact site envisioned by Alvarez and coworkers. There are only two other impact structures of comparably large size and they are about 2 billion years old and poorly preserved. The precise size of Chicxulub has been debated. Estimates range from 180 to 300 kilometres in diameter. Most recent studies indicate that the hole upon impact was approximately 120 kilometres wide.

Despite its obvious attraction, the impact hypothesis is not without problems. Paleontologists find evidence that the K-T extinction was not instantaneous and may have begun up to a million years before K-T time and continued for tens of thousands of years after. Shocked quartz and even the iridium anomaly are found to occur just above and below the K-T sediment. Disastrous environmental conditions that would have besieged the Earth after impact of a large bolide should have lasted about a decade and so none of these observations is easily explained by the crash of a single asteroid or comet. To redress this apparent short-coming of the hypothesis, some proponents have argued that more than one bolide struck Earth at about K-T time.

The volcanism hypothesis

Another competing catastrophe theory has been put forward to explain not only the chemical and physical features of the K-T boundary but are also the protracted nature of the mass extinction. Beginning in the 1970s it was observed that the largest episode of volcanism in the past 200 million years coincided with the K-T mass extinction. Remains of this volcanism are exposed today in the Deccan plateau region of western India. Here, vast quantities of basalt (a type of dark volcanic rock) known as the Deccan Traps are

exposed. Combined, the ancient flows are more than two kilometres thick and comprise roughly 3% of the entire Indian continent. Decan volcanism lasted several hundreds of thousands of years and was most active at the time of the K-T mass extinction. American geologist Dewey M. McLean and French geophysicist Vincent Courtillot, among others, argue that it was the voluminous Deccan volcanism that was responsible for the K-T mass extinction. Recall the climatic effects of the Laki eruption? Imagine the effects of continuous large-scale volcanism for hundreds of thousands of years.

The chemical composition of Earth's mantle is more like that of primitive meteorites than the crust. Deccan lavas came from the mantle. Thus instead of being derived from dust thrown up by an asteroid, the iridium anomaly and other chemical signatures of the K-T boundary could be the result of a deluge of volcanic dust. Similarly, shocked quartz, cited as critical evidence for bolide impact, can apparently be formed by eruption of some types of explosive volcanoes.

The environmental effects of large-scale volcanism and bolide impact may be similar. Volcanism, like impact, would loft large amounts of dust high into the atmosphere where it would be transported around the world. As with the impact hypothesis, the Earth might cool as the dust blocked the Sun's rays. Sulphur released by the volcanoes would cause rain to be acidic. Alternatively, McLean has argued that it was carbon dioxide, a greenhouse gas released during volcanism, that was the killer. Large amounts of carbon dioxide released into the atmosphere would have changed the chemistry of the oceans and caused global warming, both of which would be harmful to life.

An unlucky coincidence

New theoretical studies suggest that without a vulnerability to extinction, catastrophe may have little influence on the diversity of living organisms. Mass extinctions occur with a crude 30 million year periodicity. The largest, in which 90% of species disappeared, was at the end of the Palaeozoic era approximately 250 million years ago. Smaller extinctions are more common. Theoreticians have shown recently that a pattern of frequent smaller extinctions and less frequent large extinctions is the inevitable consequence of the dependence of living organisms on one another. The disappearance of an animal's prey, for example, may make the animal less fit for survival. The predator species might then vacate its ecological niche and in turn affect fitness of another species and so it goes until eventually an 'avalanche' of linked extinctions occurs. During an extinction 'avalanche' large numbers of species enter new habitats for which they are not well adapted. Mathematical simulations of such processes show that mass extinction requires the coincidence of both large numbers of vulnerable species due to an extinction avalanche, the result of normal evolutionary change, and an unusual amount of stress caused by an environmental catastrophe. Thus it seems the dinosaurs that lived during the Cretaceous period must have been ripe for expiration. Unfortunately for them, their vulnerability coincided with a particularly unlucky time in Earth's history when volcanism was rampant and a collision of the sort that occurs just once every 50 million years actually happened.

labelled compound or **tagged compound** chemical compound in which a radioactive isotope is substituted for a stable one. The path taken by such a compound through a system can be followed, for example by measuring the radiation emitted.

This powerful and sensitive technique is used in medicine, chemistry, biochemistry, and industry.

labellum lower petal of an orchid flower; it is a different shape from the two lateral petals and gives the orchid its characteristic appearance. The labellum is more elaborate and usually larger than the other petals. It often has distinctive patterning to encourage copollination by insects; sometimes it is extended backwards to form a hollow spur containing nectar.

WIZARD'S LAB

<http://library.advanced.org/11924/>

Lots of fun, accessible science with spoken commentary for all those who love the Internet style of learning. A friendly 'wizard' leads surfers through the various corners of the virtual lab, so that they can learn about such topics as electricity, sound, light, energy, and magnetism. Each presentation concludes with useful summaries, particularly entertaining when given in the wizard's own voice.

There is also a quiz section and a glossary of useful terms.

laboratory room or building equipped for scientific experiments, research, and teaching.

In Europe, private research laboratories have been used since the 16th century, and by the 18th century laboratories were also used for teaching. The German chemist Justus van Liebig established a laboratory 1826 in Giessen, Germany, where he not only instructed his students in the art of experimental chemistry, but also undertook chemical research with them.

A first-rate laboratory is one in which mediocre scientists can produce outstanding work.

Labrador retriever breed of dog. See *Chetriever*.

laburnum any of a group of flowering trees or shrubs belonging to the pea family; the seeds develop in pealike pods but are poisonous. *L. anagyroides*, native to the mountainous parts of central Europe, is often grown as an ornamental tree. The flowers, in long drooping clusters, are bright yellow and appear in early spring; some varieties have purple or reddish flowers. (Genus *Laburnum*, family Leguminosae.)

labyrinthitis inflammation of the part of the inner ear responsible for the sense of balance (the labyrinth). It results in dizziness,

which may then cause nausea and vomiting. It is usually caused by a viral infection of the ear (otitis), which resolves in a few weeks. The nausea and vomiting may respond to anti-emetic drugs.

lac resinous incrustation produced by the female of the lac insect (*Laccifer lacca*), which eventually covers the twigs of trees in India and the Far East. The gathered twigs are known as stick lac, and yield a useful crimson dye; shellac, which is used in varnishes, polishes, and leather dressings, is manufactured commercially by melting the separated resin and spreading it into thin layers or flakes.

laccolith intruded mass of igneous rock that forces apart two strata and forms a round lens-shaped mass many times wider than thick. The overlying layers are often pushed upward to form a dome. A classic development of laccoliths is illustrated in the Henry, La Sal, and Abajo mountains of SE Utah, USA, found on the Colorado plateau.

lacewing any of a group of insects found throughout the world. Lacewings take their name from the intricate veining of their two pairs of semitransparent wings. They have narrow bodies and long thin antennae. The larvae (called aphid lions) are predators, especially on aphids. (Families Hemerobiidae (brown lacewings) and Chrysopidae (green lacewings), order Neuroptera.)

The eggs of the golden-eye lacewing (*Chrysopa aculata*) are laid on the ends of plant stalks.

LACEWING

Green lacewing larvae disguise themselves to find their food. They feed on woolly alder aphids, but the aphids are guarded by ants who milk them for their honeydew. The larvae hoodwink the ants by plucking the white waxy fluff from the aphids and sticking it over themselves. With this disguise, they move among the aphids and eat them without the ants noticing.

lac insect small plant-sucking insect related to scale insects and mealy bugs. The females of most species lack legs and have reduced antennae; their bodies are globular and enclosed within a dense resinous secretion called lac. Lac insects are found mainly in the tropics and subtropics.

classification Lac insects are members of the family Lacciferidae, order Hemiptera (suborder Homoptera), class Insecta, phylum Arthropoda.

A number of species have two generations annually, in which two types of males occur: the first generation includes both winged and wingless males; the second generation is wingless.

Many species used to be of considerable commercial value, as they yielded a dye. However, with the advent of synthetic dyes the demand for lac insects has decreased.

The Indian lac insect, *Laccifer lacca*, produces stick lac, a secretion from which shellac (used in varnishes and polishes) is prepared.

lactation secretion of milk in mammals, from the mammary glands. In late pregnancy, the cells lining the lobules inside the mammary glands begin extracting substances from the blood to produce milk. The supply of milk starts shortly after birth with the production of colostrum, a clear fluid consisting largely of water, protein, antibodies, and vitamins. The production of milk continues practically as long as the baby continues to suckle.

lacteal small vessel responsible for absorbing fat in the small intestine. Occurring in the fingerlike villi of the ileum, lacteals have a milky appearance and drain into the lymphatic system.

Before fat can pass into the lacteal, bile from the liver causes its emulsification into droplets small enough for attack by the enzyme lipase. The products of this digestion form into even smaller droplets, which diffuse into the villi.

Large droplets re-form before entering the lacteal and this causes the milky appearance.

lactic acid or **2-hydroxypropanoic acid** $\text{CH}_3\text{CHOHCOOH}$ organic acid, a colourless, almost odourless liquid, produced by certain bacteria during fermentation and by active muscle cells when they are exercised hard and are experiencing oxygen debt. An accumulation of lactic acid in the muscles may cause cramp. It occurs in yoghurt, buttermilk, sour cream, poor wine, and certain plant extracts, and is used in food preservation and in the preparation of pharmaceuticals.

lactose white sugar, found in solution in milk; it forms 5% of cow's milk. It is commercially prepared from the whey obtained in cheese-making. Like table sugar (sucrose), it is a disaccharide, consisting of two basic sugar units (monosaccharides), in this case, glucose and galactose. Unlike sucrose, it is tasteless.

ladybird or **ladybug** any of various small beetles, generally red or yellow in colour, with black spots. There are more than 5,200 species worldwide. As larvae and adults, they feed on aphids and scale-insect pests. (Family Coccinellidae, order Coleoptera.)

Ladybirds have been used as a form of biological control since the 19th century and the US ladybird harvest was worth an annual \$3–5 million by 1991.

lady's smock another name for the cuckoo flower.

lagging material used for heat insulation; it may be wrapped around hot-water tanks to reduce heat loss, or around water pipes to prevent freezing in winter.

lagoon coastal body of shallow salt water, usually with limited access to the sea. The term is normally used to describe the shallow sea area cut off by a coral reef or barrier islands.

Lagrangian points five locations in space where the centrifugal and gravitational forces of two bodies neutralize each other; a third, less massive body located at any one of these points will be held in equilibrium with respect to the other two. Three of the points, L1–L3, lie on a line joining the two large bodies. The other two points, L4 and L5, which are the most stable, lie on either side of this line. Their existence was predicted in 1772 by French mathematician Joseph Louis Lagrange.

The Trojan asteroids lie at Lagrangian points L4 and L5 in Jupiter's orbit around the Sun. Clouds of dust and debris may lie at the Lagrangian points of the Moon's orbit around the Earth.

lahar mudflow formed of a fluid mixture of water and volcanic ash. During a volcanic eruption, melting ice may combine with ash to form a powerful flow capable of causing great destruction. The lahars created by the eruption of Nevado del Ruiz in Colombia, South America, in 1985 buried 22,000 people in 8 m/26 ft of mud.

lake body of still water lying in depressed ground without direct communication with the sea. Lakes are common in formerly glaciated regions, along the courses of slow rivers, and in low land near the sea. The main classifications are by origin: glacial lakes, formed by glacial scouring; barrier lakes, formed by landslides and glacial moraines; crater lakes, found in volcanoes; and tectonic lakes, occurring in natural fissures.

Crater lakes form in the calderas of extinct volcanoes, for example Crater Lake, Oregon. Subsidence of the roofs of limestone caves in karst landscape exposes the subterranean stream network and provides a cavity in which a lake can develop. Tectonic lakes form during tectonic movement, as when a rift valley is formed. Lake Tanganyika was created in conjunction with the East African Great Rift Valley. Glaciers produce several distinct types of lake, such as the lochs of Scotland and the Great Lakes of North America.

Lakes are mainly freshwater, but salt and bitter lakes are found in areas of low annual rainfall and little surface runoff, so that the rate of evaporation exceeds the rate of inflow, allowing mineral salts to accumulate. The Dead Sea has a salinity of about 250 parts per 1,000 and the Great Salt Lake, Utah, about 220 parts per 1,000. Salinity can also be caused by volcanic gases or fluids, for example Lake Natron, Tanzania.

In the 20th century large artificial lakes have been created in connection with hydroelectric and other works. Some lakes have become polluted as a result of human activity. Sometimes

eutrophication (a state of overnourishment) occurs, when agricultural fertilizers leaching into lakes cause an explosion of aquatic life, which then depletes the lake's oxygen supply until it is no longer able to support life.

lake dwelling or **pile dwelling** prehistoric habitation built on piles driven into the bottom of a lake or at the edge of a lake or river. Such villages are found throughout Europe, in W Africa, South America, Borneo, and New Guinea.

Objects recovered from lake dwellings are often unusually well preserved by the mud or peat in which they are buried. Wooden items, wickerwork, woven fabrics, fruit, and pollen grains have been retrieved.

Lakeland terrier medium-sized wire-haired terrier weighing about 7–8 kg/15.5–17.5 lb with an ideal height of no more than 37 cm/14.5 in. Its skull is moderately broad, with small, V-shaped ears and dark eyes; the body is short and the tail traditionally docked.

Lamarck, Jean Baptiste de (1744–1829)

French naturalist. His theory of evolution, known as Lamarckism, was based on the idea that acquired characteristics (changes acquired in an individual's lifetime) are inherited by the offspring, and that organisms have an intrinsic urge to evolve into better-adapted forms. *Philosophie zoologique* (Zoological Philosophy 1809) outlined his 'transformist' (evolutionary) ideas. *Zoological Philosophy* tried to show that various parts of the body developed because they were necessary, or disappeared because of disuse when variations in the environment caused a change in habit. If these body changes were inherited over many generations, new species would eventually be produced.

Lamarck was the first to distinguish vertebrate from invertebrate animals by the presence of a bony spinal column. He was also the first to establish the crustaceans, arachnids, and annelids among the invertebrates. It was Lamarck who coined the word 'biology'.

Lamarckism theory of evolution, now discredited, advocated during the early 19th century by French naturalist Jean Baptiste Lamarck.

Lamarckism is the theory that acquired characteristics were inherited. It differs from the Darwinian theory of evolution.

lambert unit of luminance (the light shining from a surface), equal to one lumen per square centimetre. In scientific work the candela per square metre is preferred.

lamina in flowering plants (angiosperms), the blade of the leaf on either side of the midrib. The lamina is generally thin and flattened, and is usually the primary organ of photosynthesis. It has a network of veins through which water and nutrients are conducted. More generally, a lamina is any thin, flat plant structure, such as the thallus of many seaweeds.

lammergeier or **bearded vulture** Old World vulture with a wingspan of 2.7 m/9 ft. It ranges over S Europe, N Africa, and Asia, in wild mountainous areas. It feeds on offal and carrion and drops

bones onto rocks to break them and so get at the marrow. (Species *Gypaetus barbatus*, family Accipitridae.)

lamp, electric device designed to convert electrical energy into light energy.

In a filament lamp such as a light bulb an electric current causes heating of a long thin coil of fine high-resistance wire enclosed at low pressure inside a glass bulb. In order to give out a good light the wire must glow white-hot and therefore must be made of a metal, such as tungsten, that has a high melting point. The efficiency of filament lamps is low because most of the electrical energy is converted to heat.

A **fluorescent lamp** uses an electrical discharge or spark inside a gas-filled tube to produce light. The inner surface of the tube is coated with a fluorescent material that converts the ultraviolet light generated by the discharge into visible light. Although a high voltage is needed to start the discharge, these lamps are far more efficient than filament lamps at producing light.

lamprey any of various eel-shaped jawless fishes. A lamprey feeds on other fish by fixing itself by its round mouth to its host and boring into the flesh with its toothed tongue. Lampreys breed in fresh water, and the young live as larvae for about five years before migrating to the sea. (Family Petromyzontidae.)

LAMPREY

King Henry I of England died from eating too many lampreys. Although lampreys always made him feel unwell, he was too fond of them to resist the temptation to eat them in large quantities.

LAN in computing, abbreviation for local area network.

lancelet any of a variety of marine animals about 2.5 cm/1 in long. They have no skull, brain, eyes, heart, vertebral column, centralized brain, or paired limbs, but there is a notochord (a supportive rod) which runs from end to end of the body, a tail, and a number of gill slits. Found in all seas, lancelets burrow in the sand but when disturbed swim freely. (Genus *Amphioxus*, phylum Chordata, subphylum Cephalochordata.)

Taxonomically they are significant since the notochord may be regarded as the precursor of the backbone (spinal column).

Landsat series of satellites used for monitoring the Earth's resources. The first was launched in 1972.

landslide sudden downward movement of a mass of soil or rocks from a cliff or steep slope. Landslides happen when a slope becomes unstable, usually because the base has been undercut or because materials within the mass have become wet and slippery.

A mudflow happens when soil or loose material is soaked so that it no longer adheres to the slope; it forms a tongue of mud that reaches downhill from a semicircular hollow. A slump occurs when the material stays together as a large mass, or several smaller masses, and these may form a tilted step-like structure as they slide. A landslide is formed when beds of rock dipping towards a cliff slide along a lower bed. Earthquakes may precipitate landslides.

langur any of various leaf-eating Old World monkeys that live in trees in S Asia. There are about 20 species. Langurs are related to the colobus monkey of Africa. (Genus *Presbytis* and other related genera.)

lanolin sticky, purified wax obtained from sheep's wool and used in cosmetics, soap, and leather preparation.

lanternfish any of about 300 species of small deep-sea bony fish. They are less than 15 cm/6 in long, with a large mouth, large eyes, and many luminous organs along the underside of the body, the function of which is not understood. They feed on plankton.

classification Lanternfish are in the order Myctophiformes, class Osteichthyes.

slump landslide

landslip landslide

landslide Types of landslide. A mudflow is a tongue of mud that slides downhill. A slump is a fall of a large mass that stays together after the fall. A landslip occurs when beds of rock move along a lower bed.

Lanier, Jaron

US computing innovator who coined the term virtual reality (VR), and set up a small company, VPL Research Inc, to produce the first VR headsets and data gloves. The headsets enabled wearers to experience graphical worlds created by high-powered computers and to 'meet' in virtual spaces. In 1996 he was chief scientist at New Leaf Systems Inc, and visiting scholar at Columbia University's Department of Computer Science and New York University's Tisch School of the Arts. Lanier is also a musician, a composer and a painter.

lantern fly one of a number of mainly tropical fly species, most of which have a narrow head that is drawn out into a long process. In some species this process looks like a lantern. Many lantern flies are large, with wing span up to 15 cm/6 in.

The head process contains a pouchlike diverticulum of the gut. The name lantern fly was originally given to the South American species *Lanternaria phosphorea*.

classification The lantern fly is a member of the family Fulgoroidea, of suborder Homoptera, order Hemiptera, class Insecta, phylum Arthropoda.

langur A grey langur *Presbytis entellus* exhibiting the leaf-eating habits of its kind. This animal is highly adapted to its diet and can digest leaves which are avoided by most other herbivorous mammals. Widespread in India and Sri Lanka, it is often found around human habitations as well as in forests. *Premaphotos Wildlife*

lanthanide any of a series of 15 metallic elements (also known as rare earths) with atomic numbers 57 (lanthanum) to 71 (lutetium).

One of its members, promethium, is radioactive. All occur in nature. Lanthanides are grouped because of their chemical similarities (most are trivalent, but some can be divalent or tetravalent), their properties differing only slightly with atomic number.

Lanthanides were called rare earths originally because they were not widespread and were difficult to identify and separate from their ores by their discoverers. The series is set out in a band in the periodic table of the elements, as are the actinides.

lanthanum Greek *lanthanein* 'to be hidden' soft, silvery, ductile and malleable, metallic element, symbol La, atomic number 57, relative atomic mass 138.91, the first of the lanthanide series. It is used in making alloys. It was named 1839 by Swedish chemist Carl Mosander (1797-1858).

laparoscope in medicine, another name for an endoscope.

laparotomy exploratory surgical procedure involving incision into the abdomen. The use of laparotomy, as of other exploratory surgery, has decreased sharply with advances in medical imaging and the direct-viewing technique known as laparoscopy.

lapis lazuli rock containing the blue mineral lazurite in a matrix of white calcite with small amounts of other minerals. It occurs in silica-poor igneous rocks and metamorphic limestones found in Afghanistan, Siberia, Iran, and Chile. Lapis lazuli was a valuable pigment of the Middle Ages, also used as a gemstone and in inlaying and ornamental work.

Laplink in computing, software that allows intelligent transfer of files between computers. Laplink is a key tool for those managing files across more than one computer, such as a mobile executive who

has both a desktop computer at his office and a laptop for traveling. It is published by US company Traveling Software.

laptop computer portable microcomputer, small enough to be used on the operator's lap. It consists of a single unit, incorporating a keyboard, floppy disc and hard disc drives, and a screen. The screen often forms a lid that folds back in use. It uses a liquid-crystal or gas-plasma display, rather than the bulkier and heavier cathode-ray tubes found in most display terminals. A typical laptop computer measures about 210 x 297 mm/8.3 x 11.7 in (A4), is 5 cm/2 in in depth, and weighs less than 3 kg/6 lb 9 oz.

lapwing bird belonging to the plover family, also known as the green plover and, from its call, as the peewit. Bottle-green above and white below, with a long thin crest and rounded wings, it is about 30 cm/1 ft long. It inhabits moorland in Europe and Asia, making a nest scratched out of the ground, and is also often seen on farmland. (Species *Vanellus vanellus*, family Charadriidae.)

larch any of a group of trees belonging to the pine family. The common larch (*L. decidua*) grows to 40 m/130 ft. It is one of the few conifers to shed its leaves annually. The small needlelike leaves are replaced every year by new bright-green foliage, which later darkens. (Genus *Larix*, family Pinaceae.)

Closely resembling it is the North American tamarack (*L. laricina*), and both are timber trees. The golden larch (*Pseudolarix amabilis*), a native of China, turns golden in autumn.

Large Electron Positron Collider (LEP) the world's largest particle accelerator, in operation from 1989 at the CERN laboratories near Geneva in Switzerland. It occupies a tunnel 3.8 m/12.5 ft wide and 27 km/16.7 mi long, which is buried 180 m/590 ft underground and forms a ring consisting of eight curved and eight straight sections.

In June 1996, LEP resumed operation after a £210 million upgrade. The upgraded machine will be known as LEP2, and can generate collision energy of 161 giga-electron volts.

Electrons and positrons enter the ring after passing through the Super Proton Synchrotron accelerator. They travel in opposite directions around the ring, guided by 3,328 bending magnets and kept within tight beams by 1,272 focusing magnets.

As they pass through the straight sections, the particles are accelerated by a pulse of radio energy. Once sufficient energy is accumulated, the beams are allowed to collide. Four giant detectors are used to study the resulting shower of particles.

In 1989 the LEP was used to measure the mass and lifetime of the Z particle, carrier of the weak nuclear force.

lark any of a group of songbirds found mainly in the Old World, but also in North America. Larks are brownish-tan in colour and usually about 18 cm/7 in long; they nest on the ground in the open. The skylark (*Alauda arvensis*) sings as it rises almost vertically in the air. It is light brown and 18 cm/7 in long. (Family Alaudidae, order Passeriformes.)

larkspur any of several plants included with the delphiniums. (Genus *Delphinium*, family Ranunculaceae.)

larva stage between hatching and adulthood in those species in which the young have a different appearance and way of life from the adults. Examples include tadpoles (frogs) and caterpillars (butterflies and moths). Larvae are typical of the invertebrates, some of which (for example, shrimps) have two or more distinct larval stages. Among vertebrates, it is only the amphibians and some fishes that have a larval stage.

The process whereby the larva changes into another stage, such as a pupa (chrysalis) or adult, is known as metamorphosis.

laryngitis inflammation of the larynx, causing soreness of the throat, a dry cough, and hoarseness. The acute form is due to a virus or other infection, excessive use of the voice, or inhalation of irritating smoke, and may cause the voice to be completely lost. With rest, the inflammation usually subsides in a few days.

larynx in mammals, a cavity at the upper end of the trachea (windpipe) containing the vocal cords. It is stiffened with cartilage and lined with mucous membrane. Amphibians and reptiles have much simpler larynxes, with no vocal cords. Birds have a similar

cavity, called the **syrix**, found lower down the trachea, where it branches to form the bronchi. It is very complex, with well-developed vocal cords.

Las Campanas Observatory site in Chile of the 2.5-m/100-in Du Pont telescope of the Carnegie Institution of Washington, opened 1977.

laser (acronym for *light amplification by stimulated emission of radiation*) device for producing a narrow beam of light, capable of travelling over vast distances without dispersion, and of being focused to give enormous power densities (10^8 watts per cm^2 for high-energy lasers). The laser operates on a principle similar to that of the maser (a high-frequency microwave amplifier or oscillator). The uses of lasers include communications (a laser beam can carry much more information than can radio waves), cutting, drilling, welding, satellite tracking, medical and biological research, and surgery. Sound wave vibrations from the window glass of a room can be picked up by a reflected laser beam. Lasers are also used as entertainment in theatres, concerts, and light shows.

laser material Any substance the majority of whose atoms or molecules can be put into an excited energy state can be used as laser material. Many solid, liquid, and gaseous substances have been used, including synthetic ruby crystal (used for the first extraction of laser light in 1960, and giving a high-power pulsed output) and a helium-neon gas mixture, capable of continuous operation, but at a lower power.

applications Carbon dioxide gas lasers (CO_2 lasers) can produce a beam of 100 watts or more power in the infrared (wavelength 10.6 μm) and this has led to an important commercial application, the cutting of material for suits and dresses in hundreds of thicknesses at a time.

Dye lasers, in which complex organic dyes in solution are the lasing material, can be turned to produce light of any chosen wavelength over a range of a sizeable fraction of the visible spectrum.

laser mass spectroscopy forensic technique whereby a laser beam is used to scan a minute sample of evidence – such as particles of paint or hair. The beam releases a gas of charged ions, each of which can be identified by mass spectroscopy.

laser printer computer printer in which the image to be printed is formed by the action of a laser on a light-sensitive drum, then transferred to paper by means of an electrostatic charge. Laser printers are page printers, printing a complete page at a time. The printed image, which can take the form of text or pictures, is made up of tiny dots, or ink particles. The quality of the image generated depends on the fineness of these dots – most laser printers can print up to 120 dots per cm^2 /300 dots per in across the page.

A typical desktop laser printer can print about 4–20 pages per minute. The first low-cost laser printer suitable for office use appeared in 1984.

laser surgery use of intense light sources to cut, coagulate, or vaporize tissue. Less invasive than normal surgery, it destroys diseased tissue gently and allows quicker, more natural healing. It can be used by way of a flexible endoscope to enable the surgeon to view the diseased area at which the laser needs to be aimed.

Lassa fever acute disease caused by an arenavirus, first detected 1969, and spread by a species of rat found only in W Africa. It is classified as a haemorrhagic fever and characterized by high fever, headache, muscle pain, and internal bleeding. There is no known cure, the survival rate being less than 50%.

lateral line system In fishes, the lateral line system detects water movement. Arranged along a line down the length of the body are two water-filled canals, just under the skin. The canals are open to the outside, and water movements cause water to move in the canals. Nerve endings detect the movements.

La Tène prehistoric settlement at the east end of Lake Neuchâtel, Switzerland, which has given its name to a culture of the Iron Age dating from the 5th century BC to the Roman conquest.

The site was probably the crossing point of a river, no longer in existence, for most of the finds are associated with a wooden structure thought to be a bridge. The richness of metalwork found, in particular the swords and weapons, and a new style of decorative art recognized as the first Celtic art distinguish the culture, but little else changed from the preceding Hallstatt period.

latent heat in physics, the heat absorbed or released by a substance as it changes state (for example, from solid to liquid) at constant temperature and pressure.

lateral line system system of sense organs in fishes and larval amphibians (tadpoles) that detects water movement. It usually consists of a row of interconnected pores on either side of the body that divide into a system of canals across the head.

latex *Latin* 'liquid' fluid of some plants (such as the rubber tree and poppy), an emulsion of resins, proteins, and other organic substances. It is used as the basis for making rubber. The name is also applied to a suspension in water of natural or synthetic rubber (or plastic) particles used in rubber goods, paints, and adhesives.

lathe machine tool, used for turning. The workpiece to be machined, usually wood or metal, is held and rotated while cutting tools are moved against it. Modern lathes are driven by electric motors, which can drive the spindle carrying the workpiece at various speeds.

lathe shape in graphics software, a cross-sectional representation of a symmetrical three-dimensional object. The object's shape can be changed by using a mouse-operated tool, much as a piece of wood can be carved on a lathe.

latifundium *Latin* for 'broad' and 'farm' in ancient Rome, a large agricultural estate designed to make maximum use of cheap labour, whether free workers or slaves.

In present-day Italy, Spain, and South America, the term *latifondo* refers to a large agricultural estate worked by low-paid casual or semiservile labour in the interests of absentee landlords.

latitude and longitude imaginary lines used to locate position on the globe. Lines of latitude are drawn parallel to the Equator, with 0° at the Equator and 90° at the north and south poles. Lines of longitude are drawn at right angles to these, with 0° (the Prime Meridian) passing through Greenwich, England.

The 0-degree line of latitude is defined by Earth's equator, a characteristic definable by astronomical observation. It was determined as early as AD 150 by Egyptian astronomer Ptolemy in his world atlas. The prime meridian, or 0-degree line of longitude, is a matter of convention rather than physics. Prior to the latter half of the 18th century, sailors navigated by referring to their position east or west of any arbitrary meridian. When Nevil Maskelyne (1732–1811), English astronomer and fifth Astronomer Royal, published the *Nautical Almanac* he referred all of his lunar-stellar distance tables to the Greenwich meridian. These tables were relied upon for computing longitudinal position and so the Greenwich meridian became widely accepted.

Chronometers, time keeping devices with sufficient accuracy for longitude determination, invented by English instrument-maker John Harrison (1693–1776) and perfected in 1759, would gradually replace the lunar distance method for navigation, but reliance on the Greenwich meridian persisted because the *Nautical Almanac* was used by sailors to verify their position. The Greenwich meridian was officially adopted as the prime meridian by the International Meridian Conference held in Washington, DC, in 1884.

lattice a network of straight lines.

lattice points the points of intersection of the lines in a lattice.

laudanum alcoholic solution (tincture) of the drug opium. Used formerly as a narcotic and painkiller, it was available in the 19th century from pharmacists on demand in most of Europe and the USA.

laughing gas popular name for nitrous oxide, an anaesthetic.

laughing jackass another name for the *çkookaburra*, an Australian kingfisher.

launch in computing, to start up a program. Many applications contain embedded programs (such as help screens or formatting options), with the result that users may launch programs without being aware they are doing so.

Laurasia northern landmass formed 200 million years ago by the splitting of the single world continent *çPangaea*. (The southern landmass was *çGondwanaland*.) It consisted of what was to become North America, Greenland, Europe, and Asia, and is believed to have broken up about 100 million years ago with the separation of North America from Europe.

laurel any of a group of European evergreen trees with glossy aromatic leaves, yellowish flowers, and black berries. The leaves of sweet bay or poet's laurel (*L. nobilis*) are used in cooking. Several species are cultivated worldwide. (Genus *Laurus*, family Lauraceae.)

laurustinus evergreen shrub belonging to the honeysuckle family, of Mediterranean origin. It has clusters of white flowers in winter. (*Viburnum tinus*, family Caprifoliaceae.)

from magma in that it is molten rock on the surface; **magma** is molten rock below the surface. Lava that is viscous and sticky does not flow far; it forms a steep-sided conical composite volcano. Less viscous lava can flow for long distances and forms a broad flat shield volcano.

The viscosity of lava, and thus the form of volcano they form, depends on silica content, temperature, and degree of solidification upon extrusion. It is often said that viscosity increases with silica content because silica polymerizes, but this rule can be misleading. Lavas having the composition of basalt, which is low in silica content, tend to flow easily and form broad flat volcanoes as in the Hawaiian Islands. But some very silica-rich lavas of rhyolite composition can also flow readily. Lavas that are especially viscous are often of andesite composition and intermediate in silica content. Andesite lavas can therefore give rise to explosive volcanoes like the island of Montserrat, West Indies.

lavender sweet-smelling purple-flowering herb belonging to the mint family, native to W Mediterranean countries. The bushy low-growing species *L. angustifolia* has long, narrow, upright leaves of a silver-green colour. The small flowers, borne on spikes, vary in colour from lilac to deep purple and are covered with small fragrant oil glands. Lavender oil is widely used in pharmacy and perfumes. (Genus *Lavandula*, family Labiatae.)

laver any of several edible purplish-red seaweeds, including purple laver (*P. umbilicalis*). Growing on the shore and in the sea, attached to rocks and stones, laver forms thin, roundish sheets of tissue up to 20 cm/8 in across. It becomes almost black when dry. (Genus *Porphyra*, family Rhodophyceae.)

Lavoisier, Antoine Laurent (1743–1794)

French chemist. He proved that combustion needs only a part of the air, which he called oxygen, thereby destroying the theory of phlogiston (an imaginary 'fire element' released during combustion). With astronomer and mathematician Pierre de Laplace, he showed in 1783 that water is a compound of oxygen and hydrogen. In this way he established the basic rules of chemical combination.

Lavoisier established that organic compounds contain carbon, hydrogen, and oxygen. From quantitative measurements of the changes during breathing, he showed that carbon dioxide and water are normal products of respiration.

law of nature scientific generalization that both explains and predicts physical phenomena; laws of nature are generally assumed to be descriptive of, and applicable to, the world. The three laws of thermodynamics are examples.

However, the first of Isaac Newton's laws of motion discusses the behaviour of a moving body not acted on by a net force, and this neither applies to the world nor describes it, because there are no such bodies. Hence, some philosophers of science have argued that the laws of nature are rules governing scientists' expectations and so are prescriptive rather than descriptive. Others have argued that laws are idealized descriptions to which the world approximates, as triangles on a blackboard approximate to Euclidean triangles.

We have no right to assume that any physical laws exist, or if they have existed up to now, that they will continue to exist in a similar manner in the future.

Lawrence, Ernest O(rlando) (1901–1958)

US physicist. His invention of the cyclotron particle accelerator pioneered the production of artificial radioisotopes and the synthesis of new transuranic elements. Nobel prize 1939.

During World War II, Lawrence was involved with the separation of uranium-235 and plutonium for the development of the atomic bomb, and he organized the Los Alamos Scientific Laboratories at which much of the work on this project was carried out. After the war, he continued as a believer in nuclear weapons and advocated the acceleration of their development.

lawrencium synthesized, radioactive, metallic element, the last of the actinide series, symbol Lr, atomic number 103, relative atomic mass 262. Its only known isotope, Lr-257, has a half-life of 4.3 seconds and was originally synthesized at the University of California at Berkeley in 1961 by bombarding californium with boron nuclei. The original symbol, Lw, was officially changed in 1963.

The element was named after Ernest Lawrence (1901–1958), the US inventor of the cyclotron.

laxative substance used to relieve constipation (infrequent bowel movement). Current medical opinion discourages regular or prolonged use. Regular exercise and a diet high in vegetable fibre are believed to be the best means of preventing and treating constipation.

The confidence and security of a people can be measured by their attitude towards laxatives.

L-dopa chemical, normally produced by the body, which is converted by an enzyme to dopamine in the brain. It is essential for

integrated movement of individual muscle groups.

L-dopa is a left-handed isomer of an amino acid $C_9H_{11}NO_2$. As a treatment, it relieves the rigidity of Parkinson's disease in 60% of sufferers, but may have significant side effects, such as extreme mood changes, hallucinations, and uncontrolled writhing movements. It is often given in combination with other drugs to improve its effectiveness at lower doses.

LDR abbreviation for light-dependent resistor.

leaching process by which substances are washed through or out of the soil. Fertilizers leached out of the soil drain into rivers, lakes, and ponds and cause water pollution. In tropical areas, leaching of the soil after the destruction of forests removes scarce nutrients and can lead to a dramatic loss of soil fertility. The leaching of soluble minerals in soils can lead to the formation of distinct soil horizons as different minerals are deposited at successively lower levels.

lead heavy, soft, malleable, grey, metallic element, symbol Pb (from Latin *plumbum*), atomic number 82, relative atomic mass 207.19. Usually found as an ore (most often in galena), it

occasionally occurs as a free metal (native metal), and is the final stable product of the decay of uranium. Lead is the softest and weakest of the commonly used metals, with a low melting point; it is a poor conductor of electricity and resists acid corrosion. As a cumulative poison, lead enters the body from lead water pipes, lead-based paints, and leaded petrol. (In humans, exposure to lead shortly after birth is associated with impaired mental health between the ages of two and four.) The metal is an effective shield against radiation and is used in batteries, glass, ceramics, and alloys such as pewter and solder.

lead-acid cell type of accumulator (storage battery).

leaded petrol petrol that contains antiknock, a mixture of the chemicals tetraethyl lead and dibromoethane. The lead from the exhaust fumes enters the atmosphere, mostly as simple lead compounds, which are poisonous to the developing nervous systems of children.

lead ore any of several minerals from which lead is extracted. The primary ore is galena or lead sulphide PbS . This is unstable, and on prolonged exposure to the atmosphere it oxidizes into the minerals cerussite PbCO_3 and anglesite PbSO_4 . Lead ores are usually associated with other metals, particularly silver – which can be mined at the same time – and zinc, which can cause problems during smelting.

Most commercial deposits of lead ore are in the form of veins, where hot fluids have leached the ore from cooling igneous masses and deposited it in cracks in the surrounding country rock, and in thermal metamorphic zones, where the heat of igneous intrusions has altered the minerals of surrounding rocks. Lead is mined in over 40 countries, but half of the world's output comes from the USA, Canada, Russia, Kazakhstan, Uzbekistan, Canada, and Australia.

lead(II) oxide or **lead monoxide** PbO yellow or red solid, an amphoteric oxide (one that reacts with both acids and bases). The other oxides of lead are the brown solid lead(IV) oxide (PbO_2) and red lead (Pb_3O_4).

leaf lateral outgrowth on the stem of a plant, and in most species the primary organ of photosynthesis. The chief leaf types are cotyledons (seed leaves), scale leaves (on underground stems), foliage leaves, and bracts (in the axil of which a flower is produced).

Typically leaves are composed of three parts: the sheath or leaf base, the petiole or stalk, and the lamina or blade. The lamina has a network of veins through which water and nutrients are conducted. Structurally the leaf is made up of mesophyll cells surrounded by the epidermis and usually, in addition, a waxy layer, termed the cuticle, which prevents excessive evaporation of water from the leaf tissues by transpiration. The epidermis is interrupted by small pores, or stomata, through which gas exchange between the plant and the atmosphere occurs.

leaf-hopper any of numerous species of plant-sucking insects. They feed on the sap of leaves. Each species feeds on a limited range of plants. (Family Cicadellidae, order Homoptera.)

leaf insect any of various insects about 10 cm/4 in long, with a green, flattened body, remarkable for closely resembling the foliage on which they live. They are most common in SE Asia. (Genus *Phyllium*, order Phasmida.)

Leakey, Richard Erskine Frere (1944–)

Kenyan palaeoanthropologist. In 1972 he discovered at Lake Turkana, Kenya, an apelike skull estimated to be about 2.9 million years old; it had some human characteristics and a brain capacity of 800 cu cm/49 cu in. In 1984 his team found an almost complete skeleton of *Homo erectus* some 1.6 million years old. He is the son of Louis and Mary Leakey.

He was appointed director of the Kenyan Wildlife Service 1988, waging a successful war against poachers and the ivory trade, but was forced to resign 1994 in the face of political interference. In 1995 he co-founded the Kenyan political party Safina (Swahili for Noah's Ark), which aims to clean up Kenya. The party was accused of racism and colonialism by President Daniel arap Moi.

learning theory in psychology, any theory or body of theories about how behaviour in animals and human beings is acquired or modified by experience. Two main theories are classical and operant conditioning.

leased line in computing, permanent dedicated digital telephone link used for round-the-clock connection within a network or between offices. For example, a bank may use leased lines to carry financial data between branches and head office. The infrastructure of the Internet is a network of leased lines that deliver guaranteed bandwidth at a fixed cost, regardless of how much traffic they carry. The enormous economies produced by the heavy use of such lines makes the Net a very cheap method of communication.

least action, principle of in physics, an alternative expression of Newton's laws of motion that states that a particle moving between two points under the influence of a force will follow the path along which its total action is least. Action is a quantity related to the average difference between the kinetic energy and the potential energy of the particle along its path. The principle is only true where no energy is lost from the system; for example an object moving in free fall in a gravitational field. It is closely related to Fermat's principle of least time which governs the path taken by a ray of light.

leather material prepared from the hides and skins of animals, by tanning with vegetable tannins and chromium salts. Leather is a durable and water-resistant material, and is used for bags, shoes, clothing, and upholstery. There are three main stages in the process of converting animal skin into leather: cleaning, tanning, and dressing. Tanning is often a highly polluting process.

The skin, usually cattle hide, is dehydrated after removal to arrest decay. Soaking is necessary before tanning in order to replace the lost water with something that will bind the fibres together. The earliest practice, at least 7,000 years old, was to pound grease into the skin. In about 400 BC the Egyptians began to use vegetable extracts containing tannic acid, a method adopted in medieval Europe. Chemical tanning using mineral salts was introduced in the late 19th century.

Le Chatelier's principle or **Le Chatelier-Braun principle** in science, the principle that if a change in conditions is imposed on a system in equilibrium, the system will react to counteract that change and restore the equilibrium.

First stated in 1884 by French chemist Henri le Chatelier (1850–1936), it has been found to apply widely outside the field of chemistry.

lecithin lipid (fat), containing nitrogen and phosphorus, that forms a vital part of the cell membranes of plant and animal cells. The name is from the Greek *lekithos* 'egg yolk', eggs being a major source of lecithin.

leech any of a group of annelid worms. Leeches live in fresh water, and in tropical countries infest damp forests. As bloodsucking animals they are injurious to people and animals, to whom they attach themselves by means of a strong mouth adapted to sucking. (Class Hirudinea.)

Formerly, the **medicinal leech** (*Hirudo medicinalis*) was used extensively for 'bleeding' for a variety of ills. It is still cultivated as the source of the anticoagulant hirudin.

LEECH

In 1824, five million leeches were exported from France to England for therapeutic use. For centuries, it was believed that virtually all diseases could be at least partly relieved by leeching.

leek onionlike plant belonging to the lily family. The cultivated leek is a variety of the wild species *A. ampeloprasum* of the Mediterranean area and Atlantic islands. The lower leaf parts and white bulb are eaten as a vegetable. (Genus *Allium*, family Liliaceae.)

left-handedness using the left hand more skillfully and in preference to the right hand for most actions. It occurs in about 9% of the population, predominantly males. It is caused by dominance of the right side of the brain.

FAMOUS LEFT-HANDERS

<http://www.indiana.edu/~primate/left.html>

Thorough listing of famous left-handers. Among this list are the last four US Presidents, Joan of Arc, Charlemagne and Queen Victoria. On a more serious note, there are accounts of ordinary people being stigmatised for left-handedness and a plea for greater understanding. There are links to many other left-handedness sites.

left-hand rule in physics, a memory aid used to recall the relative directions of motion, magnetic field, and current in an electric motor. It was devised by English physicist John Fleming. (See *Fleming's rules*).

legacy application in computing, inherited application, usually an old one that runs on a large minicomputer or mainframe, and that may be too important to scrap or too expensive to change. 'Legacy' implies that such applications are valuable and should be looked after. Those who want to be rid of legacy applications use different metaphors, such as 'slum clearance'.

legacy system in computing, old system with which new technology must be compatible.

legionnaires' disease pneumonia-like disease, so called because it was first identified when it broke out at a convention of the American Legion in Philadelphia in 1976. Legionnaires' disease is caused by the bacterium *Legionella pneumophila*, which breeds in warm water (for example, in the cooling towers of air-conditioning systems). It is spread in minute water droplets, which may be inhaled. The disease can be treated successfully with antibiotics, though mortality can be high in elderly patients.

legume plant of the family Leguminosae, which has a pod containing dry seeds. The family includes peas, beans, lentils, clover, and alfalfa (lucerne). Legumes are important in agriculture because of their specialized roots, which have nodules containing bacteria capable of fixing nitrogen from the air and increasing the fertility of the soil. The edible seeds of legumes are called **pulses**.

leishmaniasis any of several parasitic diseases caused by microscopic protozoans of the genus *Leishmania*, identified by William Leishman (1865–1926), and transmitted by sandflies.

It occurs in two main forms: **visceral** (also called kala-azar), in which various internal organs are affected, and **cutaneous**, where the disease is apparent mainly in the skin. Leishmaniasis occurs in the Mediterranean region, Africa, Asia, and Central and South America. There are 12 million cases of leishmaniasis annually.

In 1994 Indian researchers discovered a cheap and effective way of keeping sandfly populations under control, by plastering the walls of houses and outbuildings with mud and lime. The plaster deprives flies of the moist crevices in which they breed, and the lime kills any existing larvae. In trials, sandfly numbers dropped by 90%.

lek in biology, a closely spaced set of very small territories each occupied by a single male during the mating season. Leks are found in the mating systems of several ground-dwelling birds (such as grouse) and a few antelopes.

The lek is a traditional site where both males and females congregate during the breeding season. The males display to passing females in the hope of attracting them to mate. Once mated, the females go elsewhere to lay their eggs or to complete gestation.

lemming any of a group of small rodents distributed worldwide in northern latitudes. They are about 12 cm/5 in long, with thick brownish fur, a small head, and a short tail. Periodically, when their population exceeds the available food supply, lemmings undertake mass migrations. (Genus *Lemmus* and other related genera, family Cricetidae.)

lemon sharp-tasting yellow citrus fruit of the small, evergreen, semitropical lemon tree. It may have originated in NW India, and was introduced into Europe by the Spanish Moors in the 12th or 13th century. It is now grown in Italy, Spain, California, Florida, South Africa, and Australia, and is widely used for flavouring and as a garnish. (*Citrus limon*, family Rutaceae.)

lemon balm perennial herb belonging to the mint family, with lemon-scented leaves. It is widely used in teas, liqueurs, and medicines. (*Melissa officinalis*, family Labiatae.)

lemur any of various prosimian primates found in Madagascar and the Comoros Islands. There are about 16 species, ranging from mouse-sized to dog-sized animals; the pygmy mouse lemur (*Microcebus myoxinus*), weighing 30 g/1 oz, is the smallest primate. The diadem sifaka, weighing 7 kg/15 lb, is the largest species of lemur. Lemurs are arboreal, and some species are nocturnal. They have long, bushy tails, and feed on fruit, insects, and small animals. Many are threatened with extinction owing to loss of their forest habitat and, in some cases, from hunting. (Family Lemnidae.)

lens in optics, a piece of a transparent material, such as glass, with two polished surfaces – one concave or convex, and the other plane, concave, or convex – that modifies rays of light. A convex lens brings rays of light together; a concave lens makes the rays diverge. Lenses are essential to spectacles, microscopes, telescopes, cameras, and almost all optical instruments.

The image formed by a single lens suffers from several defects or aberrations, notably **spherical aberration** in which an image becomes blurred, and **chromatic aberration** in which an image in white light tends to have coloured edges. Aberrations are corrected by the use of compound lenses, which are built up from two or more lenses of different refractive index.

lens, gravitational see *gravitational lensing*.

lens The passage of light through lenses. The concave lens diverges a beam of light from a distant source. The convex and compound lenses focus light from a distant source to a point. The distance between the focus and the lens is called the focal length. The shorter the focus, the more powerful the lens.

lenticel small pore on the stems of woody plants or the trunks of trees. Lenticels are a means of gas exchange between the stem interior and the atmosphere. They consist of loosely packed cells with many air spaces in between, and are easily seen on smooth-barked trees such as cherries, where they form horizontal lines on the trunk.

lenticular galaxy in astronomy, a lens-shaped galaxy with a large central bulge and flat disc but no discernible spiral arms.

lentil annual Old World plant belonging to the pea family. The plant, which resembles vetch, grows 15–45 cm/6–18 in high and has white, blue, or purplish flowers. The seeds, contained in pods about 1.6 cm/0.6 in long, are widely used as food. (*Lens culinaris*, family Leguminosae.)

The most common varieties are the greyish French lentil and the red Egyptian lentil.

Lenz's law in physics, a law stating that the direction of an electromagnetically induced current (generated by moving a magnet near a wire or a wire in a magnetic field) will be such as to oppose the motion producing it. It is named after the German physicist Heinrich Friedrich Lenz (1804–1865), who announced it in 1833.

Leo zodiacal constellation in the northern hemisphere, represented as a lion. The Sun passes through Leo from mid-Aug to mid-Sept. Its brightest star is first-magnitude α Regulus at the base of a

pattern of stars called the Sickle. In astrology, the dates for Leo are between about 23 July and 22 Aug (see *Precession*).

leopard or **panther** large wild cat found in Africa and Asia. The background colour of the coat is golden, and the black spots form rosettes that differ according to the variety; black panthers are simply a colour variation and retain the patterning as a 'watered-silk' effect. The leopard is 1.5–2.5 m/5–8 ft long, including the tail, which may measure 1 m/3 ft. (Species *Panthera pardus*, family Felidae.)

The snow leopard or ounce (*Panthera uncia*), which has irregular rosettes of much larger black spots on a light cream or grey background, is a native of mountains in central Asia. The clouded leopard (*Neofelis nebulosa*) is rather smaller, about 1.75 m/5.8 ft overall, with large blotchy markings rather than rosettes, and is found in SE Asia. There are seven subspecies, of which six are in danger of extinction, including the Amur leopard and the South Arabian leopard. One subspecies, the Zanzibar leopard, may already be extinct. The last Judean desert leopard died May 1995, although a small population survives in the Negev Desert.

Lepenski Vir prehistoric settlement site in the valley of the river Danube, where it runs through the Iron Gates gorge, in former Yugoslavia on the Romanian border. One of Europe's oldest farming settlements, dating from the 6th millennium BC, it is possibly the earliest and best preserved late Mesolithic to Neolithic (Middle to New Stone Age) site in the Balkans. The site is now submerged by an artificial lake.

A series of unusual trapezoidal dwellings were found, dating from the mid-6th millennium BC, associated with large limestone sculptures of fishlike human beings, belonging to a preceding camp of hunter-fisher people. All the dwellings had their wide end pointing towards the river, with limestone plaster floors and probably a wooden structure over. Hearths comprised limestone blocks inside elongated pits; in some cases human burials were made close by. The roofs of the dwellings may have been covered in hides or reed thatch. A larger central house may indicate social stratification.

Diet depended on fish and the development of fishing and boat technology. The life style of the inhabitants was sedentary but had arisen out of adaptation from a previous hunting tradition. Resources included catfish, carp, deer, and wild pigs.

lepidozamia palmlike plant of the Cycad order with two species both endemic to Australia. They are among the world's oldest plants and some specimens of *Lepidozamia peroffskyana* in Queensland are thought by some botanists to be about 10,000 years old.

leprosy or **Hansen's disease** chronic, progressive disease caused by a bacterium *Mycobacterium leprae* closely related to that of tuberculosis. The infection attacks the skin and nerves. Once common in many countries, leprosy is now confined almost entirely to the tropics. It is controlled with drugs.

According to a World Health Organization estimate there were 1.3 million people with leprosy 1996; the year-2000 target for total elimination was declared unrealistic at an international leprosy conference in Delhi in 1996. There are two principal manifestations. **Lepromatous leprosy** is a contagious, progressive form distinguished by the appearance of raised blotches and lumps on the skin and thickening of the skin and nerves, with numbness, weakness, paralysis, and ultimately deformity of the affected parts. In **tuberculoid leprosy**, sensation is lost in some areas of the skin; sometimes there is loss of pigmentation and hair. The visible effects of long-standing leprosy (joint damage, paralysis, loss of fingers or toes) are due to nerve damage and injuries of which the sufferer may be unaware. Damage to the nerves remains, and the technique of using the patient's muscle material to encourage nerve regrowth is being explored.

lepton any of a class of light elementary particles that are not affected by the strong nuclear force; they do not interact strongly with other particles or nuclei. The leptons are comprised of the electron, muon, and tau, and their neutrinos (the electron neutrino, muon neutrino, and tau neutrino), plus their six antiparticles.

leptoquark in physics, a hypothetical particle made up of a quark combined with a lepton, or a new particle created by their interaction.

leptospermum shrub or small tree of the genus *Leptospermum*, family Myrtaceae, mostly native to Australia and New Zealand.

leschenaultia shrub of the predominantly Australian genus *Leschenaultia*, family Goodeniaceae, with species generally found in Western Australia and having tubular flowers of blue, red, orange, yellow, and pink. Best known is blue *leschenaultia* *L. biloba*, a spreading plant growing to 60 cm/2 ft.

lesion any change in a body tissue that is a manifestation of disease or injury.

letterpress method of printing from raised type, pioneered by Johann Gutenberg in Europe in the 1450s.

lettuce annual plant whose large edible leaves are commonly used in salads. There are many varieties, including the cabbage lettuce, with round or loose heads, the Cos lettuce, with long, upright heads, and the iceberg lettuce, with tight heads of crisp leaves. They are all believed to have been derived from the wild species *L. serriola*. (Genus *Lactuca*, especially *L. sativa*, family Compositae.)

leucine one of the nine essential amino acids.

leucocyte another name for a white blood cell.

leucotomy or **lobotomy** a brain operation to sever the connections between the frontal lobe and underlying structures. It was widely used in the 1940s and 1950s to treat severe psychotic or depressive illness. Though it achieved some success, it left patients dull and apathetic; there was also a considerable risk of epilepsy. It was largely replaced by the use of psychotropic drugs from the late 1950s.

Today, a limited amount of psychosurgery is performed in specialist centres under strict controls. It includes the creation of tiny, precise frontal lobe lesions to relieve severe conditions which have not responded to other treatments.

leukaemia any one of a group of cancers of the blood cells, with widespread involvement of the bone marrow and other blood-forming tissue. The central feature of leukaemia is runaway production of white blood cells that are immature or in some way abnormal. These rogue cells, which lack the defensive capacity of healthy white cells, overwhelm the normal ones, leaving the victim vulnerable to infection. Treatment is with radiotherapy and cytotoxic drugs to suppress replication of abnormal cells, or by bone-marrow transplantation.

Abnormal functioning of the bone marrow also suppresses production of red blood cells and blood platelets, resulting in anaemia and a failure of the blood to clot.

Leukaemias are classified into acute or chronic, depending on their known rates of progression. They are also grouped according to the type of white cell involved.

leukotriene in biology, a group of naturally occurring substances that stimulate the activity, for example contraction, of smooth muscles.

levee naturally formed raised bank along the side of a river channel. When a river overflows its banks, the rate of flow is less than that in the channel, and silt is deposited on the banks. With each successive flood the levee increases in size so that eventually the river may be above the surface of the surrounding flood plain. Notable levees are found on the lower reaches of the Mississippi in the USA and the Po in Italy.

level or **spirit level** instrument for finding horizontal level, or adjusting a surface to an even level, used in surveying, building

lever Types of lever. Practical applications of the first-order lever include the crowbar, seesaw, and scissors. The wheelbarrow is a second-order lever; tweezers or tongs are third-order levers.

construction, and archaeology. It has a glass tube of coloured liquid, in which a bubble is trapped, mounted in an elongated frame. When the tube is horizontal, the bubble moves to the centre.

lever simple machine consisting of a rigid rod pivoted at a fixed point called the fulcrum, used for shifting or raising a heavy load or applying force. Levers are classified into orders according to where the effort is applied, and the load-moving force developed, in relation to the position of the fulcrum.

A first-order lever has the load and the effort on opposite sides of the fulcrum – for example, a see-saw or pair of scissors. A second-order lever has the load and the effort on the same side of the fulcrum, with the load nearer the fulcrum – for example, nutcrackers or a wheelbarrow. A third-order lever has the effort nearer the fulcrum than the load, with both on the same side of it – for example, a pair of tweezers or tongs. The mechanical advantage of a lever is the ratio of load to effort, equal to the perpendicular distance of the effort's line of action from the fulcrum divided by the distance to the load's line of action. Thus tweezers, for instance, have a mechanical advantage of less than one.

Give me but one firm place on which to stand, and I will move the earth.

ARCHIMEDES Greek mathematician.

LF in physics, abbreviation for **low frequency**. LF radio waves have frequencies in the range 30–300 kHz.

LH abbreviation for **lutetizing hormone**.

Lhasa apso breed of toy dog from Tibet. It has a long coat, which may be solid-coloured (gold, dark grey, tawny) or bicoloured (black with white). It is similar in shape to a pekingese, having short legs.

proportionately long body, and curled tail, but differs in having hair growing over its face. It grows up to 25 cm/10 in.

liana woody, perennial climbing plant with very long stems, which grows around trees right up to the top, where there is more sunlight. Lianas are common in tropical rainforests, where individual stems may grow up to 78 m/255 ft long. They have an unusual stem structure that makes them flexible, despite being woody.

Liberty engine US-manufactured aircraft engine based on a Rolls-Royce design, used in a number of aircraft and tanks in World War I. It was designed specifically for mass-production, in order to meet wartime needs for a reliable engine which could be turned out as quickly as the rest of an aircraft. A V-12, water-cooled engine, it developed 405 bhp (brake horsepower) at 1,650 rpm (revolutions per minute).

Liberty tank US name for the British Mark VIII tank, adopted by the Anglo-American Tank Committee for production in both the UK and USA in World War I. None were produced in time for the war, but about 100 were assembled in the USA after the Armistice.

libido in Freudian psychology, the energy of the sex instinct, which is to be found even in a newborn child. The libido develops through a number of phases, described by Sigmund Freud in his theory of infantile sexuality. The source of the libido is the pld.

The phases of the libido are identified by Freud as the oral stage, when a child tests everything by mouth, the anal stage, when the child gets satisfaction from control of its body, and the genital stage, when the libido becomes concentrated in the sex organs.

Loss of adult libido is seen in some diseases.

Libra faint zodiacal constellation on the celestial equator (see celestial sphere) adjoining Scorpius, and represented as the scales of justice. The Sun passes through Libra during Nov. The constellation was once considered to be a part of Scorpius, seen as the scorpion's claws. In astrology, the dates for Libra are between about 23 September and 23 October (see precession).

library program one of a collection, or library, of regularly used software routines, held in a computer backing store. For example, a programmer might store a routine for sorting a file into key field order, and so could incorporate it easily into any new program being developed instead of having to rewrite it.

libration in astronomy, a slight, apparent wobble in the rotation of the Moon due to its variable speed of rotation and the tilt of its axis.

Generally, the Moon rotates on its axis in the same time as it takes to complete one orbit, causing it to keep one face turned permanently towards the Earth (see captured rotation). Its speed in orbit varies, however, because its orbit is not circular but elliptical, so at times the Moon's axial rotation appears to get either slightly ahead of or slightly behind its orbital motion, so that part of the 'dark side' of the Moon is visible around the east and west edges. This is known as **libration in longitude**.

Libration in latitude occurs because the Moon's axis is slightly tilted with respect to its orbital plane, so we can see over the north and south poles. In combination, these effects mean that a total of 59% of the Moon's surface is visible, rather than just 50% if libration did not occur.

lichen any organism of a unique group that consists of associations of a specific fungus and a specific alga living together in a mutually beneficial relationship. Found as coloured patches or spongelike masses on trees, rocks, and other surfaces, lichens

Some lichens are edible, for example, reindeer moss and Iceland moss; others are a source of colour dyes, such as litmus, or are used in medicine. They are sensitive to pollution in the air (see indicator species).

Lick Observatory observatory of the University of California and Mount Hamilton, California. Its main instruments are the 3.04-m/120-in Shane reflector, opened in 1959, and a 91-cm/36-in refractor, opened in 1988, the second-largest refractor in the world.

lie detector instrument that records graphically certain body activities, such as thoracic and abdominal respiration, blood pressure, pulse rate, and galvanic skin response (changes in electrical resistance of the skin). Marked changes in these activities when a person answers a question may indicate that the person is lying.

life the ability to grow, reproduce, and respond to such stimuli as light, heat, and sound. Life on Earth may have begun about 4 billion years ago when a chemical reaction produced the first organic substance. Over time, life has evolved from primitive single-celled organisms to complex multicellular ones. There are now some 10 million different species of plants and animals living on the Earth. The earliest fossil evidence of life is threadlike chains of cells discovered in 1980 in deposits in NW Australia; these have been dated as being 3.5 billion years old.

biology is the study of living organisms – their evolution, structure, functioning, classification, and distribution – while biochemistry is the study of the chemistry of living organisms. Biochemistry is especially concerned with the function of the chemical components of organisms such as proteins, carbohydrates, lipids, and nucleic acids.

Life probably originated in the primitive oceans. The original atmosphere, 4 billion years ago, consisted of carbon dioxide, nitrogen, and water. Laboratory experiments have shown that more complex organic molecules, such as amino acids and nucleotides, can be produced from these ingredients by passing electric sparks through a mixture. The climate of the early atmosphere was probably very violent, with lightning a common feature, and these conditions could have resulted in the oceans becoming rich in organic molecules, producing the so-called 'primeval soup'. These molecules may then have organized themselves into clusters capable of reproducing and eventually developing into simple cells. Soon after life developed, photosynthesis would have become the primary source of energy for life. By this process, life would have substantially affected the chemistry of the atmosphere and, in turn, that of its own environment. Once the atmosphere had changed to its present composition, life could only be created by the replication of living organisms (a process called abiogenesis).

life cycle in biology, the sequence of developmental stages through which members of a given species pass. Most vertebrates have a simple life cycle consisting of fertilization of sex cells or gametes, a period of development as an embryo, a period of juvenile growth after hatching or birth, an adulthood including sexual reproduction, and finally death. Invertebrate life cycles are generally more complex and may involve major reconstitution of the individual's appearance (metamorphosis) and completely different styles of life. Plants have a special type of life cycle with two distinct phases, known as alternation of generations. Many insects such as cicadas, dragonflies, and mayflies have a long larval or pupal phase and a short adult phase. Dragonflies live an aquatic life as larvae and an aerial life during the adult phase. In many invertebrates and protozoa there is a sequence of stages in the life

cycle, and in parasites different stages often occur in different host organisms.

life expectancy average lifespan that can be presumed of a person at birth. It depends on nutrition, disease control, environmental contaminants, war, stress, and living standards in general.

There is a marked difference between industrialized countries, which generally have an ageing population, and the poorest countries, where life expectancy is much shorter. In Bangladesh, life expectancy is currently 48; in Nigeria 49. In famine-prone Ethiopia it is only 41.

where separate figures are given for male and female life expectancy, the ranking is based on a simple average of the two

of study such as *ψ*biophysics and *ψ*sociobiology.

This approach has led to many new ideas and discoveries as well as to an emphasis on *ψ*ecology, the study of living organisms in their natural environments.

life table way of summarizing the probability that an individual will give birth or die during successive periods of life. From this, the proportion of individuals who survive from birth to any given age (survivorship) and the mean number of offspring produced (net reproductive rate) can be determined.

Insurance companies use life tables to estimate risks of death in order to set their premiums and governments use them to determine future needs for education and health services.

lift (US *elevator*) device for lifting passengers and goods vertically between the floors of a building. US inventor Elisha Graves Otis developed the first passenger lift, installed in 1857. The invention of the lift allowed the development of the skyscraper from the 1880s.

A lift usually consists of a platform or boxlike structure suspended by motor-driven cables with safety ratchets along the sides of the shaft. At first steam powered the movement, but hydraulic and then electric lifts were common from the early 1900s. Lift operators worked controls and gates until lifts became automatic.

ligament strong, flexible connective tissue, made of the protein *ψ*collagen, which joins bone to bone at moveable joints and sometimes encloses the joints. Ligaments prevent bone dislocation (under normal circumstances) but allow joint flexion. The liga-

ments around the joints are composed of white fibrous tissue. Other ligaments are composed of yellow elastic tissue, which is adapted to support a continuous but varying stress, as in the ligament connecting the various cartilages of the *ψ*larynx (voice box).

ligand in chemistry, a group that bonds symmetrically to a central atom or ion of a metal; the result is called a **coordination complex**. An example of a neutral ligand is ammonia; the nitrosyl ion NO⁺ is a charged ligand. An example of a coordination complex is hexamminecobalt chloride, [Co(NH₃)₆]Cl₃, in which the central cobalt ion (Co³⁺) is surrounded by covalent bonds with six ammonia molecules and ionic bonds with three chloride ions.

Ligands are used in medicine as an antidote to heavy metal poisoning, removing the metal ions by attaching themselves to form a harmless compound.

light electromagnetic waves in the visible range, having a wavelength from about 400 nanometres in the extreme violet to about 770 nanometres in the extreme red. Light is considered to exhibit particle and wave properties, and the fundamental particle, or quantum, of light is called the photon. The speed of light (and of all electromagnetic radiation) in a vacuum is approximately 300,000 km/186,000 mi per second, and is a universal constant denoted by *c*.

Isaac *ψ*Newton was the first to discover, in 1666, that sunlight is composed of a mixture of light of different colours in certain proportions and that it could be separated into its components by dispersion. Before his time it was supposed that dispersion of light produced colour instead of separating already existing colours.

Light: Experiments to Determine its Nature

BY JULIAN ROWE

and all was light

Alexander Pope, the poet, wrote of Isaac Newton's work: 'Nature, and Nature's Laws lay hid in Night: God said, Let Newton be! and All was Light.'

Newton discovers the spectrum

Isaac Newton, the English physicist and mathematician (1642–1727), would have been remembered as a great scientist for any one of his many discoveries. He made outstanding contributions to mathematics, astronomy, mechanics, and to understanding gravitation and the nature of light.

The first microscopes revealed the world of the very small to scientists for the very first time. They saw in great detail what microorganisms were really like. In the same way, at the other end of the scale, the first telescopes revealed to astronomers vast numbers of stars and the beauty of the Earth's planets. But there was a problem. Any image formed by the combination of the lenses then available to make microscopes or telescopes was surrounded by a colour fringe. This blurred the outline – an effect which became worse at higher magnifications.

from prisms and rainbows ...

People had long been familiar with the rainbow colours produced when light shone through a chandelier. Now, in order to improve their instruments, scientists needed to know why these colours were formed. Newton ground his own glass lenses and had, since he was an undergraduate student at Cambridge, been interested in the effect of a glass prism on sunlight.

Newton wrote: 'In the year 1666 (at which time I applied myself to the grinding of optick glass or other figures than spherical) I procured me a triangular glass prism, to try the celebrated phenomena of colours.'

Newton made a small hole in the shutter covering the window in his room to let in a beam of sunlight. He placed the prism in front of this hole and viewed the vivid and intense spectrum of rainbow colours cast on the opposite wall.

Newton now examined these colours individually, using a second prism. He took two boards, each with a small hole in it. The

first he placed behind the prism at the window. He positioned the second board so that only a single colour produced by the first prism fell on the hole in it. The second prism was placed so as to cast the light passing through the hole in the second board on to the wall. Newton saw at once that the coloured beam of light passing through the second prism was unchanged. This proved to be true for all the rainbow colours produced by the first prism.

Newton had performed the crucial experiment, because it had been assumed previously that light was basically white, and that colours could be added to it. Now it was clear that white light was a mixture of the colours of the rainbow; the prism simply split them up or refracted the light. A second prism could not 'split' them up further.

... to modern telescopes

In his book *Opticks*, published in 1704, Newton described a further experiment in which he used the second prism to recombine the rainbow colours of the spectrum to produce white light. Here for the first time was a simple explanation of the nature of light. The book had a great impact on 18th-century writers. What Newton had to say about what happened when white light passed through a prism could be immediately applied to rainbows, and this captured the imagination of artists and poets.

Because Newton suspected that the colour fringes or chromatic aberration produced by lenses in telescopes could not be avoided, in 1668 he designed a telescope that depended instead on the use of a curved mirror. Light reflected from a surface produces no colour effects, unlike light passing through a lens. Nowadays all large astronomical telescopes are of the reflecting type.

As a result of his elegant experiments with prisms and light, Newton also speculated about the ultimate nature of light itself. He proposed that light consisted of small 'corpuscles' (small particles) which are shot out from the source of light, rather in the same way that pellets are ejected from a shot gun. He was able to explain many of the known properties of light with this theory, which was widely accepted. Light has proved remarkably difficult to understand; nowadays it is regarded as having both particlelike and wavelike properties.

The ancients believed that light travelled at infinite speed; its finite speed was first discovered by Danish astronomer Ole Rømer 1676.

My design in this book is not to explain the properties of light by hypotheses, but to propose and prove them by reason and experiments.

light bulb incandescent filament lamp, first demonstrated by Joseph Swan in the UK in 1878 and Thomas Edison in the USA in 1879. The present-day light bulb is a thin glass bulb filled with an inert mixture of nitrogen and argon gas. It contains a filament made of fine tungsten wire. When electricity is passed through the wire, it glows white hot, producing light.

LIGHT BULBS

When Thomas Edison, inventor of the light bulb, died (on 18 October 1931), all non-essential electric lights in the USA – including the torch on the Statue of Liberty –

light curve in astronomy, a graph showing how the brightness of an astronomical object varies with time. Analysis of the light curves of variable stars, for example, gives information about the physical processes causing the variation.

light-dependent resistor (LDR) component of electronic circuits whose resistance varies with the level of illumination on its surface. Usually resistance decreases as illumination rises. LDRs are used in light-measuring or light-sensing instruments (for example, in the exposure-meter circuit of an automatic camera) and in switches (such as those that switch on street lights at dusk).

LDRs are made from semiconductors, such as cadmium sulphide.

light-emitting diode (LED) an electronic component that converts electrical energy into light or infrared radiation in the range of 550 nm (green light) to 1300 nm (infrared). They are used for displaying symbols in electronic instruments and devices. An LED is a diode made of semiconductor material, such as gallium arsenide phosphide, that glows when electricity is passed through it. The first digital watches and calculators had LED displays, but many later models used liquid-crystal displays.

In 1993 chemists at the University of Cambridge, England, developed LEDs from the polymer poly(*p*-phenylenevinyl) (PPV) that emit as much light as conventional LEDs and in a variety of colours.

A new generation of LEDs that can produce light in the mid-infrared range (300–1000 nm) safely and cheaply were developed by British researchers in 1995, using thin alternating layers of indium arsenide and indium arsenide antimonide.

lighthouse structure carrying a powerful light to warn ships or aeroplanes that they are approaching a place (usually land) dangerous or important to navigation. The light is magnified and directed out to the horizon or up to the zenith by a series of mirrors or prisms. Increasingly lighthouses are powered by electricity and automated rather than staffed; the more recent models also emit radio signals.

signals Lights may be either flashing (the dark period exceeding the light) or rotating (the dark period being equal or less); fixed lights are liable to cause confusion. The pattern of lighting is individually varied so that ships or aircraft can identify the lighthouse. In fog, sound signals are made (horns, sirens, explosives), and in the case of lightbuoys, fog bells and whistles are operated by the movement of the waves.

history Among early lighthouses were the Pharos of Alexandria (about 280 BC) and those built by the Romans at Ostia, Ravenna, Boulogne, and Dover. In England beacons burning in church towers served as lighthouses until the 17th century, and in the earliest lighthouses, such as the Eddystone, first built in 1698, open fires or candles were used.

modern developments Where reefs or sandbanks made erection of a lighthouse impossible, lightships were often installed; increasingly these are being replaced by fixed, small, automated lighthouses. Where it is impossible to install a fixed structure, unattended light-buoys equipped for up to a year's service may be used.

lightning high-voltage electrical discharge between two charged rainclouds or between a cloud and the Earth, caused by the build-up of electrical charges. Air in the path of lightning ionizes (becomes conducting), and expands; the accompanying noise is heard as thunder. Currents of 20,000 amperes and temperatures of 30,000°C/54,000°F are common.

LIGHTNING

Around the world there are a total of 70 to 100 lightning flashes every second.

lightning conductor device that protects a tall building from lightning strike by providing an easier path for current to flow to earth than through the building. It consists of a thick copper strip of very low resistance connected to the ground below. A good connection to the ground is essential and is made by burying a large metal plate deep in the damp earth. In the event of a direct lightning strike, the current in the conductor may be so great as to melt or even vaporize the metal, but the damage to the building will nevertheless be limited.

light pen in computing, a device resembling an ordinary pen, used to indicate locations on a computer screen. With certain computer-aided design (CAD) programs, the light pen can be used to instruct the computer to change the shape, size, position, and colours of sections of a screen image.

The pen has a photoreceptor at its tip that emits signals when light from the screen passes beneath it. From the timing of this signal and a gridlike representation of the screen in the computer memory, a computer program can calculate the position of the light pen.

light second unit of length, equal to the distance travelled by light in one second. It is equal to 2.997925×10^8 m/9.835592 $\times 10^8$ ft. See **light year**.

light watt unit of radiant power (brightness of light). One light watt is the power required to produce a perceived brightness equal to that of light at a wavelength of 550 nanometres and 680 lumens.

light year in astronomy, the distance travelled by a beam of light in a vacuum in one year, approximately 9.46 trillion (million million) km/5.88 trillion miles.

lignin naturally occurring substance produced by plants to strengthen their tissues. It is difficult for enzymes to attack lignin, so living organisms cannot digest wood, with the exception of a few specialized fungi and bacteria. Lignin is the essential ingredient of all wood and is, therefore, of great commercial importance.

Chemically, lignin is made up of thousands of rings of carbon atoms joined together in a long chain. The way in which they are linked up varies along the chain.

lignite type of coal that is brown and fibrous, with a relatively low carbon content. As a fuel it is less efficient because more of it must be burned to produce the same amount of energy generated by bituminous coal. Lignite also has a high sulphur content and is more polluting. It is burned to generate power in Scandinavia and some former eastern block countries because it is the only fuel resource available without importing.

lilac any of a group of flowering Old World shrubs, with clusters (panicles) of small, sweetly scented, white or purple flowers on the main stems. The common lilac (*S. vulgaris*) is a popular garden ornamental. (Genus *Syringa*, family Oleaceae.)

lilly pilly tree *Acmena smithii* with purplish white fruits, common along streams and in rainforests of E Australia.

lily any of a group of plants belonging to the lily family, of which there are about 80 species, most with showy, trumpet-shaped flowers growing from bulbs. The lily family includes hyacinths, tulips, asparagus, and plants of the onion genus. The name 'lily' is also applied to many lilylike plants of related genera and families. (Genus *Lilium*, family Liliaceae.)

lily of the valley plant belonging to the lily family, growing in woods in Europe, N Asia, and North America. The small bell-shaped white flowers hang downwards from short stalks attached to a central stem; they are strongly scented. The plant is often cultivated. (*Convallaria majalis*, family Liliaceae.)

lime or **quicklime** CaO (technical name *calcium oxide*) white powdery substance used in making mortar and cement. It is made commercially by heating calcium carbonate (CaCO_3), obtained from limestone or chalk, in a lime kiln. Quicklime readily absorbs water to become calcium hydroxide Ca(OH)_2 , known as slaked lime, which is used to reduce soil acidity.

LIME

The theatrical expression 'in the limelight' comes from the 19th-century method of lighting the stage. From about 1838, a powerful flood of white light was produced by heating quicklime in a stream of oxygen – a dangerous chemical reaction.

lime sharp-tasting green or greenish-yellow citrus fruit of the small thorny lime bush, native to India. The white flowers are followed by the fruits, which resemble lemons but are more round in

shape; they are rich in vitamin C. (*Citrus aurantifolia*, family Rutaceae.)

lime or **linden** any of a group of deciduous trees native to the northern hemisphere. The leaves are heart-shaped and coarsely toothed, and the flowers are cream-coloured and fragrant. (Genus *Tilia*, family Tiliaceae.)

lime kiln oven used to make quicklime (calcium oxide, CaO) by heating limestone (calcium carbonate, CaCO_3) in the absence of air. The carbon dioxide is carried away to heat other kilns and to ensure that the reversible reaction proceeds in the right direction. $\text{CaCO}_3 \leftrightarrow \text{CaO} + \text{CO}_2$

limestone sedimentary rock composed chiefly of calcium carbonate CaCO_3 , either derived from the shells of marine organisms or precipitated from solution, mostly in the ocean. Various types of limestone are used as building stone.

Marble is metamorphosed limestone. Certain so-called marbles are not in fact marbles but fine-grained fossiliferous limestones that take an attractive polish. Caves commonly occur in limestone. Karst is a type of limestone landscape.

limewater common name for a dilute solution of slaked lime (calcium hydroxide, Ca(OH)_2). In chemistry, it is used to detect the presence of carbon dioxide.

If a gas containing carbon dioxide is bubbled through limewater, the solution turns milky owing to the formation of calcium carbonate (CaCO_3). Continued bubbling of the gas causes the limewater to clear again as the calcium carbonate is converted to the more soluble calcium hydrogen carbonate ($\text{Ca(HCO}_3)_2$).

limit in mathematics, in an infinite sequence, the final value towards which the sequence is tending. For example, the limit of the sequence $\frac{1}{2}, \frac{3}{4}, \frac{7}{8}, \frac{15}{16}, \dots$ is 1, although no member of the sequence will ever exactly equal 1 no matter how many terms are added together. The limit of the ratios of a Fibonacci sequence is $(\sqrt{5} + 1)/2$. This number is also the golden section.

limiting factor in biology, any factor affecting the rate of a metabolic reaction. Levels of light or of carbon dioxide are limiting factors in photosynthesis because both are necessary for the production of carbohydrates. In experiments, photosynthesis is observed to slow down and eventually stop as the levels of light decrease.

limestone The physical weathering and erosion of a limestone landscape. The freezing and thawing of rain and its mild acidic properties cause cracks and joints to enlarge, forming limestone pavements, potholes, caves and caverns.

It is believed that the concentrations of carbon dioxide building up in the atmosphere through the burning of fossil fuels will allow faster plant growth.

limnology study of lakes and other bodies of open fresh water, in terms of their plant and animal biology, chemistry, and physical properties.

limpet any of various marine mollusks belonging to several families and genera, found in the Atlantic and Pacific oceans. A limpet has a conical shell and adheres firmly to rocks by its disclike foot. Limpets leave their fixed positions only to graze on seaweeds, always returning to the same spot. The common limpet (*P. vulgata*) can be seen on rocks at low tide. (Especially genera *Acmaea* and *Patella*.)

linac contraction of linear accelerator, a type of particle accelerator in which the particles are accelerated along a straight tube.

Lindbergh, Charles A (ugustus) (1902–1974)

US aviator. He made the first solo nonstop flight in 33.5 hours across the Atlantic (Roosevelt Field, Long Island, New York, to Le Bourget airport, Paris) 1927 in the Spirit of St Louis, a Ryan monoplane designed by him.

Lindbergh was born in Detroit, Michigan. He was a barnstorming pilot before attending the US Army School in Texas 1924 and becoming an officer in the Army Air Service Reserve 1925. Learning that Raymond B Orteig had offered a prize of \$25,000 for the person who first made a nonstop air flight between New York and Paris, he appealed to some St Louis businessmen who agreed to finance him.

linden another name for the lime tree.

Lindow Man remains of an Iron Age man discovered in a peat bog at Lindow Marsh, Cheshire, UK, in 1984. The chemicals in the bog had kept the body in an excellent state of preservation.

'Pote Marsh', as the archaeologists nicknamed him, had been knocked unconscious, strangled, and then had his throat cut before being thrown into the bog. He may have been a sacrificial victim, as Celtic peoples often threw offerings to the gods into rivers and barns. His stomach contained part of an unleavened barley 'bannock' that might have been given as a sacrificial offering. His well-cared-for nails indicate that he might have been a Druid prince who became a willing sacrifice.

linear accelerator or **linac** in physics, a type of particle accelerator in which the particles move along a straight tube. Particles pass through a linear accelerator only once – unlike those in a cyclotron (a ring-shaped accelerator), which make many revolutions, gaining energy each time.

The world's longest linac is the Stanford Linear Collider, in which electrons and positrons are accelerated along a straight track 3.2 km/2 mi long and then steered into a head-on collision with other particles.

The first linear accelerator was built in 1928 by Norwegian engineer Ralph Widerøe to investigate the behaviour of heavy ions

(large atoms with one or more electrons removed), but devices capable of accelerating smaller particles such as protons and electrons could not be built until after World War II and the development of high-power radio- and microwave-frequency generators.

linear equation in mathematics, a relationship between two variables that, when plotted on Cartesian axes produces a straight-line graph; the equation has the general form $y = mx + c$, where m is the slope of the line represented by the equation and c is the y -intercept, or the value of y where the line crosses the y -axis in the Cartesian coordinate system. Sets of linear equations can be used to describe the behaviour of buildings, bridges, trusses, and other static structures.

linear motor type of electric motor, an induction motor in which the fixed stator and moving armature are straight and parallel to each other (rather than being circular and one inside the other as in an ordinary induction motor). Linear motors are used, for example, to power sliding doors. There is a magnetic force between the stator and armature; this force has been used to support a vehicle, as in the experimental maglev linear motor train.

linear programming in mathematics and economics, a set of techniques for finding the maxima or minima of certain variables governed by linear equations or inequalities. These maxima and minima are used to represent 'best' solutions in terms of goals such as maximizing profit or minimizing cost.

line input in audio systems, direct input to a tape recorder from a device such as another recorder, rather than a microphone.

linen yarn spun and the textile woven from the fibres of the stem of the flax plant. Used by the ancient Egyptians, linen was introduced by the Romans to Europe, where production became widespread. Religious refugees from the Low Countries in the 16th century helped to establish the linen industry in England, but here and elsewhere it began to decline in competition with cotton in the 18th century.

To get the longest possible fibres, flax is pulled, rather than cut by hand or machine, just as the ripened fruits, or bolls, are beginning to set. After preliminary drying, it is steeped in water so that the fibre can be more easily separated from the wood of the stem, then hackled (combed), classified, drawn into continuous fibres, and spun. Bleaching, weaving, and finishing processes vary according to the final product, which can be sailcloth, canvas, sacking, cambric, or lawn. Because of the length of its fibre, linen yarn has twice the strength of cotton, and yet is superior in delicacy, so that it is suitable for lace making. It mixes well with synthetic fibres.

line of force in physics, an imaginary line representing the direction of force at any point in a magnetic, gravitational, or electrical field.

line printer computer printer that prints a complete line of characters at a time. Line printers can achieve very high printing speeds of up to 2,500 lines a minute, but can print in only one typeface, cannot print graphics, and are very noisy. Today, most users prefer laser printers.

ling any of several deepwater long-bodied fishes of the cod family found in the N Atlantic. (Genus *Molva*, family Gadidae.)

ling another name for common heather.

link in computing, an image or item of text in a World Wide Web document that acts as a route to another Web page or file on the Internet. Links are created by using HTML to combine an on-screen 'anchor' with a hidden Hypertext Reference (HRF), usually the URL (Web address) of the item in question.

linkage in genetics, the association between two or more genes that tend to be inherited together because they are on the same chromosome.

The closer together they are on the chromosome, the less likely they are to be separated by crossing over (one of the processes of recombination) and they are then described as being 'tightly linked'.

Linnaeus, Carolus (1707–1778)

Latinized form of Carl von Linné Swedish naturalist and physician. His botanical work *Systema naturae* 1735 contained his system for classifying plants into groups depending on shared characteristics (such as the number of stamens in flowers), providing a much-needed framework for identification. He also devised the concise and precise system for naming plants and animals, using one Latin (or Latinized) word to represent the genus and a second to distinguish the species.

For example, in the Latin name of the daisy, *Bellis perennis*,

Bellis is the name of the genus to which the plant belongs, and *perennis* distinguishes the species from others of the same genus. By tradition the generic name always begins with a capital letter. The author who first described a particular species is often indicated after the name, for example, *Bellis perennis* Linnaeus, showing that the author was Linnaeus.

linnet small seed-eating bird belonging to the finch family, which is very abundant in Europe, Asia, and N W Africa. The male has a chestnut back with a pink breast and grey head, and a red breast and forehead during the breeding season; the female is mainly a dull brown. The linnet barely measures 13 cm/5 in in length, begins to breed in April, and generally chooses low-lying bush for its home. The eggs, ranging from four to six in number, are a delicate pale blue streaked with a purplish brown. (Species *Acanthis cannabina*, family Fringillidae, order Passeriformes.)

linoleum *Latin lini oleum 'linseed oil'* floor covering made from linseed oil, tall oil, rosin, cork, woodflour, chalk, clay, and pigments, pressed into sheets with a jute backing. Oxidation of the oil is accelerated by heating, so that the oil mixture solidifies into a tough, resilient material. Linoleum tiles have a backing made of polyester and glass.

Linoleum was invented in England in 1860 by Frederick Walton. In the early 20th century he invented a straight-line inlay machine which was able to produce patterned linoleum. Today, the manufacture of linoleum still follows the basic principles of Walton's process although production is much faster. Synthetic floor coverings are now popular and the use of linoleum has declined.

Linotype trademark for a typesetting machine once universally used for newspaper work, which sets complete lines (slugs) of hot-metal type as operators type the copy at a keyboard. It was invented in the USA in 1884 by German-born Ottmar Mergenthaler. It has been replaced by phototypesetting.

linsang nocturnal, tree-dwelling, carnivorous mammal of the civet family, about 75 cm/2.5 ft long. The African linsang (*Poiana richardsoni*) is a long, low, and lithe spotted animal about 33 cm/1.1 ft long with a 38 cm/1.25 ft tail. The two species of oriental linsang (genus *Prionodon*), found in Asia, are slightly larger. (Family Viverridae.)

linseed seeds of the flax plant, from which linseed oil is produced, the residue being used as cattle feed. The oil is used in paint, wood treatments and varnishes, and in the manufacture of linoleum floor coverings.

Linux (contraction of *Linus UNIX*) in computing, operating system based on an original core program written by Linus Torvalds, a 22-

year-old student at the University of Helsinki, Finland, 1991–92. Linux is a non-proprietary system, made up of freely-available ('open') code created over several years by UNIX enthusiasts all over the world. Each programmer retains the copyright to his or her creation, but makes it freely available on the Internet. Linux retains the flexibility and many of the advanced programming features that make UNIX popular for technically-minded users, but can run on an ordinary PC instead of an expensive UNIX workstation.

AFRICAN LION

http://www.seaworld.org/animal_bytes/lionab.html

Illustrated guide to the African lion including information about genus, size, life span, habitat, gestation, diet, and a series of fun facts.

lion large wild cat with a tawny coat. The young have darker spot markings to camouflage them; these usually disappear in the adult. The male has a heavy mane and a tuft at the end of the tail. Head and body measure about 2 m/6 ft, plus 1 m/3 ft of tail; lionesses are slightly smaller. Lions produce litters of two to six cubs, and often live in groups (prides) of several adult males and females with young. They are carnivores (meat-eaters) and are found only in Africa, south of the Sahara desert, and in the Gir Forest of north-west India.

behaviour Capable of short bursts of speed, lionesses do most of the hunting, working together to run down grazing animals. Females remain with the pride permanently; young males remain until they about three years old and one or more adult males (usually brothers) stay a couple of years or so until they are supplanted by a competing coalition of males. The incoming males, or male, kill all the cubs in a pride so that the lionesses become ready to breed again. When not hunting, lions spend most of their time dozing and sleeping. The average lifespan of a lion is 15–20 years in the wild and 20–25 years in captivity.

The Asiatic lion is listed on CITES Appendix 1 (endangered); its total population numbers only 250–300 in 1996. 'Mountain lion' is a name for the puma.

classification Lions belong to the animal phylum Chordata, subphylum Vertebrata, class Mammalia (mammals), order Carnivora (carnivores). They belong to the cat family, Felidae, genus *Panthera* (which also includes tigers, leopards, and jaguars), species *P. Leo*.

lion Lions can sleep for over 18 hours a day, particularly after a large kill. Unlike other cats, lions live and hunt in groups (prides). Usually they kill only once or twice a week, hunting ruminants such as gazelles, zebra, and wildebeest. Premaphotos Wildlife

lipase enzyme responsible for breaking down fats into fatty acids and glycerol. It is produced by the pancreas and requires a slightly alkaline environment. The products of fat digestion are absorbed by the intestinal wall.

lipid any of a large number of esters of fatty acids, commonly formed by the reaction of a fatty acid with glycerol (see glyceride). They are soluble in alcohol but not in water. Lipids are the chief constituents of plant and animal waxes, fats, and oils.

Phospholipids are lipids that also contain a phosphate group, usually linked to an organic base; they are major components of biological cell membranes.

lipophilic Greek 'fat-loving' in chemistry, a term describing functional groups with an affinity for fats and oils.

lipophobic Greek 'fat-hating' in chemistry, a term describing functional groups that tend to repel fats and oils.

liposome in medicine, a minute droplet of oil that is separated from a medium containing water by a phospholipid layer. Drugs, such as cytotoxic agents, can be incorporated into liposomes and given by injection or by mouth. The liposomes allow the drug to reach the site of action, such as a tumour, without being broken down in the body.

Lippizaner pure white horse, named after its place of origin in Lippizza, Slovenia. They are trained at the Spanish Riding School of Vienna.

liquefaction the process of converting a gas to a liquid, normally associated with low temperatures and high pressures (see condensation).

liquefaction in earth science, the conversion of a soft deposit, such as clay, to a jellylike state by severe shaking. During an earthquake buildings and lines of communication built on materials prone to liquefaction will sink and topple. In the Alaskan earthquake of 1964 liquefaction led to the destruction of much of the city of Anchorage.

liquefied petroleum gas (LPG) liquid form of butane, propane, or pentane, produced by the distillation of petroleum during oil refining. At room temperature these substances are gases, although they can be easily liquefied and stored under pressure in metal containers. They are used for heating and cooking where other fuels are not available: camping stoves and cigarette lighters, for instance, often use liquefied butane as fuel.

liquid state of matter between a solid and a gas. A liquid forms a level surface and assumes the shape of its container. Its atoms do not occupy fixed positions as in a crystalline solid, nor do they have freedom of movement as in a gas. Unlike a gas, a liquid is difficult to compress since pressure applied at one point is equally transmitted throughout (Pascal's principle). Hydraulics makes use of this property.

liquid air air that has been cooled so much that it has liquefied. This happens at temperatures below about -196°C (-321°F). The various constituent gases, including nitrogen, oxygen, argon, and neon, can be separated from liquid air by the technique of fractionation.

Air is liquefied by the Linde process, in which air is alternately compressed, cooled, and expanded, the expansion resulting each time in a considerable reduction in temperature. With the lower temperature the molecules move more slowly and occupy less space, so the air changes phase to become liquid.

liquid-crystal display (LCD) display of numbers (for example, in a calculator) or pictures (such as on a pocket television screen) produced by molecules of a substance in a semiliquid state with some crystalline properties, so that clusters of molecules align in parallel formations. The display is a blank until the application of an electric field, which 'twists' the molecules so that they reflect or transmit light falling on them. There are two main types of LCD are passive matrix and active matrix.

liquorice perennial European herb belonging to the legume family. The long sweet root yields an extract which is made into a hard

black paste and used in confectionery and medicines. (*Glycyrrhiza glabra*, family Leguminosae.)

LISP (acronym for *list processing*) high-level computer-programming language designed for manipulating lists of data items. It is used primarily in research into artificial intelligence (AI).

Developed in the late 1950s, and until recently common only in university laboratories, LISP is used more in the USA than in Europe, where the language PROLOG is often preferred for AI work.

listeriosis disease of animals that may occasionally infect humans, caused by the bacterium *Listeria monocytogenes*. The bacteria multiply at temperatures close to 0°C (32°F), which means they may flourish in precooked frozen meals if the cooking has not been thorough. Listeriosis causes flu-like symptoms and inflammation of the brain and its surrounding membranes. It can be treated with penicillin.

LISTSERV in computing, program that receives incoming messages for a mailing list and redistributes them to subscribers. Listserv was originally written for IBM mainframes but there are now many alternatives for UNIX machines and PCs, such as cMajordomo.

litchi or *lychee* evergreen tree belonging to the soapberry family. The delicately flavoured egg-shaped fruit has a rough brownish outer skin and a hard seed. The litchi is native to S China, where it has been cultivated for 2,000 years. (*Litchi chinensis*, family Sapindaceae.)

liquid-crystal display A liquid-crystal display consists of a liquid crystal sandwiched between polarizing filters similar to polaroid sunglasses. When a segment of the seven-segment display is electrified, the liquid crystal twists the polarized light from the front filter, allowing the light to bounce off the rear reflector and illuminate the segment.

lithification the conversion of an unconsolidated, newly deposited sediment into solid sedimentary rock by compaction of mineral grains that make up the sediment, new growth of the original mineral grains, and cementation by crystallization of new minerals from percolating aqueous solutions. The term is less commonly used to refer to solidification of molten lava or magma to form igneous rock.

lithium *Greek lithos 'stone'* soft, ductile, silver-white, metallic element, symbol Li, atomic number 3, relative atomic mass 6.941. It is one of the alkali metals, has a very low density (far less than most woods), and floats on water (specific gravity 0.57); it is the lightest of all metals. Lithium is used to harden alloys, and in batteries; its compounds are used in medicine to treat manic depression.

Lithium was named 1818 by Swedish chemist Jöns Berzelius, having been discovered the previous year by his student Johan A. Arfwedson (1792-1841). Berzelius named it after 'stone' because it is found in most igneous rocks and many mineral springs.

lithography printmaking technique invented in 1798 by Alois Senefelder, based on the mutual repulsion of grease and water. A drawing is made with greasy crayon on an absorbent stone, which is then wetted. The wet stone repels ink (which is greasy) applied to the surface and the crayon absorbs it, so that the drawing can be printed. Lithographic printing is used in book production, posters, and prints, and this basic principle has developed into complex processes.

Many artists have made brilliant use of the process since the early 19th century, including Delacroix, Goya, Isabey, Bonington, Daumier, Gavarni, Whistler, Toulouse-Lautrec (who devised colour effects of the most striking and original kind), Bonnard, and Vuillard.

lithosphere topmost layer of the Earth's structure, forming the jigsaw of plates that take part in the movements of plate tectonics. The lithosphere comprises the crust and a portion of the upper mantle. It is regarded as being rigid and moves about on the more elastic and less rigid asthenosphere. The lithosphere is about 100 km/63 mi thick.

litmus dye obtained from various lichens and used in chemistry as an indicator to test the acidic or alkaline nature of aqueous solutions; it turns red in the presence of acid, and blue in the presence of alkali.

litre metric unit of volume (symbol l), equal to one cubic decimetre (1.76 imperial pints/2.11 US pints). It was formerly defined as the volume occupied by one kilogram of pure water at 4°C at standard pressure, but this is slightly larger than one cubic decimetre.

Little Dipper another name for the most distinctive part of the constellation Ursa Minor, the Little Bear.

Little Willie prototype British tank built 1915. It consisted of little more than a rectangular box on two 'Creeping Grip' caterpillar tracks, with a two-wheeled steering unit connected to the rear, but it proved the viability of a tracked vehicle.

liver large organ of vertebrates, which has many regulatory and storage functions. The human liver is situated in the upper abdomen, and weighs about 2 kg/4.5 lb. It is divided into four lobes. The liver receives the products of digestion, converts glucose to glycogen (a long-chain carbohydrate used for storage), and breaks down fats. It removes excess amino acids from the blood, converting them to urea, which is excreted by the kidneys. The liver also synthesizes vitamins, produces bile and blood-clotting factors, and removes damaged red cells and toxins such as alcohol from the blood.

Livermore Valley valley in California, USA, site of the Lawrence Livermore Laboratory. Part of the University of California, it shares with Los Alamos Laboratory, New Mexico, all US military research into nuclear warheads and atomic explosives. It also conducts research into nuclear fusion, using high-integrity lasers.

liverwort nonvascular plant (with no 'veins' to carry water and food), related to hornworts and mosses; it is found growing in

damp places. (Class Hepaticae, order Bryophyta.)

The plant exists in two different reproductive forms, sexual and asexual, which appear alternately (see alternation of generations). The main sexual form consists of a plant body, or thallus, which may be flat, green, and lobed like a small leaf, or leafy and mosslike. The asexual, spore-bearing form is smaller, typically parasitic on the thallus, and produces a capsule from which spores are scattered.

lizard reptile generally distinguishable from snakes, which belong to the same order, by having four legs, moveable eyelids, eardrums, and a fleshy tongue, although some lizards are legless and snake-like in appearance. There are over 3,000 species of lizard worldwide. (Suborder Lacertilia, order Squamata.)

Like other reptiles, lizards are abundant in the tropics, although some species live as far north as the Arctic circle. There are about 20 families of lizards, including geckos, chameleons, skinks, monitors, agamas, and iguanas. The common or viviparous lizard (*Lacerta vivipara*), about 15 cm/6 in long, is found throughout Europe; in the far north, it hibernates through the long winter. Like many other species, it can shed its tail as a defence, later regrowing it. The frilled lizard (*Chlamydosaurus kingi*) of Australia has an erectile collar to frighten its enemies. There are two poisonous species of lizard, the Mexican bearded lizard and the gila monster. (For flying lizard see flying dragon.)

llama South American even-toed hoofed mammal belonging to the camel family, about 1.2 m/4 ft high at the shoulder. Llamas can be white, brown, or dark, sometimes with spots or patches. They are very hardy, and require little food or water. They spit when annoyed. (Species *Lama glama*, family Camelidae.)

Llamas are used in Peru as beasts of burden, and also for their wool, milk, and meat. Llamas and alpacas are both domesticated forms of the guanaco.

loach carplike freshwater fish with a long narrow body and no teeth in the small downward-pointing mouth, which is surrounded by barbels (sensitive bristles). Loaches are native to Asian and European waters. (Family Cobitidae.)

loam type of fertile soil, a mixture of sand, silt, clay, and organic material. It is porous, which allows for good air circulation and retention of moisture.

lobelia any of a group of temperate and tropical plants with white to mauve flowers. Lobelias may grow to shrub size but are mostly small annual plants. (Genus *Lobelia*, family Lobeliaceae.)

lobotomy another name for the former brain operation, cingulotomy.

The first rule of intelligent tinkering is to save all the parts.

PAUL EHRLICH German bacteriologist.
Saturday Review 5 June 1971

lobster any of various large marine crustaceans. Lobsters are grouped with freshwater crayfish in the suborder Reptantia ('walking'), although both lobsters and crayfish can also swim, using their fanlike tails. Lobsters have eyes on stalks and long antennae, and are mainly nocturnal. They scavenge and eat dead or dying fish. (Family Homaridae, order Decapoda.)

LOBSTER

When spiny lobsters migrate, they do so by walking in queues of up to 65 along the sea-bed, each clinging with its claws to the rear of the one in front. Scientific experiments with dead lobsters, weights and pulleys have shown that such an arrangement reduces drag and allows a 25% improvement in speed through the water.

True lobsters are distinguished by having very large 'claws' or pincers on their first pair of legs, and smaller ones on their second and third pairs. Spiny lobsters (family Palinuridae) have no large pincers. They communicate by means of a serrated pad at the base of their antennae, the 'sound' being picked up by sensory nerves located on hairlike outgrowths on their fellow lobsters up to 60 m/180 ft away.

lobworm marine annelid worm also called *lugworm*.

local area network (LAN) in computing, a network restricted to a single room or building. Local area networks enable around 500 devices to be connected together.

local bus in computing, an extension of the central processing unit (CPU) (bus (electrical pathway), designed to speed up data transfer between the CPU, discs, graphics boards, and other devices. The *Q*PCI bus has become the standard on PCs and more recently has been adopted for the Apple Macintosh.

Local Group in astronomy, a cluster of about 30 galaxies that includes our own, the Milky Way. Like other groups of galaxies, the Local Group is held together by the gravitational attraction among its members, and does not expand with the expanding universe. Its two largest galaxies are the Milky Way and the Andromeda galaxy; most of the others are small and faint.

local variable in computing, a *Q*variable that can be accessed only by the instructions within a particular *Q*subroutine.

lock construction installed in waterways to allow boats or ships to travel from one level to another. The earliest form, the **flash lock**,

lock Travelling downstream, a boat enters the lock with the lower gates closed. The upper gates are then shut and the water level lowered by draining through sluices. When the water level in the lock reaches the downstream level, the lower gates are opened.

was first seen in the East in 1st-century-AD China and in the West in 11th-century Holland. By this method barriers temporarily dammed a river and when removed allowed the flash flood to propel the waiting boat through or over any obstacle. This was followed in 12th-century China and 14th-century Holland by the pound lock. In this system the lock has gates at each end. Boats enter through one gate when the levels are the same both outside and inside. Water is then allowed in (or out of) the lock until the level rises (or falls) to the new level outside the other gate.

Locks are important to shipping where canals link oceans of differing levels, such as the Panama Canal, or where falls or rapids are replaced by these adjustable water 'steps'.

lock and key devices that provide security, usually fitted to a door of some kind. In 1778 English locksmith Robert Barron made the forerunner of the mortise lock, which contains levers that the key must raise to an exact height before the bolt can be moved. The Yale lock, a pin-tumbler cylinder design, was invented by US locksmith Linus Yale, Jr. in 1865. More secure locks include combination locks, with a dial mechanism that must be turned certain distances backwards and forwards to open, and time locks, which are set to be opened only at specific times.

Locks originated in the Far East over 4,000 years ago. The Romans developed the warded lock, which contains obstacles (wards) that the key must pass to turn.

Lockheed US aircraft manufacturer, the USA's largest military contractor. The company was founded in 1916 by two brothers, Allan and Malcolm Loughheed (they later changed the spelling of their name), who had built their first seaplane in 1913, with headquarters in Burbank, California. Lockheed built the Vega plane in 1926 (later used by Amelia Earhart in her solo transatlantic flight), the first fully pressurized aircraft, the XC-35, 1937, the P-38 Lightning fighter of World War II, and the TriStar passenger plane of the 1960s.

The P-38 Lightning shot down more Japanese aircraft than any other US fighter in the Pacific campaign. In 1974, the company was implicated in a scandal with the Japanese government, in which the then premier, Kakuei Tanaka, was found guilty of accepting bribes from the Lockheed corporation and forced to resign.

After a merger the company became Lockheed Martin Aeronautical Systems.

lockjaw former name for *tetanus*, a type of bacterial infection.

locomotion the ability to move independently from one place to another, occurring in most animals but not in plants. The development of locomotion as a feature of animal life is closely linked to another vital animal feature, that of nutrition. Animals cannot make their food, as can plants, but must find it first; often the food must be captured and killed, which may require great speed. Locomotion is also important in finding a mate, in avoiding predators, and in migrating to favourable areas.

locomotive engine for hauling railway trains. In 1804 Cornish engineer Richard Trevithick built the first steam engine to run on rails. Locomotive design did not radically improve until British engineer George Stephenson built the *Rocket* in 1829, which featured a multitube boiler and blastpipe, standard in all following steam locomotives. Today most locomotives are diesel or electric: diesel locomotives have a powerful diesel engine, and electric locomotives draw their power from either an overhead cable or a third rail alongside the ordinary track.

In a steam locomotive, fuel (usually coal, sometimes wood) is burned in a furnace. The hot gases and flames produced are drawn through tubes running through a huge water-filled boiler and heat up the water to steam. The steam is then fed to the cylinders, where it forces the pistons back and forth. Movement of the pistons is conveyed to the wheels by cranks and connecting rods. Diesel locomotives have a powerful diesel engine, burning oil.

The engine may drive a generator to produce electricity to power electric motors that turn the wheels, or the engine drives the wheels mechanically or through a hydraulic link. A number of gas-turbine locomotives are in use, in which a turbine spun by hot gases provides the power to drive the wheels.

locus *Latin 'place'* in mathematics, traditionally the path traced out by a moving point, but now defined as the set of all points on a curve satisfying given conditions. For example, the locus of a point that moves so that it is always at the same distance from another fixed point is a circle; the locus of a point that is always at the same distance from two fixed points is a straight line that perpendicularly bisects the line joining them.

LOCUST

Locust swarms can contain up to 10 billion individuals and cover a surface of 1,000 sq km/400 sq mi. The swarm can remain together for weeks, devastating crops and other vegetation for thousands of kilometres. Each square kilometre of locusts (up to 80 million) can consume 250 tonnes of food a day, the daily amount required to feed 80,000 people.

locust swarming grasshopper with short feelers, or antennae, and hearing organs on the abdomen (rear segment of the body). As winged adults, flying in swarms, locusts may be carried by the wind hundreds of miles from their breeding grounds; on landing they devour all vegetation. Locusts occur in nearly every continent. (Family Acrididae, order Orthoptera.)

locust tree another name for the *ôcarob*, a small tree of the Mediterranean region. It is also the name of several North American trees of the *ôlegume* family (Leguminosae).

lode geological deposit rich in certain minerals, generally consisting of a large vein or set of veins containing ore minerals. A system of veins that can be mined directly forms a lode, for example the mother lode of the California gold rush.

Lodes form because hot hydrothermal liquids and gases from magmas penetrate surrounding rocks, especially when these are limestones; on cooling, veins of ores formed from the magma then extend from the igneous mass into the local rock.

lodestar or *loadstar* a star used in navigation or astronomy, often *ôPolaris*, the Pole Star.

loess yellow loam, derived from glacial meltwater deposits and accumulated by wind in periglacial regions during the *ôice* ages. Loess usually attains considerable depths, and the soil derived from it is very fertile. There are large deposits in central Europe (Hungary), China, and North America. It was first described in 1821 in the Rhine area, and takes its name from a village in Alsace.

log in mathematics, abbreviation for *ôlogarithm*.

log any apparatus for measuring the speed of a ship; also the daily record of events on board a ship or aircraft.

The log originally consisted of a piece of weighted wood attached to a line with knots at equal intervals that was cast from the rear of a ship. The vessel's speed was estimated by timing the passage of the knots with a sandglass (like an egg timer). Today logs use electromagnetism and sonar.

loganberry hybrid between a *ôblackberry* and a *ôraspberry* with large, tart, dull-red fruit. It was developed in 1881 by US judge James H Logan.

logarithm or *log* the *ôexponent* or index of a number to a specified base – usually 10. For example, the logarithm to the base 10 of 1,000 is 3 because $10^3 = 1,000$; the logarithm of 2 is 0.3010 because $2 = 10^{0.3010}$. Before the advent of cheap electronic calculators, multiplication and division could be simplified by being replaced with the addition and subtraction of logarithms.

For any two numbers x and y (where $x = b^a$ and $y = b^c$) $x \times y = b^a \times b^c = b^{a+c}$; hence we would add the logarithms of x and y , and

look up this answer in antilogarithm tables.

Tables of logarithms and antilogarithms are available that show conversions of numbers into logarithms, and vice versa.

For example, to multiply 6,560 by 980, one looks up their logarithms (3.8169 and 2.9912), adds them together (6.8081), then looks up the antilogarithm of this to get the answer (6,428,800). Natural or Napierian logarithms are to the base e , an *ôirrational* number equal to approximately 2.7183.

The principle of logarithms is also the basis of the slide rule. With the general availability of the electronic pocket calculator, the need for logarithms has been reduced. The first log tables (to base e) were published by the Scottish mathematician John Napier in 1614. Base-ten logs were introduced by the Englishman Henry Briggs (1561–1631) and Dutch mathematician Adriaen Vlacq (1600–1667).

log file in computing, file that keeps a record of computer transactions. A log file might track the length and type of connection made to a network, or compile details of faxes sent by computer.

logic gate or *logic circuit* in electronics, one of the basic components used in building *ôintegrated* circuits. The five basic types of gate make logical decisions based on the functions NOT, AND, OR, NAND (NOT AND), and NOR (NOT OR). With the exception of the NOT gate, each has two or more inputs.

Information is fed to a gate in the form of binary-coded input signals (logic value 0 stands for 'off' or 'low-voltage pulse', logic 1 for 'on' or 'high-voltage'), and each combination of input signals yields a specific output (logic 0 or 1). An OR gate will give a logic 1 output if one or more of its inputs receives a logic 1 signal; however, an AND gate will yield a logic 1 output only if it receives a logic 1 signal through both its inputs. The output of a NOT or inverter gate is the opposite of the signal received through its single input, and a NOR or NAND gate produces an output signal that is the opposite of the signal that would have been produced by an OR or AND gate respectively. The properties of a logic gate, or of a combination of gates, may be defined and presented in the form of a diagram called a truth table, which lists the output that will be triggered by each of the possible combinations of input signals. The process has close parallels in computer programming, where it forms the basis of binary logic.

logic gate The circuit symbols for the five basic types of logic gate: OR, AND, NOT, NOR, and NAND. The truth table displays the output results of each possible combination of input signal.

LOGO Greek *ôlogos* 'word' high-level computer programming language designed to teach mathematical concepts. Developed in about 1970 at the Massachusetts Institute of Technology, it became popular in schools and with home computer users because of its 'turtle graphics' feature. This allows the user to write programs that create line drawings on a computer screen, or drive a small mobile robot (a 'turtle' or 'buggy') around the floor.

LOGO encourages the use of languages in a logical and structured way, leading to 'microworlds', in which problems can be solved by using a few standard solutions.

log off or **log out** in computing, the process by which a user identifies himself or herself to a multiuser computer and leaves the system.

log on or **log in** in computing, the process by which a user identifies himself or herself to a multiuser computer and enters the system. Logging on usually requires the user to enter a password before access is allowed.

lomomentum fruit similar to a pod but constricted between the seeds. When ripe, it splits into one-seeded units, as seen, for example, in the fruit of sainfoin *Onobrychis viciifolia* and radish *Raphanus raphanistrum*. It is a type of ζ schizocarp.

lone pair in chemistry, a pair of electrons in the outermost shell of an atom that are not used in bonding. In certain circumstances, they will allow the atom to bond with atoms, ions, or molecules (such as boron trifluoride, BF_3) that are deficient in electrons, forming coordinate covalent (dative) bonds in which they provide both of the bonding electrons.

longhorn beetle beetle with extremely long antennae, usually equalling the length of the entire body, and often twice its length. Their bodies are 2–150 mm/0.1–6 in long, usually cylindrical, and often mimic wasps, moss, or lichens. The larvae, white or yellow grubs, are wood-borers, mostly attacking decaying or dead wood, but they may bore into healthy trees causing much damage.

classification Longhorn beetles are in order Coleoptera, class Insecta, phylum Arthropoda.

longitude see ζ latitude and longitude.

The real scientist ... is ready to bear privations and, if need be, starvation rather than let anyone dictate to him which direction his work must take.

ALBERT SZENT-GYÖRGYI Hungarian-born US biochemist.
Science Needs Freedom 1943

longitudinal wave ζ wave in which the displacement of the medium's particles is in line with or parallel to the direction of travel of the wave motion.

long-sightedness or **hypermetropia** defect of vision in which a person is able to focus on objects in the distance, but not on close objects. It is caused by the failure of the lens to return to its normal rounded shape, or by the eyeball being too short, with the result that the image is focused on a point behind the retina. Long-sight-

edness is corrected by wearing spectacles fitted with ζ converging lenses, each of which acts like a magnifying glass.

loofah or **luffa** fibrous skeleton of the cylindrical fruit of the dish-cloth gourd *Luffa cylindrica*, family Cucurbitaceae, used as a bath sponge.

look-and-feel in computing, the general appearance of a user interface (usually a ζ graphical user interface). The concept of look-and-feel was the subject of several court cases in the USA. ζ Apple sued ζ Microsoft on the basis that the look-and-feel of Microsoft ζ Windows infringed its copyright. The case was decided principally in Microsoft's favour.

loom any machine for weaving yarn or thread into cloth. The first looms were used to weave sheep's wool about 5000 BC. A loom is a frame on which a set of lengthwise threads (warp) is strung.

A second set of threads (weft), carried in a shuttle, is inserted at right angles over and under the warp.

In most looms the warp threads are separated by a device called a treadle to create a gap, or shed, through which the shuttle can be passed in a straight line. A kind of comb called a reed presses each new line of weave tight against the previous ones. All looms have similar features, but on the power loom, weaving takes place automatically at great speed. Mechanization of weaving began in 1733 when British inventor John Kay invented the flying shuttle. In 1785 British inventor Edmund Cartwright introduced a steam-powered loom. Among recent developments are shuttleless looms, which work at very high speed, passing the weft through the warp by means of 'rapiers', and jets of air or water.

loon North American name for the ζ diver bird.

loop in computing, short for ζ program loop.

loop the part of a curve which encloses a space when the curve crosses itself. In a ζ flow chart, a path which keeps on returning to the same question. In a ζ flow chart, a path which keeps on returning to the same question.

loopback in computing, any connection that sends an output signal to the same system's input. Loopback adaptors are used in electrical testing.

loosestrife any of several plants belonging to the primrose family, including the yellow loosestrife (*L. vulgaris*), with spikes of yellow flowers, and the low-growing creeping jenny (*L. nummularia*). The striking purple loosestrife (*Lythrum salicaria*) belongs to a different family. (Genus *Lysimachia*, family Primulaceae; purple loosestrife family Lythraceae.)

loquat evergreen tree native to China and Japan, also known as the **Japan medlar**. The golden pear-shaped fruit has a delicate sweet-sour taste. (*Eriobotrya japonica*, family Rosaceae.)

longitudinal wave The diagram illustrates the motion of a longitudinal wave. Sound, for example, travels through air in longitudinal waves: the waves vibrate back and forth in the direction of travel. In the compressions the particles are pushed together, and in the rarefactions they are pulled apart.

The Determination of Longitude

BY TONY JONES

Being lost at sea was one of the greatest fears of the early navigators. Although the system of latitude and longitude had been used since the time of Ptolemy in the 2nd century, it was not until the late 18th century that navigation became a reliable art.

The problem is that while the latitude of any point of the Earth – its angular distance north or south of the equator – can be determined by careful measurements of the altitude of the Sun or stars, longitude is a different matter. Longitude is measured east or west from an arbitrary prime meridian, connecting the Earth's poles. Until it settled on Greenwich in 1884, the prime meridian was often that of the ship's home port. To find longitude at sea, a navigator had to note the time when the Sun or a star appeared due south and compare it with the predicted time the same body appeared due south from the prime meridian. The difference in times (where 1 h of time is 15°), was the ship's longitude.

Unfortunately, there were no clocks which could keep time on board ships. Throughout the great voyages of discovery from the 15th–18th centuries sailors were largely ignorant of their longitude, which is why Columbus, sailing westwards along a line of latitude, had no idea where he was when he landed in the New World in 1492.

In 1610, Galileo Galilei (1564–1642) discovered the four large moons of Jupiter. Every now and then the moons would pass in and out of the shadow of Jupiter and Galileo saw that these eclipses could provide a celestial clock for navigators. All that was needed were accurate predictions for the eclipses for a number of ports. By observing these eclipses, sailors would know the precise time at home and so be able to calculate their longitude by noting which stars were then due south.

Astronomers put a great deal of effort into studying the motions of Jupiter's moons (one such, Danish, astronomer Ole Rømer (1644–1710), found that the times of eclipses deviated systematically from predictions with the varying distance of Jupiter from the Earth, and so made the first measurement of the speed of light). However, the method was only usable when Jupiter was above the horizon in a dark, clear sky and an eclipse was imminent.

National observatories were founded in Paris (1667) and Greenwich (1675) with the prime purpose of developing astronomical methods of finding longitude. None the less, as the 18th century dawned no better method had come along and the increasing toll of lost ships and lives was causing growing concern. In a notorious accident in 1707, four Royal Navy ships, believing themselves to be in deeper water further east, were wrecked on the Scilly Isles with the loss of almost 2,000 lives.

Other ideas showed how desperate this problem had become. One proposal in 1713 would have stationed signal boats at 600-mile intervals across the Atlantic, delivering time signals in the form of exploding cannon shells.

Finally in 1714, under pressure from shipping and naval concerns, the British government set up a 'Board of Longitude' empowered to award a prize of £20,000 for a method of determining longitude at sea to a precision of half a degree.

The idea of a sea-going clock had been revived on several occasions since the 16th century, and Dutch astronomer Christiaan Huygens (1629–1695) had built and tested one in 1664. Yet no clock had been devised that could keep good time on a rolling ship through changes of temperature, barometric pressure and gravity while enduring the rigours of life at sea.

In 1735, a Lincolnshire clock-maker, John Harrison, presented his answer to the challenge. His sea-clock (known as H1) employed many novel features to ensure steady running and performed well in sea trials. Rather than claim the award, Harrison insisted on making an improved version, H2, which he delivered in 1741. An even better model, H3, was not completed until 1759, and in the intervening years another method was coming into contention.

The 'Board of Longitude' was dominated by astronomers who were hoping for a celestial rather than a mechanical solution. One such method, proposed as long ago as 1514, was to use the Moon as a clock. If the steadily shifting position of the Moon among the stars could be predicted, then precise measurements of its position should enable the time to be reckoned accurately enough for the determination of longitude. It was known as the lunar distance method. The problem was that the positions of the stars were poorly known, and sufficiently precise tables for the Moon's motion were not available.

While Harrison laboured on his clocks, these problems were gradually overcome. In 1725, former Astronomer Royal John Flamsteed's (1646–1719) catalogue of 3000 star positions was published and in 1757, cartographer Johann Tobias Mayer (1723–1762) of Nuremberg delivered accurate tables of the Moon's motion to the 'Board of Longitude'. Together with the recently invented sextant, navigators now had everything they needed to make use of the lunar distance method.

Shortly after completing H3, Harrison devised a dramatically different solution in the compact form of H4, an outside pocket watch. H4 seemed to be the perfect solution to the longitude problem and performed exceedingly well in sea trials, losing only 5 s on its first transatlantic voyage in 1761. However, a leading advocate of the lunar distance method, astronomer Nevil Maskelyne (1732–1811), stalled the development of Harrison's clocks in the hope of gaining the award himself. In 1765, he became Astronomer Royal and took up his *ex officio* seat on the Board of Longitude. Under Maskelyne's influence, Harrison was denied his award for the next eight years while the Board prevaricated, demanding additional tests and the construction of more clocks.

Finally, in faltering health, Harrison appealed directly to King George III who intervened with the Board and ensured in 1773 that Harrison was given his just reward, three years before his death.

Between 1772 and 1779, James Cook (1728–1779) took several replicas of H4 on his voyages of discovery, and by the turn of the century the 'marine chronometer' was in mass production by several clock-makers and had become a common sight on ocean-going ships.

radio transmitter and two to four secondary transmitters situated within 1,000–2,000 km/600–1,250 mi. Signals from the transmitters are detected by the ship or aircraft's navigation receiver, and slight differences (phase differences) between the master and secondary transmitter signals indicate the position of the receiver. The system is accurate to within 500 m/1,640 ft at a range of 2,000 km/1,250 mi, and covers the N Atlantic and N Pacific oceans, and adjacent areas such as the Mediterranean and Arabian Gulf.

The original Loran stem (Loran A) was used to guide bombers on night raids in Europe and N Africa in 1944.

lorikeet any of various small, brightly coloured parrots found in SE Asia and Australasia.

loris any of a group of small prosimian primates native to S and SE Asia. Lorises are slow-moving, tree-dwelling, and nocturnal. They have very large eyes; true lorises have no tails. They climb without leaping, gripping branches tightly and moving on or hanging below them. (Family Lorisidae.)

The slender loris (*Loris tardigradus*) of S India and Sri Lanka is about 20 cm/8 in long. The tubbier slow loris (*Nycticebus coucang*) of SE Asia is 30 cm/1 ft.

The **angwantibo** (genus *Arctocebus*), **potto** (genus *Perodicticus*), and **galagos** or **bushbabies** (genera *Galago* and *Euticus*) are similar African forms.

lory any of various small Australasian parrots. Lorries are very brightly coloured and characterized by a tongue with a brushlike tip adapted for feeding on pollen and nectar from flowers. (Subfamily Lorinae, order Psittaciformes.)

There is a bibliography of books about these parrots and a list of addresses of lori and parakeet clubs around the world.

Los Alamos town in New Mexico, USA, which has had a centre for atomic and space research since 1942. In World War II the first atom (nuclear fission) bomb was built there (under Robert Oppenheimer); the hydrogen bomb was also developed there.

lossless compression in computing, a data compression technique that reduces the number of bits used to represent data in a file, thereby reducing its size while retaining all the original information. This makes it suitable for computer code and text files. Lossless compression typically achieves space savings of 30%.

lossy compression in computing, a data compression technique that dramatically reduces the size of a file by eliminating superfluous data. The lost information is either unnoticeable to the user, or can be recovered during decompression by extrapolation of the existing data. JPEG and MPEG are lossy methods that can reduce the size of graphics, audio, and video files by over 90%.

lotus any of several different plants, especially the **water lily** (*Nymphaea lotus*), frequent in Egyptian art, and the pink Asiatic lotus (*Nelumbo nucifera*), a sacred symbol in Hinduism and Buddhism, whose flower head floats erect above the water.

Others are those of the genus *Lotus* (family Leguminosae), including the bird's foot trefoil (*L. corniculatus*); the **zizyphus shrub** (*Zizyphus lotus*), known to the ancient Greeks who used its fruit to make a type of bread and also a wine supposed to induce happy oblivion – hence **lotus-eaters**; and the **American lotus** (*Nelumbo lutea*), a pale yellow water lily of the southern USA.

LOTUS

The sacred lotus *Nelumbo nucifera* heats up when it is ready for pollination. For up to four days it maintains steamy temperatures of 30–35°C to attract insects and encourage them to move from one flower to another.

Lotus 1–2–3 Spreadsheet computer program, produced by Lotus Development Corporation. It first appeared in 1982 and its combination of spreadsheet, graphics display, and data management contributed to the rapid acceptance of the IBM Personal Computer in businesses.

Lotus Notes in computing, business software combining database and message facilities to help people in an organization to share information and work together. Notes is a very versatile

groupware program that can be customized to suit the needs of the organization.

loudness subjective judgement of the level or power of sound reaching the ear. The human ear cannot give an absolute value to the loudness of a single sound, but can only make comparisons between two different sounds. The precise measure of the power of a sound wave at a particular point is called its **intensity**.

Accurate comparisons of sound levels may be made using sound-level meters, which are calibrated in units called **decibels**.

loudspeaker electromechanical device that converts electrical signals into sound waves, which are radiated into the air. The most common type of loudspeaker is the **moving-coil speaker**. Electrical signals from, for example, a radio are fed to a coil of fine wire wound around the top of a cone. The coil is surrounded by a magnet. When signals pass through it, the coil becomes an electromagnet, which by moving causes the cone to vibrate, setting up sound waves.

loudspeaker A moving-coil loudspeaker. Electrical signals flowing through the wire coil turn it into an electromagnet, which moves as the signals vary. The attached cone vibrates, producing sound waves.

louse parasitic insect that lives on mammals. It has a flat, segmented body without wings, and a tube attached to the head, used for sucking blood from its host. (Order Anoplura.)

Some lice occur on humans, including the head louse (*Pediculus capitis*) and the body louse (*P. corporis*), a typhus carrier. Pediculosis is a skin disease caused by infestation of lice. Most mammals have a species of lice adapted to living on them. Biting lice belong to a different order of insects (Mallophaga) and feed on the skin, feathers, or hair.

LOUSE

The human pubic (crab) louse, *Phthirus pubis*, lives on any coarse hair on the body, and may thus be found in eyebrows, beards, and armpits. It spends almost all its life attached to the same hair.

lovebird any of a group of birds belonging to the parrot family, found in Africa south of the Sahara. They take their name from the

affection the male displays towards the female. Lovebirds are generally just larger than sparrows (about 16 cm/6 in) and coloured green with red, yellow, and black markings on the head. (Genus *Agapornis*, family Psittacidae, order Psittaciformes.)

love-in-a-mist perennial plant of S Europe with fine leaves that create a soft haze around the delicate blue or white flowers; these are followed by large seedheads and, later, a profusion of new plants. (*Nigella damascena*, family Ranunculaceae.)

Lowell Observatory US astronomical observatory founded by Percival Lowell at Flagstaff, Arizona, with a 61-cm/24-in refractor opened in 1896. The observatory now operates other telescopes at a nearby site on Anderson Mesa including the 1.83-m/72-in Perkins reflector of Ohio State and Ohio Wesleyan universities.

lowest common denominator (lcd) the smallest number that is a multiple and thus divides exactly into each of the denominators of a set of fractions.

lowest common multiple (lcm) the smallest number that is a multiple of all of the numbers of a given set. See **lowest common denominator**.

low-level language in computing, a programming language designed for a particular computer and reflecting its internal machine code; low-level languages are therefore often described as **machine-oriented languages**. They cannot easily be converted to run on a computer with a different central processing unit, and they are relatively difficult to learn because a detailed knowledge of the internal working of the computer is required. Since they must be translated into machine code by an assembler program, low-level languages are also called **assembly languages**.

A mnemonic-based low-level language replaces binary machine-code instructions, which are very hard to remember, write down, or correct, with short codes chosen to remind the programmer of the instructions they represent. For example, the binary-code instruction that means 'store the contents of the accumulator' may be represented with the mnemonic STA.

In contrast, high-level languages are designed to solve particular problems and are therefore described as **problem-oriented languages**.

LPG abbreviation for **liquefied petroleum gas**.

LSD (abbreviation for **lysergic acid diethylamide**) psychedelic drug, an ψ hallucinogen. Colourless, odourless, and easily synthesized, it is nonaddictive and nontoxic, but its effects are unpredictable. Its use is illegal in most countries.

The initials are from the German lyserg-säure-diethylamid; the drug was first synthesized by a German chemist, Albert Hofmann, in 1943. In 1947 the US Central Intelligence Agency began experiments with LSD, often on unsuspecting victims. Many psychiatrists in North America used it in treatment in the 1950s. Its use as a means to increased awareness and enhanced perception was popularized in the 1960s by US psychologist Timothy Leary (1920-1997), novelist Ken Kesey, and chemist Augustus Owsley Stanley III. A series of laws to ban LSD were passed in the USA from 1965 (by which time 4 million Americans were estimated to have taken it) and in the UK in 1966; other countries followed suit. The drug had great influence on the hippie movement.

LSI (abbreviation for **large-scale integration**) the technology that enables whole electrical circuits to be etched into a piece of semiconducting material just a few millimetres square.

By the late 1960s a complete computer processor could be integrated on a single chip, or ψ integrated circuit, and in 1971 the US electronics company Intel produced the first commercially available ψ microprocessor. Very large-scale integration (VLSI) results in even smaller chips.

lubricant substance used between moving surfaces to reduce friction. Carbon-based (organic) lubricants, commonly called grease and oil, are recovered from petroleum distillation.

Extensive research has been carried out on chemical additives to lubricants, which can reduce corrosive wear, prevent the accumulation of 'cold sludge' (often the result of stop-start driving in city

traffic jams), keep pace with the higher working temperatures of aviation gas turbines, or provide radiation-resistant greases for nuclear power plants. Silicon-based spray-on lubricants are also used; they tend to attract dust and dirt less than carbon-based ones.

A solid lubricant is graphite, an allotropic form of carbon, either flaked or emulsified (colloidal) in water or oil.

lucerne another name for the plant ψ alfalfa.

lugworm any of a group of marine ψ annelid worms that grow up to 10 in/25 cm long. They are common burrowers between tide-marks and are useful for their cleansing and powdering of the beach sand, of which they may annually bring to the surface about 5,000 tonnes per hectare/2,000 tons per acre. (Genus *Arenicola*.)

lumbago pain in the lower region of the back, usually due to strain or faulty posture. If it occurs with ψ sciatica, it may be due to pressure on spinal nerves by a slipped disc. Treatment includes rest, application of heat, and skilled manipulation. Surgery may be needed in rare cases.

lumbar puncture or **spinal tap** insertion of a hollow needle between two lumbar (lower back) vertebrae to withdraw a sample of cerebrospinal fluid (CSF) for testing. Normally clear and colourless, the CSF acts as a fluid buffer around the brain and spinal cord. Changes in its quantity, colour, or composition may indicate neurological damage or disease.

lumen SI unit (symbol lm) of luminous flux (the amount of light passing through an area per second).

The lumen is defined in terms of the light falling on a unit area at a unit distance from a light source of luminous intensity of one ψ candela. One lumen at a wavelength of 5,550 angstroms equals 0.0014706 watts.

lumen in biology, the space enclosed by an organ, such as the bladder, or a tubular structure, such as the gastrointestinal tract.

luminescence emission of light from a body when its atoms are excited by means other than raising its temperature. Short-lived

Lumière

Auguste Marie Louis Nicolas (1862-1954) and Louis Jean (1864-1948) French brothers who pioneered cinematography. In February 1895 they patented their cinematograph, a combined camera and projector operating at 16 frames per second, screening short films for the first time on 22 March, and in December opening the world's first cinema in Paris. Among their first films were the simple documentaries *La Sortie des usines Lumière/Workers Leaving the Lumière Factory* 1895 and *L'Arrivée d'un train en gare de La Ciotat/The Arrival of a Train at Ciotat Station* 1895, and the comedy *L'Arroseur arrosé/The Hoser Hosed* 1895.

Between 1896 and 1900, the Lumières employed a number of camera operators to travel around the world and both demonstrate their invention and film new documentary shorts. Production was abandoned in 1900 after their films were displayed at the Paris Exposition. The brothers withdrew from filmmaking itself to concentrate on developing film technology and marketing their inventions.

luminescence is called fluorescence; longer-lived luminescence is called phosphorescence.

When exposed to an external source of energy, the outer electrons in atoms of a luminescent substance absorb energy and 'jump' to a higher energy level. When these electrons 'jump' back to their former level they emit their excess energy as light. Many different exciting mechanisms are possible: visible light or other forms of electromagnetic radiation (ultraviolet rays or X-rays), electron bombardment, chemical reactions, friction, and radioactivity. Certain living organisms produce bioluminescence.

luminosity or **brightness** in astronomy, the amount of light emitted by a star, measured in magnitudes. The apparent brightness of an object decreases in proportion to the square of its distance from the observer. The luminosity of a star or other body can be expressed in relation to that of the Sun.

luminous paint preparation containing a mixture of pigment, oil, and a phosphorescent sulphide, usually calcium or barium. After exposure to light it appears luminous in the dark. The luminous paint used on watch faces contains radium, is radioactive and therefore does not require exposure to light.

lumpsucker marine bony fish so called from the frequent presence of a sucking disc formed from the united ventral fins. It is also distinguished by an absence of scales and the presence of spined plates along its side. Lumpsuckers feed mainly on small crustaceans and jellyfish.

classification The lumpsuckers belong to the genus *Cyclopterus*, family Cyclopteridae, order Scorpaeniformes, class Osteichthyes.

lung large cavity of the body, used for \dot{o} gas exchange. It is essentially a sheet of thin, moist membrane that is folded so as to occupy less space. Most tetrapod (four-limbed) vertebrates have a pair of lungs occupying the thorax. The lung tissue, consisting of multitudes of air sacs and blood vessels, is very light and spongy, and functions by bringing inhaled air into close contact with the blood so that oxygen can pass into the organism and waste carbon dioxide can be passed out. The efficiency of lungs is enhanced by breathing movements, by the thinness and moistness of their surfaces, and by a constant supply of circulating blood.

In humans, the principal diseases of the lungs are tuberculosis, pneumonia, bronchitis, emphysema, and cancer.

lungfish any of a group of fleshy-finned bony fishes found in South America, Australia, and Africa. They have elongated bodies,

lung The human lungs contain 300,000 million tiny blood vessels which would stretch for 2,400 km/1,500 mi if laid end to end. A healthy adult at rest breathes 12 times a minute; a baby breathes at twice this rate. Each breath brings 350 millilitres of fresh air into the lungs, and expels 150 millilitres of stale air from the nose and throat.

and grow to about 2 m/6 ft, and in addition to gills have 'lungs' with which they can breathe air during periods of drought conditions. (Genera *Lepidosiren*, *Neoceratodus*, and *Protopterus*, subclass Dipnoi.)

Lungfish are related to the lobe-fins such as the coelacanth, and were abundant 350 million years ago.

lupin any of a group of leguminous plants (see *legume*) that comprises about 300 species. Lupins are native to Mediterranean regions and parts of North and South America, and some species are naturalized in Britain. Their spikes of pea-like flowers may be white, yellow, blue, or pink. *L. albus* is cultivated in some places for cattle fodder and for green manuring; other varieties are cultivated in Europe as cottage garden plants. (Genus *Lupinus*, family Leguminosae.)

lupus in medicine, any of various diseases characterized by lesions of the skin. One form (*lupus vulgaris*) is caused by the tubercle bacillus (see *tuberculosis*). The organism produces ulcers that spread and eat away the underlying tissues. Treatment is primarily with standard antituberculous drugs, but ultraviolet light may also be used.

Lupus erythematosus (LE) has two forms: *discoid LE*, seen as red, scaly patches on the skin, especially the face; and *disseminated or systemic LE*, which may affect connective tissue anywhere in the body, often involving the internal organs. The latter is much more serious. Treatment is with δ corticosteroids. LE is an δ autoimmune disease.

lurcher British hunting dog of no established breed but of greyhound or deerhound type, often crossed with a collie. It was traditionally used by poachers to catch rabbits and hares, as it would hunt without drawing attention to itself by barking.

lurk in computing, to read a USENET newsgroup without making a contribution. Before introducing themselves to the group, it is advisable for newcomers to lurk for a week or two in order to assess its members and their methods. That way, they can avoid posting an inappropriate message and attracting δ flames.

luteinizing hormone δ hormone produced by the pituitary gland. In males, it stimulates the testes to produce androgens (male sex hormones). In females, it works together with follicle-stimulating hormone to initiate production of egg cells by the ovary. If fertilization occurs, it plays a part in maintaining the pregnancy by controlling the levels of the hormones oestrogen and progesterone in the body.

lutetium *Latin Lutetia 'Paris'* silver-white, metallic element, the last of the δ lanthanide series, symbol Lu, atomic number 71, relative atomic mass 174.97. It is used in the 'cracking', or breakdown, of petroleum and in other chemical processes. It was named by its discoverer, French chemist Georges Urbain, (1872-1938) after his native city.

lux SI unit (symbol lx) of illuminance or illumination (the light falling on an object). It is equivalent to one δ lumen per square metre or to the illuminance of a surface one metre distant from a point source of one δ candela.

LW abbreviation for *long wave*, a radio wave with a wavelength of over 1,000 m/3,300 ft; one of the main wavebands into which radio frequency transmissions are divided.

lychee alternative spelling of δ litchi, a fruit-bearing tree.

Lycos in computing, δ search engine for the δ World Wide Web. Lycos is a database compiled by Web δ crawlers that comb the Internet for Web, δ FTP and δ Gopher sites, indexing them by title, headings, keywords, and text.

Lycos, named after a particularly voracious hunting spider, started as a research project at Carnegie Mellon University in Pittsburgh, USA, but became a commercial venture in 1995. By August 1996 Lycos had indexed over 60 million δ URLs.

Lyddite British explosive used for filling artillery shells in World War I. Actually molten and cast picric acid, the name was adopted

in order to conceal the nature of the substance and taken from the initial trials which were conducted at Lydd, in S England.

Lyell, Charles (1797-1875)

Scottish geologist. In his *Principles of Geology* 1830-33, he opposed the French anatomist Georges Cuvier's theory that the features of the Earth were formed by a series of catastrophes, and expounded the Scottish geologist James Hutton's view, known as uniformitarianism, that past events were brought about by the same processes that occur today - a view that influenced Charles Darwin's theory of evolution. Knighted 1848.

Lyell suggested that the Earth was as much as 240 million years old (in contrast to the 6,000 years of prevalent contemporary theory), and provided the first detailed description of the Tertiary period, dividing it into the Eocene, Miocene, and older and younger Pliocene periods. Darwin simply applied Lyell's geological method - explaining the past through what is observable in the present - to biology.

lymph fluid found in the lymphatic system of vertebrates.

Lymph is drained from the tissues by lymph capillaries, which empty into larger lymph vessels (lymphatics). These lead to lymph nodes (small, round bodies chiefly situated in the neck, armpit, groin, thorax, and abdomen), which process the lymphocytes produced by the bone marrow, and filter out harmful substances and bacteria. From the lymph nodes, vessels carry the lymph to the thoracic duct and the right lymphatic duct, which drain into the large veins in the neck. Some vertebrates, such as amphibians, have a lymph heart, which pumps lymph through the lymph vessels.

lymph nodes small masses of lymphatic tissue in the body that occur at various points along the major lymphatic vessels. Tonsils and adenoids are large lymph nodes. As the lymph passes through them it is filtered, and bacteria and other microorganisms are engulfed by cells known as macrophages.

Lymph nodes are sometimes mistakenly called lymph 'glands', and the term 'swollen glands' refers to swelling of the lymph nodes caused by infection.

lymphocyte type of white blood cell with a large nucleus, produced in the bone marrow. Most occur in the δ lymph and blood, and around sites of infection. B lymphocytes or δ B cells are responsible for producing δ antibodies. T lymphocytes or δ T cells have several roles in the mechanism of δ immunity.

lymphokines chemical messengers produced by lymphocytes that carry messages between the cells of the immune system (see δ immunity). Examples include interferon, which initiates defensive reactions to viruses, and the interleukins, which activate specific δ immune cells.

lynx wild cat found in rocky and forested regions of North America and Europe. About 1 m/3 ft in length, it has a short tail and tufted ears, and the long, silky fur is reddish brown or grey with dark spots. The North American bobcat or bay lynx (*Felis rufus*) looks similar but is smaller. Some zoologists place the lynx, the bobcat, and the δ caracal in a separate genus, *Lynx*. (Species *Felis lynx*, family Felidae.)

lymph Lymph is the fluid that carries nutrients and white blood cells to the tissues. Lymph enters the tissue from the capillaries (right) and is drained from the tissues by lymph vessels. The lymph vessels form a network (left) called the lymphatic system. At various points in the lymphatic system, lymph nodes (centre) filter and clean the lymph.

Lynx in computing, text-only Web browser for UNIX computers.

lyophilization technical term for the freeze-drying process used for foods and drugs and in the preservation of organic archaeological remains.

Progress in science depends on new techniques, new discoveries, and new ideas, probably in that order.

Lyra small but prominent constellation of the northern hemisphere, represented as the lyre of Orpheus. Its brightest star is Vega.

Epsilon Lyrae is a system of four gravitationally linked stars. Beta Lyrae is an eclipsing binary. The Ring nebula, M57, is a planetary nebula.

lyrebird either of two species of large birds found in SE Australia. They have very stout beaks and short, rounded wings; the tail has 16 feathers, and in the males the exterior pair of feathers are curved in the shape of a lyre; the tail of the female is long, broad,

and normal in shape. Lyrebirds nest on the ground, and feed on insects, worms, and snails. (Genus *Menura*, family Menuridae, order Passeriformes.)

Lyrebirds live in the thick undergrowth, or sandy gullies of forests; they rarely fly, but run or strut with the tail spread horizontally. *M. superba* is 1 m/3 ft long, and of a brownish colour, with blue tinges; *M. alberti* is of a warmer, reddish colour.

lyretail African freshwater fish, 6 cm/2.4 in long, whose tail has two outward-curving fin supports for a central fin area which looks like the strings of a lyre. The male is bright blue with red markings; the less brightly coloured female has plainer fins. (Species *Aphyosemion australe*.)

Lyretails lay their eggs in mud at the bottom of swamps. In the event of a drought, the eggs usually survive in a dormant state and hatch with the next rainfall.

lysis in biology, any process that destroys a cell by rupturing its membrane or cell wall (see *olysosome*).

lysosome membrane-enclosed structure, or organelle, inside a cell, principally found in animal cells. Lysosomes contain enzymes that can break down proteins and other biological substances. They play a part in digestion, and in the white blood cells known as phagocytes the lysosome enzymes attack ingested bacteria.

M

m symbol for metre.

MA abbreviation for mechanical advantage.

McAdam, John Loudon (1756–1836)

Scottish engineer, inventor of the macadam road surface. It originally consisted of broken granite bound together with slag or gravel, raised for drainage. Today, it is bound with tar or asphalt.

McAdam introduced a method of road building that raised the road above the surrounding terrain, compounding a surface of small stones bound with gravel on a firm base of large stones.

A camber, making the road slightly convex in section, ensured that rainwater rapidly drained off the road and did not penetrate the foundation. By the end of the 19th century, most of the main roads in Europe were built in this way.

macadamia edible nut of a group of trees native to Australia, especially *M. ternstroemia*, and cultivated in Hawaii, South Africa, Zimbabwe, and Malawi. The nuts are slow-growing; they are harvested when they drop. (Genus *Macadamia*, family Proteaceae.)

macaque any of a group of medium-sized Old World monkeys. Various species live in forests from the Far East to N Africa. The rhesus monkey and the Barbary ape belong to this group. (Genus *Macaca*.)

Macaques range from long-tailed to tailless types, and have well-developed cheek pouches to carry food.

macaw any of a group of large, brilliantly coloured, long-tailed tropical American parrots, such as the blue and yellow macaw *Ara ararauna*. They can be recognized by the massive beak, about half the size of the head, and by the extremely long tail. (Genera *Ara*, *Aratinga*, and *Anodorhynchus*.)

Every statement in physics has to state relations between observable quantities.

ERNST MACH Austrian physicist and philosopher.
Mach's Principle

Mach, Ernst (1838–1916)

Austrian philosopher and physicist. He was an empiricist, believing that science is a record of facts perceived by the senses, and that acceptance of a scientific law depends solely on its standing the practical test of use; he opposed such concepts as Isaac Newton's 'absolute motion'. GMach numbers are named after him.

McDonald Observatory observatory of the University of Texas on Mount Locke, Texas. It is the site of a 2.72-m/107-in reflector opened in 1969 and a 2.08-m/82-in reflector opened in 1939.

machine device that allows a small force (the effort) to overcome a larger one (the load). There are three basic machines: the inclined plane (ramp), the lever, and the wheel and axle. All other machines are combinations of these three basic types. Simple machines derived from the inclined plane include the wedge, the gear, and the screw; the spanner is derived from the lever; the pulley from the wheel.

The principal features of a machine are its mechanical advantage, which is the ratio of load to effort, its velocity ratio, and its efficiency, which is the work done by the load divided by the work done by the effort; the latter is expressed as a percentage. In a perfect machine, with no friction, the efficiency would be 100%. All practical machines have efficiencies of less than 100%, otherwise perpetual motion would be possible.

One machine can do the work of fifty ordinary men. No machine can do the work of one extraordinary man.

machine code in computing, a set of instructions that a computer's central processing unit (CPU) can understand and obey directly, without any translation. Each type of CPU has its own machine code. Because machine-code programs consist entirely of binary digits (bits), most programmers write their programs in an easy-to-use high-level language. A high-level program must be translated into machine code – by means of a compiler or interpreter program – before it can be executed by a computer.

Where no suitable high-level language exists or where very efficient machine code is required, programmers may choose to write programs in a low-level, or assembly, language, which is eventually translated into machine code by means of an assembler program.

Microprocessors (CPUs based on a single integrated circuit) may be classified according to the number of machine-code instructions that they are capable of obeying: CISC (complex instruction set computer) microprocessors support up to 200 instructions, whereas RISC (reduced instruction set computer) microprocessors support far fewer instructions but execute programs more rapidly.

machine-readable of data, readable directly by a computer without the need for retyping. The term is usually applied to files on disc or tape, but can also be applied to typed or printed text that can be scanned for optical character recognition or bar codes.

machine tool automatic or semi-automatic power-driven machine for cutting and shaping metals. Machine tools have powerful electric motors to force cutting tools into the metal: these are made from hardened steel containing heat-resistant metals such as tungsten and chromium. The use of precision machine tools in mass-production assembly methods ensures that all duplicate parts produced are virtually identical.

Many machine tools now work under computer control and are employed in factory automation. The most common machine tool is the lathe, which shapes shafts and similar objects. A milling

machine cuts metal with a rotary toothed cutting wheel. Other machine tools cut, plane, grind, drill, and polish.

Mach number ratio of the speed of a body to the speed of sound in the undisturbed medium through which the body travels. Mach 1 is reached when a body (such as an aircraft) has a velocity greater than that of sound ('passes the sound barrier'), namely 331 m/1,087 ft per second at sea level. It is named after Austrian physicist Ernst Mach (1838-1916).

MACHO (abbreviation for *massive astrophysical compact halo object*) component of the Galaxy's dark matter. Most MACHOs are believed to be brown dwarfs, tiny failed stars with a mass of about 8% that of the Sun, but they may also include neutron stars left behind after supernova explosions. MACHOs are identifiable when they move in front of stars causing microlensing (magnification) of the star's light. Astronomers first identified MACHOs in 1993 and estimate that they account for 20% of the dark matter.

Macintosh range of microcomputers originally produced by Apple Computer. The Apple Macintosh, introduced 1984, was the first popular microcomputer with a graphical user interface. The success of the Macintosh prompted other manufacturers and software companies to create their own graphical user interfaces. Most notable of these are Microsoft Windows, which runs on IBM PC-compatible microcomputers, and OS/2, from the Open Software Foundation, which is used with many UNIX systems.

The success of PCs running Microsoft's Windows 3, launched in 1990, put pressure on Apple and the arrival of Windows 95 started Apple's decline. Apple's annual revenues peaked at \$11.1 billion in 1995, and by 1997 had slumped to \$7.1 billion. For comparison, Compaq, the market-leading PC supplier, increased its sales from \$10.9 billion in 1995 to \$18.1 billion in 1997. In 1997, however, Microsoft heavily invested in Apple.

mackerel any of various fish of the mackerel family, especially the common mackerel (*Scomber scombrus*) found in the N Atlantic and Mediterranean. It weighs about 0.7 kg/1.5 lb, and is blue with irregular black bands down its sides, the sides and under surface having a metallic sheen. Like all mackerels, it has a deeply forked tail, and a sleek, streamlined body form. (Family Scombroidea.)

The largest of the mackerels is the tuna, which weighs up to 700 kg/1,550 lb.

macro in computer programming, a new command created by combining a number of existing ones. For example, a word processing macro might create a letterhead or fax cover sheet, inserting words, fonts, and logos with a single keystroke or mouse click. Macros are also useful to automate computer communications - for example, users can type a macro to ask their computer to dial an Internet Service Provider (ISP), retrieve e-mail and USENET articles, and then disconnect. A macro key on the keyboard combines the effects of pressing several individual keys.

macro- a prefix meaning on a very large scale, as opposed to micro.

macromolecule in chemistry, a very large molecule, generally a polymer.

macrophage type of white blood cell, or leucocyte, found in all vertebrate animals. Macrophages specialize in the removal of bacteria and other microorganisms, or of cell debris after injury. Like phagocytes, they engulf foreign matter, but they are larger than phagocytes and have a longer life span. They are found throughout the body, but mainly in the lymph and connective tissues, and especially the lungs, where they ingest dust, fibres, and other inhaled particles.

Macropodidae family of marsupials with large powerful hind feet, comprising all the kangaroos.

Macrozamia genus of Australian cycad with stiff, palm-like pinnae leaves. Macrozamia are an ancient group of plants and do not produce flowers; a pineapple-like seed cone develops from male and female cones which are on separate plants.

Madagascar teal or *Bernier's teal* a small duck apparently confined to a few small lakes and marshy areas in W Madagascar and now severely threatened with extinction. It is thought that there are at most a few hundred teal left alive and the opening of an airstrip nearby greatly increases the risk of sport shooting. (Species *Anas bernieri*.)

mad cow disease common name for bovine spongiform encephalopathy, an incurable brain condition in cattle.

madder any of a group of plants bearing small funnel-shaped flowers, especially the perennial vine *R. tinctorum* which grows in Europe and Asia, the red root of which yields a red dye called alizarin (now made synthetically from coal tar). (Genus *Rubia*, family Rubiaceae.)

mafic rock plutonic rock composed chiefly of dark-coloured minerals containing abundant magnesium and iron, such as olivine and pyroxene. It is derived from magnesium and ferric (iron). The term mafic also applies to dark-coloured minerals rich in iron and magnesium as a group.

Magdalenian final cultural phase of the Palaeolithic (Old Stone Age) in W Europe, best known for its art, and lasting from c. 16,000-10,000 BC. It was named after the rock-shelter of La Madeleine in SW France.

Magellan NASA space probe to Venus, launched in May 1989; it went into orbit around Venus Aug 1990 to make a detailed map of the planet by radar. It revealed volcanoes, meteorite craters, and fold mountains on the planet's surface. *Magellan* mapped 98% of Venus.

In Oct 1994 *Magellan* was instructed to self-destruct by entering the atmosphere around Venus where it burned up.

MAGELLAN MISSION TO VENUS

Details of the NASA Magellan project that sent a probe to Venus. It includes a full mission overview, technical details about the planet, many images, and an animated view of Venus.

Magellanic Clouds in astronomy, the two galaxies nearest to our own galaxy. They are irregularly shaped, and appear as detached parts of the Milky Way, in the southern constellations Dorado, Tucana, and Mensa.

The Large Magellanic Cloud spreads over the constellations of Dorado and Mensa. The Small Magellanic Cloud is in Tucana. The Large Magellanic Cloud is 169,000 light years from Earth, and about a third the diameter of our Galaxy; the Small Magellanic Cloud, 180,000 light years away, is about a fifth the diameter of our Galaxy. They are named after the navigator Ferdinand Magellan, who first described them.

maggot soft, plump, limbless larva of flies, a typical example being the larva of the blowfly which is deposited as an egg on flesh.

MAGGOT

Wounds infested with maggots heal quickly and without spread of gangrene or other infection. This is because the maggots eat only the dead and suppurating flesh within a wound. This fact, first noted by World War I doctors in the trenches, is still used today in 'maggot therapy'.

magic bullet term sometimes used for a drug that is specifically targeted on certain cells or tissues in the body, such as a small collection of cancerous cells (see *cancer*) or cells that have been invaded by a virus. Such drugs can be made in various ways, but *monoclonal antibodies* are increasingly being used to direct the drug to a specific target.

The term was originally associated with the German chemist Paul Ehrlich (1854–1915) who discovered the first specific against *syphilis*.

magic numbers in atomic physics certain numbers of *neutrons* or *protons* (2, 8, 20, 28, 50, 82, 126) in the nuclei of elements of outstanding stability, such as lead and helium.

Such stability is the result of neutrons and protons being arranged in completed 'layers' or 'shells'.

magic square in mathematics, a square array of numbers in which the rows, columns, and diagonals add up to the same total. A simple example employing the numbers 1 to 9, with a total of 15, has a first row of 6, 7, 2, a second row of 1, 5, 9, and a third row of 8, 3, 4.

maglev (acronym for *magnetic levitation*) high-speed surface transport using the repellant force of superconductive magnets (see *superconductivity*) to propel and support, for example, a train above a track.

Technical trials on a maglev train track began in Japan in the 1970s, and a speed of 500 kph/310 mph has been reached, with a cruising altitude of 10 cm/4 in. The train is levitated by electro-magnets and forward thrust is provided by linear motors aboard the cars, propelling the train along a reaction plate.

The German government approved a plan to build the world's first commercial maglev 1994. The Berlin–Hamburg line will cost DM8.9 billion (£3.5 billion). The three-hour journey time will be reduced by a third.

maglev The repulsion of superconducting magnets and electromagnets in the track keeps a maglev train suspended above the track. By varying the strength and polarity of the track electromagnets, the train can be driven forward.

magma molten rock material beneath the Earth's (or any of the terrestrial planets) surface from which *igneous rocks* are formed. *Lava* is magma that has extruded on to the surface.

magnesia common name for *magnesium oxide*.

magnesium lightweight, very ductile and malleable, silver-white, metallic element, symbol Mg, atomic number 12, relative atomic mass 24.305. It is one of the alkaline-earth metals, and the lightest of the commonly used metals. Magnesium silicate, carbonate, and chloride are widely distributed in nature. The metal is used in alloys and flash photography. It is a necessary trace element in the human diet, and green plants cannot grow without it since it is an essential constituent of the photosynthetic pigment *chlorophyll* ($C_{55}H_{72}MgN_4O_5$).

It was named after the ancient Greek city of Magnesia, near where it was first found. It was first recognized as an element by Scottish chemist Joseph Black 1755 and discovered in its oxide by English chemist Humphry Davy 1808. Pure magnesium was isolated 1828 by French chemist Antoine-Alexandre-Brutus Bussy.

magnesium oxide or *magnesia* MgO white powder or colourless crystals, formed when magnesium is burned in air or oxygen; a typical basic oxide. It is used to treat acidity of the stomach, and in some industrial processes; for example, as a lining brick in furnaces, because it is very stable when heated (refractory oxide).

magnet any object that forms a magnetic field (displays *magnetism*), either permanently or temporarily through induction, causing it to attract materials such as iron, cobalt, nickel, and alloys of these. It always has *two* magnetic poles, called north and south. The world's strongest magnet is at the Lawrence Berkeley National Laboratory in California. The magnet, which is a superconducting coil made of a niobium-tin alloy, has a field that is 250,000 times stronger than the Earth's magnetic field.

magnetic compass device for determining the direction of the horizontal component of the Earth's magnetic field. It consists of a magnetized needle with its north-seeking pole clearly indicated, pivoted so that it can turn freely in a plane parallel to the surface of the Earth (in a horizontal circle).

The needle will turn so that its north-seeking pole points towards the Earth's magnetic north pole. See also *compass*.

Walkers, sailors, and other travellers use a magnetic compass to find their direction. The direction of the geographic, or true, North Pole is, however, slightly different from that of the magnetic north pole, and so the readings obtained from a compass of this sort must be adjusted using tables of magnetic corrections or information marked on local maps.

magnetic declination see *angle of declination*.

magnetic dip see *dip*, *magnetic* and *angle of dip*.

magnetic dipole the pair of north and south magnetic poles, separated by a short distance, that makes up all magnets. Individual magnets are often called 'magnetic dipoles'. Single magnetic poles, or monopoles, have never been observed despite being searched for. See also *magnetic domain*.

magnetic field region around a permanent magnet, or around a conductor carrying an electric current, in which a force acts on a moving charge or on a magnet placed in the field. The field can be represented by lines of force, which by convention link north and south poles and are parallel to the directions of a small compass needle placed on them. A magnetic field's magnitude and direction are given by the *magnetic flux density*, expressed in *teslas*. See also *polar reversal*.

magnetic flux measurement of the strength of the magnetic field around electric currents and magnets. Its SI unit is the weber; one weber per square metre is equal to one tesla.

The amount of magnetic flux through an area equals the product of the area and the magnetic field strength at a point within that area.

magnetic induction the production of magnetic properties in unmagnetized iron or other ferromagnetic material when it is brought close to a magnet. The material is influenced by the mag-

magnetic field The Earth's magnetic field is similar to that of a bar magnet with poles near, but not exactly at, the geographic poles. Compass needles align themselves with the magnetic field, which is horizontal near the equator and vertical at the magnetic poles.

net's magnetic field and the two are attracted. The induced magnetism may be temporary, disappearing as soon as the magnet is removed, or permanent depending on the nature of the iron and the strength of the magnet.

Electromagnets make use of temporary induced magnetism to lift sheets of steel: the magnetism induced in the steel by the approach of the electromagnet enables it to be picked up and transported. To release the sheet, the current supplying the electromagnet is temporarily switched off and the induced magnetism disappears.

magnetic-ink character recognition (MICR) in computing, a technique that enables special characters printed in magnetic ink to be read and input rapidly to a computer. MICR is used extensively in banking because magnetic-ink characters are difficult to forge and are therefore ideal for marking and identifying cheques.

magnetic-ink character recognition An example of one of the uses of magnetic ink in automatic character recognition. Because of the difficulties in forging magnetic-ink characters, and the speed with which they can be read by computer systems, MICR is used extensively in banking.

magnetic material one of a number of substances that are strongly attracted by magnets and can be magnetized. These include iron, nickel, and cobalt, and all those alloys that contain a proportion of these metals.

Soft magnetic materials can be magnetized very easily, but the magnetism induced in them (see magnetic induction) is only

temporary. They include Stalloy, an alloy of iron with 4% silicon used to make the cores of electromagnets and transformers, and the materials used to make 'iron' nails and paper clips.

Hard magnetic materials can be permanently magnetized by a strong magnetic field. Steel and special alloys such as Alcomax, Alnico, and Ticonal, which contain various amounts of aluminium, nickel, cobalt, and copper, are used to make permanent magnets. The strongest permanent magnets are ceramic, made under high pressure and at high temperature from powders of various metal oxides.

magnetic pole region of a magnet in which its magnetic properties are strongest. Every magnet has two poles, called north and south.

The north (or north-seeking) pole is so named because a freely suspended magnet will turn so that this pole points towards the Earth's magnetic north pole. The north pole of one magnet will be attracted to the south pole of another, but will be repelled by its north pole.

Unlike poles may therefore be said to attract, like poles to repel.

magnetic resonance imaging (MRI) diagnostic scanning system based on the principles of nuclear magnetic resonance. MRI yields finely detailed three-dimensional images of structures within the body without exposing the patient to harmful radiation. The technique is invaluable for imaging the soft tissues of the body, in particular the brain and the spinal cord.

Claimed as the biggest breakthrough in diagnostic imaging since the discovery of X-rays, MRI is a noninvasive technique based on a magnet which is many thousands of times stronger than the Earth's magnetic field. It causes nuclei within the atoms of the body to align themselves in one direction. When a brief radio pulse is beamed at the body the nuclei spin, emitting weak radio signals as they realign themselves to the magnet. These signals, which are characteristic for each type of tissue, are converted electronically into images on a viewing screen.

Also developed around magnetic technology, **magnetic resonance spectroscopy (MRS)** is a technique for investigating conditions in which there is a disturbance of the body's energy metabolism, including ischaemia and toxic damage due to drugs or other chemicals. MRS is also of value in diagnosing some cancers.

magnetic storm in meteorology, a sudden disturbance affecting the Earth's magnetic field, causing anomalies in radio transmissions and magnetic compasses. It is probably caused by sunspot activity.

magnetic strip or **magnetic stripe** thin strip of magnetic material attached to a plastic card (such as a credit card) and used for recording data.

magnetic tape narrow plastic ribbon coated with an easily magnetizable material on which data can be recorded. It is used in sound recording, audiovisual systems (videotape), and computing. For mass storage on commercial mainframe computers, large reel-to-reel tapes are still used, but cartridges are becoming popular. Various types of cartridge are now standard on minis and PCs, while audio cassettes are sometimes used with home computers.

Magnetic tape was first used in sound recording in 1947, and made overdunding possible, unlike the direct-to-disc system it replaced. Two-track tape was introduced in the 1950s and four-track in the early 1960s; today, studios use 16-, 24-, or 32-track tape, from which the tracks are mixed down to a stereo master tape.

In computing, magnetic tape was first used to record data and programs in 1951 as part of the UNIVAC 1 system. It was very popular as a storage medium for external memory in the 1950s and 1960s. Since then it has been largely replaced by magnetic discs as a working medium, although tape is still used to make backup copies of important data. Information is recorded on the tape in binary form, with two different strengths of signal representing 1 and 0.

magnetism phenomena associated with magnetic fields. Magnetic fields are produced by moving charged particles: in electromagnets, electrons flow through a coil of wire connected to a

battery; in permanent magnets, spinning electrons within the atoms generate the field.

susceptibility Substances differ in the extent to which they can be magnetized by an external field (susceptibility). Materials that can be strongly magnetized, such as iron, cobalt, and nickel, are said to be **ferromagnetic**; this is due to the formation of areas called domains in which atoms, weakly magnetic because of their spinning electrons, align to form areas of strong magnetism. Magnetic materials lose their magnetism if heated to the Curie temperature. Most other materials are **paramagnetic**, being only weakly pulled towards a strong magnet. This is because their atoms have a low level of magnetism and do not form domains. **Diamagnetic** materials are weakly repelled by a magnet since electrons within their atoms act as electromagnets and oppose the applied magnetic force. **Antiferromagnetic** materials have a very low susceptibility that increases with temperature; a similar phenomenon in materials such as ferrites is called **ferrimagnetism**.

application Apart from its universal application in dynamos, electric motors, and switch gears, magnetism is of considerable importance in advanced technology – for example, in particle accelerators for nuclear research, memory stores for computers, tape recorders, and cryogenics.

magnetite black, strongly magnetic opaque mineral, Fe_3O_4 , of the spinel group, an important ore of iron. Widely distributed, magnetite is found in nearly all igneous and metamorphic rocks. Some deposits, called lodestone, are permanently magnetized. Lodestone has been used as a compass since the first millennium BC. Today the orientations of magnetite grains in rocks are used in the study of the Earth's magnetic field (see palaeomagnetism).

Science can be introduced to children well or poorly. If poorly, children can be turned away from science; they can develop a lifelong antipathy; they will be in far worse condition than if they had never been introduced to science at all.

ISAAC ASIMOV Russian-born US writer.

magneto simple electric generator, often used to provide the electricity for the ignition system of motorcycles and used in early cars.

It consists of a rotating magnet that sets up an electric current in a coil, providing the spark.

magnetohydrodynamics (MHD) field of science concerned with the behaviour of ionized gases or liquid in a magnetic field. Systems have been developed that use MHD to generate electrical power.

MND-driven ships have been tested in Japan. In 1991 two cylindrical thrusters with electrodes and niobium-titanium superconducting coils, soaked in liquid helium, were placed under the passenger boat *Yamato 1*. The boat, 30 m/100 ft long, was designed to travel at 8 knots. An electric current passed through the electrodes accelerates water through the thrusters, like air through a jet engine, propelling the boat forward.

magnetomotive force or **magnetic potential** the work done in carrying a unit magnetic pole around a magnetic circuit. The concept is analogous to electromotive force in an electric circuit.

magnetosphere volume of space, surrounding a planet, controlled by the planet's magnetic field, and acting as a magnetic 'shell'. The Earth's magnetosphere extends 64,000 km/40,000 mi towards the Sun, but many times this distance on the side away from the Sun.

The extension away from the Sun is called the **magnetotail**. The outer edge of the magnetosphere is the **magnetopause**. Beyond this is a turbulent region, the **magnetosheath**, where the solar wind is deflected around the magnetosphere. Inside the magnetosphere, atomic particles follow the Earth's lines of magnetic force. The magnetosphere contains the Van Allen radiation belts. Other planets have magnetospheres, notably Jupiter.

magnetron thermionic valve (electron tube) for generating very high-frequency oscillations, used in radar and to produce

microwaves in a microwave oven. The flow of electrons from the tube's cathode to one or more anodes is controlled by an applied magnetic field.

magnification measure of the enlargement or reduction of an object in an imaging optical system. Linear magnification is the ratio of the size (height) of the image to that of the object.

Angular magnification is the ratio of the angle subtended at the observer's eye by the image to the angle subtended by the object when viewed directly.

magnifying glass the simplest optical instrument, a hand-held converging lens used to produce a magnified, erect and virtual image. The image, being virtual, or an illusion created by the refraction of light rays in the lens, can only be seen by looking through the magnifying glass.

magnitude in astronomy, measure of the brightness of a star or other celestial object. The larger the number denoting the magnitude, the fainter the object. Zero or first magnitude indicates some of the brightest stars. Still brighter are those of negative magnitude, such as Sirius, whose magnitude is -1.46 . **Apparent magnitude** is the brightness of an object as seen from Earth; **absolute magnitude** is the brightness at a standard distance of 10 parsecs (32.6 light years).

Each magnitude step is equal to a brightness difference of 2.512 times. Thus a star of magnitude 1 is $(2.512)^5$ or 100 times brighter than a sixth-magnitude star just visible to the naked eye. The apparent magnitude of the Sun is -26.8 , its absolute magnitude $+4.8$.

magnitude size irrespective of sign, used especially for vectors irrespective of direction.

magnolia any of a group of trees or shrubs belonging to the magnolia family, native to North America and E Asia, and cultivated as ornamentals. Magnolias vary in height from 60 cm/2 ft to 30 m/150 ft. The large, fragrant single flowers are white, pink, or purple. The southern magnolia (*M. grandiflora*) of the USA grows up to 24 m/80 ft tall and has white flowers 23 cm/9 in across. (Genus *Magnolia*, family Magnoliaceae.)

Magnox early type of nuclear reactor used in the UK, for example in Calder Hall, the world's first commercial nuclear power station. This type of reactor uses uranium fuel encased in tubes of magnesium alloy called Magnox. Carbon dioxide gas is used as a coolant to extract heat from the reactor core. See also nuclear energy.

magpie any of various birds belonging to the crow family. They feed on insects, snails, young birds, and carrion, and are found in Europe, Asia, N Africa, and W North America. (Genus *Pica*, family Corvidae, order Passeriformes.)

mahogany timber from any of several trees found in the Americas and Africa. Mahogany is a tropical hardwood obtained chiefly by rainforest logging. It has a warm red colour and can be highly polished. True mahogany comes mainly from *S. mahagoni* and *S. macrophylla*, but other types come from the Spanish and Australian cedars, the Indian redwood, and other trees of the mahogany family, native to Africa and the East Indies. (True mahogany genus *Swietenia*, family Meliaceae.)

S. mahagoni is under threat due to its popularity in the West for use in musical instruments, furniture, and veneers. There are attempts to make it the first hardwood tree listed under the CITES convention (the Convention on International Trade in Endangered Species).

maidenhair any of a group of ferns, especially *A. capillus-veneris*, with delicately hanging hairlike fronds ending in small kidney-shaped spore-bearing lobes. It is widely distributed in the Americas, and is sometimes found in the British Isles. (Genus *Adiantum*, family Polypodiaceae.)

maidenhair tree another name for the ginkgo, a surviving member of an ancient group of plants.

mail-bombing or **dumping** in computing, sending large amounts of e-mail to an individual or organization, usually in retaliation for

a breach of etiquette. The aim is to completely fill the recipient's hard disc with immense, useless files, causing at best irritation, and at worst total computer failure. While mail-bombing often achieves its aim of annoying the individual concerned, it also inconveniences systems administrators and other users.

mailbox in computing, folder in which electronic mail is stored, typically divided into 'in' and 'out' trays. Users usually have two mailboxes: one on their PC, and another at their mail server at the Internet Service Provider (ISP), where incoming messages await collection.

mailbox name in an e-mail address, the name to the left of the @ sign, signifying the individual's mailbox for handling mail. All e-mail addresses appear in the form mailbox name@domain name.

mail-enabled in computing, a piece of software that can generate e-mail without launching a separate electronic mail program.

mailing list in computing, list of people who receive a given piece of e-mail. Mailing lists are an easy way for people to share professional and technical information: hackers (see *chacking*) often set up ad hoc mailing lists so that they can collaborate on a single piece of programming. It is also possible to join mailing lists devoted to special topics, social and leisure interests.

mail merge in computing, a feature offered by some word-processing packages that enables a list of personal details, such as names and addresses, to be combined with a general document outline to produce individualized documents.

For example, a club secretary might create a file containing a mailing list of the names and addresses of the club members. Whenever a letter is to be sent to all club members, a general letter outline is prepared with indications as to where individual names and addresses need to be added. The mail-merge feature then combines the file of names and addresses with the letter outline to produce and print individual letters addressed to each club member.

mail reflector in computing, an e-mail address that acts as an alias, redistributing all mail received to another address or to a mailing list. Individuals use mail reflectors to hide their true identities or to forward messages following a change of e-mail address.

The same method can be used to address a particular group of people - for example, Blogs College might create mail reflectors for all staff (staff@blogs.ac.uk), for students (students@blogs.ac.uk), former students (alumni@blogs.ac.uk), and so on.

mail server software in client/server computing (see *client-server architecture*), software that stores e-mail and distributes it only to the authorized recipient.

Maine Coon breed of domestic longhaired cat native to North America. It is the oldest American breed and one of the largest. Its fur is shaggy and uneven in length and of a coppery brown colour with black markings. It has a thick, bushy tail similar to the raccoon from which it gets its name.

The breed was registered in 1861, but was only officially recognized in the USA in 1976.

mainframe large computer used for commercial data processing and other large-scale operations. Because of the general increase in computing power, the differences between the mainframe, (supercomputer, minicomputer, and microcomputer (personal computer)) are becoming less marked.

Mainframe manufacturers include IBM, Amdahl, Fujitsu, and Hitachi. Typical mainframes have from 128 MB to 4 GB of memory and hundreds of gigabytes of disc storage.

mains electricity the domestic electricity-supply system. In the UK, electricity is supplied to houses, offices, and most factories as an alternating current at a frequency of 50 hertz and a root-mean-square voltage of 230 volts. An advantage of having an alternating supply is that it may easily be changed, using a transformer, to a lower and safer voltage, such as 9 volts, for operating toys and for recharging batteries.

main sequence in astronomy, the part of the Hertzsprung-Russell diagram that contains most of the stars, including the Sun. It runs diagonally from the top left of the diagram to the lower right. The most massive (and hence brightest) stars are at the top left, with the least massive (coolest) stars at the bottom right.

maize (North American *corn*) tall annual cereal plant that produces spikes of yellow grains which are widely used as an animal feed. Grown extensively in all subtropical and warm temperate regions, its range has been extended to colder zones by hardy varieties developed in the 1960s. (*Zea mays*.)

Sweetcorn, a variety of maize in which the sugar is not converted to starch, is a familiar vegetable, known as corn on the cob: other varieties are made into hominy, polenta, popcorn, and corn bread. Sweetcorn is used in corn oil and fermented to make alcohol; its stalks are made into paper and hardboard.

It might seem unfair to reward a person for having so much pleasure over the years, asking the maize plant to solve specific problems and then watching its responses.

malachite common copper ore, basic copper carbonate, $\text{Cu}_2\text{CO}_3(\text{OH})_2$. It is a source of green pigment and is used as an antifungal agent in fish farming, as well as being polished for use in jewellery, ornaments, and art objects.

malacology branch of zoology concerned with the study of molluscs. It is distinguished from conchology, which is the study of mollusc shells only.

malamute breed of dog that takes its name from an Inuit people of Alaska. Stockily built and very hardy, it was prized as a sled dog. The malamute stands up to 63 cm/25 in tall, has a thick, bristly coat of grey or black with white markings, and carries its tail curved over its back.

It is similar in size, markings, and abilities to the Siberian husky.

malaria infectious parasitic disease of the tropics transmitted by mosquitoes, marked by periodic fever and an enlarged spleen. When a female mosquito of the *Anopheles* genus bites a human who has malaria, it takes in with the human blood one of four malaria protozoa of the genus *Plasmodium*. This matures within the insect and is then transferred when the mosquito bites a new victim. Malaria affects about 267 million people in 103 countries, and in 1995 around 2.1 million people died of the disease. In sub-Saharan Africa alone between 1.5 and 2 million children die from malaria and its consequences each year.

liver, then multiplies to attack the red blood cells. Within the red blood cells the parasites multiply, eventually causing the cells to rupture and other cells to become infected. The cell rupture tends to be synchronized, occurring every 2–3 days, when the symptoms of malaria become evident.

In Brazil a malaria epidemic broke out among new settlers in the Amazon region, with 287,000 cases 1983 and 500,000 cases 1988. **treatment** Quinine, the first drug used against malaria, has now been replaced by synthetics, such as chloroquine, used to prevent or treat the disease. However, chloroquine-resistant strains of the main malaria parasite, *Plasmodium falciparum*, are spreading rapidly in many parts of the world.

The drug mefloquine (Lariam) is widely prescribed for use in areas where chloroquine-resistant malaria prevails. It is surrounded by controversy, however, as it has been linked to unpleasant side effects, including psychiatric disturbances such as anxiety and hallucinations, epileptic seizures, and memory loss.

Another drug, artemether, derived from the shrub wormwood, was found in 1996 trials to be as effective as quinine in the treatment of cerebral malaria.

An experimental malaria vaccine SPf66, developed by Colombian scientist Manuel Patarroyo, was trialled in 1994 in rural Tanzania, where villagers are bitten an average of 300 times a year by infected mosquitoes. It reduced the incidence of malaria by one third. However, further trials of SPf66 in the Gambia concluded in 1995 that the vaccine provided only 8% protection for young children. A further trial in Thailand in 1996 failed to provide any evidence of its effectiveness.

In 1993 research began into using chelating agents, which remove surplus iron from the blood, to treat malaria.

malic acid $\text{HOOCCH}_2\text{CH}(\text{OH})\text{COOH}$ organic crystalline acid that can be extracted from apples, plums, cherries, grapes, and other fruits, but occurs in all living cells in smaller amounts, being one of the intermediates of the Krebs cycle.

mallard common wild duck from which domestic ducks were bred, found almost worldwide. The male can grow to a length of 60 cm/2 ft and usually has a glossy green head, white collar, and chestnut brown breast with a pale grey body, while the female is mottled brown. Mallards are omnivorous dabbling ducks. (Species *Anas platyrhynchos*, subfamily Anatinae, order Anseriformes.)

mallee any of a group of small eucalyptus trees and shrubs with many small stems and thick underground roots that retain water. Before irrigation farming began, dense thickets of mallee characterized most of NW Victoria, Australia, known as the mallee region. (Genus *Eucalyptus*, family Myrtaceae.)

mallee fowl Australian bird *Leipoa ocellata*, family Megapodiidae. It is found in arid areas where the mallee grows. Its young are born with feathers and are immediately independent, never needing any parental care. Mallee fowl grow to a length of around 60 cm/23 in.

The males have a unique method of incubating eggs by digging a pit in winter, then filling it with leaves and grass, and covering the resulting mound with sand. This compost heap then begins to rot and to generate heat. The female lays one egg every several days in a hole dug by the male, who then keeps the temperature at 33°C/91°F by testing the mound with his tongue, and adding or removing sand. When the chick hatches, it digs its way out.

mallow any flowering plant of the mallow family, including the European common mallow (*M. sylvestris*), the tree mallow (*A. arborea*), marsh mallow (*A. officinalis*), and hollyhock (*A. rosea*). Most mallows have pink or purple flowers. (Genera *Malva*, *Lavatera*, and *Althaea*, family Malvaceae.)

malnutrition condition resulting from a defective diet where certain important food nutrients (such as protein, vitamins, or carbohydrates) are absent. It can lead to deficiency diseases.

A related problem is undernourishment . The World Health Organization estimated 1995 that one-third of the world's children are undernourished. According to UNICEF, in 1996 around 86 million children under the age of five (50% of all under-fives) in South Asia were malnourished, compared to 32 million (25%) in sub-

Saharan Africa.

In a report released at the World Food Summit in Rome in 1996, the World Bank warned of an impending international food crisis. In 1996, more than 800 million people were unable to get enough food to meet their basic needs. Eighty-two countries, half of them in Africa, did not grow enough food for their own people; nor could they afford to import it. The World Bank calculated that food production would have to double over the next 30 years as the world population increases. Contrary to earlier predictions, food stocks and particularly grain stocks have fallen during the 1990s.

By 1996, 20 countries did not have enough water to meet people's needs, and water tables were falling in crucial regions such as the American Midwest, India, and China. Meanwhile, 90 million people are added to the planet's population every year. The increasingly prosperous and populous nations of East Asia are placing pressure on supplies, as people become wealthier they often eat more meat, which is a less efficient use of resources.

malt in brewing, grain (barley, oats, or wheat) artificially germinated and then dried in a kiln. Malts are fermented to make beers or lagers, or fermented and then distilled to produce spirits such as whisky.

maltase enzyme found in plants and animals that breaks down the disaccharide maltose into glucose.

Maltese-cross tube cathode-ray tube used to demonstrate some of the properties of cathode rays. The cathode rays, or electron streams, emitted by the tube's electron gun are directed towards a fluorescent screen in front of which hangs a metal Maltese cross. Those electrons that hit the screen give up their kinetic energy and cause its phosphor coating to fluoresce. However, the sharply defined cross-shaped shadow cast on the screen shows that electrons are unable to pass through the Maltese cross. Cathode rays are thereby shown to travel in straight lines, and to be unable to pass through metal.

Maltese dog breed of long-coated lap dog. Its white coat is straight and silky and parted from head to tail and the short tail is doubled into the coat on the back. Maltese dogs have dark eyes, long drooping ears, and small feet. The ideal maximum height is 25 cm/10 in, and the weight is 3–4 kg/6.5–9 lb.

Maltese dogs are the most ancient lap-dog breed, their characteristics having been preserved for over 2,000 years.

maltose $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ a disaccharide sugar in which both monosaccharide units are glucose.

It is produced by the enzymic hydrolysis of starch and is a major constituent of malt, produced in the early stages of beer and whisky manufacture.

mamba either of two venomous snakes belonging to the cobra family, found in Africa south of the Sahara. Unlike cobras, they are not hooded. (Genus *Dendroaspis*, family Elapidae.)

The green mamba (*D. angusticeps*) is 1.5 m/5 ft long or more and lives in trees, feeding on birds and lizards. The black mamba (*D. polylepsis*) is the largest venomous snake in Africa, occasionally as long as 3.4 m/11 ft, and spends more time on the ground.

mammal any of a large group of warm-blooded vertebrate animals characterized by having mammary glands in the female; these are used for suckling the young. Other features of mammals are hair (very reduced in some species, such as whales); a middle ear formed of three small bones (ossicles); a lower jaw consisting of two bones only; seven vertebrae in the neck; and no nucleus in the red blood cells. (Class Mammalia.)

Mammals are divided into three groups: placental mammals,

Less than 3% of mammals are monogamous. Where monogamy is the norm, females usually synchronize their breeding as an extra precaution.

where the young develop inside the mother's body, in the uterus, receiving nourishment from the blood of the mother via the placenta; marsupials, where the young are born at an early stage of development and develop further in a pouch on the mother's body where they are attached to and fed from a nipple; and monotremes, where the young hatch from an egg outside the mother's body and are then nourished with milk.

The monotremes are the least evolved and have been largely displaced by more sophisticated marsupials and placentals, so that there are only a few types surviving (platypus and echidna). Placentals have spread to all parts of the globe, and where placentals have competed with marsupials, the placentals have in general displaced marsupial types. However, marsupials occupy many specialized niches in South America and, especially, Australasia.

According to the Red List of endangered species published by the World Conservation Union (IUCN) for 1996, 25% of mammal species are threatened with extinction.

The theory that marsupials succeed only where they do not compete with placentals was shaken 1992, when a tooth, 55 million years old and belonging to a placental mammal, was found in Murgon, Australia, indicating that placental animals appeared in Australia at the same time as the marsupials. The marsupials, however, still prevailed.

There are over 4,000 species of mammals, adapted to almost every way of life. The smallest shrew weighs only 2 g/0.07 oz, the largest whale up to 140 tonnes.

mammary gland in female mammals, a milk-producing gland derived from epithelial cells underlying the skin, active only after the production of young. In all but monotremes (egg-laying mammals), the mammary glands terminate in teats which aid infant suckling. The number of glands and their position vary between species. In humans there are 2, in cows 4, and in pigs between 10 and 14.

The hatched young of monotremes simply lick milk from a specialized area of skin on the mother's abdomen.

mammography X-ray procedure used to screen for breast cancer. It can detect abnormal growths at an early stage, before they can be seen or felt.

mammoth extinct elephant, remains of which have been found worldwide. Some were 50% taller than modern elephants; others were much smaller. (Genus *Mammuthus* (or *Elephas*).)

The woolly mammoth (*M. primigenius*) of northern zones, the size of an Indian elephant, had long fur and large inward-curving tusks. Various species of mammoth were abundant in both the Old World and the New World from Pleistocene times, and were hunted by humans for food.

manakin any of a group of birds found in South and Central America, about 15 cm/6 in long and often brightly coloured. They feed on berries and other small fruits. The males of the genus *Manacus* clear a patch of the forest floor with a small tree as a display perch. (Family Pipridae, order Passeriformes.)

manatee any of a group of plant-eating aquatic mammals found in marine bays and sluggish rivers, usually in thick, muddy water. They have flippers as forelimbs, no hindlimbs, and a short rounded and flattened tail used for swimming. The marine manatees can grow up to about 4.5 m/15 ft long and weigh up to 600 kg/1,323 lb. (Genus *Trichechus*, family Trichechidae, order Sirenia.)

All three species of manatee are in danger of becoming extinct as a result of pollution and because they are hunted for food. They are the Amazonian manatee (*T. inunguis*), found in the river Amazon; the African manatee (*T. senegalensis*), which lives in the rivers and coastal areas of W Africa; and the West Indian manatee (*T. manatus*), which lives in the Caribbean Sea and along the east coasts of tropical North and South America. Only about 2,400 West Indian manatees remain in the main population around Florida; more than 200 died in 1996, poisoned by an algal toxin.

Manchester terrier breed of smooth-haired black-and-tan terrier. Manchester terriers have a long, wedge-shaped head, small dark eyes, and V-shaped ears, hanging close to the head. The usual weight is 8 kg/17.5 lb and the height 38–41 cm/15–16 in.

MANATEE FACTS

<http://www.objectlinks.com/Manatee/manfacts.htm>

Information provided by the Save the Manatee Club of Florida, USA, describing the manatee and its habitat, behaviour, life span, and reproduction. Detailed information is also provided on conservation measures employed to protect the species.

The breed has a long neck tapering from the sloping shoulders to the head, and a narrow and deep chest. The legs are quite straight and the tail is thick where it joins the body, tapering to a point. The glossy coat should be jet black and rich mahogany tan on the head; the muzzle should be tanned to the nose, which, with the nasal bone, is jet black; the forelegs should be half tanned and the hind legs tanned on the inside, but not on the outside.

The earliest recognizable Manchester terrier is portrayed in an illuminated manuscript book of hours of the 15th century. It is generally accepted that the pure breed had its origin in and around Manchester, England.

mandarin type of small orange.

mandragora or **mandrake** any of a group of almost stemless Old World plants with narcotic (pain-killing and sleep-inducing) properties, belonging to the nightshade family. They have large leaves, pale blue or violet flowers, and round berries known as devil's apples. (Genus *Mandragora*, family Solanaceae.)

The humanlike shape of the root of *M. officinarum* gave rise to the superstition that it shrieks when pulled from the ground.

mandrake another name for the plant mandragora.

mandrill large W African forest-living baboon, active mainly on the ground. It has large canine teeth like the drill (*M. leucophaeus*), to which it is closely related. The nose is bright red and the cheeks are striped with blue; the thick skin of the buttocks is also red, and the fur is brown, apart from a yellow beard. (Species *Mandrillus sphinx*.)

Males are much larger than females, showing greater sexual dimorphism than any other primate. Males weigh up to 35 kg/77 lb and females usually less than 12 kg/26 lb. Females exhibit none of the bright coloration of the male. A single infant is born after 5 months' gestation; it is weaned at 6 months. Females reach

MANDRILL

The splendidly-coloured male mandrill is nearly three times heavier than his drab mate. No other primate exhibits such marked differences between the sexes. Females mature at about the age of three, whereas males may not reach maturity for ten years.

sexual maturity at about three years; males at around ten years.

MANGABEYS

<http://www.uni.edu/museum/cercopan/mangabey.html>

Well-presented information on mangabeys from a conservation trust. Their life history, behaviour, and ecology is described, together with information about a conservation project in Nigeria. There are notes on the classification and distribution of the various subspecies.

mangabey any of a group of tropical African monkeys. The four species have long tails that can be used for support, although they are not fully prehensile (functional as additional limbs). They feed on shoots, leaves, fruit, and some animal food. (Genus *Cercocebus*.)

manganese hard, brittle, grey-white metallic element, symbol Mn, atomic number 25, relative atomic mass 54.9380. It resembles iron (and rusts), but it is not magnetic and is softer. It is used chiefly in making steel alloys, also alloys with aluminium and copper.

It is used in fertilizers, paints, and industrial chemicals. It is a necessary trace element in human nutrition. The name is old, deriving from the French and Italian forms of Latin for *magnesia* (MgO), the white tasteless powder used as an antacid from ancient times.

manganese ore any mineral from which manganese is produced. The main ores are the oxides, such as pyrolusite, MnO_2 ; hausmannite, Mn_3O_4 ; and manganite, $\text{MnO}(\text{OH})$.

Manganese ores may accumulate in metamorphic rocks or as sedimentary deposits, frequently forming nodules on the sea floor (since the 1970s many schemes have been put forward to harvest deep-sea manganese nodules). The world's main producers are Georgia, Ukraine, South Africa, Brazil, Gabon, and India.

manganese(IV) oxide or **manganese dioxide** MnO_2 brown solid that acts as a depolarizer in dry batteries by oxidizing the hydrogen gas produced to water; without this process, the performance of the battery is impaired.

mangelwurzel or **mangold** variety of the common beet *Beta vulgaris* used chiefly as feed for cattle and sheep.

mango evergreen tree belonging to the cashew family, native to India but now widely cultivated for its large oval fruits in other tropical and subtropical areas, such as the West Indies. (*Mangifera indica*, family Anacardiaceae.)

mangold another name for ϕ mangelwurzel.

mangrove any of several shrubs and trees, especially of the mangrove family, found in the muddy swamps of tropical and subtropical coastlines and estuaries. By sending down aerial roots from their branches, they rapidly form close-growing mangrove thickets. Their timber is resistant to water penetration and damage by marine worms. Mangrove swamps are rich breeding grounds for fish and shellfish, but these habitats are being destroyed in many countries. (Genera *Rhizophora* and *Avicennia*, families Rhizophoraceae (mangrove) and Avicenniaceae (related).)

mangrove swamp muddy swamp found on tropical coasts and estuaries, characterized by dense thickets of mangrove trees. These low trees are adapted to live in creeks of salt water and send down special breathing roots from their branches to take in oxygen from the air. The roots trap silt and mud, creating a firmer drier environment over time. Mangrove swamps are common in the Amazon delta and along the coasts of W Africa, N Australia, and Florida, USA.

manic depression or **bipolar disorder** mental disorder characterized by recurring periods of either ϕ depression or mania (inappropriate elation, agitation, and rapid thought and speech) or both.

Sufferers may be genetically predisposed to the condition. Some cases have been improved by taking prescribed doses of ϕ lithium.

manioc another name for the plant ϕ assava.

manometer instrument for measuring the pressure of liquids (including human blood pressure) or gases. In its basic form, it is a U-tube partly filled with coloured liquid. Greater pressure on the liquid surface in one arm will force the level of the liquid in the other arm to rise. A difference between the pressures in the two arms is therefore registered as a difference in the heights of the liquid in the arms.

manta another name for the ϕ devil ray, a large fish.

mantis any of a group of carnivorous insects related to cockroaches. There are about 2,000 species of mantis, mainly tropical;

some can reach a length of 20 cm/8 in. (Family Mantidae, order Dictyoptera.)

Mantises are often called 'praying mantises' because of the way they hold their front legs, adapted for grasping prey, when at rest. The eggs are laid in September and hatch early the following summer.

mantissa in mathematics, the decimal part of a ϕ logarithm. For example, the logarithm of 347.6 is 2.5411; in this case, the 0.5411 is the mantissa, and the integral (whole number) part of the logarithm, the 2, is the ϕ characteristic.

mantle intermediate zone of the Earth between the ϕ crust and the core, accounting for 82% of Earth's volume. The boundary between the mantle and the crust above is the ϕ Mohorovičić discontinuity, located at an average depth of 32 km/20 mi. The lower boundary with the core is the Gutenberg discontinuity at an average depth of 2,900 km/1813 mi.

The mantle is subdivided into **upper mantle**, **transition zone**, and **lower mantle**, based upon the different velocities with which seismic waves travel through these regions. The upper mantle includes a zone characterized by low velocities of seismic waves, called the low velocity zone, at 72 km/45 mi to 250 km/155 mi depth. This zone corresponds to the ϕ aesthenosphere upon which Earth's tectonic plates of ϕ lithosphere glide. Seismic velocities in the upper mantle are overall less than those in the transition zone and those of the transition zone are in turn less than those of the lower mantle. Faster propagation of seismic waves in the lower mantle implies that the lower mantle is more dense than the upper mantle.

The mantle is composed primarily of magnesium, silicon, and oxygen in the form of ϕ silicate minerals. In the upper mantle, the silicon in silicate minerals, such as olivine, is surrounded by four oxygen atoms. Deeper in the transition zone greater pressures promote denser packing of oxygen such that some silicon is surrounded by six oxygen atoms, resulting in magnesium silicates with garnet and pyroxene structures. Deeper still, all silicon is surrounded by six oxygen atoms so that the new mineral MgSiO_3 -perovskite predominates.

manufacturing industry or **secondary industry** industry that involves the processing of raw materials or the assembly of components. Examples are aluminium smelting, car assembly, and computer assembly. In the UK many traditional manufacturing industries, built up in the Industrial Revolution, are now declining in importance; for example, shipbuilding. Developing countries may lack the capital and expertise necessary for these industries.

Manx cat breed of domestic shorthaired cat originally bred in the Isle of Man, Britain. Its most distinctive feature is its nonexistent tail, the result of a natural mutation. The true Manx cat or 'rumpy' has a dimple at the base of the spine, while the variety with a residual tail or 'stumpy' is also recognized. The forelegs are short with longer hindlegs giving rise to the characteristic 'Manx hop', a rabbit-like gait. It has a strong, muscular body type. Most recognized colour combinations are permitted for the Manx.

manometer The manometer indicates gas pressure by the rise of liquid in the tube.

map diagrammatic representation of an area – for example, part of the Earth's surface or the distribution of the stars. Modern maps of the Earth are made using satellites in low orbit to take a series of overlapping stereoscopic photographs from which a three-dimensional image can be prepared. The earliest accurate large-scale maps appeared about 1580.

Conventional aerial photography, laser beams, microwaves, and infrared equipment are also used for land surveying. Many different kinds of map projection (the means by which a three-dimensional body is shown in two dimensions) are used in map-making. Detailed maps requiring constant updating are kept in digital form on computer so that minor revisions can be made without redrafting.

maple any of a group of deciduous trees with lobed leaves and green flowers, followed by two-winged fruits, or samaras. There are over 200 species, chiefly in northern temperate regions. (Genus *Acer*, family Aceraceae.)

map projection ways of depicting the spherical surface of the Earth on a flat piece of paper. Traditional projections include the conic, azimuthal, and cylindrical. The most famous cylindrical projection is the Mercator projection, which dates from 1569. The weakness of these systems is that countries in high latitudes are shown disproportionately large, and lines of longitude and latitude appear distorted.

map projection Three widely used map projections. If a light were placed at the centre of a transparent Earth, the shapes of the countries would be thrown as shadows on a sheet of paper. If the paper is flat, the azimuthal projection results; if it is wrapped around a cylinder or in the form of a cone, the cylindrical or conic projections result.

In 1973 Germ.Oan historian Arno Peters devised the Peters projection in which the countries of the world retain their relative areas. In 1992 the US physicist Mitchell Feigenbaum devised the optimal conformal projection, using a computer program designed to take data about the boundary of a given area and calculate the projection that produces the minimum of inaccuracies.

The theory behind traditional map projection is that, if a light were placed at the centre of a transparent Earth, the surface features could be thrown as shadows on a piece of paper close to the surface.

This paper may be flat and placed on a pole (azimuthal or zenithal), or may be rolled around the equator (cylindrical), or may be in the form of a tall cone resting on the equator (conical). The resulting maps differ from one another, distorting either area or direction, and each is suitable for a particular purpose. For example, projections distorting area the least are used for distribution maps, and those with least distortion of direction are used for navigation charts.

maquis general term for a largely evergreen type of vegetation common in many Mediterranean countries, consisting of scrub woodland with many low-growing tangled bushes and shrubs, typically including species of broom, gorse, and heather.

mara either of two species of rodents belonging to the guinea-pig family, found in Argentina, with long back limbs and a short tail. They can grow to 75 cm/2.5 ft long and are sometimes known as 'Patagonian cavies' or 'hares'. (Genus *Dolichotis*, family Caviidae.)

marabou African stork, about 120 cm/4 ft tall, with a bald head, long heavy bill, black back and wings and white underparts, and an inflatable throat pouch. It eats snakes, lizards, insects, and carrion. The bald head avoids blood clogging the plumage when the stork feeds on carcasses left by predators such as lions. (Species *Leptoptilos crumeniferus*, family Ciconiidae, order Ciconiiformes.)

marble rock formed by metamorphism of sedimentary limestone. It takes and retains a good polish, and is used in building and sculpture. In its pure form it is white and consists almost entirely of calcite CaCO_3 . Mineral impurities give it various colours and patterns. Carrara, Italy, is known for white marble.

Marconi, Guglielmo (1874-1937)

Italian electrical engineer and pioneer in the invention and development of radio. In 1895 he achieved radio communication over more than a mile, and in England 1896 he conducted successful experiments that led to the formation of the company that became Marconi's Wireless Telegraph Company Ltd. He shared the Nobel Prize for Physics 1909.

After reading about radio waves, Marconi built a device to convert them into electrical signals. He then tried to transmit and receive radio waves over increasing distances. In 1898 he successfully transmitted signals across the English Channel, and in 1901 established communication with St John's, Newfoundland, from Poldhu in Cornwall, and in 1918 with Australia.

mare (plural *maria*) dark lowland plain on the Moon. The name comes from Latin 'sea', because these areas were once wrongly

thought to be water.

margay small wild cat living in forested areas from the southern USA to South America, where it hunts birds and small mammals. It is about 60 cm/2 ft long with a 40 cm/1.3 ft tail, and has a rounded head and yellowish-brown fur marked with black spots and blotches. (Species *Felis wiedi*, family Felidae.)

marginal land in farming, poor-quality land that is likely to yield a poor return. It is the last land to be brought into production and the first land to be abandoned. Examples are desert fringes in Africa and mountain areas in the UK.

marquerite European plant belonging to the daisy family. It is a shrubby perennial with white daisylike flowers. Marguerite is also the name of a cultivated variety of *Chrysanthemum*. (*Leucanthemum vulgare*, family Compositae.)

Mariana Trench lowest region on the Earth's surface; the deepest part of the sea floor. The trench is 2,400 km/1,500 mi long and is situated 300 km/200 mi E of the Mariana Islands, in the NW Pacific Ocean. Its deepest part is the gorge known as the Challenger Deep, which extends 11,034 m/36,210 ft below sea level.

marigold any of several plants belonging to the daisy family, including pot marigold (*C. officinalis*) and the tropical American *T. patula*, commonly known as French marigold. (Genera *Calendula* and *Tagetes*, family Compositae.)

marijuana dried leaves and flowers of the hemp plant *Cannabis*, used as a drug; it is illegal in most countries. Mexico is the world's largest producer.

Mariner spacecraft series of US space probes that explored the planets Mercury, Venus, and Mars 1962-75.

Mariner 1 (to Venus) had a failed launch. *Mariner 2* 1962 made the first fly-by of Venus, at 34,000 km/21,000 mi, confirmed the existence of solar wind, and measured Venusian temperature. *Mariner 3* did not achieve its intended trajectory to Mars. *Mariner 4* 1965 passed Mars at a distance of 9,800 km/6,100 mi, and took photographs, revealing a dry, cratered surface. *Mariner 5* 1967 passed Venus at 4,000 km/2,500 mi, and measured Venusian temperature, atmosphere, mass, and diameter. *Mariner 6* and *7* 1969 photographed Mars' equator and southern hemisphere respectively, and also measured temperature, atmospheric pressure and composition, and diameter. *Mariner 8* (to Mars) had a failed launch. *Mariner 9* 1971 mapped the entire Martian surface, and photographed Mars' moons. Its photographs revealed the changing of the polar caps, and the extent of volcanism, canyons, and features, which suggested that there might once have been water on Mars. *Mariner 10* 1974-75 took close-up photographs of Mercury and Venus, and measured temperature, radiation, and magnetic fields.

marjoram aromatic herb belonging to the mint family. Wild marjoram (*O. vulgare*) is found both in Europe and Asia and has become naturalized in the Americas; the sweet marjoram (*O. majorana*) used in cooking is widely cultivated. (Genus *Origanum* or *Marjorana*, family Labiatae.)

market gardening farming system that specializes in the commercial growing of vegetables, fruit, or flowers. It is an intensive agriculture with crops often being grown inside greenhouses on small farms.

Market gardens may be located within easy access of markets, on the fringes of urban areas; for example, in the Home Counties for the London market. Such areas as the Channel Islands, where early crops can be grown outside because of a mild climate, are especially suitable.

markhor large wild goat with spirally twisted horns and a long shaggy coat. It is found in the Himalayas. (Species *Capra falconeri*, family Bovidae.)

Markov chain in statistics, an ordered sequence of discrete states (random variables) $x_1, x_2, \dots, x_i, \dots, x_n$ such that the probability of x_i depends only on n and/or the state x_{i-1} which has preceded it. If independent of n , the chain is said to be homogeneous.

mark sensing in computing, a technique that enables pencil marks made in predetermined positions on specially prepared forms to be rapidly read and input to a computer. The technique makes use of the fact that pencil marks contain graphite and therefore conduct electricity. A **mark sense reader** scans the form by passing small metal brushes over the paper surface. Whenever a brush touches a pencil mark a circuit is completed and the mark is detected.

marl crumbling sedimentary rock, sometimes called clayey limestone, including various types of calcareous clays and fine-grained limestones. Marls are often laid down in freshwater lakes and are usually soft, earthy, and of a white, grey, or brownish colour. They are used in cement-making and as fertilizer.

marlin or **spearfish** any of several open-sea fish known as billfishes. Some 2.5 m/7 ft long, they are found in warmer waters and have elongated snouts and high-standing dorsal (back) fins. Members of the family include the sailfish (*Istiophorus platypterus*), the fastest of all fishes over short distances - reaching speeds of 100 kph/62 mph - and the blue marlin (*Makaira nigricans*), highly prized as a 'game' fish. (Family Istiophoridae, order Perciformes.)

marlock medium-height tree, *Eucalyptus redunca*, with thick, narrow or elliptical leaves, horn-shaped buds, and mottled bark, found in SW Australia.

marmoset any of a group of small tree-dwelling monkeys found in South and Central America; some only reach a body length of 18 cm/7 in. Most species have characteristic tufted ears, clawlike nails, and a handsome tail, which is not prehensile (it cannot be used to grip branches in the same way as the arms and legs). Some marmosets are known as tamarins. (Genus *Callithrix* and related genera, family Callitrichidae.)

Best-known is the common marmoset *C. jacchus* of Brazil, often kept there as a pet. The discovery of a new species of Brazilian marmoset, *C. sateri*, was announced in 1996. The black-capped dwarf marmoset was discovered in Brazil in 1997.

marmot any of several large burrowing rodents belonging to the squirrel family. There are about 15 species, distributed throughout Canada and the USA, and from the Alps to the Himalayas. They eat plants and some insects, and live in colonies, make burrows (one to each family), and hibernate in winter. In North America they are called woodchucks or groundhogs. (Genus *Marmota*, family Sciuridae.)

marram grass coarse perennial grass that flourishes in sandy areas. Because of its tough, creeping roots, it is widely used to hold coastal dunes in place. (*Ammophila arenaria*, family Gramineae.)

marri tree *Eucalyptus calophylla*, endemic to Western Australia, which, together with its hybrids with the flame gum *E. ficifolia*, is widely cultivated for its coloured flowers.

marrow or **vegetable marrow** trailing vine that produces large pulpy fruits, used as vegetables and in preserves; the young fruits of one variety are known as courgettes (US zucchini). (*Cucurbita pepo*, family Cucurbitaceae.)

Mars fourth planet from the Sun. It is much smaller than Venus or Earth, with a mass 0.11 that of Earth. Mars is slightly pear-shaped, with a low, level northern hemisphere, which is comparatively uncratered and geologically 'young', and a heavily cratered 'ancient' southern hemisphere.

mean distance from the Sun 227.9 million km/141.6 million mi
equatorial diameter 6,780 km/4,210 mi
rotation period 24 hr 37 min
year 687 Earth days

atmosphere 95% carbon dioxide, 3% nitrogen, 1.5% argon, and 0.15% oxygen. Red atmospheric dust from the surface whipped up by winds of up to 450 kph/280 mph accounts for the light pink sky. The surface pressure is less than 1% of the Earth's atmospheric pressure at sea level.

MARS

<http://www.hawastsoc.org/solar/eng/mars.htm>

Detailed description of the planet Mars, commonly referred to as the Red Planet. It includes statistics and information about the surface, volcanoes, satellites, and clouds of the planet, supported by a good selection of images.

white polar caps (water ice and frozen carbon dioxide) that advance and retreat with the seasons.

satellites two small satellites: Phobos and Deimos.

There are four enormous volcanoes near the equator, of which the largest is Olympus Mons 24 km/15 mi high, with a base 60 km/37 mi across, and a crater 65 km/40 mi wide. To the east of the four volcanoes lies a high plateau cut by a system of valleys, Valles Marineris, some 4,000 km/2,500 mi long, up to 200 km/120 mi wide and 6 km/4 mi deep; these features are apparently caused by faulting and wind erosion. Recorded temperatures vary from -100°C/-148°F to 0°C/32°F.

Mars may approach Earth to within 54.7 million km/34 million mi. The first human-made object to orbit another planet was *Mariner 9*. *Viking 1* and *Viking 2*, which landed, also provided much information. Studies in 1985 showed that enough water might exist to sustain prolonged missions by space crews.

In January 1997 NASA launched the *Mars Pathfinder*, which made a successful landing on Mars in July 1997 on a flood plain called Ares Vallis. After initial technical problems, its 0.3-m rover, Sojourner, began to explore the Martian landscape and to transmit data back to earth. Photographs from the *Mars Pathfinder* indicated that the planet is rusting. NASA announced this in July 1997 and said that a supercorrosive force was eroding rocks on the surface due to iron oxide in the soil.

In May 1997 American scientists announced that Mars is becoming increasingly colder and cloudier. Images from the Hubble Space Telescope showed that dust storms had covered areas of the planet that had been dark features in the early century, including one section as large as California.

The *Global Surveyor*, that entered Martian orbit in September 1997, revealed that Mars' magnetic field is a mere 800th that of the Earth.

Mars Global Surveyor US spacecraft that went into orbit around Mars on 12 September 1997 to conduct a detailed photographic survey of the planet commencing March 1998. The spacecraft used a previously untried technique called **aerobraking** to turn its initially highly elongated orbit into a 400 km/249 mi circular orbit by dipping into the outer atmosphere of the planet.

marsh low-lying wetland. Freshwater marshes are common wherever groundwater, surface springs, streams, or run-off cause frequent flooding or more or less permanent shallow water. A marsh is alkaline whereas a bog is acid. Marshes develop on inorganic silt or clay soils. Rushes are typical marsh plants. Large marshes dominated by papyrus, cattail, and reeds, with standing water throughout the year, are commonly called swamps. Near the sea, salt marshes may form.

marsh gas gas consisting mostly of methane. It is produced in swamps and marshes by the action of bacteria on dead vegetation.

marsh marigold plant belonging to the buttercup family, known as the kingcup in the UK and as the cowslip in the USA. It grows in moist, sheltered places and has brilliant yellow five-sepal flowers. (*Caltha palustris*, family Ranunculaceae.)

marsh rose shrub native to South Africa, which grows to 1-4 m/3-13 ft high. It is under threat, partly because its beautiful

flowers are frequently picked, but also because of fungi, probably introduced by footwear or equipment, and by changes in management practice that have prevented periodic fires which are necessary for seed germination. Ironically, numbers of the shrub are now so low that uncontrolled fires could wipe out the remaining adult specimens. Although protected, they remain highly threatened. (*Orothamnus zeyheri*.)

Mars Observer NASA space probe launched in 1992 to orbit Mars and survey the planet, its atmosphere, and the polar caps over two years. The probe was also scheduled to communicate information from the robot vehicles delivered by Russia's Mars 94 mission. The \$1 billion project miscarried, however, when the probe unaccountably stopped transmitting in August 1993, three days before it was due to drop into orbit.

Mars Pathfinder US spacecraft that landed in the Ares Vallis region of Mars on 4 July 1997. It carried a small six-wheeled roving vehicle called Sojourner which examined rock and soil samples around the landing site. *Mars Pathfinder* was the first to use air bags instead of retro-rockets to cushion the landing.

marsupial *Greek marsupium 'little purse'* mammal in which the female has a pouch where she carries her young (born tiny and immature) for a considerable time after birth. Marsupials include omnivorous, herbivorous, and carnivorous species, among them the kangaroo, wombat, opossum, phalanger, bandicoot, dasyure, and wallaby.

The Australian marsupial anteater known as the numbat is an exception to the rule in that it has no pouch.

Marsupialia order of mammals consisting of the marsupials.

marten small bushy-tailed carnivorous mammal belonging to the weasel family. Martens live in North America, Europe, and temperate regions of Asia, and are agile tree climbers. (Genus *Martes*, family Mustelidae.)

The sable (*M. zibellina*) lives in E Siberia, and provides the most valued fur. The largest marten is the fisher (*M. pennanti*) of North America, with black fur and reaching 125 cm/4 ft in length.

martin any of several species of birds belonging to the swallow family. (Family Hirundinidae, order Passeriformes.)

Martinsyde British aircraft manufacturer during World War I. Martinsyde began making monoplanes 1908 and after the outbreak of World War I produced several extremely good biplane scout-fighter aircraft for the Royal Flying Corps.

The F 4 Buzzard was a single-seat biplane powered by a 300 hp Hispano engine which had a top speed of 235 kph/145 mph, faster than any other single-seat aircraft of the period. The Buzzard was armed with two Vickers machine guns firing through the propeller arc.

maser (acronym for *microwave amplification by stimulated emission of radiation*) in physics, a high-frequency microwave amplifier or oscillator in which the signal to be amplified is used to stimulate excited atoms into emitting energy at the same frequency. Atoms or molecules are raised to a higher energy level and then allowed to lose this energy by radiation emitted at a precise frequency. The principle has been extended to other parts of the electromagnetic spectrum as, for example, in the laser.

The two-level ammonia-gas maser was first suggested in 1954 by US physicist Charles Townes at Columbia University, New York, and independently the same year by Nikolai Basov and Aleksandr Prokhorov in Russia. The solid-state three-level maser, the most sensitive amplifier known, was envisaged by Nicolaas Bloembergen (1920–) at Harvard in 1956. The ammonia maser is used as a frequency standard oscillator (see clock), and the three-level maser as a receiver for satellite communications and radio astronomy.

mask in computing, restriction placed on the type of character that can be entered in a given field of a database or spreadsheet. For example, a 'dd-mm-yy' mask will only allow operators to enter a date in the field, and a field operating under a text mask will accept only letters, not numbers. See also validation.

masochism desire to subject oneself to physical or mental pain, humiliation, or punishment, for erotic pleasure, to alleviate guilt, or out of destructive impulses turned inward. The term is derived from Leopold von Sacher-Masoch.

mass in physics, the quantity of matter in a body as measured by its inertia. Mass determines the acceleration produced in a body by a given force acting on it, the acceleration being inversely proportional to the mass of the body. The mass also determines the force exerted on a body by gravity on Earth, although this attraction varies slightly from place to place. In the SI system, the base unit of mass is the kilogram.

At a given place, equal masses experience equal gravitational forces, which are known as the weights of the bodies. Masses may, therefore, be compared by comparing the weights of bodies at the same place.

The standard unit of mass to which all other masses are compared is a platinum-iridium cylinder of 1 kg, which is kept at the International Bureau of Weights and Measures in Sèvres, France.

mass action, law of in chemistry, a law stating that at a given temperature the rate at which a chemical reaction takes place is proportional to the product of the active masses of the reactants. The active mass is taken to be the molar concentration of the each reactant.

massage manipulation of the soft tissues of the body, the muscles, ligaments, and tendons, either to encourage the healing of specific injuries or to produce the general beneficial effects of relaxing muscular tension, stimulating blood circulation, and improving the tone and strength of the skin and muscles.

The benefits of massage were known to the ancient Chinese, Egyptian, and Greek cultures. The techniques most widely practised today were developed by the Swedish physician Per Henrik Ling (1776–1838).

A car can massage organs which no masseur can reach. It is the one remedy for the disorders of the great sympathetic nervous system.

mass-energy equation Albert Einstein's equation $E = mc^2$, denoting the equivalence of mass and energy, where E is the energy in joules, m is the mass in kilograms, and c is the speed of light, in a vacuum, in metres per second.

mass extinction an event that produces the extinction of many species at about the same time. One notable example is the boundary between the Cretaceous and Tertiary periods (known as the K-T boundary) that saw the extinction of the dinosaurs and other big reptiles, and many of the marine invertebrates as well. Mass extinctions have taken place frequently during Earth's history.

The largest mass extinction occurred approximately 245 million years ago at the boundary between the Permian period of the Paleozoic era and the Triassic period of the Mesozoic era; 90% of all species became extinct.

mass number or **nucleon number** sum (symbol A) of the numbers of protons and neutrons in the nucleus of an atom. It is used along with the atomic number (the number of protons) in nuclear notation: in symbols that represent nuclear isotopes, such as $^{14}_6\text{C}$, the lower number is the atomic number, and the upper number is the mass number.

mass production manufacture of goods on a large scale, a technique that aims for low unit cost and high output. In factories mass production is achieved by a variety of means, such as division and specialization of labour and mechanization. These speed up production and allow the manufacture of near-identical, interchangeable parts. Such parts can then be assembled quickly into a finished product on an assembly line.

Division of labour means that a job is divided into a number of steps, and then groups of workers are employed to carry each step out, specializing and therefore doing the job in a routine way, producing more than if each individually had to carry out all the stages of manufacture. However, the system has been criticized for neglecting the skills of workers and removing their involvement with the end product.

Many of the machines now used in factories are robots (for example, on car-assembly lines); they work automatically under computer control. Such automation further streamlines production and raises output.

mass spectrometer in physics, an apparatus for analysing chemical composition. Positive ions (charged particles) of a substance are separated by an electromagnetic system, which permits accurate measurement of the relative concentrations of the various ionic masses present, particularly isotopes.

mastiff breed of powerful dog, usually fawn in colour, that was originally bred in Britain for hunting purposes. It has a large head, wide-set eyes, and broad muzzle. It can grow up to 90 cm/36 in at the shoulder, and weigh 100 kg/220 lb.

mastodon any of an extinct family of mammals belonging to the elephant order. They differed from elephants and mammoths in the structure of their grinding teeth. There were numerous species, among which the American mastodon (*Mastodon americanum*), about 3 m/10 ft high, of the Pleistocene era, is well known. They were hunted by humans for food. (Family Mastodontidae, order Proboscidea.)

matamora South American freshwater turtle or terrapin with a shell up to 40 cm/15 in long. The head is flattened, with a 'suorcel' nose, and the neck has many projections of skin. The movement of these in the water may attract prey, which the matamora catches by opening its mouth suddenly to produce an inrush of water. (Species *Chelys fimbriata*.)

match small strip of wood or paper, tipped with combustible material for producing fire. Friction matches containing phosphorus were first made in 1816 in France by François Derosne.

A safety match is one in which the oxidizing agent and the combustible body are kept apart, the former being incorporated into the striking surface on the side of the box, the latter into the match. Safety matches were patented by a Swede, J E Lundström in 1855. Book matches were invented in the USA in 1892 by Joshua Pusey.

maté dried leaves of the Brazilian Cholly (*Ilex paraguariensis*), an evergreen shrub that grows in Paraguay and Brazil. The roasted, powdered leaves are made into a tea. (Family Aquifoliaceae.)

mathematical induction formal method of proof in which the proposition $P(n+1)$ is proved true on the hypothesis that the proposition $P(n)$ is true. The proposition is then shown to be true for a particular value of n , say k , and therefore by induction the proposition must be true for $n = k+1, k+2, k+3, \dots$. In many cases $k=1$, so then the proposition is true for all positive integers.

A theory with mathematical beauty is more likely to be correct than an ugly one that fits some experimental data. God is a mathematician of a very high order, and He used very advanced mathematics in constructing the universe.

MATHS PROBLEM OF THE MONTH

<http://www.srl.rmit.edu.au/mav/PSTC/>

Australian site, updated monthly, containing not just one, but several problems each month. They are each designed for different levels of difficulty. The main problems are divided into lower/middle primary, upper primary/lower secondary, and upper secondary levels.

The site also includes a database of previous problems and a 'challenging problem of the month'. In other words, there is something to tease every level of mathematical brain.

least up to ten on their fingers. The ancient Egyptians (3rd millennium BC), Sumerians (2000–1500 BC), and Chinese (1500 BC) had systems for writing down numbers and could perform calculations using various types of *qabacus*. They used some fractions. Mathematicians in ancient Egypt could solve simple problems which involved finding a quantity that satisfied a given linear relationship. Sumerian mathematicians knew how to solve problems that involved quadratic equations. The fact that, in a right-angled triangle, the square of the longest side is equal to the sum of the squares of the other two sides (Pythagoras' theorem) was known in various forms in these cultures and also in Vedic India (1500 BC).

The first theoretical mathematician is held to be Thales of Miletus (c. 580 BC) who is believed to have proposed the first theorems in plane geometry. His disciple Pythagoras established geometry as a recognized science among the Greeks. Pythagoras began to insist that mathematical statements must be proved using a logical chain of reasoning starting from acceptable assumptions. Undoubtedly the impetus for this demand for logical proof came from the discovery by this group of the surprising fact that the square root of 2 is a number which cannot be expressed as the ratio of two whole numbers. The use of logical reasoning, the methods of which were summarized by Aristotle, enabled Greek mathematicians to make general statements instead of merely solving individual problems as earlier mathematicians had done.

The spirit of Greek mathematics is typified in one of its most lasting achievements, the *Elements* by Euclid. This is a complete treatise on geometry in which the entire subject is logically deduced from a handful of simple assumptions. The ancient Greeks lacked a simple notation for numbers and nearly always relied on expressing problems geometrically. Although the Greeks were extremely successful with their geometrical methods they never developed a general theory of equations or any algebraic ideas of structure. However, they made considerable advances in techniques for solving particular kinds of equations and these techniques were summarized by Diophantus of Alexandria.

Medieval period When the Hellenic civilization declined, Greek mathematics (and the rest of Greek science) was kept alive by the Arabs, especially in the scientific academy at the court of the caliphs of Baghdad. The Arabs also learned of the considerable scientific achievements of the Indians, including the invention of a system of numerals (now called 'arabic' numerals) which could be used to write down calculations instead of having to resort to an abacus. One mathematician can be singled out as a bridge between the ancient and medieval worlds: al-Khwarizmi summarized Greek and Indian methods for solving equations and wrote the first treatise on the Indian numerals and calculating with them. Al-Khwarizmi's books and other Arabic works were translated into Latin and interest in mathematics in Western Europe began to increase in the 12th century. It was the demands of commerce which gave the major impetus to mathematical development and north Italy, the centre of trade at the time, produced a succession of important mathematicians beginning with Italian mathematician Leonardo Fibonacci who introduced Arabic numerals. The Italians made considerable advances in elementary arithmetic which was needed for money-changing and for the technique of double-entry bookkeeping invented in Venice. Italian mathematicians began to express equations in symbols instead of words. This algebraic notation made it possible to shift attention from solving individual equations to investigating the relationship between equations and their

Mathematics: chronology

BC

- c. 2500** The people of Mesopotamia (now Iraq) developed a positional numbering (place-value) system, in which the value of a digit depends on its position in a number.
- c. 2000** Mesopotamian mathematicians solved quadratic equations (algebraic equations in which the highest power of a variable is 2).
- 876** A symbol for zero was used for the first time, in India.
- c. 350** Greek mathematician Pythagoras formulated a theorem relating the lengths of the sides of a right-angled triangle. The theorem was already known by earlier mathematicians in China, Mesopotamia, and Egypt.
- c. 450** Hipparchos of Metapontum discovered that some numbers are irrational (cannot be expressed as the ratio of two integers).
- 300** Euclid laid out the laws of geometry in his book *Elements*, which was to remain a standard text for 2,000 years.
- c. 230** Eratosthenes developed a method for finding all prime numbers.
- c. 100** Chinese mathematicians began using negative numbers.
- c. 190** Chinese mathematicians used powers of 10 to express magnitudes.

AD

- c. 210** Diophantus of Alexandria wrote the first book on algebra.
- c. 600** A decimal number system was developed in India.
- 829** Persian mathematician Muhammad ibn-Muhammad [s]al-*Khwarizmi* published a work on algebra that made use of the decimal number system.
- 1202** Italian mathematician Leonardo Fibonacci studied the sequence of numbers (1, 1, 2, 3, 5, 8, 13, 21, ...) in which each number is the sum of the two preceding ones.
- 1550** In Germany, Rheticus published trigonometrical tables that simplified calculations involving triangles.
- 1614** Scottish mathematician John Napier invented logarithms, which enable lengthy calculations involving multiplication and division to be carried out by addition and subtraction.
- 1623** Wilhelm Schickard invented the mechanical calculating machine.
- 1637** French mathematician and philosopher René Descartes introduced coordinate geometry.
- 1654** In France, Blaise Pascal and Pierre de Fermat developed probability theory.
- 1666** Isaac Newton developed differential calculus, a method of calculating rates of change.
- 1675** German mathematician Gottfried Wilhelm Leibniz introduced the modern notation for integral calculus, a method of calculating volumes.
- 1679** Leibniz introduced binary arithmetic, in which only two symbols are used to represent all numbers.
- 1684** Leibniz published the first account of differential calculus.
- 1718** Jakob Bernoulli in Switzerland published his work on the calculus of variations (the study of functions that are close to their minimum or maximum values).
- 1742** German mathematician Christian Goldbach conjectures that every even number greater than two can be written as the sum of two prime numbers. Goldbach's conjecture has still not been proven.
- 1746** In France, Jean le Rond d'Alembert developed the theory of complex numbers.
- 1747** D'Alembert used partial differential equations in mathematical physics.
- 1798** Norwegian mathematician Caspar Wessel introduced the vector representation of complex numbers.
- 1799** Karl Friedrich Gauss of Germany proved the fundamental theorem of algebra: the number of solutions of an algebraic equation is the same as the exponent of the highest term.
- 1810** In France, Jean Baptiste Joseph Fourier published his method of

representing functions by a series of trigonometric functions.

- 1812** French mathematician Pierre Simon Laplace published the first complete account of probability theory.
- 1822** In the UK, Charles Babbage began construction of the first mechanical computer, the difference machine, a device for calculating logarithms and trigonometric functions.
- 1827** Gauss introduced differential geometry, in which small features of curves are described by analytical methods.
- 1829** In Russia, Nikolai Ivanovich Lobachevsky developed hyperbolic geometry, in which a plane is regarded as part of a hyperbolic surface, shaped like a saddle. In France, Evariste Galois introduced the theory of groups (collections whose members obey certain simple rules of addition and multiplication).
- 1844** French mathematician Joseph Liouville found the first transcendental number, which cannot be expressed as an algebraic equation with rational coefficients. In Germany, Hermann Grassmann studied vectors with more than three dimensions.
- 1854** George Boole in the UK published his system of symbolic logic, now called Boolean algebra.
- 1858** English mathematician Arthur Cayley developed calculations using ordered tables called matrices.
- 1865** August Ferdinand Möbius in Germany described how a strip of paper can have only one side and one edge.
- 1892** German mathematician Georg Cantor showed that there are different kinds of infinity and studied transfinite numbers.
- 1895** Jules Henri Poincaré published the first paper on topology, often called 'the geometry of rubber sheets'.
- 1931** In the USA, Austrian-born mathematician Kurt Gödel proved that any formal system strong enough to include the laws of arithmetic is either incomplete or inconsistent.
- 1937** English mathematician Alan Turing published the mathematical theory of computing.
- 1944** John Von Neumann and Oscar Morgenstern developed game theory in the USA.
- 1945** The first general purpose, fully electronic digital computer, ENIAC (electronic numerator, integrator, analyser, and computer), was built at the University of Pennsylvania, USA.
- 1961** Meteorologist Edward Lorenz at the Massachusetts Institute of Technology, USA, discovered a mathematical system with chaotic behaviour, leading to a new branch of mathematics – chaos theory.
- 1962** Benoit Mandelbrot in the USA invented fractal images, using a computer that repeats the same mathematical pattern over and over again.
- 1975** US mathematician Mitchell Feigenbaum discovered a new fundamental constant (approximately 4.699201609103), which plays an important role in chaos theory.
- 1980** Mathematicians worldwide completed the classification of all finite and simple groups, a task that took over a hundred mathematicians more than 35 years to complete and whose results took up more than 14,000 pages in mathematical journals.
- 1989** A team of US computer mathematicians at Amdehl Corporation, California, discovered the highest known prime number (it contains 65,087 digits).
- 1993** British mathematician Andrew Wiles published a 1,000-page proof of Fermat's last theorem, one of the most baffling challenges in pure mathematics.
- 1996** Wiles's proof was accepted after revision.
- 1997** The largest number to be factorized to date has 167 digits: (3349-1)⁹² was split into its 80- and 87-digit factors by a team of US mathematicians after 100,000 hours of computing.

solutions, and led eventually to the discovery of methods of solving cubic equations (about 1515) and quartic equations. They began to use the square roots of negative numbers (complex numbers) in their solutions to equations.

early modern period In the 17th century the focus of mathematical

activity moved to France and Britain though continuing with the major themes of Italian mathematics: improvements in methods of calculation, development of algebraic symbolism, and the development of mathematical methods for use in physics and astronomy. Geometry was revitalized by the invention of coordinate geometry

by René Descartes 1637; Blaise Pascal and Pierre de Fermat developed probability theory; John Napier invented logarithms; and Isaac Newton and Gottfried Leibniz invented calculus, later put on a more rigorous footing by Augustin Cauchy. In Russia, Nikolai Lobachevsky rejected Euclid's parallelism and developed a non-Euclidean geometry; this was subsequently generalized by Bernhard Riemann and later utilized by Einstein in his theory of relativity. In the mid-19th century a new major theme emerged: investigation of the logical foundations of mathematics. George Boole showed how logical arguments could be expressed in algebraic symbolism. Friedrich Frege and Giuseppe Peano considerably developed this symbolic logic.

the present In the 20th century, mathematics has become much more diversified. Each specialist subject is being studied in far greater depth and advanced work in some fields may be unintelligible to researchers in other fields. Mathematicians working in universities have had the economic freedom to pursue the subject for its own sake. Nevertheless, new branches of mathematics have been developed which are of great practical importance and which have basic ideas simple enough to be taught in secondary schools. Probably the most important of these is the mathematical theory of statistics in which much pioneering work was done by Karl Pearson. Another new development is operations research, which is concerned with finding optimum courses of action in practical situations, particularly in economics and management. As in the late medieval period, commerce began to emerge again as a major impetus for the development of mathematics.

Higher mathematics has a powerful tool in the high-speed electronic computer, which can create and manipulate mathematical 'models' of various systems in science, technology, and commerce.

Modern additions to school syllabuses such as sets, group theory, matrices, and graph theory are sometimes referred to as 'new' or 'modern' mathematics.

matrix in mathematics, a square ($n \times n$) or rectangular ($m \times n$) array of elements (numbers or algebraic variables). They are a means of condensing information about mathematical systems and can be used for, among other things, solving simultaneous linear equations (see simultaneous equations and transformation).

Much early matrix theory was developed by the British mathematician Arthur Cayley, although the term was coined by his contemporary James Sylvester (1814-1897).

Matsushita Japanese electrical and electronics hardware company, the world's 12th-largest company in 1990 with annual revenues of \$45 billion, controlling 87 companies in Japan and almost as many abroad, including film and record industries in the USA. The company was founded in 1918 in Osaka by businessman Konosuke Matsushita (1894-1979).

Matsushita developed the VHS video format, which eventually conquered the market (though considered technically inferior to Sony's Betamax). Its electronics products are sold under the brand names National, Panasonic, Technics, and Quasar. Matsushita's US arm, the JVC corporation, earned over \$6 billion in 1988. In 1989 Matsushita invested \$100 million in a new Hollywood film studio, Largo, and in 1990 Matsushita bought MCA, the US entertainment conglomerate, for \$6.5 billion; this includes MCA Records, Universal film and TV, the Putnam publishing group, music publishing, and theme park interests.

matter in physics, anything that has mass. All matter is made up of atoms, which in turn are made up of elementary particles; it exists ordinarily as a solid, liquid, or gas. The history of science and philosophy is largely taken up with accounts of theories of matter, ranging from the hard 'atoms' of Democritus to the 'waves' of modern quantum theory.

Mauna Kea astronomical observatory in Hawaii, USA, built on a dormant volcano at 4,200 m/13,784 ft above sea level. Because of its elevation high above clouds, atmospheric moisture, and artificial lighting, Mauna Kea is ideal for infrared astronomy. The first telescope on the site was installed in 1970.

Telescopes include the 2.24 m/88 in University of Hawaii reflector (1970). In 1979 three telescopes were erected: the 3.8 m/150 in United Kingdom Infrared Telescope (UKIRT) (also used for optical observations); the 3 m/120 in NASA Infrared Telescope Facility (IRTF); and the 3.6 m/142 in Canada-France-Hawaii Telescope (CFHT), designed for optical and infrared work. The 15 m/50 ft diameter UK/Netherlands James Clerk Maxwell Telescope (JCMT) is the world's largest telescope specifically designed to observe millimetre wave radiation from nebulae, stars, and galaxies. The JCMT is operated via satellite links by astronomers in Europe. The world's largest optical telescope, the Keck Telescope, is also situated on Mauna Kea.

In 1996 the capacity of the JCMT was enhanced by the addition of SCUBA (Submillimetre Common-user Bolometer Array). SCUBA is a camera comprised of numerous detectors cooled to within a tenth of a degree of absolute zero (0 K) and is the world's most sensitive instrument at the 0.3-1.0 mm wavelength.

Maunder minimum in astronomy, the period 1645-1715 when sunspots were rarely seen and no aurorae ('northern lights') were recorded. The Maunder minimum coincided with a time of unusually low temperature on Earth, known as the Little Ice Age, and is often taken as evidence that changes in solar activity can affect Earth's climate. The Maunder minimum is named after the English astronomer E W Maunder, who drew attention to it.

maximum and minimum in coordinate geometry, points at which the slope of a curve representing a function changes from positive to negative (maximum), or from negative to positive (minimum). A tangent to the curve at a maximum or minimum has zero gradient.

Maxima and minima can be found by differentiating the function for the curve and setting the differential to zero (the value of the slope at the turning point). For example, differentiating the function for the parabola $y = 2x^2 - 8x$ gives $dy/dx = 4x - 8$. Setting this equal to zero gives $x = 2$, so that $y = -8$ (found by substituting $x = 2$ into the parabola equation). Thus the function has a minimum at the point (2, -8).

maxwell c.g.s. unit (symbol Mx) of magnetic flux (the strength of a magnetic field in an area multiplied by the area). It is now replaced by the SI unit, the weber (one maxwell equals 10^{-8} weber).

The maxwell is a very small unit. It is equal to the flux through one square centimetre normal to a magnetic field with an intensity of one gauss.

Maxwell, James Clerk (1831–1879)

Scottish physicist. His main achievement was in the understanding of electromagnetic waves: Maxwell's equations bring together electricity, magnetism, and light in one set of relations. He studied gases, optics, and the sensation of colour, and his theoretical work in magnetism prepared the way for wireless telegraphy and telephony.

In developing the kinetic theory of gases, Maxwell gave the first proof that heat resides in the motion of molecules.

Studying colour vision, Maxwell explained how all colours could be built up from mixtures of the primary colours red, green, and blue. Maxwell confirmed English physicist Thomas Young's theory that the eye has three kinds of receptors sensitive to the primary colours, and showed that colour blindness is due to defects in the receptors. In 1861 he produced the first colour photograph to use a three-colour process.

Maxwell-Boltzmann distribution in physics, a statistical equation describing the distribution of velocities among the molecules of a gas. It is named after James Maxwell and Ludwig Boltzmann, who derived the equation, independently of each other, in the 1860s.

One form of the distribution is $n = N \exp(-E/RT)$, where N is the total number of molecules, n is the number of molecules with energy in excess of E , T is the absolute temperature (temperature in kelvin), R is the gas constant, and \exp is the exponential function.

Maxwell's screw rule in physics, a rule formulated by Scottish physicist James Maxwell that predicts the direction of the magnetic field produced around a wire carrying electric current. It states that if a right-handed screw is turned so that it moves forward in the same direction as the conventional current, its direction of rotation will give the direction of the magnetic field.

MBONE (contraction of *multicast backbone*) in computing, layer of the Internet designed to deliver packets of multimedia data, enabling video and audio communication. It can be used for telephony and video-conferencing – however, it can deliver a maximum of only five video frames per second, as opposed to television's 30. Large rock concerts are occasionally broadcast on the MBONE.

McDonnell Douglas US aircraft manufacturer that produces fighter planes and the DC-10 Airbus. It was formed in 1967 in a merger. Douglas, founded in 1920 by Donald W Douglas (1892–1981), was known for its DC (Douglas Commercial) planes from the 1930s; McDonnell, founded in 1939 by James S McDonnell (1899–1980), was the first company to make jet-propelled planes to operate from aircraft carriers. The company's headquarters are in St Louis, Missouri. It came second place in the world number of planes ordered 1995.

The company announced in 1996 that it would merge with Boeing aircraft manufacturers and would operate under the Boeing name.

MCI in computing, US-based long distance telecommunications company, active in Net communications since the 1980s, when it ran the backbone for the National Science Foundation's NSFnet. In 1996 MCI announced Concert Internet Plus, a joint venture with British Telecom aiming to provide a single network spanning the globe.

MDMA (3,4-methylenedioxy-methylamphetamine) psychedelic drug, also known as Ecstasy.

ME abbreviation for *myalgic encephalomyelitis*, a popular name for chronic fatigue syndrome.

meal-worm any larva of the beetle genus *Tenebrio*, especially *T. molitor*. Meal-worms are slender and round, about 2.5 cm/1 in long, and tawny with bright rusty bands. They are pests of stored grain.

The adult of *T. molitor* is black, measures about 1.3 cm/0.5 in in length, has stout legs, and antennae with 11 joints, **classification** Meal-worms are in genus *Tenebrio* of the family Tenebrionidae, class Insecta, phylum Arthropoda.

mealy bug kind of scale insect.

mean in mathematics, a measure of the average of a number of terms or quantities. The simple **arithmetic mean** is the average value of the quantities, that is, the sum of the quantities divided by their number. The **weighted mean** takes into account the frequency of the terms that are summed; it is calculated by multiplying each term by the number of times it occurs, summing the results and dividing this total by the total number of occurrences. The **geometric mean** of n quantities is the n

th root of their product. In statistics, it is a measure of central tendency of a set of data.

meander loop-shaped curve in a river flowing across flat country. As a river flows, any curve in its course is accentuated by the current. The current is fastest on the outside of the curve where it cuts into the bank; on the curve's inside the current is slow and deposits any transported material. In this way the river changes its course across the flood plain.

A loop in a river's flow may become so accentuated that it becomes cut off from the normal course and forms an oxbow lake. The word comes from the river Menderes in Turkey.

mean deviation in statistics, a measure of the spread of a population from the mean.

mean free path in physics, the average distance travelled by a particle, atom, or molecule between successive collisions. It is of importance in the kinetic theory of gases.

mean life in nuclear physics, the average lifetime of a nucleus of a radioactive isotope equal to 1.44 times the half-life. See radioactivity.

measles acute virus disease (rubeola), spread by airborne infection.

Symptoms are fever, severe catarrh, small spots inside the mouth, and a raised, blintchy red rash appearing for about a week after two weeks' incubation. Prevention is by vaccination.

In industrialized countries it is not usually a serious disease, though serious complications may develop. More than 1 million children a year die of measles (1995); a high percentage of them are Third World children. The North and South American Indians died by the thousands in epidemics of the 17th, 18th, and 19th centuries.

mechanical advantage (MA) in physics, the number of times the load moved by a machine is greater than the effort applied to that machine. In equation terms: $MA = \text{load/effort}$.

The exact value of a working machine's MA is always less than its predicted value because there will always be some frictional resistance that increases the effort necessary to do the work.

TO REMEMBER THE DEFINITION OF MECHANICAL ADVANTAGE:

MEN ALWAYS LIKE EATING.

MA - LOAD OVER EFFORT (L/E)

mechanical equivalent of heat in physics, a constant factor relating the calorie (the c.g.s. unit of heat) to the joule (the unit of

mechanical energy), equal to 4,1868 joules per calorie. It is redundant in the SI system of units, which measures heat and all forms of energy in joules (so that the mechanical equivalent of heat is 1).

mechanics branch of physics dealing with the motions of bodies and the forces causing these motions, and also with the forces acting on bodies in equilibrium. It is usually divided into dynamics and statics.

Quantum mechanics is the system based on the quantum theory, which has superseded Newtonian mechanics in the interpretation of physical phenomena on the atomic scale.

mechanization the use of machines in place of manual labour or the use of animals. Until the 1700s there were few machines available to help people in the home, on the land, or in industry. There were no factories, only cottage industries, in which people carried out work, such as weaving, in their own homes for other people. The 1700s saw a long series of inventions, initially in the textile industry, that ushered in a machine age and brought about the Industrial Revolution.

Among the first inventions in the textile industry were those made by John Kay (flying shuttle, 1773), James Hargreaves (spinning jenny, 1764), and Richard Arkwright (water frame, 1769). Arkwright pioneered the mechanized factory system by installing many of his spinning machines in one building and employing people to work them.

media (singular **medium**) in computing, the collective name for materials on which data can be recorded. For example, paper is a medium that can be used to record printed data; a floppy disc is a medium for recording magnetic data.

median in mathematics and statistics, the middle number of an ordered group of numbers. If there is no middle number (because there is an even number of terms), the median is the mean (average) of the two middle numbers. For example, the median of the group 2, 3, 7, 11, 12 is 7; that of 3, 4, 7, 9, 11, 13 is 8 (the average of 7 and 9).

In geometry, the term refers to a line from the vertex of a triangle to the midpoint of the opposite side.

median The median is the name given to a line from the vertex (corner) of a triangle to the mid-point of the opposite side.

medical ethics moral guidelines for doctors governing good professional conduct. The basic aims are considered to be doing good, avoiding harm, preserving the patient's autonomy, telling the truth, and pursuing justice. Ethical issues provoke the most discussion in medicine where these five aims cannot be simultaneously achieved.

MEDICINETET

<http://www.medicinenet.com/>

Traditionally these principles have been set out in the Hippocratic Oath (introduced by Greek physician (Hippocrates and including such injunctions as the command to preserve confidentiality, to help the sick to the best of one’s ability, and to refuse fatal draughts), but in the late 20th century rapidly advancing technology has raised the question of how far medicine should intervene in natural processes.

MEDICINE

King Charles II of England died five days after medical treatment that was intended to cure him. He was bled, his scalp was cauterized (burned with a hot iron), and he was given an emetic, a rectal purge and numerous draughts and concoctions to drink.

medicine the practice of preventing, diagnosing, and treating disease, both physical and mental; also any substance used in the treatment of disease. The basis of medicine is anatomy (the structure and form of the body) and physiology (the study of the body’s functions).

In the West, medicine increasingly relies on new drugs and sophisticated surgical techniques, while diagnosis of disease is more and more by noninvasive procedures. The time and cost of Western-type medical training makes it inaccessible to many parts of the Third World, where health care of this kind is provided it is often by auxiliary medical helpers trained in hygiene and the administration of a limited number of standard drugs for the prevalent diseases of a particular region.

One of the first duties of the physician is to educate the masses not to take medicine.

medicine, alternative forms of medical treatment that do not use synthetic drugs or surgery in response to the symptoms of a disease, but aim to treat the patient as a whole (holism). The emphasis is on maintaining health (with diet and exercise) and on dealing with the underlying causes rather than just the symptoms of illness. It may involve the use of herbal remedies and techniques like acupuncture, homeopathy, and chiropractic. Some alternative treatments are increasingly accepted by orthodox medicine, but the absence of enforceable standards in some fields has led to the proliferation of eccentric or untrained practitioners.

medlar small shrub or tree native to SE Europe. It is widely cultivated for its fruits, resembling small brown-green pears or quinces. These are palatable when they have begun to decay. (*Mespilus germanica*, family Rosaceae.)

medulla central part of an organ. In the mammalian kidney, the medulla lies beneath the outer cortex and is responsible for the reabsorption of water from the filtrate. In plants, it is a region of packing tissue in the centre of the stem. In the vertebrate brain, the medulla is the posterior region responsible for the coordination of basic activities, such as breathing and temperature control.

medusa the free-swimming phase in the life cycle of a coelenterate, such as a jellyfish or coral. The other phase is the sedentary polyp.

Medicine, Western: chronology

c. 400 BC Hippocrates recognized that disease had natural causes.

c. AD 200 Galen consolidated the work of the Alexandrian doctors.

1543 Andreas Vesalius gave the first accurate account of the human body.

1628 William Harvey discovered the circulation of the blood.

1768 John Hunter began the foundation of experimental and surgical pathology.

1785 Digitalis was used to treat heart disease; the active ingredient was isolated 1904.

1798 Edward Jenner published his work on vaccination.

1877 Patrick Manson studied animal carriers of infectious diseases.

1882 Robert Koch isolated the bacillus responsible for tuberculosis.

1884 Edwin Klebs isolated the diphtheria bacillus.

1885 Louis Pasteur produced a vaccine against rabies.

1890 Joseph Lister demonstrated antiseptic surgery.

1895 Wilhelm Röntgen discovered X-rays.

1897 Martinus Beijerinck discovered viruses.

1899 Felix Hoffman developed aspirin; Sigmund Freud founded psychiatry.

1900 Karl Landsteiner identified the first three blood groups, later designated A, B, and O.

1910 Paul Ehrlich developed the first specific antibacterial agent, Salvarsan, a cure for syphilis.

1922 Insulin was first used to treat diabetes.

1928 Alexander Fleming discovered penicillin.

1932 Gerhard Domagk discovered the first antibacterial sulphonamide drug, Prontosil.

1937 Electro-convulsive therapy (ECT) was developed.

1940s Lithium treatment for manic-depressive illness was developed.

1950s Antidepressant drugs and beta-blockers for heart disease were developed. Manipulation of the molecules of synthetic chemicals became the main source of new drugs. Peter Medawar studied the body’s tolerance of transplanted organs and skin grafts.

1950 Proof of a link between cigarette smoking and lung cancer was established.

1953 Francis Crick and James Watson announced the structure of DNA. Jonas Salk developed a vaccine against polio.

1958 Ian Donald pioneered diagnostic ultrasound.

1960s A new generation of minor tranquilizers called benzodiazepines was developed.

1967 Christian Barnard performed the first human heart-transplant operation.

1971 Viroids, disease-causing organisms even smaller than viruses, were isolated outside the living body.

1972 The CAT scan, pioneered by Godfrey Hounsfield, was first used to image the human brain.

1975 César Milstein developed monoclonal antibodies.

1978 World’s first ‘test-tube baby’ was born in the UK.

1980s AIDS (acquired immune-deficiency syndrome) was first recognized in the USA. Barbara McClintock’s discovery of the transposable gene was recognized.

1980 The World Health Organization reported the eradication of smallpox.

1983 The virus responsible for AIDS, now known as human immunodeficiency virus (HIV), was identified by Luc Montagnier at the Institut Pasteur, Paris, Robert Gallo at the National Cancer Institute, Maryland, USA discovered the virus independently 1984.

1984 The first vaccine against leprosy was developed.

1987 The world’s longest-surviving heart-transplant patient died in France, 18 years after his operation.

1989 Grafts of fetal brain tissue were first used to treat Parkinson’s disease.

1990 Gene for maleness discovered by UK researchers.

1991 First successful use of gene therapy (to treat severe combined immune deficiency) was reported in the USA.

1993 First trials of gene therapy against cystic fibrosis took place in the USA.

1996 An Australian man, Ben Dent, was the first person to end his life by legally sanctioned euthanasia.

Complementary Therapy

by Pamela Morley

The term 'complementary therapy' is used to encompass any practice or system of beliefs about treatment that is not included in what is generally understood as Western scientific medicine. Science and much of Western medical practice is incompatible with many of the practices of complementary therapy, as such practices do not have a scientific basis, though this should not be seen as an obstacle to its understanding and acceptance. Practitioners of complementary therapy are seeing their role increasingly as offering something that Western scientific medicine does not, and something that adds to it without denying that scientific medicine has an essential role.

Medical intervention is restricted to qualified medical practitioners in many Western countries and a significant proportion of them use complementary therapy. Not all complementary practitioners are regulated and this has caused concern as complementary therapy grows in popularity. However, organizations concerned with the training and registration of complementary practitioners have developed at a rapid rate recently to meet the growing demands of the public for a pluralist, holistic, effective, and safe approach to health care.

Homeopathy

The roots of homeopathy lie in the work of Samuel Hahnemann, an 18th-century German physician. The brutalities of medical practice, which included purging, bleeding, and the use of poisons, were instrumental in his decision to explore other avenues in which he could use his skills. He was prompted to investigate the use of cinchona bark in the treatment of fever while he was working on a *Materia Medica*. Cinchona bark produced many of the symptoms associated with fever without inducing pyrexia. This led him to speculate that a substance that was effective against a disease would produce symptoms resembling those of that disease if it was given to a healthy person.

Homeopathy recognizes a need for balance and harmony. Disturbances in the harmony of the body due to illness can precede the appearance of symptoms as the body reacts to the illness. Symptoms of the same illness differ between individuals, and the establishment of a detailed profile of the patient and a complete symptom picture are an essential part of the diagnosis. Homeopathic remedies are intended to stimulate the resources of the body to restore its natural harmony, following Hahnemann's principle that the appropriate treatment is one that produces the same symptoms in a healthy person. Many of these principles pose a problem to the scientist, but the greatest obstacle to scientific acceptance is the observation that homeopathic remedies become more potent when subject to serial dilution and mechanical shock in the process known as 'succussion'. Theories have been developed in an attempt to explain why more dilute preparations are more powerful, but none of these have yet been proven.

Herbal Medicine

A wide range of medical practices that use unrefined and refined plant materials for treatment is encompassed by the term 'herbal medicine'. They do not necessarily have a common belief system and they range from traditional herbal medicine to many ethnic medical systems, such as Chinese and Ayurvedic medicine.

Plants were used medicinally in China, Egypt, Greece, Rome, and other ancient civilizations up to 5,000 years ago. The central position of herbalism in health care was challenged by changes in medical thinking in Renaissance Europe, and by the consequent emphasis on the management of symptoms with specific remedies by the emerging medical establishment.

Samuel Thomson, an American physician, documented much of this early herbalist knowledge in the early 19th century, and he is now credited as the founder of Western herbal medicine. He developed a theory resembling that of the four humours, in which life and health were represented by heat; illness and death by cold; motion by air; and energy or life force by fire. He believed that the fever associated with infection was a healthy sign and, unlike his contemporaries, he wanted to facilitate it rather than to suppress it. He considered that coughing, vomiting, and diarrhoea were healthy signs of the body removing toxins.

The underlying belief in herbalism is that health depends on maintaining the natural state of the body. The natural state of the body, or 'vital pulse', is represented by the rhythmic variation in

tissue and cell activity, which protects, regulates, and renews the body. A herbal remedy is a preparation of the entire plant rather than an active ingredient extracted from it. The constituent components may have many different activities that restore the balance of the body, which is lost with the onset of illness. They are not specific for a particular symptom and they are thought to act by stimulating the natural defences of the body and enhancing the elimination of toxins. Attention to diet is often used as an adjunct to treatment by herbalists.

Aromatherapy

The therapeutic use of volatile oils can be traced back to the ancient civilizations of India, China, Egypt, Babylon, and Greece, and their use in medicine survived until challenged by the advent of scientific chemistry in the 17th century.

Aromatherapists believe that health depends on a balance of mental, emotional, and physical processes which is disturbed in illness. A holistic approach is taken to diagnosis and treatment. The volatile oils used in aromatherapy are complex mixtures of chemicals that occur naturally in plants. Specific disorders are treated with particular oils. They are believed to be absorbed through the skin or by inhalation before exerting their subtle effects on physical symptoms and emotional well-being. The pleasant smell and application of the oils by massage can enhance the beneficial effects of aromatherapy through reduction of tension and pain, increased relaxation, and improved circulation. Aromatherapy is widely used as an adjunct to conventional care in patients who are terminally ill.

Acupuncture

Traditional Chinese medicine is based on the fundamental principle that a life force known as *qi* flows around the body in 12 channels known as meridians. The flow of *qi* is important for good health. The balance between *yin* and *yang*, qualities possessed by all things including the internal functions and processes of the body and the meridians, is also vital to health. *Yin* is cold, dark, passive, and negative; *yin* organs include the heart, spleen, kidney, and liver. *Yang* is warm, light, active, and positive; *yang* organs include the small intestine, stomach, bladder, and gall bladder. Illness occurs when either *yin* or *yang* is dominant, and treatment helps to restore their balance.

Acupuncture is one form of treatment used in traditional Chinese medicine. It involves the insertion of fine needles into the skin at particular points on the body to correct the imbalances between *yin* and *yang*. There are about 2,000 acupoints that lie on the meridians through which *qi* flows. The imbalance between *yin* and *yang* may be associated with many factors, such as stress, emotion, diet, or injury, and these are considered in conjunction with the medical history of the patient, and examination of the 12 pulses and the condition of the tongue before a diagnosis is made. The acupoints to be stimulated are then selected and needles are inserted to a depth of about 1/2 of an inch (6 mm) and rotated. The direction of insertion and rotation of the needles regulates the flow of *qi* and the collection or dispersion of energy.

Acupuncture can be used to treat a wide range of acute and chronic illnesses, such as pain, anxiety, asthma, migraine, menstrual disorders, and gastrointestinal complaints. It can also be used as an aid to dieting and giving up smoking.

Osteopathy

Osteopaths perceive the function of muscles and the skeletal system to be central to a range of health problems. Osteopathy was conceived as a system of diagnosis and treatment by Andrew Taylor Still in the USA in the 19th century. He believed that a lack of balance in the mechanical functioning of the body, such as muscle groups being too tense or joints moving incorrectly, may cause illness. He developed a range of manipulative techniques to correct the imbalances and claimed therapeutic success. These include massage, passive movement, and stretching of the limbs. Despite opposition from the medical profession, osteopathy has slowly achieved success because it can produce a dramatic improvement in disorders that are difficult to treat by conventional medicine, such as chronic back pain and sciatica.

These are just a few of the more popular forms of complementary therapy that are available today. There are many others: chiropractic, reflexology, and relaxation techniques such as hypnotherapy, to name but a few.

meerkat or *suricate* small mammal with long soft grey fur, which is found in southern Africa, and belongs to the mongoose family. A third of its length of 35 cm/14 in is occupied by the tail. It feeds on succulent bulbs, insects, and small vertebrates, and is sociable, living in large extended family groups.

The Madagascan cat and *Cynictis penicillata* are also termed meerkats.

classification Meerkats *Suricata suricatta* are in family Viverridae, order Carnivora.

meerschau aggregate of minerals, usually the soft white clay mineral sepiolite, hydrous magnesium silicate. It floats on water and is used for making pipe bowls.

mega- prefix denoting multiplication by a million. For example, a megawatt (MW) is equivalent to a million watts.

megabyte (MB) in computing, a unit of memory equal to 1,024 kilobytes.

It is sometimes used, less precisely, to mean 1 million bytes.

megalith *Greek megalos 'great', lithos 'stone'* prehistoric stone monument of the late Neolithic (New Stone Age) or early Bronze Age. Most common in Europe, megaliths include single large uprights or *menhirs* (for example, the Five Kings, Northumberland, England); rows or alignments (for example, Carnac, Brittany, France); stone circles; and the hutlike remains of burial chambers after the covering earth has disappeared, known as *dolmens* (for example, Kits Coty, Kent, England, where only the entrance survives).

A number of explanations have been put forward for the building of megaliths during the Neolithic period in areas including Denmark, Ireland, NE Scotland, England, W France, and Spain. These range from economic reasons to expressions of dominance (neo-Marxist) and symbolism. The great stone monuments at Carnac in W Brittany, France; in Jersey, such as La Hougue Bie; and in W Britain and Ireland, suggest possible cultural links through trade among megalith builders whose rural economy encompassed arable farming, stockrearing, and the development of pottery and weaving.

In the later Neolithic, in Wessex, S England, the construction of stone monuments such as Avebury and Stonehenge involved large numbers of working hours and considerable organization; possibly the stone was transported over a great distance, as has been suggested in the case of the bluestone at Stonehenge, although glacial deposition is another explanation.

Changes in social structure and diversification of labour probably caused the practice of megalith building to be abandoned.

Megalosaurus large bipedal carnivorous *dinosaur*. Fragmentary fossil remains occur in European Jurassic deposits.

megamouth deep-sea shark that feeds on plankton. It has a bulbous head with protruding jaws and blubbery lips, is 4.5 m/15 ft long, and weighs 750 kg/1,650 lb. Although first discovered 1976, the first live specimen was found in 1992 off the coast of Los Angeles. The first female was found in 1994 in Hakata Bay, Kyushu, Japan; she was 4.8 m/16 ft long and weighed 790 kg/1,740 lb. (Species *Megachasma pelagios*.)

megapode or mound-builder any of a group of chicken-like birds found in the Malay Archipelago and Australia. They pile up large mounds of vegetable matter, earth, and sand 4 m/13 ft across, in which to deposit their eggs, then cover the eggs and leave them to

be incubated by the heat produced by the rotting vegetation. There are 19 species, all large birds, 50–70 cm/20–27.5 in in length, with very large feet. They include brush turkeys. (Family Megapodiidae, order Galliformes.)

In some species the male bird feels the mound with his tongue and adds or takes away vegetation to provide the correct temperature.

megathere any of a group of extinct giant ground sloths of North and South America. Various species lived from about 7 million years ago until geologically recent times. They were plant-eaters, and some grew to 6 m/20 ft long. (Genus *Megatherium*.)

megaton one million (10^6) tons. Used with reference to the explosive power of a nuclear weapon, it is equivalent to the explosive force of one million tons of trinitrotoluene (TNT).

megavitamin therapy the administration of large doses of vitamins to combat conditions considered wholly or in part due to their deficiency.

Developed by US chemist Linus Pauling in the 1960s, and alternatively known as 'orthomolecular psychiatry', the treatment has proved effective with addicts, schizophrenics, alcoholics, and depressives.

meiosis in biology, a process of cell division in which the number of chromosomes in the cell is halved. It only occurs in eukaryotic cells, and is part of a life cycle that involves sexual reproduction because it allows the genes of two parents to be combined without the total number of chromosomes increasing.

In sexually reproducing diploid animals (having two sets of chromosomes per cell), meiosis occurs during formation of the gametes (sex cells, sperm and egg), so that the ϕ gametes are haploid (having only one set of chromosomes). When the gametes unite during fertilization, the diploid condition is restored. In plants, meiosis occurs just before spore formation. Thus the spores are haploid and in lower plants such as mosses they develop into a haploid plant called a gametophyte which produces the gametes (see alternation of generations). See also mitosis.

meitnerium synthesized radioactive element of the ϕ transactinide series, symbol Mt, atomic number 109, relative atomic mass 266. It was first produced in 1982 at the Laboratory for Heavy Ion Research in Darmstadt, Germany, by fusing bismuth and iron nuclei; it took a week to obtain a single new, fused nucleus. It was named in 1997 after the Austrian-born Swedish physicist Lise Meitner. Its temporary name was unilennium.

mela-leuca tree or shrub of the predominantly Australian genus *Melaleuca*, family Myrtaceae, many of which are found on river banks or in swamps; commonly known as paperbarks because of their papery and usually spongy bark.

mela-leuca tree or **paperbark** tropical tree belonging to the myrtle family. The leaves produce cajuput oil, which is used in medicine. (*Melaleuca leucadendron*, family Myrtaceae.)

In favourable conditions, such as in the Florida Everglades, the tree reproduces rapidly. Attempts are being made to root out and destroy it because in a forest fire its crown becomes a ball of flame, rapidly spreading the blaze in all directions.

melamine $C_3H_6N_6$ ϕ thermosetting polymer based on urea-formaldehyde. It is extremely resistant to heat and is also scratch-resistant. Its uses include synthetic resins.

The 'nests' in which scrub fowl lay their eggs are the largest structures created by any bird. These nests are in fact mounds of rotting vegetation, up to 5 m/16 ft in height and 12 m/40 ft in diameter. As the vegetation rots, it generates enough heat to incubate the eggs.

meiosis Meiosis is a type of cell division that produces gametes (sex cells, sperm and egg). This sequence shows an animal cell but only four chromosomes are present in the parent cell (1). There are two stages in the division process. In the first stage (2–6), the chromosomes come together in pairs and exchange genetic material. This is called crossing over. In the second stage (7–9), the cell divides to produce four gamete cells, each with only one copy of each chromosome from the parent cell.

helps protect the skin against ultraviolet radiation from sunlight. Both genetic and environmental factors determine the amount of melanin in the skin.

melanism black coloration of animal bodies caused by large amounts of the pigment melanin. Melanin is of significance in insects, because melanin ones warm more rapidly in sunshine than do pale ones, and can be more active in cool weather. A fall in temperature may stimulate such insects to produce more melanin. In industrial areas, dark insects and pigeons match sooty backgrounds and escape predation, but they are at a disadvantage in rural areas where they do not match their backgrounds. This is known as **industrial melanism**.

melanoma highly malignant tumour of the melanin-forming cells (melanocytes) of the skin. It develops from an existing mole in up to two thirds of cases, but can also arise in the eye or mucous membranes.

Malignant melanoma is the most dangerous of the skin cancers; it is associated with brief but excessive exposure to sunlight. It is easily treated if caught early but deadly once it has spread. There is a genetic factor in some cases.

Once rare, this disease is increasing at the rate of 7% in most countries with a predominantly fair-skinned population, owing to the increasing popularity of holidays in the sun. Most at risk are

melon any of several large, juicy (95% water), thick-skinned fruits of trailing plants of the gourd family. The muskmelon (*Cucumis melo*), of which the honeydew melon is a variety, and the large red watermelon (*Citrullus vulgaris*) are familiar edible varieties. (Family Cucurbitaceae.)

Thought to have originated in Asia, the melon became naturalized in the Nile Valley and was introduced to Europe at the end of the 15th century.

meltdown the melting of the core of a nuclear reactor, due to overheating.

To prevent such accidents all reactors have equipment intended to flood the core with water in an emergency. The reactor is housed in a strong containment vessel, designed to prevent radiation escaping into the atmosphere. The result of a meltdown would be an area radioactively contaminated for 25,000 years or more.

At Three Mile Island, Pennsylvania, USA, in March 1979, a partial meltdown occurred caused by a combination of equipment failure and operator error, and some radiation was released into the air. In April 1986, a reactor at Chernobyl, near Kiev, Ukraine, exploded, causing a partial meltdown of the core. Radioactive fallout was detected as far away as Canada and Japan.

melting point temperature at which a substance melts, or changes from solid to liquid form. A pure substance under standard conditions of pressure (usually one atmosphere) has a definite melting point. If heat is supplied to a solid at its melting point, the temperature does not change until the melting process is complete. The melting point of ice is 0°C or 32°F.

membrane in living things, a continuous layer, made up principally of fat molecules, that encloses a cell or organelles within a cell. Small molecules, such as water and sugars, can pass through the cell membrane by diffusion. Large molecules, such as proteins, are transported across the membrane via special channels, a process often involving energy input. The Golgi apparatus within the cell is thought to produce certain membranes.

In cell organelles, enzymes may be attached to the membrane at specific positions, often alongside other enzymes involved in the same process, like workers at a conveyor belt. Thus membranes help to make cellular processes more efficient.

memory in computing, the part of a system used to store data and programs either permanently or temporarily. There are two main types: immediate access memory and backing storage. Memory capacity is measured in bytes or, more conveniently, in kilobytes (units of 1,024 bytes) or megabytes (units of 1,024 kilobytes).

Immediate access memory, or **internal memory**, describes the memory locations that can be addressed directly and individually by the central processing unit. It is either read-only (stored in ROM, PROM, and EPROM chips) or read/write (stored in RAM chips). Read-only memory stores information that must be constantly available and is unlikely to be changed. It is nonvolatile – that is, it is not lost when the computer is switched off. Read/write memory is volatile – it stores programs and data only while the computer is switched on.

Backing storage, or **external memory**, is nonvolatile memory, located outside the central processing unit, used to store programs and data that are not in current use. Backing storage is provided by such devices as magnetic discs (floppy and hard discs), magnetic tape (tape streamers and cassettes), optical discs (such as CD-ROM), and bubble memory. By rapidly switching blocks of information between the backing storage and the immediate-access memory, the limited size of the immediate-access memory may be increased artificially. When this technique is used to give the appearance of a larger internal memory than physically exists, the additional capacity is referred to as **virtual memory**.

memory ability to store and recall observations and sensations. Memory does not seem to be based in any particular part of the brain; it may depend on changes to the pathways followed by nerve impulses as they move through the brain. Memory can be improved by regular use as the connections between nerve cells (neurons) become 'well-worn paths' in the brain. Events stored in **short-term memory** are forgotten quickly, whereas those in **long-term memory** can last for many years, enabling recall of information and recognition of people and places over long periods of time.

Short-term memory is the most likely to be impaired by illness or drugs whereas long-term memory is very resistant to such damage. Memory changes with age and otherwise healthy people may experience a natural decline after the age of about 40. Research is just beginning to uncover the biochemical and electrical bases of the human memory.

memory address in computing, number specifying the location of a particular item in a computer's RAM.

memory resident present in the main (RAM) memory of the computer. For an application to be run, it has to be memory resident.

Mendel, Gregor Johann (1822–1884)

Austrian biologist, founder of genetics. His experiments with successive generations of peas gave the basis for his theory of particulate inheritance rather than blending, involving dominant and recessive characters; see Mendelism. His results, published 1865–69, remained unrecognized until the early 20th century.

Mendel formulated two laws now recognized as fundamental laws of heredity: the law of segregation and the law of independent assortment of characters. Mendel concluded that each parent plant contributes a 'factor' to its offspring that determines a particular trait and that the pairs of factors in the offspring do not give rise to a blend of traits.

Much of his work was performed on the edible pea *Pisum*, which he grew in the monastery garden. He carefully self-pollinated and wrapped (to prevent accidental pollination by insects) each individual plant, collected the seeds produced by the plants, and

studied the offspring of these seeds. Seeing that some plants bred true and others not, he worked out the pattern of inheritance of various traits.

He found that dwarf plants produced only dwarf offspring and that the seeds produced by this second generation also produced only dwarf offspring. With tall plants, however, he found that both tall and dwarf offspring were produced and concluded that there were two types of tall plants, those that bred true and those that did not. Next he cross-bred dwarf plants with true-breeding tall plants and found that all the offspring in the first generation were tall but that the offspring from subsequent generations were a mixture: one-quarter true-breeding dwarf plants, one-quarter true-breeding tall plants, and one-half non-true-breeding tall plants.

Mendel also studied other characteristics in pea plants, such as flower colour, seed shape and flower position, finding that, as with height, simple laws governed the inheritance of these traits. He reported his findings in 'Experiments with Plant Hybrids' 1866, but the importance of his work was not recognized at the time, even by the eminent botanist Karl Wilhelm von Naegeli, to whom Mendel sent a copy of his paper. It was not until 1900, when his work was rediscovered by Hugo De Vries, Carl Erich Correns, and Erich Tschermak von Seysenegg, that Mendel achieved fame – 16 years after his death.

dent. Some applications are kept in memory (see terminate and stay resident), while most are deleted from the memory when their task is complete. However, the memory is usually not large enough to hold all applications and swapping in and out of memory is necessary. This slows down the application.

menagerie small collection of wild animals kept in captivity for display. Rulers of early times used to bring back wild animals from abroad for public exhibition. Private collections later became common, and until the early 19th century one was maintained at the Tower of London, England. From these collections developed present-day zoos.

mendelevium synthesized, radioactive metallic element of the actinide series, symbol Md, atomic number 101, relative atomic mass 258. It was first produced by bombardment of Es-253 with helium nuclei. Its longest-lived isotope, Md-258, has a half-life of about two months. The element is chemically similar to thulium. It was named by the US physicists at the University of California at Berkeley who first synthesized it in 1955 after the Russian chemist Mendeleyev, who in 1869 devised the basis for the periodic table of the elements.

Mendeleyev, Dmitri Ivanovich (1834-1907)

Russian chemist who framed the periodic law in chemistry in 1869, which states that the chemical properties of the elements depend on their relative atomic masses. This law is the basis of the periodic table of the elements, in which the elements are arranged by atomic number and organized by their related groups.

Mendeleyev was the first chemist to understand that all elements are related members of a single ordered system. From his table he predicted the properties of elements then unknown, of which three (gallium, scandium, and germanium) were discovered in his lifetime. Meanwhile Lothar Meyer in Germany presented a similar but independent classification of the elements.

menhaden or **hardhead** or **mossbunker** marine bony fish allied to hshads and common on the Atlantic coast of North America. It is employed as bait, but is chiefly valuable for its rich oil. The residue remaining after extraction is used as a fertilizer.

classification The menhaden *Brevoortia tyrannus* is in order Clupeiformes, class Osteichthyes.

menhir **Breton 'long stone'** prehistoric tall, upright stone monument or megalith. Menhirs may be found singly as monoliths or in groups. They have a wide geographical distribution in the Americas (mainly as monoliths), and in Europe, Asia, and Africa, and belong to many different periods. Most European examples were erected in the late Neolithic (New Stone Age) or early Bronze Age.

The menhirs at Carnac in Brittany, NW France, are particularly impressive, one example standing about 10 m/39 ft high. In nearby Morbihan, Le Grand Menhir Brisé once stood almost 21 m/68 ft high.

In the British Isles, standing stones in England include the Devil's Arrows, Boroughbridge, W Yorkshire, and the Five Kings, Upper Coqueredale, Northumberland; and in Wales, Harold's Stones, Trelleck, Gwent. Numerous Irish examples, known as **goulaun**, **galan**, **dallan**, or **bagan**, were built from the Neolithic to the early Christian period. In Scotland, groups of menhirs are often called **cat stones**, from Gaelic *cath* 'a battle'.

Ménière's disease or **Ménière's syndrome** recurring condition of the inner ear affecting mechanisms of both hearing and balance. It usually develops in the middle or later years. Symptoms, which include deafness, ringing in the ears, nausea, vertigo, and loss of balance, may be eased by drugs, but there is no cure.

meningitis inflammation of the meninges (membranes) surrounding the brain, caused by bacterial or viral infection. Bacterial meningitis, though treatable by antibiotics, is the more serious threat. Diagnosis is by lumbar puncture.

Bacterial meningitis is caused by *Neisseria meningitidis*, a bacterium that colonizes the lining of the throat and is carried by 2-10% of the healthy population. Illness results if the bacteria enter the bloodstream, but normally the epithelial lining of the throat is a sufficient barrier.

Many common viruses can cause the occasional case of meningitis, although not usually in its more severe form. The treatment for viral meningitis is rest.

There are three strains of meningitis: serogroups A, B, and C. Vaccines exist only for A and C. However, they do not provide long-term protection nor are they suitable for children under the age of two. B is the most prevalent of the groups, causing over 50% of cases in Europe and the USA.

The severity of the disease varies from mild to rapidly lethal, and symptoms include fever, headache, nausea, neck stiffness, delirium, and (rarely) convulsions.

Mendelism in genetics, the theory of inheritance originally outlined by Austrian biologist Gregor Mendel. He suggested that, in sexually reproducing species, all characteristics are inherited

meniscus in physics, the curved shape of the surface of a liquid in a thin tube, caused by the cohesive effects of surface tension (capillary action). When the walls of the container are made wet by the liquid, the meniscus is concave, but with highly viscous liquids (such as mercury) the meniscus is convex. Meniscus is also the name of a concavo-convex or convexo-concave lens.

meniscus in biology, the fibro-cartilage in joints, such as the knee joint.

menopause in women, the cessation of reproductive ability, characterized by menstruation (see menstrual cycle) becoming irregular and eventually ceasing. The onset is at about the age of 50, but varies greatly. Menopause is usually uneventful, but some women suffer from complications such as flushing, excessive bleeding, and nervous disorders. Since the 1950s, hormone-replacement therapy (HRT), using oestrogen alone or with progesterone, a synthetic form of progesterone, has been developed to counteract such effects.

Long-term use of HRT was previously associated with an increased risk of cancer of the uterus, and of clot formation in the blood vessels, but newer formulations using natural oestrogens are not associated with these risks. Without HRT there is increased risk of osteoporosis (thinning of the bones) leading to broken bones, which may be indirectly fatal, particularly in the elderly.

The menopause is also known as the 'change of life'.

menstrual cycle cycle that occurs in female mammals of reproductive age, in which the body is prepared for pregnancy. At the beginning of the cycle, a Graafian (egg) follicle develops in the ovary, and the inner wall of the uterus forms a soft spongy lining. The egg is released from the ovary, and the uterus lining (endometrium) becomes vascularized (filled with blood vessels). If fertilization does

not occur, the corpus luteum (remains of the Graafian follicle) degenerates, and the uterine lining breaks down, and is shed. This is what causes the loss of blood that marks menstruation. The cycle then begins again. Human menstruation takes place from puberty to menopause, except during pregnancy, occurring about every 28 days.

The cycle is controlled by a number of hormones, including oestrogen and progesterone. If fertilization occurs, the corpus luteum persists and goes on producing progesterone.

mental disability arrested or incomplete development of mental capacities. It can be very mild, but in more severe cases is associated with social problems and difficulties in living independently. A person may be born with a mental disability (for example, Down's syndrome) or may acquire it through brain damage. Between 90 and 130 million people in the world suffer from such disabilities.

Clinically, mental disability is graded as profound, severe, moderate, or mild, roughly according to IQ and the sufferer's ability to cope with everyday tasks. Among its many causes are genetic defect (phenylketonuria), chromosomal errors (Down's syndrome), infection before birth (rubella) or in infancy (meningitis), trauma (brain damage at birth or later), respiratory difficulties at the time of birth, toxins (lead poisoning), physical deprivation (lack of, or defective, thyroid tissue, as in cretinism), and gross psychological deprivation. No clear cause of disability can be established for more than half of individuals with an IQ of less than 70.

mental illness disordered functioning of the mind. Since normal working cannot easily be defined, the borderline between mild mental illness and normality is a matter of opinion (not to be confused with normative behaviour). It is broadly divided into two categories: psychosis, in which the patient remains in touch with reality; and psychosis, in which perception, thought, and belief are disordered.

menu in computing, a list of options, displayed on screen, from which the user may make a choice – for example, the choice of services offered to the customer by a bank cash dispenser: withdrawal, deposit, balance, or statement. Menus are used extensively in graphical user interface (GUI) systems, where the menu options are often selected using a pointing device called a mouse.

Mercalli scale scale used to measure the intensity of an earthquake. It differs from the Richter scale, which measures magnitude. It is named after the Italian seismologist Giuseppe Mercalli (1850–1914).

MENSTRUAL CYCLE

The menstrual cycles of women living in close proximity to each other become synchronized. This could be due to pheromones released in the sweat and may have evolved as means of thwarting male infidelity.

menstrual cycle From puberty to the menopause, most women produce a regular rhythm of hormones that stimulate the various stages of the menstrual cycle. The change in hormone levels may cause premenstrual tension. This diagram shows an average menstrual cycle. The dates of each stage vary from woman to woman.

The Mercalli scale

The Mercalli scale is a measure of the intensity of an earthquake. It differs from the Richter scale, which measures magnitude. It is named after the Italian seismologist Giuseppe Mercalli (1850–1914).

The scale shown here is the Modified Mercalli Intensity Scale, developed in 1931 by US seismologists Harry Wood and Frank Neumann.

| Intensity value | Description |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I | not felt except by a very few under especially favourable conditions |
| II | felt only by a few persons at rest, especially on upper floors of buildings |
| III | felt quite noticeably by persons indoors, especially on upper floors of buildings; many people do not recognize it as an earthquake; standing motor cars may rock slightly; vibrations similar to the passing of a truck; duration estimated |
| IV | felt indoors by many, outdoors by few during the day, at night, some awakened; dishes, windows, doors disturbed; walls make cracking sound; sensation like heavy truck striking building; standing motor cars rock noticeably |
| V | felt by nearly everyone; many awakened; some dishes, windows broken; unstable objects overturned; pendulum clocks may stop |
| VI | felt by all, many frightened; some heavy furniture moved; a few instances of fallen plaster; damage slight |
| VII | damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable damage in poorly-built or badly-designed structures; some chimneys broken |
| VIII | damage slight in specially-designed structures; considerable damage in ordinary substantial buildings with partial collapse; damage great in poorly-built structures; fall of chimneys, factory stacks, columns, monuments, walls; heavy furniture overturned |
| IX | damage considerable in specially-designed structures; well-designed frame structures thrown out of plumb; damage great in substantial buildings, with partial collapse; buildings shifted off foundations |
| X | some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations; rails bent |
| XI | few, if any (masonry) structures remain standing; bridges destroyed; rails bent greatly |
| XII | damage total; lines of sight and level are distorted; objects thrown into the air |

Intensity is a subjective value, based on observed phenomena, and varies from place to place with the same earthquake.

merchant navy the passenger and cargo ships of a country. Most are owned by private companies. To avoid strict regulations on safety, union rules on crew wages, and so on, many ships are today registered under 'flags of convenience', that is, flags of countries that do not have such rules.

During wartime, merchant shipping may be drafted by the national government for military purposes.

mercury or *quicksilver* Latin *mercurius* heavy, silver-grey, metallic element, symbol Hg (from Latin *hydrargyrum*), atomic number 80, relative atomic mass 200.59. It is a dense, mobile liquid with a low melting point (−38.87°C/−37.96°F). Its chief source is the mineral cinnabar, HgS, but it sometimes occurs in nature as a free metal.

uses Its alloys with other metals are called amalgams (a silver-mercury amalgam is used in dentistry for filling cavities in teeth). Industrial uses include drugs and chemicals, mercury-vapour lamps, arc rectifiers, power-control switches, barometers, and thermometers.

hazards Mercury is a cumulative poison that can contaminate the food chain, and cause intestinal disturbance, kidney and brain damage, and birth defects in humans. (The World Health Organization's 'safe' limit for mercury is 0.5 milligrams of mercury per kilogram of muscle tissue). The discharge into the sea by industry of organic mercury compounds such as dimethylmercury is the chief cause of mercury poisoning in the latter half of the 20th century. Between 1953 and 1975, 684 people in the Japanese fishing village of Minamata were poisoned (115 fatally) by organic mercury wastes that had been dumped into the bay and had accumulated in the bodies of fish and shellfish.

In a landmark settlement, a British multinational chemical company in April 1997 agreed to pay £1.3 million in compensation to 20 South African workers who were poisoned by mercury. Four of the black workers had died and a number of others were suffering severe brain and other neurological damage. The workers had accused Thor Chemical Holdings of adopting working practices in South Africa which would not have been allowed in Britain. The claimants had all worked at Thor's mercury plant at Cato Ridge in Natal. Thor had operated a mercury plant at Margate, in Kent, which during the 1980s was repeatedly criticised by the Health and Safety Executive (HSE) for bad working practices and over-exposure of British workers to mercury. Under pressure from the HSE, Thor closed down its mercury operations in Britain in 1987 and expanded them in South Africa.

history The element was known to the ancient Chinese and Hindus, and is found in Egyptian tombs of about 1500 BC. It was named by the alchemists after the fast-moving god, for its fluidity.

Mercury in astronomy, the closest planet to the Sun. Its mass is 0.056 that of Earth. On its sunward side the surface temperature reaches over 400°C/752°F, but on the 'night' side it falls to −170°C/−274°F.

mean distance from the Sun 58 million km/36 million mi

Detailed description of the planet Mercury. It includes statistics and information about the planet, along with a chronology of its exploration supported by a good selection of images.

mercury fulminate highly explosive compound used in detonators and percussion caps. It is a grey, sandy powder and extremely poisonous.

Mercury project US project to put a human in space in the one-seat Mercury spacecraft 1961–63.

The first two Mercury flights, on Redstone rockets, were short flights to the edge of space and back. The orbital flights, beginning with the third in the series (made by John Glenn), were launched by Atlas rockets.

merganser any of several diving ducks with long, slender, serrated bills for catching fish, widely distributed in the northern hemisphere. Most have crested heads. (Genus *Mergus*, family Anatidae.)

The male common merganser or goosander (*M. merganser*) has a greenish-black head, black back, and a pinkish-white breast and

underparts; the male **red-breasted merganser** (*M. serrator*) drake has a crested glossy green head, white neck, red breast and black upper surface with white margins. The females of both are very similar, with crested chestnut heads, white underparts, and grey backs. *M. australis* is a rare species found only in the Auckland Islands.

meridian half a great circle drawn on the Earth's surface passing through both poles and thus through all places with the same longitude. Terrestrial longitudes are usually measured from the Greenwich Meridian.

An astronomical meridian is a great circle passing through the celestial pole and the zenith (the point immediately overhead).

merino breed of sheep. Its close-set, silky wool is highly valued. Originally from Spain, the merino is now found all over the world, and is the breed on which the Australian wool industry is built.

meristem region of plant tissue containing cells that are actively dividing to produce new tissues (or have the potential to do so). Meristems found in the tip of roots and stems, the apical meristems, are responsible for the growth in length of these organs.

The cambium is a lateral meristem that is responsible for increase in girth in perennial plants. Some plants also have intercalary meristems, as in the stems of grasses, for example. These are responsible for their continued growth after cutting or grazing has removed the apical meristems of the shoots.

Meristem culture involves growing meristems taken from shoots on a nutrient-containing medium, and using them to grow new plants.

It is used to propagate infertile plants or hybrids that do not breed true from seed and to generate virus-free stock, since viruses rarely infect apical meristems.

merlin small falcon of Europe, Asia, and North America, where it is also called a pigeon hawk. The male, 26 cm/10 in long, has a grey-blue back and reddish-brown barred front; the female, 32 cm/13 in long, has a dark brown back and lighter front with streaks. Merlins fly relatively low over the ground when hunting and 'stoop' quickly onto their prey, which consists mainly of small birds. (Species *Falco columbarius*, order Falconiformes.)

They are found mainly on rocks and moors. On moorland the nest is generally built on a slope among the heather, and in other localities on rock ledges. The eggs are bluish-white, blotched with brown markings; four or five are laid.

MERLIN array radiotelescope network centred on Jodrell Bank, N England.

mermaid's purse purse-shaped egg case of the skates and many chsharks.

mesa Spanish 'table' flat-topped, steep-sided plateau, consisting of horizontal weak layers of rock topped by a resistant formation; in particular, those found in the desert areas of the USA and Mexico. A small mesa is called a butte.

MYSTERY OF THE MESA: A SCIENCE DETECTIVE STORY

<http://www.blm.gov/education/mesas/mesa.html>

Sponsored by the US Bureau of Land Management, this site explores an archaeological discovery on a remote Alaskan mesa and explains how scientists study artefacts and draw conclusions about the ancient inhabitants of this land. Articles highlight the essential role of scientists in writing the earliest chapters of the USA's history.

mescaline psychedelic drug derived from a small, spineless cactus *Lophophora williamsii* of N Mexico and the SW USA, known as peyote. The tops (called mescal buttons), which scarcely appear above ground, are dried and chewed, or added to alcoholic drinks.

Mescaline is a crystalline alkaloid $C_{11}H_{17}NO_3$. It is used by some North American Indians in religious rites.

mesoglea layer of jelly-like noncellular tissue that separates the endoderm and ectoderm in jellyfish and other coelenterates.

meson in physics, a group of unstable subatomic particles made up of two indivisible elementary particles called quarks. It has a mass intermediate between that of the electron and that of the proton, is found in cosmic radiation, and is emitted by nuclei under bombardment by very high-energy particles.

The mesons form a subclass of the hadrons and include the kaons and pions. Their existence was predicted in 1935 by Japanese physicist Hideki Yukawa.

mesophyll the tissue between the upper and lower epidermis of a leaf blade (lamina), consisting of parenchyma-like cells containing numerous chloroplasts.

In many plants, mesophyll is divided into two distinct layers. The palisade mesophyll is usually just below the upper epidermis and is composed of regular layers of elongated cells. Lying below them is the spongy mesophyll, composed of loosely arranged cells of irregular shape. This layer contains fewer chloroplasts and has many intercellular spaces for the diffusion of gases (required for respiration and photosynthesis), linked to the outside by means of stomata.

mesosphere layer in the Earth's atmosphere above the stratosphere and below the thermosphere. It lies between about 50 km/31 mi and 80 km/50 mi above the ground.

Mesozoic era of geological time 245–65 million years ago, consisting of the Triassic, Jurassic, and Cretaceous periods. At the beginning of the era, the continents were joined together as Pangaea; dinosaurs and other giant reptiles dominated the sea and air; and ferns, horsetails, and cycads thrived in a warm climate worldwide. By the end of the Mesozoic era, the continents had begun to assume their present positions, flowering plants were dominant, and many of the large reptiles and marine fauna were becoming extinct.

message-ID in computing, special number given to every item of e-mail as it travels across the Internet. Message-IDs are especially important for controlling traffic in USENET. Articles are initially offered across the network by their message-IDs, enabling news servers to check whether they have already received them and either take the rest of the message or move on to the next message-ID.

Messier catalogue in astronomy, a catalogue of 103 galaxies, nebulas, and star clusters (the Messier objects) published in 1784 by French astronomer Charles Messier. Catalogue entries are denoted by the prefix 'M'. Well known examples include M31 (the Andromeda galaxy), M42 (the Orion Nebula), and M45 (the Pleiades star cluster).

Messier compiled the catalogue to identify fuzzy objects that could be mistaken for comets. The list was later extended to 109.

metabolism the chemical processes of living organisms enabling them to grow and to function. It involves a constant alternation of building up (anabolism) and breaking down (catabolism). For example, green plants build up complex organic substances from water, carbon dioxide, and mineral salts (photosynthesis); by digestion animals partially break down complex organic substances, ingested as food, and subsequently resynthesize them for use in their own bodies.

metal any of a class of chemical elements with specific physical and chemical characteristics. Metallic elements compose about 75% of the 112 elements in the periodic table of the elements.

Physical properties include a sonorous tone when struck, good conduction of heat and electricity, opacity but good reflection of light, malleability, which enables them to be cold-worked and rolled into sheets, ductility, which permits them to be drawn into thin wires, and the possible emission of electrons when heated (thermionic effect) or when the surface is struck by light (photoelectric effect).

The majority of metals are found in nature in a combined form only, as compounds or mineral ores; about 16 of them also occur in the elemental form, as native metals. Their chemical properties are largely determined by the extent to which their atoms can lose one or more electrons and form positive ions (cations).

metal detector electronic device for detecting metal, usually below ground, developed from the wartime mine detector. In the head of the metal detector is a coil, which is part of an electronic circuit. The presence of metal causes the frequency of the signal in the circuit to change, setting up an audible note in the headphones worn by the user.

They are used to survey areas for buried metallic objects, occasionally by archaeologists. However, their indiscriminate use by treasure hunters has led to their being banned on recognized archaeological sites in some countries.

metal fatigue condition in which metals fail or fracture under relatively light loads, when these loads are applied repeatedly. Structures that are subject to flexing, such as the airframes of aircraft, are prone to metal fatigue.

metallic bond the force of attraction operating in a metal that holds the atoms together. In the metal the valency electrons are able to move within the crystal and these electrons are said to be delocalized (see *electrons, delocalized*). Their movement creates short-lived, positively charged ions. The electrostatic attraction between the delocalized electrons and the ceaselessly forming ions constitutes the metallic bond.

metallic character chemical properties associated with those elements classed as metals. These properties, which arise from the element's ability to lose electrons, are: the displacement of hydrogen from dilute acids; the formation of basic oxides; the formation of ionic chlorides; and their reducing reaction, as in the thermite process (see *reduction*).

In the periodic table of the elements, metallic character increases down any group and across a period from right to left.

metallic glass substance produced from metallic materials (non-corrosive alloys rather than simple metals) in a liquid state which, by very rapid cooling, are prevented from reverting to their regular metallic structure. Instead they take on the properties of glass, while retaining the metallic properties of malleability and relatively good electrical conductivity.

metalloid or semimetal any chemical element having some of but not all the properties of metals; metalloids are thus usually electrically semiconducting. They comprise the elements germanium, arsenic, antimony, and tellurium.

metallurgy the science and technology of producing metals, which includes extraction, alloying, and hardening. Extractive, or process, metallurgy is concerned with the extraction of metals from their ores and refining and adapting them for use. Physical metallurgy is concerned with their properties and application. Metallurgy establishes the microscopic structures that contribute to hardness, ductility, and strength.

Metals can be extracted from their ores in three main ways: dry processes, such as smelting, volatilization, or amalgamation (treatment with mercury); wet processes, involving chemical reactions; and electrolytic processes, which work on the principle of electrolysis.

The foundations of metallurgical science were laid about 3500 BC in Egypt, Mesopotamia, China, and India, where the art of smelting metals from ores was discovered, starting with the natural alloy bronze. Later, gold, silver, copper, lead, and tin were worked in various ways, although they had been cold-hammered as native metals for thousands of years. The smelting of iron was discovered about 1500 BC. The Romans hardened and tempered iron into steel, using heat treatment. From then until about AD 1400, advances in metallurgy came into Europe by way of Arabian chemists. Cast iron began to be made in the 14th century in a crude blast furnace. The demands of the Industrial Revolution led to an enormous increase in wrought iron production. The invention by British civil engineer Henry Bessemer of the Bessemer

process in 1856 made cheap steel available for the first time, leading to its present widespread use and the industrial development of many specialized steel alloys.

metal, porous lightweight metal made by melting metals such as copper, or iron alloys, in a sealed furnace filled with hydrogen, or other gas, under pressure. The formation of pores can be controlled by varying pressures and cooling times. They vary in density from 5% to 75% of the metal and in diameter from 5 micrometres (millionths of a metre) to 10 mm/0.39 in. The direction and positioning of the pores can also be controlled.

Porous metals were developed in the Ukraine in the 1960s and used in space rockets. Kerosene was forced through the pores to form a fine mist for optimum combustion.

metamorphic rock rock altered in structure and composition by pressure, heat, or chemically active fluids after original formation. (If heat is sufficient to melt the original rock, technically it becomes an igneous rock upon cooling.) The term was coined in 1833 by Scottish geologist Charles Lyell (1797-1875).

metamorphism geological term referring to the changes in rocks of the Earth's crust caused by increasing pressure and temperature. The resulting rocks are metamorphic rocks. All metamorphic changes take place in solid rocks. If the rocks melt and then harden, they become igneous rocks.

metamorphosis period during the life cycle of many invertebrates, most amphibians, and some fish, during which the individual's body changes from one form to another through a major reconstitution of its tissues. For example, adult frogs are produced by metamorphosis from tadpoles, and butterflies are produced from caterpillars following metamorphosis within a pupa.

In classical thought and literature, metamorphosis is the transformation of a living being into another shape, either living or inanimate (for example Niobe). The Roman poet Ovid wrote about this theme.

metazoa another name for animals. It reflects an earlier system of classification, in which there were two main divisions within the animal kingdom, the multicellular animals, or metazoa, and the single-celled 'animals' or protozoa. The protozoa are no longer included in the animal kingdom, so only the metazoa remain.

meteor flash of light in the sky, popularly known as a shooting or falling star, caused by a particle of dust, a meteoroid, entering the atmosphere at speeds up to 70 kps/45 mps and burning up by friction at a height of around 100 km/60 mi. On any clear night, several sporadic meteors can be seen each hour.

Several times each year the Earth encounters swarms of dust shed by comets, which give rise to a meteor shower.

This appears to radiate from one particular point in the sky, after which the shower is named; the Perseid meteor shower in August appears in the constellation Perseus. A brilliant meteor is termed a fireball. Most meteoroids are smaller than grains of sand. The Earth sweeps up an estimated 16,000 tonnes of meteoric material every year.

meteor-burst communications technique for sending messages by bouncing radio waves off the trails of meteors. High-speed computer-controlled equipment is used to sense the presence of a meteor and to broadcast a signal during the short time that the meteor races across the sky.

The system, first suggested in the late 1920s, remained impracticable until data-compression techniques were developed, enabling messages to be sent in automatic high-speed bursts each time a meteor trail appeared. There are usually enough meteor trails in the sky at any time to permit continuous transmission of a message. The technique offers a communications link that is difficult to jam, undisturbed by storms on the Sun, and would not be affected by nuclear war.

meteorite piece of rock or metal from space that reaches the surface of the Earth, Moon, or other body. Most meteorites are thought to be fragments from asteroids, although some may be pieces from the heads of comets. Most are stony, although some are made of

iron and a few have a mixed rock-iron composition.

Stony meteorites can be divided into two kinds: **chondrites** and **achondrites**. Chondrites contain chondrules, small spheres of the silicate minerals olivine and orthopyroxene, and comprise 85% of meteorites. Achondrites do not contain chondrules. Meteorites provide evidence for the nature of the Solar System and may be similar to the Earth's core and mantle, neither of which can be observed directly.

meteoroid chunk of rock in interplanetary space. There is no official distinction between meteoroids and asteroids, except that the term asteroid is generally reserved for objects larger than 1.6 km/1 mi in diameter, whereas meteoroids can range anywhere from pebble-size up.

Meteoroids are believed to result from the fragmentation of asteroids after collisions. Some meteoroids strike the Earth's atmosphere, and their fiery trails are called meteors. If they fall to Earth, they are named meteorites.

meteorology scientific observation and study of the atmosphere, so that (weather) can be accurately forecast.

Data from meteorological stations and weather satellites are collected by computer at central agencies, and forecast and weather maps based on current readings are issued at regular intervals. Modern analysis, employing some of the most powerful computers, can give useful forecasts for up to six days ahead.

At meteorological stations readings are taken of the factors determining weather conditions: atmospheric pressure, temperature, humidity, wind (using the Beaufort scale), cloud cover (measuring both type of cloud and coverage), and precipitation such as rain, snow, and hail (measured at 12-hour intervals). Satellites are used either to relay information transmitted from the Earth-based stations, or to send pictures of cloud development, indicating wind patterns, and snow and ice cover.

history Apart from some observations included by Aristotle in his book *Meteorologia*, meteorology did not become a precise science until the end of the 16th century, when Galileo and the Florentine academicians constructed the first thermometer of any importance, and when Evangelista Torricelli in 1643 discovered the principle of the barometer. Robert Boyle's work on gases, and that of his assistant, Robert Hooke, on barometers, advanced the physics necessary for the understanding of the weather. Gabriel Fahrenheit's invention of a superior mercury thermometer provided further means for temperature recording.

weather maps In the early 19th century a chain of meteorological stations was established in France, and weather maps were constructed from the data collected. The first weather map in England, showing the trade winds and monsoons, was made in 1688, and the first telegraphic weather report appeared 31 Aug 1848. The first daily telegraphic weather map was prepared at the Great Exhibition in 1851, but the Meteorological Office was not established in London until 1855. The first regular daily collections of weather observations by telegraph and the first British daily weather reports were made in 1860, and the first daily printed maps appeared 1868.

collecting data Observations can be collected not only from land stations, but also from weather ships, aircraft, and self-recording and automatic transmitting stations, such as the radiosonde. Radar may be used to map clouds and storms. Satellites have played an important role in televising pictures of global cloud distribution.

WORLD METEOROLOGICAL ORGANISATION

<http://www.wmo.ch/>

Internet voice of the World Meteorological Organisation, a UN division coordinating global scientific activity related to climate and weather. The site offers ample material on the long term objectives and immediate policies of the organization. It also disseminates important information on WMO's databases, training programmes, and satellite activities, as well as its projects related to the protection of the environment.

meter any instrument used for measurement. The term is often compounded with a prefix to denote a specific type of meter: for example, ammeter, voltmeter, flowmeter, or pedometer.

methanal (common name **formaldehyde**) HCHO gas at ordinary temperatures, condensing to a liquid at $-21^\circ\text{C}/-5.8^\circ\text{F}$. It has a powerful, penetrating smell. Dissolved in water, it is used as a biological preservative. It is used in the manufacture of plastics, dyes, foam (for example urea-formaldehyde foam, used in insulation), and in medicine.

methane CH_4 the simplest hydrocarbon of the paraffin series. Colourless, odourless, and lighter than air, it burns with a bluish flame and explodes when mixed with air or oxygen. It is the chief constituent of natural gas and also occurs in the explosive fire-damp of coal mines. Methane emitted by rotting vegetation forms marsh gas, which may ignite by spontaneous combustion to produce the pale flame seen over marshland and known as *quill-o'-the-wisp*.

Methane causes about 38% of the warming of the globe through the greenhouse effect; weight for weight it is 60–70 times more potent than carbon dioxide at trapping solar radiation in the atmosphere and so heating the planet. The amount of methane in the air is predicted to double over the next 60 years. An estimated 15% of all methane gas into the atmosphere is produced by cows and other cud-chewing animals, and 20% is produced by termites that feed on soil.

METHANE

The flatulence of a single sheep could power a small lorry for 40 km/25 mi a day. The digestive process produces methane gas, which can be burnt as fuel. According to one New Zealand scientist, the methane from 72 million sheep could supply the entire fuel needs of his country.

methanogenic bacteria one of a group of primitive microorganisms, the *Archaea*. They give off methane gas as a by-product of their metabolism, and are common in sewage treatment plants and hot springs, where the temperature is high and oxygen is absent. Archaeans were originally classified as bacteria, but were found to be unique in 1996 following the gene sequencing of the deep-sea vent *Methanococcus jannaschii*.

methanoic acid (common name **formic acid**) HCOOH , a colourless, slightly fuming liquid that freezes at $8^\circ\text{C}/46.4^\circ\text{F}$ and boils at $101^\circ\text{C}/213.8^\circ\text{F}$. It occurs in stinging ants, nettles, sweat, and pine needles, and is used in dyeing, tanning, and electroplating.

methanol (common name **methyl alcohol**) CH_3OH the simplest of the alcohols. It can be made by the dry distillation of wood (hence it is also known as wood alcohol), but is usually made from coal or natural gas. When pure, it is a colourless, flammable liquid with a pleasant odour, and is highly poisonous.

Methanol is used to produce formaldehyde (from which resins and plastics can be made), methyl-tert-butyl ether (MTB, a replacement for lead as an octane-booster in petrol), vinyl acetate (largely used in paint manufacture), and petrol. In 1993 Japanese engineers built an engine, made largely of ceramics, that runs on methanol. The prototype is lighter and has a cleaner exhaust than comparable metal, petrol-powered engines.

methionine one of the nine essential amino acids. It is also used as an antidote to paracetamol poisoning.

methyl alcohol common name for ϕ methanol.

methylated spirit alcohol that has been rendered undrinkable, and is used for industrial purposes, as a fuel for spirit burners or a solvent.

It is nevertheless drunk by some individuals, resulting eventually in death. One of the poisonous substances in it is ϕ methanol, or methyl alcohol, and this gives it its name. (The 'alcohol' of alcoholic drinks is ethanol.)

methyl benzene alternative name for ϕ toluene.

methyl bromide pesticide gas used to fumigate soil. It is a major ϕ zone depleter. Industry produces 50,000 tonnes of methyl bromide annually (1995). The European Union has promised a 25% reduction in manufacture by 1998, and the USA intends to ban use by 2001. The European Union (EU) proposed a total ban on usage by 2005 at a meeting in Sept 1997.

methyl orange $C_{14}H_{14}N_3NaO_5S$ orange-yellow powder used as an acid-base indicator in chemical tests, and as a stain in the preparation of slides of biological material. Its colour changes with pH; below pH 3.1 it is red, above pH 4.4 it is yellow.

metre SI unit (symbol m) of length, equivalent to 1.093 yards. It is defined by scientists as the length of the path travelled by light in a vacuum during a time interval of $1/299,792,458$ of a second.

METRE

The metre was originally (in 1791) defined as one ten-millionth of the distance from the North Pole to the equator, on a line through Paris.

metric system system of weights and measures developed in France in the 18th century and recognized by other countries in the 19th century.

In 1960 an international conference on weights and measures recommended the universal adoption of a revised International System (Système International d'Unités, or SI), with seven prescribed 'base units': the metre (m) for length, kilogram (kg) for mass, second (s) for time, ampere (A) for electric current, kelvin (K) for thermodynamic temperature, candela (cd) for luminous intensity, and mole (mol) for quantity of matter.

supplementary units Two supplementary units are included in the SI system – the radian (rad) and steradian (sr) – used to measure plane and solid angles. In addition, there are recognized derived units that can be expressed as simple products or divisions of powers of the basic units, with no other integers appearing in the expression; for example, the watt.

non-SI units Some non-SI units, well established and internationally recognized, remain in use in conjunction with SI: minute, hour, and day in measuring time; multiples or submultiples of base or derived units which have long-established names, such as tonne for mass, the litre for volume; and specialist measures such as the metric carat for gemstones.

prefixes Prefixes used with metric units are tera (T) million million times; giga (G) billion (thousand million) times; mega (M) million times; kilo (k) thousand times; hecto (h) hundred times; deca (da) ten times; deci (d) tenth part; centi (c) hundredth part; milli (m) thousandth part; micro (μ) millionth part; nano (n) billionth part; pico (p) trillionth part; femto (f) quadrillionth part; atto (a) quintillionth part.

KILOMETRES / METRE

Mexican hairless dog breed of dog remarkable for being without hair, except for tufts on its head and tail tip. Its skin may be grey or pinkish, and it stands about 40–50 cm/15–20 in tall. It may be descended from dogs of the ϕ Chinese crested dog type that were brought to the New World by Spanish colonists at the end of the 16th century.

mg symbol for milligram.

MHD abbreviation for ϕ magnetohydrodynamics.

mho SI unit of electrical conductance, now called the ϕ siemens; equivalent to a reciprocal ohm.

mi symbol for ϕ mile.

mica group of silicate minerals that split easily into thin flakes along lines of weakness in their crystal structure (perfect basal cleavage). They are glossy, have a pearly lustre, and are found in many igneous and metamorphic rocks. Their good thermal and electrical insulation qualities make them valuable in industry.

Their chemical composition is complicated, but they are silicates with silicon-oxygen tetrahedra arranged in continuous sheets, with weak bonding between the layers, resulting in perfect cleavage.

A common example of mica is muscovite (white mica), $KAl_2Si_3AlO_{10}(OH,F)_2$.

Michaelmas daisy popular name for a species of ϕ aster, and also for the sea aster or starwort.

MICR abbreviation for ϕ magnetic-ink character recognition.

micro- prefix (symbol μ) denoting a one-millionth part (10^{-6}). For example, a micrometre, μ m, is one-millionth of a metre.

microbe another name for ϕ microorganism.

MICROBE ZOO

<http://commtechlab.msu.edu/sites/dlc-me/zoo/>

Colourful and interactive zoo of some of the microbes that surround us. It includes sections on the 'domestic' microbes, the vampire ones that suck the life from other bacteria, the killers which destroy stone buildings, those in aquatic environments, and those that are to be found in beer, bread, chocolate, wine and other food services and legal assistance.

microbilling in computing, technique of charging for software by usage. Instead of being sold to users in a box over the counter, programs are divided into small segments which can be quickly downloaded over a network on demand. Each time the program is used, the customer's account is debited by a small amount.

microbiology the study of microorganisms, mostly viruses and single-celled organisms such as bacteria, protozoa, and yeasts. The practical applications of microbiology are in medicine (since many microorganisms cause disease); in brewing, baking, and other food and beverage processes, where the microorganisms carry out fermentation; and in genetic engineering, which is creating increasing interest in the field of microbiology.

microchip popular name for the silicon chip, or ϕ integrated circuit.

microclimate the climate of a small area, such as a woodland, lake, or even a hedgerow. Significant differences can exist between the climates of two neighbouring areas – for example, a town is usually warmer than the surrounding countryside (forming a heat island), and a woodland cooler, darker, and less windy than an area of open land.

Microclimates play a significant role in agriculture and horticulture, as different crops require different growing conditions.

microcomputer The component parts of the microcomputer: the system unit contains the hub of the system, including the central processing unit (CPU), information on all of the computer's peripheral devices, and often a fixed disc drive. The monitor (or visual display unit) displays text and graphics, the keyboard and mouse are used to input data, and the floppy disc and CD-ROM drives read data stored on discs.

microcomputer or *micro* or *personal computer* small desktop or portable computer, typically designed to be used by one person at a time, although individual computers can be linked in a network so that users can share data and programs.

Its central processing unit is a μ microprocessor, contained on a single integrated circuit.

Microcomputers are the smallest of the four classes of computer (the others are Ψ supercomputer, mainframe, and μ minicomputer). Since the appearance in 1975 of the first commercially available microcomputer, the Altair 8800, micros have become ubiquitous in commerce, industry, and education.

microfiche sheet of film on which printed text is photographically reduced. See μ microform.

microform generic name for media on which text or images are photographically reduced. The main examples are microfilm (similar to the film in an ordinary camera) and microfiche (flat sheets of film, generally 105 mm/4 in x 148 mm/6 in, holding the equivalent of 420 standard pages). Microform has the advantage of low reproduction and storage costs, but it requires special devices for reading the text. It is widely used for archiving and for storing large volumes of text, such as library catalogues.

Computer data may be output directly and quickly in microform by means of COM (computer output on microfilm/microfiche) techniques.

microglia type of glial cell surrounding the nerve cells in the brain and spinal cord. They have an immune function.

micrometer instrument for measuring minute lengths or angles with great accuracy; different types of micrometer are used in astronomical and engineering work.

The type of micrometer used in astronomy consists of two fine wires, one fixed and the other movable, placed in the focal plane of a telescope; the movable wire is fixed on a sliding plate and can be positioned parallel to the other until the object appears between the wires.

The movement is then indicated by a scale on the adjusting screw.

micrometre one-millionth of a metre (symbol μm).

microminiaturization reduction in size and weight of electronic components. The first size reduction in electronics was brought about by the introduction of the transistor. Further reductions were achieved with μ integrated circuits and the Ψ silicon chip.

micron obsolete name for the micrometre, one millionth of a metre.

microorganism or *microbe* living organism invisible to the naked eye but visible under a microscope. Microorganisms include viruses and single-celled organisms such as bacteria, protozoa, yeasts, and some algae. The term has no taxonomic significance in biology. The study of microorganisms is known as microbiology.

microphone primary component in a sound-reproducing system, whereby the mechanical energy of sound waves is converted into electrical signals by means of a μ transducer. One of the simplest is

the telephone receiver mouthpiece, invented by Scottish-US inventor Alexander Graham Bell in 1876; other types of microphone are used with broadcasting and sound-film apparatus.

Telephones have a **carbon microphone**, which reproduces only a narrow range of frequencies. For live music, a **moving-coil microphone** is often used. In it, a diaphragm that vibrates with sound waves moves a coil through a magnetic field, thus generating an electric current. The **ribbon microphone** combines the diaphragm and coil. The **condenser microphone** is most commonly used in recording and works by a capacitor. They are always used in telephones.

microprocessor complete computer central processing unit contained on a single integrated circuit, or chip. The appearance of the first microprocessor 1971 designed by Intel for a pocket calculator manufacturer heralded the introduction of the microcomputer. The microprocessor has led to a dramatic fall in the size and cost of computers, and dedicated computers can now be found in washing machines, cars, and so on. Examples of microprocessors are the Intel Pentium family and the IBM/Motorola PowerPC, used by Apple Computer.

Texas Instruments introduced in January 1997 a digital-signal microprocessor chip that can process 1.6 billion instructions a second. This is about 40 times more powerful than a chip now found in today's computer modem. The new chip can reduce the time needed to download a file from the Internet from ten minutes to less than five seconds.

micropropagation the mass production of plants by placing tiny pieces of plant tissue in sterile glass containers along with nutrients. Perfect clones of superplants are produced in sterile cabinets, with filtered air and carefully controlled light, temperature, and humidity. The system is used for the house-plant industry and for forestry – micropropagation gives immediate results, whereas obtaining genetically homogenous tree seed by traditional means would take over 100 years.

micropyle in flowering plants, a small hole towards one end of the ovule. At pollination the pollen tube growing down from the stigma eventually passes through this pore. The male gamete is contained within the tube and is able to travel to the egg in the interior of the ovule. Fertilization can then take place, with subsequent seed formation and dispersal.

microscope instrument for forming magnified images with high resolution for detail. Optical and electron microscopes are the ones chiefly in use; other types include acoustic, scanning tunnelling, and atomic force microscopes.

The **optical microscope** usually has two sets of glass lenses and an eyepiece. It was invented 1609 in the Netherlands by Zacharias Janssen (1580–c. 1638). **Fluorescence microscopy** makes use of fluorescent dyes to illuminate samples, or to highlight the presence of particular substances within a sample. Various illumination systems are also used to highlight details.

The **transmission electron microscope**, developed from 1932, passes a beam of electrons, instead of a beam of light, through a specimen. Since electrons are not visible, the eyepiece is replaced with a fluorescent screen or photographic plate; far higher magnification and resolution are possible than with the optical microscope.

The **scanning electron microscope (SEM)**, developed in the mid-1960s, moves a fine beam of electrons over the surface of a specimen, the reflected electrons being collected to form the image. The specimen has to be in a vacuum chamber.

The **acoustic microscope** passes an ultrasonic (ultrahigh-frequency sound) wave through the specimen, the transmitted sound being used to form an image on a computer screen.

The **scanned-probe microscope**, developed in the late 1980s, runs a probe, with a tip so fine that it may consist only of a single atom, across the surface of the specimen. In the **scanning tunnelling microscope**, an electric current that flows through the probe is used to construct an image of the specimen. In 1988 a scanning tunnelling microscope was used to photograph a single protein molecule for the first time. In the **atomic force microscope**, the force felt by the probe is measured and used to form the image.

These instruments can magnify a million times and give images of single atoms.

Microsoft US corporation, now the world's largest software supplier. Microsoft's first major product was a version of Basic, written for the MITS Altair 1975, and adopted by most of the desktop computer industry. Through QMS-DOS, written for IBM, Windows, and related applications it has steadily increased its hold on the personal computer market. Microsoft was founded by Bill Gates and Paul Allen in 1975.

Together with Intel, the company supplied operating systems and computer chips for about 90% of the world's personal computers in 1997.

In 1996, Microsoft launched another new operating system, Windows CE (Consumer Electronics), for handheld computers, pen-operated personal digital assistants, in-car systems and similar applications. Suppliers of CE-based HPCs (handheld personal computers) include Casio, Compaq, Hewlett-Packard, Philips and Sharp. Windows CE version 2 is also used in an improved version of WebTV: a set-top box that enables users to surf the Internet on their television sets. Microsoft purchased WebTV Networks for \$425 million in 1997. The first companies to supply WebTV systems were Philips, Sony and Mitsubishi.

microscope Terms used to describe an optical microscope. In essence, the optical microscope consists of an eyepiece lens and an objective lens, which are used to produce an enlarged image of a small object by focusing light from a light source. Optical microscopes can achieve magnifications of up to 1,500–2,000. Higher magnifications and resolutions are obtained by electron microscopes.

A US federal probe into charges that Microsoft was engaging in anticompetitive behaviour was carried out 1990-93, from which date the US Justice Department launched its own investigations. Under a settlement reached in 1994, Microsoft agreed to end the uncompetitive practice 'per processor' pricing, whereby PC manufacturers paid a fee for each machine produced irrespective of the software to be installed. The Justice Department started another case in 1997, accusing Microsoft of breaking this settlement by tying the installation of Windows 95 to the installation of Microsoft's free Web browser, Internet Explorer. In December the company was ordered to change its marketing policy.

Microsoft Word in computing, versatile and powerful word processing program for IBM-compatible and Apple ϕ Macintosh PCs. The program began its life as an QMS-DOS program in 1983, and a year later it was released as one of the first programs for the Macintosh. The advanced features and ease of use of Version 6.0, released in 1994, established Word as the market leader in its field.

microsurgery part or all of an intricate surgical operation - rejoining a severed limb, for example - performed with the aid of a binocular microscope, using miniaturized instruments. Sewing of the nerves and blood vessels is done with a nylon thread so fine that it is only just visible to the naked eye.

The technique permits treatment of previously inaccessible lesions in the eye or brain.

microtubules tiny tubes found in almost all cells with a nucleus. They help to define the shape of a cell by forming scaffolding for cilia and they also form the fibres of mitotic spindle (see ϕ mitosis).

microwave ϕ electromagnetic wave with a wavelength in the range 0.3 to 30 cm/0.1 to 12 in, or 300-300,000 megahertz (between radio waves and infrared radiation). Microwaves are used in radar, in radio broadcasting, and in microwave heating and cooking.

microwave heating heating by means of microwaves. Microwave ovens use this form of heating for the rapid cooking or reheating of foods, where heat is generated throughout the interior of the food. If food is not heated completely, there is a danger of bacterial growth that may lead to food poisoning. Industrially, microwave heating is used for destroying insects in grain and enzymes in processed food, pasteurizing and sterilizing liquids, and drying timber and paper.

Mid-Atlantic Ridge ϕ ocean ridge, formed by the movement of plates described by ϕ plate tectonics, that runs along the centre of the Atlantic Ocean, parallel to its edges, for some 14,000 km/8,800 mi - almost from the Arctic to the Antarctic.

The Mid-Atlantic Ridge is central because the ocean crust beneath the Atlantic Ocean has continually grown outwards from the ridge at a steady rate during the past 200 million years. Iceland straddles the ridge and was formed by volcanic outpourings.

midge common name for many insects resembling ϕ gnats, generally divided into biting midges (family Ceratopogonidae) that suck blood and non-biting midges (family Chironomidae).

The larvae of some midges are the 'bloodworms' of stagnant water.

MIDI (acronym for *musical instrument digital interface*) manufacturer's standard allowing different pieces of digital music equipment used in composing and recording to be freely connected.

The information-sending device (any electronic instrument) is called a controller, and the reading device (such as a computer) the sequencer. Pitch, dynamics, decay rate, and stereo position can all

be transmitted via the interface. A computer with a MIDI interface can input and store the sounds produced by the connected instruments, and can then manipulate these sounds in many different ways. For example, a single keystroke may change the key of an entire composition. Even a full written score for the composition may be automatically produced.

midsummer the time of the summer ϕ solstice, about 21 June. Midsummer Day, 24 June, is the Christian festival of St John the Baptist.

midwifery assistance of women in childbirth. Traditionally, it was undertaken by experienced specialists; in modern medical training it is a nursing speciality for practitioners called midwives.

The English physician William Harvey's 1653 work on generation contained an influential chapter on labour. Dr Peter Chamberlen II (1560-1631) made an important contribution to midwifery, particularly with his development of the first midwifery forceps.

mifepristone (RU486) anti-progesterone drug used, in combination with a ϕ prostaglandin, to procure early ϕ abortion (up to the tenth week in pregnancy). It is administered only in hospitals or recognized clinics and a success rate of 95% is claimed. Formerly known as RU486, it was developed and first used in France in 1989. It was licensed in the UK in 1991.

Mid-Atlantic Ridge The Mid-Atlantic Ridge is the boundary between the crustal plates that form America, and Europe and Africa. An oceanic ridge cannot be curved since the material welling up to form the ridge flows at a right angle to the ridge. The ridge takes the shape of small straight sections offset by fractures transverse to the main ridge.

By March 1991, 60,000 abortions had been carried out in France by this method.

mignonette sweet-scented plant, native to N Africa, with yellowish-green flowers in racemes (along the main stem) and abundant foliage; it is widely cultivated. (*Reseda odorata*, family Resedaceae.)

migraine acute, sometimes incapacitating headache (generally only on one side), accompanied by nausea, that recurs, often with advance symptoms such as flashing lights. No cure has been discovered, but ergotamine normally relieves the symptoms. Some sufferers learn to avoid certain foods, such as chocolate, which suggests an allergic factor.

MIGRATION

The grey whale migrates further than any other mammal. It makes a round trip of 20,400 km/12,500 mi between its summer feeding grounds in the Arctic and its winter breeding lagoons off the western coast

migration the movement, either seasonal or as part of a single life cycle, of certain animals, chiefly birds and fish, to distant breeding or feeding grounds.

The precise methods by which animals navigate and know where to go are still obscure. Birds have much sharper eyesight and better visual memory of ground clues than humans, but in long-distance flights appear to navigate by the Sun and stars, possibly in combination with a 'reading' of the Earth's magnetic field through an inbuilt 'magnetic compass', which is a tiny mass of tissue between the eye and brain in birds. Similar cells occur in 'homing' honeybees and in certain bacteria that use it to determine which way is 'down'. Leatherback turtles use the contours of underwater mountains and valleys to navigate by. Most striking, however, is the migration of young birds that have never flown a route before and are unaccompanied by adults. It is postulated that they may inherit as part of their genetic code an overall 'sky chart' of their journey that is triggered into use when they become aware of how the local sky pattern, above the place in which they hatch, fits into it. Similar theories have been advanced in the case of fish, such as eels and salmon, with whom vision obviously plays a lesser role, but for whom currents and changes in the composition and temperature of the sea in particular locations may play a part – for example, in enabling salmon to return to the precise river in which they were spawned. Migration also occurs with land animals; for example, lemmings and antelope.

Species migration is the spread of the home range of a species over many years, for example the spread of the collared dove (*Streptopelia decaocto*) from Turkey to Britain over the period 1920–52. Any journey which takes an animal outside of its normal home range is called **individual migration**, when the animal does not return to its home range it is called **removal migration**. An example of **return migration** is the movement of birds that fly south for the winter and return to their home ranges in the spring. Many types of whale also make return migrations. In **remigration**, the return leg of the migration is completed by a subsequent generation, for example locust swarms migrate, but each part of the circuit is completed by a different generation.

Related to migration is the homing ability of pigeons, bees, and other creatures.

Milankovitch hypothesis the combination of factors governing the occurrence of ice ages proposed in 1930 by the Yugoslav geophysicist M Milankovitch (1879–1958). These include the variation in the angle of the Earth's axis, and the geometry of the Earth's orbit around the Sun.

mildew any fungus that appears as a destructive growth on plants, paper, leather, or wood when they become damp for a certain length of time; such fungi usually form a thin white coating on the surface.

milk secretion of the mammary glands of female mammals, with which they suckle their young (during lactation). Over 85% is water, the remainder comprising protein, fat, lactose (a sugar), calcium, phosphorus, iron, and vitamins. The milk of cows, goats, and sheep is often consumed by humans, but regular drinking of milk after infancy is principally a Western practice.

milking machine machine that uses suction to milk cows. The first milking machine was invented in the USA by L O Colvin in 1860. Later it was improved so that the suction was regularly released by a pulsating device, since it was found that continuous suction is harmful to cows.

milk teeth or **deciduous teeth** teeth that erupt in childhood between the ages of 6 and 30 months. They are replaced by the permanent teeth, which erupt between the ages of 6 and 21 years. See also *dentition* and *tooth*.

Milky Way faint band of light crossing the night sky, consisting of stars in the plane of our Galaxy. The name Milky Way is often used for the Galaxy itself. It is a spiral galaxy, 100,000 light years in diameter and 2,000 light years thick, containing at least 100 billion stars. The Sun is in one of its spiral arms, about 25,000 light years from the centre, not far from its central plane.

The densest parts of the Milky Way, towards the Galaxy's centre, lie in the constellation Sagittarius. In places, the Milky Way is interrupted by lanes of dark dust that obscure light from the stars beyond, such as the Coal-sack nebula in Crux (the Southern Cross). It is because of these that the Milky Way is irregular in width and appears to be divided into two between Centaurus and Cygnus.

millers thumb another name for *bullhead*, a small fish.

millet any of several grasses of which the grains are used as a cereal food and the stems as animal fodder. Species include *Panicum miliaceum*, extensively cultivated in the warmer parts of Europe, and *Sorghum bicolor*, also known as *durra*. (Family Gramineae.)

milli- prefix (symbol m) denoting a one-thousandth part (10^{-3}).

For example, a millimetre, mm, is one thousandth of a metre.

millibar unit of pressure, equal to one-thousandth of a bar.

millilitre one-thousandth of a litre (ml), equivalent to one cubic centimetre (cc).

millimetre of mercury unit of pressure (symbol mmHg), used in medicine for measuring blood pressure defined as the pressure exerted by a column of mercury one millimetre high, under the action of gravity.

millipede any of a group of arthropods that have segmented bodies, each segment usually bearing two pairs of legs, and a pair of short clubbed antennae on the distinct head. Most millipedes are no more than 2.5 cm/1 in long; a few in the tropics are 30 cm/12 in. (Class Diplopoda.)

Millipedes live in damp, dark places, feeding mainly on rotting vegetation. Some species injure crops by feeding on tender roots, and some produce a poisonous secretion in defence. Certain orders have silk glands.

Mills Cross type of radio telescope consisting of two rows of aerials at right angles to each other, invented in 1953 by the Australian radio astronomer Bernard Mills (1920–). The cross-shape produces a narrow beam useful for pinpointing the positions of radio sources.

Milstar (acronym for *Military Strategic and Tactical Relay*) US communications satellite launched February 1994. It was designed to function in a nuclear war and broadcast orders to launch weapons. After the breakup of the Soviet Union the continuation of its development became controversial.

It consists of a network of four communications satellites and around 1,200 portable ground terminals. It will cost \$17.3 billion. The second satellite was launched in 1995. The third satellite is due for launch in 1998.

MIME (acronym for *Multipurpose Internet Mail Extensions*) in computing, standard for transferring multimedia e-mail messages and World Wide Web hypertext documents over the Internet. Under MIME, binary files (any file not in plain text, such as graphics and audio) are translated into a form of ASCII before transmission, and then turned back into binary form by the recipient. See also ϕ Uencode.

mimicry imitation of one species (or group of species) by another. The most common form is Batesian mimicry (named after English naturalist H W Bates), where the mimic resembles a model that is poisonous or unpleasant to eat, and has aposematic, or warning, coloration; the mimic thus benefits from the fact that predators have learned to avoid the model. Hoverflies that resemble bees or wasps are an example. Appearance is usually the basis for mimicry, but calls, songs, scents, and other signals can also be mimicked.

In Mullerian mimicry, two or more equally poisonous or distasteful species have a similar colour pattern, thereby reinforcing the warning each gives to predators. In some cases, mimicry is not for protection, but allows the mimic to prey on, or parasitize, the model.

mimosa any of a group of leguminous trees, shrubs, or herbs belonging to the mimosa family, found in tropical and subtropical regions. They all have small, fluffy, golden, ball-like flowers. A similar but unrelated plant, *Acacia dealbata*, is sold as mimosa by European florists. (True mimosa genus *Mimosa*, family Mimosaceae.)

Certain species, such as the sensitive plant of Brazil *M. pudica*, shrink momentarily on being touched.

mineral naturally formed inorganic substance with a particular chemical composition and a regularly repeating internal structure. Either in their perfect crystalline form or otherwise, minerals are the constituents of rocks. In more general usage, a mineral is any substance economically valuable for mining (including coal and oil,

despite their organic origins).

Mineral forming processes include: melting of pre-existing rock and subsequent crystallization of a mineral to form magmatic or volcanic rocks; weathering of rocks exposed at the land surface, with subsequent transport and grading by surface waters, ice or wind to form sediments; and recrystallization through increasing temperature and pressure with depth to form metamorphic rocks.

Minerals are usually classified as magmatic, sedimentary, or metamorphic. The magmatic minerals include the feldspars, quartz, pyroxenes, amphiboles, micas, and olivines that crystallize from silica-rich rock melts within the crust or from extruded lavas.

The most commonly occurring sedimentary minerals are either pure concentrates or mixtures of sand, clay minerals, and carbonates (chiefly calcite, aragonite, and dolomite).

Minerals typical of metamorphism include andalusite, cordierite, garnet, tremolite, lawsonite, pumpellyite, glaucophane, wollastonite, chlorite, micas, hornblende, staurolite, kyanite, and diopside.

mineral dressing preparing a mineral ore for processing. Ore is seldom ready to be processed when it is mined; it often contains unwanted rock and dirt. Therefore it is usually crushed into uniform size and then separated from the dirt, or gangue. This may be done magnetically (some iron ores), by washing (gold), by treatment with chemicals (copper ores), or by flotation.

mineral extraction recovery of valuable ores from the Earth's crust. The processes used include open-past mining, shaft mining, and quarrying, as well as more specialized processes such as those used for oil and sulphur (see, for example, ϕ Frasch process).

mineralogy study of minerals. The classification of minerals is based chiefly on their chemical composition and the kind of chemical bonding that holds these atoms together. The mineralogist also studies their crystallographic and physical characters, occurrence, and mode of formation.

Main Dietary Minerals

| Mineral | Main dietary sources | Major functions in the body | Deficiency symptoms |
|------------|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Calcium | milk, cheese, green vegetables, dried legumes | constituent of bones and teeth; essential for nerve transmission, muscle contraction, and clotting | tetany |
| Chromium | vegetable oils, meat | involved in energy metabolism | impaired glucose metabolism |
| Copper | drinking water, meat | associated with iron metabolism | anaemia |
| Fluoride | drinking water, tea, seafoods | helps to keep bones and teeth healthy | increased rate of tooth decay |
| Iodine | seafoods, dairy products, many vegetables, iodized table salt | essential for healthy growth and development | goitre |
| Iron | meat (especially liver), legumes, green vegetables, whole grains, eggs | constituent of haemoglobin; involved in energy metabolism | anaemia |
| Magnesium | whole grains, green vegetables | involved in protein synthesis | growth failure, weakness, behavioural disturbances |
| Manganese | widely distributed in foods | involved in fat synthesis | not known in humans |
| Molybdenum | legumes, cereals, offal | constituent of some enzymes | not known in humans |
| Phosphorus | milk, cheese, meat, legumes, cereals | formation of bones and teeth, maintenance of acid-base balance | weakness, demineralization of bone |
| Potassium | milk, meat, fruits | maintenance of acid-base balance, fluid balance, nerve transmission | muscular weakness, paralysis |
| Selenium | seafoods, meat, cereals, egg yolk | role associated with that of vitamin E | not known in humans |
| Sodium | widely distributed in foods | as for potassium | cramp, loss of appetite, apathy |
| Zinc | widely distributed in foods | involved in digestion | growth failure, underdevelopment of reproductive organs |

The systematic study of minerals began in the 18th century, with the division of minerals into four classes: earths, metals, salts, and bituminous substances, distinguished by their reactions to heat and water.

mineral oil oil obtained from mineral sources, for example coal or petroleum, as distinct from oil obtained from vegetable or animal sources.

mineral salt in nutrition, a simple inorganic chemical that is required by living organisms. Plants usually obtain their mineral salts from the soil, while animals get theirs from their food. Important mineral salts include iron salts (needed by both plants and animals), magnesium salts (needed mainly by plants, to make chlorophyll), and calcium salts (needed by animals to make bone or shell). A ϕ trace element is required only in tiny amounts.

minicomputer multiuser computer with a size and processing power between those of a ϕ mainframe and a ϕ microcomputer. Nowadays almost all minicomputers are based on ϕ microprocessors.

Minicomputers are often used in medium-sized businesses and in university departments handling ϕ database or other commercial programs and running scientific or graphical applications.

Mini Disc digital audio disc that resembles a computer floppy disc in a 5 cm/2 in square case, with up to an hour's playing time. The system was developed by Sony for release in 1993.

Their small size makes Mini Discs particularly suitable for personal and car stereos, and the players are equipped with memory chips that store up to three seconds of music in order to compensate for any skips and jumps in playback.

mining extraction of minerals from under the land or sea for industrial or domestic uses. Exhaustion of traditionally accessible resources has led to development of new mining techniques; for example, extraction of oil from offshore deposits and from land shale reserves. Technology is also under development for the exploitation of minerals from entirely new sources such as mud deposits and mineral nodules from the sea bed.

Mud deposits are laid down by hot springs (about 350°C/660°F): sea water penetrates beneath the ocean floor and carries copper, silver, and zinc with it on its return. Such springs occur along the midocean ridges of the Atlantic and Pacific and in the geological rift between Africa and Arabia under the Red Sea.

Mineral nodules form on the ocean bed and contain manganese, cobalt, copper, molybdenum, and nickel; they stand out on the surface, and 'grow' by only a few millimetres every 100,000 years.

The deepest mine in Europe is a 1100 m deep working salt and potash mine at Boulby near Whitby on the northeast coast of England.

Minitel in computing, the dedicated terminal attached to France's teletext system, Teletel, which was launched in 1981 and has millions of users. Many Minitels – most of which have small black and white screens – were installed on free loan by France Telecom to subscribers who opted not to have telephone directories, and the online directory is still the most widely-used Minitel service. Erotic 'chat lines' have also proved very popular. Today in France, many PC users access Teletel using software that emulates a Minitel terminal.

mink either of two species of carnivorous mammals belonging to the weasel family, usually found in or near water. They have rich brown fur, and are up to 50 cm/1.6 ft long with bushy tails 20 cm/8 in long. They live in Europe and Asia (*M. lutreola*) and North America (*M. vison*). (Genus *Mustela*.)

They produce an annual litter of six in their riverbank burrows. The demand for their fur led to the establishment from the 1930s of mink ranches for breeding of the animals in a wide range of fur colours. In 1997 world production of mink skins was 26 million, which represented a 36% decline since 1986.

minnow any of various small freshwater fishes of the carp family, found in streams and ponds worldwide. Most species are small and dull in colour, but some are brightly coloured. They feed on larvae and insects. (Family Cyprinidae.)

Minoan civilization Bronze Age civilization on the Aegean island of Crete. The name is derived from Minos, the legendary king of Crete. The civilization is divided into three main periods: early Minoan, about 3000–2000 BC; middle Minoan, about 2000–1550 BC; and late Minoan, about 1550–1050 BC.

With the opening of the Bronze Age, about 3000 BC, the Minoan culture proper began. Each period was marked by cultural advances in copper and bronze weapons, pottery of increasingly intricate design, frescoes, and the construction of palaces and fine houses at Phaistos and Mallia, in addition to ϕ Knossos. About 1400 BC, in the late Minoan period, the civilization was suddenly destroyed by earthquake or war. A partial revival continued until about 1100.

The earlier (Linear A) of two languages used in Crete remains undeciphered; Linear B, which is also found at sites on the mainland of Greece, was deciphered by Michael Ventris.

In religion the Minoans seem to have worshipped principally a great mother goddess with whom was associated a young male god. The tales of Greek mythology about Rhea, the mother of Zeus, and the birth of Zeus himself in a Cretan cave seem to be based on Minoan religion.

minor planet another name for an ϕ asteroid.

Minsmere coastal marshland bird reserve (1948) near Aldeburgh, Suffolk, attracting a greater number of species than any other in Britain, and containing the Scrape, an artificial breeding habitat.

mint in botany, any aromatic plant of the mint family, widely distributed in temperate regions. The plants have square stems, creeping roots, and spikes of usually pink or purplish flowers. The family includes garden mint (*M. spicata*) and peppermint (*M. piperita*). (Genus *Mentha*, family Labiatae.)

minute unit of time consisting of 60 seconds; also a unit of angle equal to one sixtieth of a degree.

Miocene 'middle recent' fourth epoch of the Tertiary period of geological time, 23.5–5.2 million years ago. At this time grasslands spread over the interior of continents, and hoofed mammals rapidly evolved.

mips (acronym for *million instructions per second*) in computing, a measure of the speed of a processor. It does not equal the computer power in all cases.

Mir Russian 'peace' or 'world' Soviet space station, the core of which was launched on 20 February 1986. It is intended to be a permanently occupied space station.

A small wheat crop was harvested aboard the *Mir* space station on 6 December 1996. It was the first successful cultivation of a plant from seed in space.

Mira or **Omicron Ceti** brightest long-period pulsating ϕ variable star, located in the constellation ϕ Cetus. Mira was the first star discovered to vary periodically in brightness.

In 1596 Dutch astronomer David Fabricius noticed Mira as a third-magnitude object. Because it did not appear on any of the star charts available at the time, he mistook it for a ϕ nova. The German astronomer Johann Bayer included it on his star atlas in 1603 and designated it Omicron Ceti. The star vanished from view again, only to reappear within a year. It was named 'Stella Mira', 'the wonderful star', by Hevelius, who observed it 1659–82.

It has a periodic variation between third or fourth magnitude and ninth magnitude over an average period of 331 days. It can sometimes reach second magnitude and once almost attained first magnitude 1779. At times it is easily visible to the naked eye, being the brightest star in that part of the sky, while at others it cannot be seen without a telescope.

mirage illusion seen in hot weather of water on the horizon, or of distant objects being enlarged. The effect is caused by the ϕ refraction, or bending, of light.

Light rays from the sky bend as they pass through the hot layers of air near the ground, so that they appear to come from the horizon.

Because the light is from a blue sky, the horizon appears blue and watery. If, during the night, cold air collects near the ground, light can be bent in the opposite direction, so that objects below the horizon appear to float above it. In the same way, objects such as trees or rocks near the horizon can appear enlarged.

mirror any polished surface that reflects light; often made from 'silvered' glass (in practice, a mercury-alloy coating of glass). A plane (flat) mirror produces a same-size, erect 'virtual' image located behind the mirror at the same distance from it as the object is in front of it. A spherical concave mirror produces a reduced, inverted real image in front or an enlarged, erect virtual image behind it (as in a shaving mirror), depending on how close the object is to the mirror. A spherical convex mirror produces a reduced, erect virtual image behind it (as in a car's rear-view mirror).

formula In a plane mirror the light rays appear to come from behind the mirror but do not actually do so. The inverted real image from a spherical concave mirror is an image in which the rays of light pass through it. The focal length f of a spherical mirror is half the radius of curvature; it is related to the image distance v and object distance u by the equation $1/v + 1/u = 1/f$.

mirror site in computing, archive site which keeps a copy of another site's files for downloading by GTP. Software archives such as those of the University of Michigan, and the many companies that distribute software by FTP, have several mirror sites around the world, so that users can choose the nearest site.

miscarriage spontaneous expulsion of a fetus from the womb before it is capable of independent survival. Often, miscarriages are due to an abnormality in the developing fetus.

missile thrush bird belonging to the thrush family.

missile rocket-propelled weapon, which may be nuclear-armed. Modern missiles are often classified as surface-to-surface missiles (SSM), air-to-air missiles (AAM), surface-to-air missiles (SAM), or air-to-surface missiles (ASM). A cruise missile is in effect a pilotless, computer-guided aircraft; it can be sea-launched from submarines or surface ships, or launched from the air or the ground.

Rocket-propelled weapons were first used by the Chinese about AD 1100, and were encountered in the 18th century by the British forces. The rocket missile was then re-invented by William Congreve in England around 1805, and remained in use with various armies in the 19th century. The first wartime use of a long-range missile was against England in World War II, by the jet-propelled German V1 (*Vergeltungswaffe*, 'revenge weapon' or Flying Bomb), a monoplane (wingspan about 6 m/18 ft, length 8.5 m/26 ft); the first rocket-propelled missile with a preset guidance system was the German V2, also launched by Germany against Britain in World War II.

Modern missiles are also classified as strategic or tactical: strategic missiles are the large, long-range intercontinental ballistic missiles (ICBMs), capable of reaching targets over 5,500 km/3,400 mi, and tactical missiles are the short-range weapons intended for use in limited warfare (with a range under 1,100 km/680 mi).

Not all missiles are large. There are many missiles that are small enough to be carried by one person. The Stinger, for example, is an anti-aircraft missile fired by a single soldier from a shoulder-held tube. Most fighter aircraft are equipped with missiles to use against enemy aircraft or against ground targets. Other small missiles are launched from a type of truck, called a MLRS (multiple-launch rocket system), that can move around a battlefield. Ship-to-ship missiles like the Exocet have proved very effective in naval battles.

The vast majority of missiles have systems that guide them to

their target. The guidance system may consist of radar and computers, either in the missile or on the ground. These devices track the missile and determine the correct direction and distance required for it to hit its target. In the radio-guidance system, the computer is on the ground, and guidance signals are radio-transmitted to the missile. In the inertial guidance system, the computer is on board the missile. Some small missiles have heat-seeking devices fitted to their noses to seek out the engines of enemy aircraft, or are guided by laser light reflected from the target. Others (called TOW missiles) are guided by signals sent along wires that trail behind the missile in flight.

Outside the industrialized countries, 22 states had active ballistic-missile programmes by 1989, and 17 had deployed these weapons: Afghanistan, Argentina, Brazil, Cuba, Egypt, India, Iran, Iraq, Israel, North Korea, South Korea, Libya, Pakistan, Saudi Arabia, South Africa, Syria, and Taiwan. Non-nuclear short-range missiles were used during the Iran-Iraq War 1980-88 against Iraqi cities.

Battlefield missiles used in the 1991 Gulf War included antitank missiles and short-range attack missiles. NATO announced in 1990 that it was phasing out ground-launched nuclear battlefield missiles, and these are being replaced by types of tactical air-to-surface missile (TASM), also with nuclear warheads.

In the Falklands conflict in 1982, small, conventionally armed sea-skimming missiles were used (the French Exocet) against British ships by the Argentine forces, and similar small missiles have been used against aircraft and ships elsewhere.

Mississippian US term for the Lower or Early Carboniferous period of geological time, 363-323 million years ago. It is named after the state of Mississippi.

mistletoe parasitic evergreen plant, native to Europe. It grows on trees as a small bush with translucent white berries. Used in many Western countries as a Christmas decoration, it also featured in the pagan religion Druidism. (*Viscum album*, family Loranthaceae.)

The seeds of the European mistletoe are dispersed by birds, but the dwarf mistletoe (*Arceuthobium pusillum*) of North America shoots out its ripe seeds at 100 kph/60 mph as far as 15 m/16 yd. Mistletoes lose water more than ten times as fast as other plants in order to draw nutrients to themselves; as a result, the dwarf mistletoe causes the loss of 20 million cubic metres of wood fibre a year.

mistral cold, dry, northerly wind that occasionally blows during the winter on the Mediterranean coast of France, particularly concentrated along the Rhône valley. It has been known to reach a velocity of 145 kph/90 mph.

mite minute φ arachnid related to the ticks. Some mites are free-living scavengers or predators. Some are parasitic, such as the itch mite (*Sarcoptes scabiei*), which burrows in skin causing scabies in humans and mange in dogs, and the red mite (*Dermanyssus gallinae*), which sucks blood from poultry and other birds. Others parasitize plants. (Order Acarina.)

The harvest mite (genus *Trombicula*) is harmless as an adult, but in the larval stage attacks people and animals, penetrating the skin and setting up great irritation. The red spider mite (*Tetranychus telarius*) is a troublesome pest in greenhouses as it feeds on plant juices. A number of mites live in cheese, flour, and other foodstuffs. They are conveyed from place to place in the larval stage by attaching themselves to flies. Some mites live entirely in the water, and many are parasitic on insects. See also chigger.

MITE

Human eyelashes are home to whole colonies of tiny mites. The follicle mite is 0.33 mm/0.01 in long and lives head-down inside the hair follicle. These mites do not restrict themselves to eyelashes, however, but also frequent other parts of the human body with large sebaceous glands – such as nipples.

MIT media lab in computing, one of several important computer research centres at the Massachusetts Institute of Technology in Cambridge, Massachusetts, USA. The MIT media lab is at the forefront of multimedia technology.

mitochondria (singular *mitochondrion*) membrane-enclosed organelles within eukaryotic cells, containing enzymes responsible for energy production during aerobic respiration. These rod-like or spherical bodies are thought to be derived from free-living bacteria that, at a very early stage in the history of life, invaded larger cells and took up a symbiotic way of life inside. Each still contains its own small loop of DNA called mitochondrial DNA, and new mitochondria arise by division of existing ones.

Mutations in mitochondrial genes are always inherited from the mother. These mutations have been linked to a number of disorders, mainly degenerative, including Alzheimer's disease and diabetes.

mitosis in biology, the process of cell division by which identical daughter cells are produced. During mitosis the DNA is duplicated and the chromosome number doubled, so new cells contain the same amount of DNA as the original cell.

The genetic material of eukaryotic cells is carried on a number of chromosomes. To control movements of chromosomes during cell division so that both new cells get the correct number, a system of protein tubules, known as the spindle, organizes the chromosomes into position in the middle of the cell before they replicate.

TO REMEMBER THE FIVE SUB-PHASES OF THE PROPHASE OF MITOSIS:

LAZY ZEBRAS PONDER DIRE DISASTERS

LEPTOTENE, ZYGOTENE, POLYTENE, DIPTOTENE, DIAKINESIS

The spindle then controls the movement of chromosomes as the cell goes through the stages of division: **interphase**, **prophase**, **metaphase**, **anaphase**, and **telophase**. See also meiosis.

Mitsubishi world's largest electronics conglomerate and one of the big six cartels (*zaibatsu*) in Japan. Shipbuilding, banking, mineral-, and coalmining are among its activities.

The company began in 1870 as a shipping service, founded by Yatarō Iwasaki (1834–1885); after a series of name changes and a merger, the Mitsubishi Company was formed 1886. During World War II, the company was a major manufacturer of military aircraft, such as the high performance Zero naval fighter. There are now three distinct companies, all based in Tokyo: Mitsubishi Electric Corporation, Mitsubishi Motors Corporation, and Mitsubishi Heavy Industries Ltd.

mitosis The stages of mitosis, the process of cell division that takes place when a plant or animal cell divides for growth or repair. The two daughter cells each receive the same number of chromosomes as were in the original cell.

monoculture. If climate, pests, or market prices are unfavourable for one crop or type of livestock, another may be more successful and the risk is shared. Animals provide manure for the fields and help to maintain soil fertility.

mixer in sound recording, equipment that allows an engineer to set a different volume level for each individual sound track so that solos can be highlighted and loud instruments can be kept from dominating softer ones. Multimedia systems that allow recording generally include similar, though not as sophisticated, functions through software. This is useful in applications such as adding background music to a scene where two people are talking and it is important to hear the voices clearly over the music.

mixture in chemistry, a substance containing two or more compounds that still retain their separate physical and chemical properties. There is no chemical bonding between them and they can be separated from each other by physical means (compare *compound*).

m.k.s. system system of units in which the base units metre, kilogram, and second replace the centimetre, gram, and second of the c.g.s. system. From it developed the SI system (see *SI units*).

It simplifies the incorporation of electrical units into the metric system, and was incorporated in SI. For application to electrical and magnetic phenomena, the ampere was added, creating what is called the m.k.s.a. system.

ml symbol for millilitre.

mm symbol for millimetre.

mmHg symbol for *millimetre of mercury*.

MMX in computing, umbrella name for improvements to the Intel Pentium line of processors in 1996, including 57 new instructions to handle multimedia and communications data. From 1997, all new Pentium chips included MMX as standard, such as the Pentium II range. MMX may be an abbreviation for Multimedia eXtensions.

mnemonic in computing, a short sequence of letters used in low-level programming languages (see *low-level language*) to represent a *machine code* instruction.

moa any of a group of extinct flightless kiwi-like birds that lived in New Zealand. There were 19 species; they varied from 0.5 to 3.5 m/2 to 12 ft, with strong limbs, a long neck, and no wings. The largest species was *Dinornis maximus*. The last moa was killed in the 1800s. (Order *Dinornithiformes*.)

The Maori used them as food, and with the use of European firearms killed them in excessive numbers.

mobile ion in chemistry, an ion that is free to move; such ions are only found in the aqueous solutions or melts (molten masses) of an electrolyte. The mobility of the ions in an electrolyte is what allows it to conduct electricity.

mobile phone in computing, cordless telephone linked to a digital cellular radio network. Mobile phones can connect to the Internet via a datacard, which converts computer data into a form that can be passed over the network and vice versa. Users can connect them to a laptop computer and others incorporate a full pocket organizer. A trend for greater integration of phone and computer emerged in 1996.

Möbius strip structure made by giving a half twist to a flat strip of paper and joining the ends together. It has certain remarkable

properties, arising from the fact that it has only one edge and one side. If cut down the centre of the strip, instead of two new strips of paper, only one long strip is produced. It was invented by the German mathematician August Möbius.

mockingbird North American songbird of the mimic thrush family, found in the USA and Mexico. About 25 cm/10 in long, it is brownish grey, with white markings on the black wings and tail. It is remarkable for its ability to mimic the songs of other species. (Species *Mimus polyglottos*, family Mimidae, order Passeriformes.)

mock orange or *syringa* any of a group of deciduous shrubs, including *P. coronarius*, which has white, strongly scented flowers similar to those of the orange tree. (Genus *Philadelphus*, family Philadelphaceae.)

mode in mathematics, the element that appears most frequently in a given set of data. For example, the mode for the data 0, 0, 9, 9, 9, 12, 87, 87 is 9.

model in computing, set of assumptions and criteria based on actual phenomena, used to conduct a computer simulation. Models are used to predict the behaviour of a system such as the movement of a hurricane or the flow of goods from a store. In industry, they are an important tool for testing new products: engineers subject virtual prototypes of aircraft or bridges to various scenarios to find out what adjustments are necessary to the design. However, a model is only as good as the assumptions that underlie it.

Models may run at the same speed of the real situation (real-time models) or run at faster or slower speeds.

Models are also the basis for expert systems, which simulate the knowledge of a human expert.

A theory has only the alternative of being right or wrong. A model has a third possibility: it may be right, but irrelevant.

MANFRED EIGEN German physical chemist.

Quoted in Jagdish Mehra (ed) *The Physicist's Conception of Nature* 1973

model simplified version of some aspect of the real world. Models are produced to show the relationships between two or more factors, such as land use and the distance from the centre of a town (for example, concentric-ring theory). Because models are idealized, they give only a general guide to what may happen.

modem (acronym for *modulator/demodulator*) device for transmitting computer data over telephone lines. Such a device is necessary because the digital signals produced by computers cannot, at present, be transmitted directly over the telephone network, which uses analogue signals. The modem converts the digital signals to analogue, and back again.

Modems are used for linking remote terminals to central computers and enable computers to communicate with each other anywhere in the world. In 1997, the fastest standard modems transmitted data at a nominal rate of about 33,600 bps (bits per second), often abbreviated to 33.6K.

56K modems launched in 1997 achieve higher speeds by using a digital connection to the user's computer, while using a conventional analogue connection in the other direction. In theory the downstream link can transfer data at 56Kbps but in practice, speeds are usually 45–50K or less, depending on the quality of the phone line and other factors.

Initially there were two competing 56K systems – K56Flex from Rockwell and Lucent Technologies, and X2 from 3Com/US Robotics – with many users waiting for the ITU to agree a standard system.

modern tax in computing, urban legend that surfaces regularly on Internet bulletin boards. It says that the US government's Federal Communications Commission (FCC) is planning to introduce a telecommunications surcharge for using a modem on the public telephone network, and urges readers to write to the FCC to complain. The FCC, however, has no such plans.

Möbius strip The Möbius strip has only one side and one edge. It consists of a strip of paper connected at its ends with a half-twist in the middle.

modem Modems are available in various forms: microcomputers may use an external device connected through a communications port, or an internal device, which takes the form of an expansion board inside the computer. Notebook computers use an external modem connected via a special interface card.

moderator in computing, person or group of people that screens submissions to certain newsgroups and mailing lists before passing them on for wider circulation. The aim of moderation is not to censor, but to ensure that the quality of debate is maintained by filtering out spamming, irrelevant ('off-topic'), or gratuitously offensive postings.

moderator in a nuclear reactor, a material such as graphite or heavy water used to reduce the speed of high-energy neutrons. Neutrons produced by nuclear fission are fast-moving and must be slowed to initiate further fission so that nuclear energy continues to be released at a controlled rate.

Slow neutrons are much more likely to cause fission in a uranium-235 nucleus than to be captured in a U-238 (nonfissile uranium) nucleus. By using a moderator, a reactor can thus be made to work with fuel containing only a small proportion of U-235.

modulation in radio transmission, the variation of frequency, or amplitude, of a radio carrier wave, in accordance with the audio characteristics of the speaking voice, music, or other signal being transmitted. See pulse-code modulation, AM (amplitude modulation), and CFM (frequency modulation).

module in construction, a standard or unit that governs the form of the rest. For example, Japanese room sizes are traditionally governed by multiples of standard tatami floor mats; today prefabricated buildings are mass-produced in a similar way. The components of a spacecraft are designed in coordination; for example, for the Apollo Moon landings the craft comprised a command module (for working, eating, sleeping), service module (electricity generators, oxygen supplies, manoeuvring rocket), and lunar module (to land and return the astronauts).

modulus in mathematics, a number that divides exactly into the difference between two given numbers. Also, the multiplication factor used to convert a logarithm of one base to a logarithm of another base. Also, another name for absolute value.

Mohorovičić discontinuity also *Moho* or *M-discontinuity* boundary that separates the Earth's crust and mantle, marked by a rapid increase in the speed of earthquake waves. It follows the variations in the thickness of the crust and is found approximately 32 km/20 mi below the continents and about 10 km/6 mi below the oceans. It is named after the Yugoslav geophysicist Andrija Mohorovičić (1857–1936), who suspected its presence after analysing seismic waves from the Kulpa Valley earthquake in 1909.

Mohs' scale scale of hardness for minerals (in ascending order): 1 talc; 2 gypsum; 3 calcite; 4 fluorite; 5 apatite; 6 orthoclase; 7 quartz; 8 topaz; 9 corundum; 10 diamond.

The scale is useful in mineral identification because any mineral will scratch any other mineral lower on the scale than itself, and similarly it will be scratched by any other mineral higher on the scale.

TO REMEMBER THE ORDER OF HARDNESS:

molar one of the large teeth found towards the back of the mammalian mouth. The structure of the jaw, and the relation of the muscles, allows a massive force to be applied to molars. In herbivores the molars are flat with sharp ridges of enamel and are used for grinding, an adaptation to a diet of tough plant material. Carnivores have sharp powerful molars called carnassials, which are adapted for cutting meat.

molarity in chemistry, concentration of a solution expressed as the number of moles in grams of solute per cubic decimetre of solution.

molar solution in chemistry, solution that contains one mole of a substance per litre of solvent.

molar volume volume occupied by one mole (the molecular mass in grams) of any gas at standard temperature and pressure, equal to $2.24136 \times 10^{-2} \text{ m}^3$.

mole SI unit (symbol mol) of the amount of a substance. It is defined as the amount of a substance that contains as many elementary entities (atoms, molecules, and so on) as there are atoms in 12 g of the isotope carbon-12.

One mole of an element that exists as single atoms weighs as many grams as its atomic number (so one mole of carbon weighs 12 g), and it contains 6.022045×10^{23} atoms, which is Avogadro's number.

mole in construction, a mechanical device for boring horizontal holes underground without the need for digging trenches. It is used for laying pipes and cables.

mole small burrowing mammal with typically dark, velvety fur. Moles grow up to 18 cm/7 in long, and have acute senses of hearing, smell, and touch, but poor eyesight. They have short, muscular forelimbs and shovel-like, clawed front feet for burrowing in search of insects, grubs, and worms. Their fur lies without direction so that they can move forwards or backwards in their tunnels without discomfort. Moles are greedy eaters; they cannot live more than a few hours without food. (Family Talpidae, order Insectivora.)

North American moles differ from those of the Old World in having tusklike front upper incisor teeth. The same ecological role is taken in Africa by the golden moles (family Chrysochloridae), and in Australia by marsupial moles (genus *Notoryctes*, order Marsupialia).

Some members of the Talpidae family are aquatic, such as the Russian desman (*Desmana moschata*) and the North American star-nosed mole (*Condylura cristata*).

mole cricket dark brown burrowing insect about 35–50 mm/1.5–2 in long, covered with soft hairs. Over 50 species of mole crickets have been identified. They feed mainly on worms and other insects.

Mole crickets are particularly adapted for burrowing, the first pair of legs being large, flattened, and serrated for digging. The eyes are reduced, and the ovipositor (egg-laying organ) is vestigial. Some species have wings, which they use to fly at night. Other species have vestigial wings or the wings may be lacking.

Occasionally mole crickets may attack crops: for example the Puerto Rico mole cricket *Scapteriscus vicinus* is a serious pest.

classification Mole crickets are members of family Gryllotalpidae, order Orthoptera, class Insecta, phylum Arthropoda.

molecular biology study of the molecular basis of life, including the biochemistry of molecules such as DNA, RNA, and proteins, and the molecular structure and function of the various parts of living cells.

molecular clock use of rates of mutation in genetic material to calculate the length of time elapsed since two related species diverged from each other during evolution. The method can be based on comparisons of the DNA or of widely occurring proteins, such as haemoglobin.

Since mutations are thought to occur at a constant rate, the length of time that must have elapsed in order to produce the difference between two species can be estimated. This information

can be compared with the evidence obtained from palaeontology to reconstruct evolutionary events.

molecular cloud in astronomy, an enormous cloud of cool interstellar dust and gas containing hydrogen molecules and more complex molecular species. Giant molecular clouds (GMCs), about a million times as massive as the Sun and up to 300 light years in diameter, are regions in which stars are being born. The ϕ Orion Nebula is part of a GMC.

molecular formula in chemistry, formula indicating the actual number of atoms of each element present in a single molecule of a chemical compound. This is determined by two pieces of information: the empirical formula and the relative molecular mass, which is determined experimentally.

molecular mass (also known as *relative molecular mass*) the mass of a molecule, calculated relative to one-twelfth the mass of an atom of carbon-12. It is found by adding the relative atomic masses of the atoms that make up the molecule.

molecular solid in chemistry, solid composed of molecules that are held together by relatively weak intermolecular forces. Such solids are low-melting and tend to dissolve in organic solvents. Examples of molecular solids are sulphur, ice, sucrose, and solid carbon dioxide.

molecule group of two or more atoms bonded together. A molecule of an element consists of one or more like atoms; a molecule of a compound consists of two or more different atoms bonded together. Molecules vary in size and complexity from the hydrogen molecule (H_2) to the large macromolecules of proteins. They are held together by ionic bonds, in which the atoms gain or lose electrons to form ions, or by covalent bonds, where electrons from each atom are shared in a new molecular orbital.

mole rat, naked small underground mammal, almost hairless, with a disproportionately large head. The mole rat is of importance to zoologists as one of the very few mammals that are eusocial, that is, living in colonies with sterile workers and one fertile female. (Species *Heterocephalus glaber*.)

The mole rat has the smallest brain relative to body size of any small mammal. Its underground colonies comprise one breeding female, some breeding males, and many functionally sterile workers of both sexes.

mollusc any of a group of invertebrate animals, most of which have a body divided into three parts: a head, a central mass containing the main organs, and a foot for movement; the more sophisticated octopuses and related molluscs have arms to capture their prey. The majority of molluscs are marine animals, but some live in fresh water, and a few live on dry land. They include clams, mussels, and oysters (bivalves), snails and slugs (gastropods), and cuttlefish, squids, and octopuses (cephalopods). The body is soft, without limbs (except for the cephalopods), and cold-blooded. There is no internal skeleton, but many species have a hard shell covering the body. (Phylum Mollusca.)

Molluscs have varying diets, the carnivorous species feeding mainly on other molluscs. Some are vegetarian. Reproduction is by means of eggs and is sexual; many species are hermaphrodite (having both male and female reproductive organs). The shells of molluscs take a variety of forms: single or univalve (like the snail), double or bivalve (like the clam), chambered (like the nautilus), and many other variations. In some cases (for example cuttlefish and squid), the shell is internal. Every mollusc has a fold of skin, the

mantle, which covers either the whole body or only the back, and secretes the chalky substance that forms the shell. The lower ventral surface (belly area) of the body forms the foot, which enables the mollusc to move about.

Mollusca invertebrate animal phylum that contains the molluscs.

molybdenite molybdenum sulphide, MoS_2 , the chief ore mineral of molybdenum. It possesses a hexagonal crystal structure similar to graphite, has a blue metallic lustre, and is very soft (1–1.5 on Mohs's scale).

molybdenum Greek *molybdos* 'lead' heavy, hard, lustrous, silver-white, metallic element, symbol Mo, atomic number 42, relative atomic mass 95.94. The chief ore is the mineral molybdenite. The element is highly resistant to heat and conducts electricity easily. It is used in alloys, often to harden steels. It is a necessary trace element in human nutrition. It was named in 1781 by Swedish chemist Karl Scheele, after its isolation by P J Hjelm (1746–1813), for its resemblance to lead ore.

moment of a force in physics, measure of the turning effect, or torque, produced by a force acting on a body. It is equal to the product of the force and the perpendicular distance from its line of action to the point, or pivot, about which the body will turn. Its unit is the newton metre.

If the magnitude of the force is F newtons and the perpendicular distance is d metres then the moment is given by:

$$\text{moment} = Fd$$

See also couple.

moment of inertia in physics, the sum of all the point masses of a rotating object multiplied by the squares of their respective distances from the axis of rotation. It is analogous to the mass of a stationary object or one moving in a straight line.

In linear dynamics, Newton's second law of motion states that the force F on a moving object equals the products of its mass m and acceleration a ($F = ma$); the analogous equation in rotational dynamics is $T = I\alpha$, where T is the torque (the turning effect of a force) that causes an angular acceleration α and I is the moment of inertia. For a given object, I depends on its shape and the position of its axis of rotation.

momentum the product of the mass of a body and its velocity. If the mass of a body is m kilograms and its velocity is v m s⁻¹, then its momentum is given by:

$$\text{momentum} = mv$$

Its unit is the kilogram metre-per-second (kg m s⁻¹) or the newton second.

The momentum of a body does not change unless a resultant or unbalanced force acts on that body (see Newton's laws of motion).

According to Newton's second law of motion, the magnitude of a resultant force F equals the rate of change of momentum brought about by its action, or:

$$F = (mv - mu)/t$$

where mu is the initial momentum of the body, mv is its final momentum, and t is the time in seconds over which the force acts. The change in momentum, or impulse, produced can therefore be expressed as:

$$\text{impulse} = mv - mu = Ft$$

The law of conservation of momentum is one of the fundamental concepts of classical physics. It states that the total momentum of all bodies in a closed system is constant and unaffected by processes occurring within the system.

The angular momentum of an orbiting or rotating body of mass m travelling at a velocity v in a circular orbit of radius R is expressed as mRv . Angular momentum is conserved, and should any of the values alter (such as the radius of orbit), the other values (such as the velocity) will compensate to preserve the value of angular momentum, and that lost by one component is passed to another.

monazite mineral, $(\text{Ce}, \text{La}, \text{Th})\text{PO}_4$, yellow to red, valued as a source of lanthanides or rare earths, including cerium and europium; generally found in placer deposit (alluvial) sands.

mongolism former name (now considered offensive) for Down's syndrome.

mongoose any of a group of carnivorous tropical mammals. The Indian mongoose (*H. mungo*) is greyish in colour and about 50 cm/1.5 ft long, with a long tail. It can be tamed and is often kept for its ability to kill snakes. Like the snakes themselves, the acetylcholine receptors connecting the mongooses' nerves and muscle cells are unaffected by the venom. (Genera *Herpestes*, *Ichneumia*, and other related genera, family Viverridae.)

Most mongooses are solitary, but the banded mongoose *Mungo mungo* is highly gregarious, living in groups of 15–40 individuals. They feed on small reptiles and invertebrates and spend about 60% of their day foraging.

The white-tailed mongoose (*I. albicauda*) of central Africa has a distinctive grey or white bushy tail.

mongoose The ring-tailed mongoose *Galidia elegans* is found in Madagascar where it is active by day in both wet and dry forests. Like many mongooses, it has a very varied diet, including birds' eggs, snails, insects, lizards, and small mammals. Premaphotos Wildlife

monitor or screen output device on which a computer displays information for the benefit of the operator user – usually in the form of a graphical user interface such as Windows. The commonest type is the cathode-ray tube (CRT), which is similar to a television screen. Portable computers often use liquid crystal display (LCD) screens. These are harder to read than CRTs, but require less power, making them suitable for battery operation.

monitor any of various lizards found in Africa, S Asia, and Australasia. Monitors are generally large and carnivorous, with well-developed legs and claws and a long powerful tail that can be swung in defence. (Family Varanidae.)

Monitors include the Komodo dragon (*Varanus komodoensis*), the largest of all lizards, and also the slimmer Salvador's monitor (*V. salvadorii*), which may reach 2.5 m/8 ft. Several other monitors, such as the lace monitor (*V. varius*), the perentie (*V. giganteus*) of Australia, and the Nile monitor (*V. niloticus*) of Africa, are up to 2 m/6 ft long.

monkey any of the various smaller, mainly tree-dwelling anthropoid primates, excluding humans and the apes. There are 125 species, living in Africa, Asia, and tropical Central and South America. Monkeys eat mainly leaves and fruit, and also small animals. Several species are endangered due to loss of forest habitat,

for example the woolly spider monkey and black saki of the Amazonian forest.

Old World monkeys (family Cercopithecidae) of tropical Africa and Asia are distinguished by their close-set nostrils and differentiated thumbs, some also having cheek pouches and rumps with bare patches (callosities) of hardened skin. They include baboons, langurs, macaques, and guenons.

New World monkeys of Central and South America are characterized by wide-set nostrils, and some have highly sensitive prehensile tails that can be used as additional limbs, to grasp and hold branches or objects. They include two families:

(1) the family Cebidae, which includes the larger species saki, capuchin, squirrel, howler, and spider monkeys;

(2) the family Callitrichidae, which includes the small marmosets and tamarins.

There are one hundred and ninety-three living species of monkeys and apes. One hundred and ninety-two are covered with hair. The exception is the naked ape self-named

monkey puzzle or *Chilean pine* coniferous evergreen tree, native to Chile; its branches, growing in circular arrangements (whorls) around the trunk and larger branches, are covered in prickly, leathery leaves. (*Araucaria araucana*, family Araucariaceae.)

Cut down for valuable timber, it is now listed as 'rare' on the Red Data list published by the International Union for the Conservation of Nature. International trade in any part of the tree is banned.

monkfish marine bony fish also known as angelfish.

monocarpic or **hapaxanthic** describing plants that flower and produce fruit only once during their life cycle, after which they die. Most annual plants and biennial plants are monocarpic, but there are also a small number of monocarpic perennial plants that flower just once, sometimes after as long as 90 years, dying shortly afterwards, for example, century plant *Agave* and some species of bamboo *Bambusa*. The general biological term related to organisms that reproduce only once during their lifetime is semelparity.

monoclonal antibody (MAB) antibody produced by fusing an antibody-producing lymphocyte with a cancerous myeloma (bone-marrow) cell. The resulting fused cell, called a hybridoma, is immortal and can be used to produce large quantities of a single, specific antibody. By choosing antibodies that are directed against antigens found on cancer cells, and combining them with cytotoxic drugs, it is hoped to make so-called magic bullets that will be able to pick out and kill cancers.

It is the antigens on the outer cell walls of germs entering the body that provoke the production of antibodies as a first line of defence against disease. Antibodies 'recognize' these foreign antigens, and, in locking on to them, cause the release of chemical signals in the bloodstream to alert the immune system for further action. MABs are copies of these natural antibodies, with the same ability to recognize specific antigens. Introduced into the body, they can be targeted at disease sites.

The full potential of these biological missiles, developed by César Milstein and others at Cambridge University, England, 1975, is still under investigation. However, they are already in use in blood-grouping, in pinpointing viruses and other sources of disease, in tracing cancer sites, and in developing vaccines.

monocotyledon angiosperm (flowering plant) having an embryo with a single cotyledon, or seed leaf (as opposed to dicotyledons, which have two). Monocotyledons usually have narrow leaves with parallel veins and smooth edges, and hollow or soft stems. Their flower parts are arranged in threes. Most are small plants such as orchids, grasses, and lilies, but some are trees such as palms.

monoculture farming system where only one crop is grown. In Third World countries this is often a cash crop, grown on plantations, for example, sugar and coffee. Cereal crops in the industrialized world are also frequently grown on a monoculture basis; for example, wheat in the Canadian prairies.

Monoculture allows the farmer to tailor production methods to the requirements of one crop, but it is a high-risk strategy since the crop may fail (because of pests, disease, or bad weather) and world prices for the crop may fall. Monoculture without crop rotation is likely to result in reduced soil quality despite the addition of artificial fertilizers, and it contributes to soil erosion.

monocyte in biology, type of white blood cell. They are found in the tissues, the lymphatic and circulatory systems where their purpose is to remove foreign particles, such as bacteria and tissue debris, by ingesting them.

monoecious having separate male and female flowers on the same plant. Maize (*Zea mays*), for example, has a tassel of male flowers at the top of the stalk and a group of female flowers (on the ear, or cob) lower down. Monoecism is a way of avoiding self-fertilization.

Dioecious plants have male and female flowers on separate plants.

monohybrid inheritance pattern of inheritance seen in simple genetics experiments, where the two animals (or two plants) being crossed are genetically identical except for one gene.

This gene may code for some obvious external features such as seed colour, with one parent having green seeds and the other having yellow seeds. The offspring are monohybrids, that is, hybrids for one gene only, having received one copy of the gene from each parent. Known as the F1 generation, they are all identical, and

usually resemble one parent, whose version of the gene (the dominant (allele) masks the effect of the other version (the recessive allele). Although the characteristic coded for by the recessive allele (for example, green seeds) completely disappears in this generation, it can reappear in offspring of the next generation if they have two recessive alleles. On average, this will occur in one out of four offspring from a cross between two of the monohybrids. The next generation (called F2) show a 3:1 ratio for the characteristic in question, 75% being like the original parent with the recessive allele. Austrian biologist Gregor (Mendel) first carried out experiments of this type (crossing varieties of artificially bred plants, such as peas) and they revealed the principles of genetics. The same basic mechanism underlies all inheritance, but in most plants and animals there are so many genetic differences interacting to produce the external appearance (phenotype) that such simple, clear-cut patterns of inheritance are not evident.

monolith Greek *monos* 'sole', *lithos* 'stone' single isolated stone or column, usually standing and of great size, used as a form of monument. Some are natural features, such as the Buck Stone in the Forest of Dean, England. Other monoliths may be quarried, resited, finished, or carved; those in Egypt of about 3000 BC take the form of obelisks. They have a wide distribution including Europe, South America, N Africa, and the Middle East.

Apart from their ritual or memorial function, monoliths have been used as sundials and calendars in the civilizations of the Aztecs, Egyptians, and Chaldeans (ancient peoples of southern Babylonia). In landscape archaeology, monoliths are interpreted in a wider context, possibly as boundary markers. The largest cut stone, weighing about 1,500 tonnes, is sited in the ancient Syrian city of Baalbek.

monomer chemical compound composed of simple molecules from which polymers can be made. Under certain conditions the simple molecules (of the monomer) join together (polymerize) to form a very long chain molecule (macromolecule) called a polymer. For example, the polymerization of ethene (ethylene) monomers produces the polymer polyethene (polyethylene).

Mononychus olecranus flightless bird from the Cretaceous period between 65 and 85 million years ago. Two well-preserved skeletons found in Mongolia 1987 and 1992 show *Mononychus* to have been about 1 m/3 ft in length with a long neck and tail, slender hindlimbs, short, sturdy forelimbs, and teeth.

monorail railway that runs on a single rail; the cars can be balanced on it or suspended from it. It was invented in 1882 to carry light loads, and when run by electricity was called a *telpher*.

The Wuppertal Schwebebahn, which has been running in Germany since 1901, is a suspension monorail, where the passenger cars hang from an arm fixed to a trolley that runs along the rail. Today most monorails are of the straddle type, where the passenger cars run on top of the rail. They are used to transport passengers between terminals at some airports; Japan has a monorail (1964) running from the city centre to Hameda airport.

monosaccharide or *simple sugar* carbohydrate that cannot be hydrolysed (split) into smaller carbohydrate units. Examples are glucose and fructose, both of which have the molecular formula $\text{C}_6\text{H}_{12}\text{O}_6$.

TO REMEMBER THE MOLECULAR SHAPE OF FRUCTOSE AND GLUCOSE:

THERE ARE TWO SIMPLE SUGARS (MONOSACCHARIDES) — FRUCTOSE AND GLUCOSE — WHICH COMBINE IN A SPECIFIC WAY TO FORM SUCROSE. REMEMBER THE MOLECULAR SHAPE OF FRUCTOSE HAS FIVE CARBONS (LETTER F STARTS BOTH WORDS) AND HEXAGON IS THE SHAPE OF GLUCOSE (LETTER G IN BOTH WORDS)

monosodium glutamate (MSG) $\text{NaC}_4\text{H}_7\text{NO}_4$ a white, crystalline powder, the sodium salt of glutamic acid (an amino acid found in proteins that plays a role in the metabolism of plants and animals). It has no flavour of its own, but enhances the flavour of foods such as meat and fish. It is used to enhance the flavour of many packaged and 'fast foods', and in Chinese cooking. Ill effects may arise from its overconsumption, and some people are very sensitive to it, even in small amounts. It is commercially derived from vegetable protein. It occurs naturally in soybeans and seaweed.

Monotremata order of mammals consisting of the ϕ monotremes.

monotreme any of a small group of primitive egg-laying mammals, found in Australasia. They include the ϕ echidnas (spiny anteaters) and the ϕ platypus. (Order Monotremata.)

In 1995 Australian palaeontologists announced a new (extinct) family of monotreme, the Kollikodontidae, following the discovery of a 120-million-year-old jawbone in New South Wales.

monsoon wind pattern that brings seasonally heavy rain to S Asia; it blows towards the sea in winter and towards the land in summer. The monsoon may cause destructive flooding all over India and SE Asia from April to September, leaving thousands of people homeless each year.

The monsoon cycle is believed to have started about 12 million years ago with the uplift of the Himalayas.

monstera or *Swiss cheese plant* evergreen climbing plant belonging to the arum family, native to tropical America. *M. deliciosa* is grown as a house plant. Areas between the veins of the leaves dry up, forming deep notches and eventually holes. (Genus *Monstera*, family Araceae.)

montbretia plant belonging to the iris family, native to South Africa, with orange or reddish flowers on long stems. They are grown as ornamental pot plants. (*Tritonia crocosmiflora*, family Iridaceae.)

month unit of time based on the motion of the Moon around the Earth.

The time from one new or full Moon to the next (the *synodic* or *lunar month*) is 29.53 days. The time for the Moon to complete one orbit around the Earth relative to the stars (the *sidereal month*) is 27.32 days. The *solar month* equals 30.44 days, and is exactly one-twelfth of the solar or tropical year, the time taken for the Earth to orbit the Sun. The *calendar month* is a human invention, devised to fit the calendar year.

Montréal Protocol international agreement, signed in 1987, to stop the production of chemicals that are ϕ ozone depleters by the year 2000.

Originally the agreement was to reduce the production of ozone depleters by 35% by 1999. The green movement criticized the agreement as inadequate, arguing that an 85% reduction in ozone depleters would be necessary just to stabilize the ozone layer at 1987 levels. The protocol (under the Vienna Convention for the Protection of the Ozone Layer) was reviewed in 1992. Amendments added another 11 chemicals to the original list of eight chemicals suspected of harming the ozone layer. A controversial amendment concerns a fund established to pay for the transfer of ozone-safe technology to poor countries.

MOO (abbreviation for *MUD*, *object-oriented*) in computing, a ϕ MUD (multi-user deamon) that uses ϕ object-oriented programming, enabling participants to create their own personalized characters — which may well be specially equipped to attack the characters created by other players.

moon in astronomy, any natural ϕ satellite that orbits a planet. Mercury and Venus are the only planets in the Solar System that do not have moons.

Moon natural satellite of Earth, 3,476 km/2,160 mi in diameter, with a mass 0.012 (approximately one-eightieth) that of Earth.

Its surface gravity is only 0.16 (one-sixth) that of Earth. Its average distance from Earth is 384,400 km/238,855 mi, and it orbits in a west-to-east direction every 27.32 days (the *sidereal month*). It

spins on its axis with one side permanently turned towards Earth. The Moon has no atmosphere and was thought to have no water till ice was discovered on its surface in 1998.

phases The Moon is illuminated by sunlight, and goes through a cycle of phases of shadow, waxing from new (dark) via first quarter (half Moon) to full, and waning back again to new every 29.53 days (the synodic month, also known as a lunation). On its sunlit side, temperatures reach $110^{\circ}\text{C}/230^{\circ}\text{F}$, but during the two-week lunar night the surface temperature drops to $-170^{\circ}\text{C}/-274^{\circ}\text{F}$.

origins The origin of the Moon is still open to debate. Scientists suggest the following theories: that it split from the Earth; that it was a separate body captured by Earth's gravity; that it formed in orbit around Earth; or that it was formed from debris thrown off when a body the size of Mars struck Earth. Future exploration of the Moon may detect water permafrost, which could be located at the permanently shadowed lunar poles.

research The far side of the Moon was first photographed from the Soviet *Lunik 3* in October 1959. Much of our information about the Moon has been derived from this and other photographs and measurements taken by US and Soviet Moon probes, from geological samples brought back by US Apollo astronauts and by Soviet Luna probes, and from experiments set up by the US astronauts in 1969-72. The US probe, *Lunar Prospector*, launched January 1998, is intended to examine the composition of the lunar crust, record gamma rays, and map the lunar magnetic field.

composition The Moon's composition is rocky, with a surface heavily scarred by meteorite impacts that have formed craters up to 240 km/150 mi across. Seismic observations indicate that the Moon's surface extends downwards for tens of kilometres; below this crust is a solid mantle about 1,100 km/688 mi thick, and below that a silicate core, part of which may be molten. Rocks brought back by astronauts show the Moon is 4.6 billion years old, the same age as Earth. It is made up of the same chemical elements as Earth, but in different proportions, and differs from Earth in that most of the Moon's surface features were formed within the first billion years of its history when it was hit repeatedly by meteorites.

The youngest craters are surrounded by bright rays of ejected rock. The largest scars have been filled by dark lava to produce the lowland plains called seas, or maria (plural of mare). These dark patches form the so-called 'man-in-the-Moon' pattern. Inside some craters that are permanently in shadow is up to 300 million tonnes of ice existing as a thin layer of crystals.

One of the Moon's easiest features to observe is the mare Plato, which is about 100 km/62 mi in diameter and 2,700 m/8,860 ft deep, and at times is visible with the naked eye alone.

Detailed description of the Moon. It includes statistics and information about the surface, eclipses, and phases of the Moon, along with details of the Apollo landing missions. The site is supported by a good selection of images.

Moon probe crewless spacecraft used to investigate the Moon. Early probes flew past the Moon or crash-landed on it, but later ones achieved soft landings or went into orbit. Soviet probes included the Luna/Lunik series. US probes (Ranger, Surveyor, Lunar Orbiter) prepared the way for the Apollo crewed flights.

moor in earth science, a stretch of land, usually at a height, which is characterized by a vegetation of heather, coarse grass, and bracken. A moor may be poorly drained and contain boggy hollows.

moorhen marsh bird belonging to the rail family, common in swamps, lakes, and ponds throughout Europe, Asia, Africa, and North and South America. It is about 33 cm/13 in long, brown above and dark grey below, with a red bill and forehead, a white stripe along the edge of the folded wings, a vivid white underside

to the tail, and green legs. Its big feet are not webbed or lobed, but the moorhen can swim well. The nest is built by the waterside, and the eggs are buff-coloured with orange-brown spots. (Species *Gallinula chloropus*, family Rallidae, order Gruiformes.)

moose North American name for the elk.

monape worm caterpillar of the southern African emperor moth *Gonimbrasia belina* that is eaten in South Africa, either dried as a snack or rehydrated in stews. They grow to around 10 cm/4 in in length and are very high in protein.

moped lightweight motorcycle with pedals. Early mopeds (like the auticycle) were like motorized bicycles, using the pedals to start the bike and assist propulsion uphill. The pedals have little function in many mopeds today.

moraine rocky debris or till carried along and deposited by a glacier. Material eroded from the side of a glaciated valley and carried along the glacier's edge is called a lateral moraine; that worn from the valley floor and carried along the base of the glacier is called a ground moraine. Rubble dropped at the snout of a melting glacier is called a terminal moraine.

When two glaciers converge their lateral moraines unite to form a medial moraine. Debris that has fallen down crevasses and becomes embedded in the ice is termed an englacial moraine; when this is exposed at the surface due to partial melting it becomes ablation moraine.

moray eel with strong jaws armed with daggerlike teeth. The large species that hide in the crevices of coral reefs can inflict savage bites. Most species of moray are found in tropical seas.

classification Morays are in family Muraenidae belonging to the order Anguilliformes, class Osteichthyes.

morel any of a group of edible mushrooms. The common morel (*M. esculenta*) grows in Europe and North America. The yellowish-brown cap is pitted with holes like a sponge and is about 2.5 cm/1 in long. It is used for seasoning gravies, soups, and sauces and is second only to the truffle as the world's most sought-after mushroom. (Genus *Morchella*, order Pezizales.)

Morgan horse breed of riding and driving show horse originating in the USA in the 1780s from a single stallion named *Justin Morgan* after his owner. They are marked by high, curved necks and a high-stepping action. The breed is valued for its strength, endurance, and speed.

morning glory any of a group of twining or creeping plants native to tropical America, especially *I. purpurea*, with dazzling blue flowers. Small quantities of substances similar to the hallucinogenic drug LSD are found in the seeds of some species. (Genus *Ipomoea*, family Convolvulaceae.)

morphine narcotic alkaloid $\text{C}_{17}\text{H}_{19}\text{NO}_3$ derived from opium and prescribed only to alleviate severe pain. Its use produces serious side effects, including nausea, constipation, tolerance, and addiction, but it is highly valued for the relief of the terminally ill.

The risk of addiction arising from the use of morphine for pain relief is much lower than for recreational use (about 1 in 3,000) as the drug is processed differently by the body when pain is present.

morphing the metamorphosis of one shape or object into another by computer-generated animation. First used in filmmaking in 1990, it has transformed cinema special effects. Conventional animation is limited to two dimensions; morphing enables the creation of three-dimensional transformations.

To create such effects, the start and end of the transformation must be specified on screen using a wire-frame model that mathematically defines the object. To make the object three-dimensional, the wire can be extruded from a cross-section or turned as on a lathe to produce an evenly turned surface. This is then rendered, or filled in and shaded. Once the beginning and end objects have been created, the computer can calculate the morphing process.

morphogen in medicine, one of a class of substances believed to be present in the growing embryo, controlling its growth pattern.

It is thought that variations in the concentration of morphogens in different parts of the embryo cause them to grow at different rates.

morphology in biology, the study of the physical structure and form of organisms, in particular their soft tissues.

Morse, Samuel Finley Breese (1791-1872)

US inventor. In 1835 he produced the first adequate electric telegraph (see telegraphy), and in 1843 was granted \$30,000 by Congress for an experimental line between Washington DC and Baltimore. With his assistant Alexander Bain (1810-1877) he invented the Morse code.

Mary Evans Picture Library

Morse code international code for transmitting messages by wire or radio using signals of short (dots) and long (dashes) duration, originated by US inventor Samuel Morse for use on his invention, the telegraph (see telegraphy).

The letters SOS (3 short, 3 long, 3 short) form the international distress signal, being distinctive and easily transmitted (popularly but erroneously save our souls). Its use was discontinued in 1997. By radio telephone the distress call is 'Mayday', for similar reasons (popularly alleged to derive from French *m'aidez*, help me).

Morse code The Morse telegraph and workable code was first demonstrated in 1844. When a message was received, a series of short or long dashes ('dots' and 'dashes') were recorded onto a moving strip of paper. The pattern of the dots and dashes could be interpreted using Morse's Alphabetical Code.

Mosaic browser program used for searching the World Wide Web. It was distributed for free on the Internet as NCSA Mosaic, and made a significant contribution to the huge growth in the Internet's popularity.

Mosaic was developed at the National Center for Supercomputing Applications at the University of Illinois in 1993, and the team behind it went on to create Netscape Navigator, which quickly became a killer application for browsing the Web.

mosquito Though most of the more than 2,400 species of mosquito are tropical, they are found worldwide. The largest mosquito in the British Isles is the banded-legged *Culiseta annulata*, seen here. Premaphotos Wildlife

mosquito any of a group of flies in which the female has needle-like mouthparts and sucks blood before laying eggs. The males feed on plant juices. Some mosquitoes carry diseases such as malaria. (Family Culicidae, order Diptera.)

Human odour in general is attractive to mosquitoes, as well as the lactic acid in sweat and the heat of the human body at close range. Peoples' varying reactions to mosquito bites depend on their general allergic reaction and not on the degree of the bite; the allergic reaction is caused by the saliva injected from the mosquito's salivary glands to prevent the host's blood from clotting. The mosquito consumes 4 microlitres of blood when it feeds. Natural mosquito repellents include lavender oil, citronella (from lemon grass), thyme, and eucalyptus oils.

moss small nonflowering plant of the class Musci (10,000 species), forming with the liverworts and the hornworts the order Bryophyta. The stem of each plant bears rhizoids that anchor it; there are no true roots. Leaves spirally arranged on its lower portion have sexual organs at their tips. Most mosses flourish best in damp conditions where other vegetation is thin.

The peat or bog moss *Sphagnum* was formerly used for surgical dressings. The smallest moss is the Cape pygmy moss *Ephemernum capensis*, only slightly larger than a pin head.

Mössbauer effect the recoil-free emission of gamma rays from atomic nuclei under certain conditions. The effect was discovered in 1953 by German physicist Rudolf Mössbauer, and used in 1960 to provide the first laboratory test of Einstein's general theory of relativity.

The absorption and subsequent re-emission of a gamma ray by an atomic nucleus usually causes it to recoil, so affecting the wavelength of the emitted ray. Mössbauer found that at low temperatures, crystals will absorb gamma rays of a specific wavelength and resonate so that the crystal as a whole recoils while individual nuclei do not. The wavelength of the re-emitted gamma rays is therefore virtually unaltered by recoil and may be measured to a high degree of accuracy. Changes in the wavelength may therefore be studied as evidence of the effect of, say, neighbouring electrons or gravity. For example, the effect provided the first verification of the general theory of relativity by showing that gamma-ray wavelengths become longer in a gravitational field, as predicted by Einstein.

moth any of a large number of mainly night-flying insects closely related to butterflies. Their wings are covered with microscopic scales. Most moths have a long sucking mouthpart (proboscis) for feeding on the nectar of flowers, but some have no functional mouthparts and rely instead upon stores of fat and other reserves

MOTH

Males of the US moth *Gluphisia septentrionis* spend up to three hours at a time 'puddling'. Puddling is like drinking, except that the water passes straight through the insect after its sodium has been extracted. As it puddles, the moth squirts out the unwanted liquid from its anus about 18 times per minute. It passes the water equivalent of 600 times its own body mass.

built up during the caterpillar stage. At least 100,000 different species of moth are known. (Order Lepidoptera.)

Moths feed chiefly on nectar and other fluid matter; some, like the hawk moths, frequent flowers and feed while hovering. The females of some species (such as bagworm moths) have no wings at all or wings that are reduced to tiny flaps. Moths vary greatly in size: the minute Nepticulidae sometimes have a wingspread less than 3 mm/0.1 in, while the giant Noctuid or owl moth (*Erebus agrippina*) measures about 280 mm/11 in across. In many cases the males are smaller and more brightly coloured than the females.

The larvae (caterpillars) have a well-developed head and three thoracic (middle) and ten abdominal (end) segments. Each thoracic segment has a pair of short legs, ending in single claws; a pair of suckerlike feet is present on segments three to six and ten of the end part of the body. In the family Geometridae the caterpillars have abdominal feet only on segments six and ten of the end part of the body. They move in a characteristic looping way and are known as 'loopers', 'inchworms', or geometers. Projecting from the middle of the lower lip of a caterpillar is a tiny tube or spinneret, through which silk is produced to make a cocoon within which the change to the pupa or chrysalis occurs. Silk glands are especially large in the silkworm moth. Many caterpillars, including the

geometers, which are hunted by birds, are protected by their resemblance in both form and colour to their immediate surroundings. Others, which are distasteful to such enemies, are brightly coloured or densely hairy.

The feeding caterpillars of many moths cause damage: the codling moth, for example, attacks fruit trees; and several species of clothes moth eat natural fibres.

motherboard printed circuit board that contains the main components of a microcomputer. The power, memory capacity, and capability of the microcomputer may be enhanced by adding expansion boards to the motherboard.

mother-of-pearl or **nacre** the smooth lustrous lining in the shells of certain molluscs – for example pearl oysters, abalones, and mussels. When this layer is especially thick it is used commercially for jewellery and decorations. Mother-of-pearl consists of calcium carbonate. See **pearl**.

motility the ability to move spontaneously. The term is often restricted to those cells that are capable of independent locomotion, such as spermatozoa. Many single-celled organisms are motile, for example, the amoeba. Research has shown that cells capable of movement, including vertebrate muscle cells, have certain biochemical features in common. Filaments of the proteins actin and myosin are associated with motility, as are the metabolic processes needed for breaking down the energy-rich compound **ATP** (adenosine triphosphate).

motor anything that produces or imparts motion; a machine that provides mechanical power – for example, an electric motor. Machines that burn fuel (petrol, diesel) are usually called engines, but the internal-combustion engine that propels vehicles has long been called a motor, hence 'motoring' and 'motorcar'. Actually the motor is a part of the car engine.

motorboat small, waterborne craft for pleasure cruising or racing, powered by a petrol, diesel, or gas-turbine engine. A boat not

equipped as a motorboat may be converted by a detachable outboard motor. For increased speed, such as in racing, motorboat hulls are designed to skim the water (aquaplane) and reduce frictional resistance. Plastics, steel, and light alloys are now used in construction as well as the traditional wood.

In recent designs, drag is further reduced with hydrofoils and hydrofoils, which enable the hull to rise clear of the water at normal speeds. Notable events in motorboat or 'powerboat' racing include the American Gold Cup in 1947 (over a 145 km/90 mi course) and the Round-Britain race in 1969.

motorcar another term for *car*.

BRAVE NEW WORLD

Aldous Huxley's novel *Brave New World* is set in 632AF – that is, 632 years after Henry Ford mass-produced the motor car.

motorcycle or **motorbike** two-wheeled vehicle propelled by a *petrol* engine. The first successful motorized bicycle was built in France in 1901, and British and US manufacturers first produced motorbikes 1903.

history In 1868 Ernest and Pierre Michaux in France experimented with a steam-powered bicycle, but the steam-power unit was too heavy and cumbersome. Gottlieb Daimler, a German engineer, created the first motorcycle when he installed his lightweight petrol engine in a bicycle frame 1886. Daimler soon lost interest in two wheels in favour of four and went on to pioneer the *car*.

The first really successful two-wheel design was devised by Michael and Eugene Werner in France in 1901. They adopted the classic motorcycle layout with the engine low down between the wheels.

Harley Davidson in the USA and Triumph in the UK began manufacture in 1903. Road races like the Isle of Man TT (Tourist Trophy), established in 1907, helped improve motorcycle design and it soon evolved into more or less its present form. British bikes included the Vincent, BSA, and Norton.

industry In the 1970s British manufacturers were overtaken by Japanese ones, and such motorcycles as Honda, Kawasaki, Suzuki, and Yamaha now dominate the world market. They make a wide variety of machines, from *compets* (lightweights with pedal assistance) to streamlined superbikes capable of speeds up to 250 kph/160 mph. There is still a smaller but thriving Italian motorcycle industry, making more specialist bikes. Laverda, Moto Guzzi, and Ducati continue to manufacture in Italy.

technical description The lightweight bikes are generally powered by a two-stroke petrol engine (see *two-stroke cycle*), while bikes with an engine capacity of 250 cc or more are generally four-strokes (see *four-stroke cycle*). However, many special-use larger bikes (such as those developed for off-road riding and racing) are two-stroke. Most motorcycles are air-cooled – their engines are surrounded by metal fins to offer a large surface area – although some have a water-cooling system similar to that of a car. Most small bikes have single-cylinder engines, but larger machines can have as many as six. The single-cylinder engine is economical and was popular in British manufacture, then the Japanese developed multiple-cylinder models, but there has recently been some return to single-cylinder engines. In the majority of bikes a chain carries the drive from the engine to the rear wheel, though some machines are now fitted with shaft drive.

motor effect tendency of a wire carrying an electric current in a magnetic field to move. The direction of the movement is given by the left-hand rule (see *O Fleming's rules*). This effect is used in the electric *motor*. It also explains why streams of electrons produced, for instance, in a television tube can be directed by electromagnets.

motor nerve in anatomy, any nerve that transmits impulses from the central nervous system to muscles or organs. Motor nerves

cause voluntary and involuntary muscle contractions, and stimulate glands to secrete hormones.

motor neuron disease or **amyotrophic lateral sclerosis** chronic disease in which there is progressive degeneration of the nerve cells which instigate movement. It leads to weakness, wasting, and loss of muscle function and usually proves fatal within two to three years of onset. Motor neuron disease occurs in both hereditary and sporadic forms but its causes remain unclear. A gene believed to be implicated in familial cases was discovered in 1993. In Britain some 1,200 new cases are diagnosed each year.

Results of a US trial in 1995 showed that the drug Myotrophin, a genetically engineered version of a chemical produced in the muscles, slowed deterioration in sufferers of MND by 25%.

Motorola US semiconductor and electronics company. In computing Motorola is best known for the 680x0 series of microprocessors used for many years by the Apple Macintosh range and other computers. Its main microprocessor is the *PowerPC* chip.

motorway main road for fast motor traffic, with two or more lanes in each direction, and with special access points (junctions) fed by slip roads. The first motorway (85 km/53 mi) ran from Milan to Varese, Italy, and was completed in 1924; by 1939 some 500 km/300 mi of motorway (*autostrada*) had been built, although these did not attain the standards of later express highways. In Germany some 2,100 km/1,310 mi of *Autobahnen* had been completed by 1942. After World War II motorways were built in a growing number of countries, for example the USA, France, and the UK. The most ambitious building programme was in the USA, which by 1974 had 70,800 km/44,000 mi of 'expressway'. Construction of new motorways causes much environmental concern.

mouflon wild sheep found in mountain areas of Cyprus, Corsica, and Sardinia. It has woolly underfur in winter, but this is covered by heavy guard hairs. The coat is brown with a white belly and rump. Males have strong, curving horns. (Species *Ovis ammon*, family Bovidae.)

mould furlike growth caused by any of a group of fungi (see *fungus*) living on foodstuffs and other organic matter; a few are parasitic on plants, animals, or each other. Many moulds are of medical or industrial importance, for example, the antibiotic penicillin comes from a type of mould.

moulding use of a pattern, hollow form, or matrix to give a specific shape to something in a plastic or molten state. It is commonly used for shaping plastics, clays, and glass. When metals are used, the process is called *casting*.

In **injection moulding**, molten plastic, for example, is injected into a water-cooled mould and takes the shape of the mould when it solidifies. In **blow moulding**, air is blown into a blob of molten plastic inside a hollow mould. In **compression moulding**, synthetic resin powder is simultaneously heated and pressed into a mould.

moulting periodic shedding of the hair or fur of mammals, feathers of birds, or skin of reptiles. In mammals and birds, moulting is usually seasonal and is triggered by changes of day length.

The term is also often applied to the shedding of the *exoskeleton* of arthropods, but this is more correctly called *ecdysis*.

mountain natural upward projection of the Earth's surface, higher and steeper than a hill. The process of mountain building (*orogeny*) consists of volcanism, folding, faulting, and thrusting, resulting from the collision and welding together of two tectonic plates (see *plate tectonics*). This process deforms the rock and compresses it between the two plates into mountain chains.

mountain ash or **rowan** European flowering tree. It grows to 15 m/50 ft and has pinnate leaves (leaflets growing either side of the stem) and large clusters of whitish flowers, followed by scarlet berries in autumn. (*Sorbus aucuparia*, family Rosaceae.)

In Australia, the tallest growing hardwood species in the world (*Eucalyptus regnans*), found in forests of Victoria, is called mountain ash.

mountain devil woody shrub *Lambertia formosa*, family Proteaceae, of sandstone areas of New South Wales, Australia. It

has a red, tubular flower which develops into a woody 'horned devil' seed pod.

mountain gorilla highly endangered ape found in bamboo and rainforest on the Rwanda, Congo (formerly Zaire), and Uganda borders in central Africa, with a total population of around 600 (1995). It is threatened by deforestation and illegal hunting for skins and the zoo trade. (Subspecies *Gorilla gorilla beringei*.)

mountain lion another name for the puma.

MOUNTAIN LION

Good profile of *Felis concolor*, largest cat in the USA. The contents include a description, information on habitat, diet, hunting technique, reproduction, and survival threats. Among the interesting facts in this well-written account is that there are some hundred indigenous names for this common wildcat and that the purr of the puma is 20 times louder than that of the domestic cat.

Mount Palomar astronomical observatory, 80 km/50 mi NE of San Diego, California, USA. It has a 5-m/200-in diameter reflector called the Hale. Completed in 1948, it was the world's premier observatory during the 1950s.

Mount Stromlo Observatory astronomical observatory established in Canberra, Australia, in 1923. Important observations

have been made there on the Magellanic Clouds, which can be seen clearly from southern Australia.

Mount Wilson site near Los Angeles, California, of the 2.5 m/100 in Hooker telescope, opened in 1917, with which Edwin Hubble discovered the expansion of the universe. Two solar telescopes in towers 18.3 m/60 ft and 45.7 m/150 ft tall, and a 1.5 m/60 in reflector opened in 1908, also operate there.

mouse in computing, an input device used to control a pointer on a computer screen. It is a feature of graphical user interface (GUI) systems. The mouse is about the size of a pack of playing cards, is connected to the computer by a wire, and incorporates one or more buttons that can be pressed. Moving the mouse across a flat surface causes a corresponding movement of the pointer. In this way, the operator can manipulate objects on the screen and make menu selections.

The mouse was invented 1963 at the Stanford Research Institute, USA, by Douglas Engelbart, and developed by the Xerox Corporation in the 1970s. The first was made of wood; the Microsoft mouse was introduced in 1983, and the Apple Macintosh mouse in 1984. Mice work either mechanically (with electrical contacts to sense the movement in two planes of a ball on a level surface), or optically (photocells detecting movement by recording light reflected from a grid on which the mouse is moved).

MOUNT STROMLO AND SIDING SPRING OBSERVATORIES

<http://msowww.anu.edu.au/>

Searchable site of Australia's leading observatory. In addition to scientific data of interest only to astronomers, there is general information on the research work being undertaken, downloadable images of space, and information about the observatory.

mouse in zoology, one of a number of small rodents with small ears and a long, thin tail. The house mouse (*Mus musculus*) is distributed worldwide. It is 75 mm/3 in long, with a naked tail of the same length, and has a grey-brown body. (Family Muridae.)

mousebird any of a family of small crested birds found only in Africa. They have hairlike feathers, long tails, and move with a mouse-like agility. The largest is the **blue-naped mousebird** (*Colius macrourus*), about 35 cm/14 in long. (Family Coliidae, order Coliiformes.)

Moustier, Le rock shelter in the Dordogne, SW France, with prehistoric remains. It gave the name Mousterian to a type of flint-tool culture associated with Neanderthal sites of 100,000–40,000 years ago.

mouth cavity forming the entrance to the digestive tract. In land vertebrates, air from the nostrils enters the mouth cavity to pass down the trachea. The mouth in mammals is enclosed by the jaws, cheeks, and palate.

moving-coil meter instrument used to detect and measure electrical current. A coil of wire pivoted between the poles of a permanent magnet is turned by the motor effect of an electric current (by which a force acts on a wire carrying a current in a magnetic field). The extent to which the coil turns can then be related to the magnitude of the current.

The sensitivity of the instrument depends directly upon the strength of the permanent magnet used, the number of turns making up the moving coil, and the coil's area. It depends inversely upon the strength of the controlling springs used to restrain the rotation of the coil. By the addition of a suitable resistor, a moving-coil meter can be adapted to read potential difference in volts.

moving-coil meter A simple moving-coil meter. Direct electric current (DC) flowing through the wire coil combined with the presence of a magnetic field causes the coil to rotate; this in turn moves a pointer across a calibrated scale so that the degree of rotation can be related to the magnitude of the current.

mower an implement used to cut grass crops or lawns. Agricultural mowers used for haymaking have a long reciprocating knife leaving a broad swathe that will dry in the sun. Mowers used for cutting silage have one or more rotary blades that leave a deep pile of grass suitable for immediate loading. The rotary blade has also been adapted to lawnmowers, replacing the older mechanism of a cylinder with cutting bars attached.

mp in chemistry, abbreviation for **melting point**.

MPC (abbreviation for **Multimedia PC**) standard defining the minimum specification for developing and running CD-ROM

software. It has been rendered largely obsolete by the fact that most of today's PCs include multimedia features as a matter of course. The current MPC specification, MPC III, requires at least 8 MB of RAM, a 75MHz Pentium processor, a VGA monitor, and a quad-speed CD-ROM disc drive.

MPEG (pronounced 'empeg'; acronym for **Moving Picture Experts Group**) in computing, committee of the International Standards Organisation, formed in 1988, that sets standards for digital audio and video compression; hence, any file that has been compressed using those standards. The MPEG-1 is the standard for the digital coding of video pictures for CD recording; MPEG-2 is a common standard for broadcast-quality video; and MPEG-4 for Internet telephony. (There is no MPEG-3 as it was absorbed into MPEG-2.)

MPR-II (*Mat och ProRad*) in computing, Swedish standard that limits the amount of possibly harmful electromagnetic radiation that may be produced by visual display units (VDUs). A monitor tested for MPR-II compliance should have low emission rates.

MSCDEX.EXE (**Microsoft Compact Disc Extensions**) in computing, device driver used by Microsoft MS-DOS and Windows 3 to provide access to files on CD-ROM drives as though they were on a hard drive or floppy disc.

MS-DOS (abbreviation for **Microsoft Disc Operating System**) computer operating system produced by Microsoft Corporation, widely used on microcomputers with Intel x 86 and Pentium family microprocessors. A version called PC-DOS is sold by IBM specifically for its personal computers. MS-DOS and PC-DOS are usually referred to as DOS. MS-DOS first appeared in 1981, and was similar to an earlier system from Digital Research called CP/M.

MTBF abbreviation for **mean time between failures**, the statistically average time a component can be used before it goes wrong. The MTBF of a computer hard disc, for example, is around 150,000 hours.

mucous membrane thin skin lining all animal body cavities and canals that come into contact with the air (for example, eyelids, breathing and digestive passages, genital tract). It secretes mucus, a moistening, lubricating, and protective fluid.

mucus lubricating and protective fluid, secreted by mucous membranes in many different parts of the body. In the gut, mucus smooths the passage of food and keeps potentially damaging digestive enzymes away from the gut lining. In the lungs, it traps airborne particles so that they can be expelled.

MUD (acronym for **multi-user dungeon** or **multi-user domain**) in computing, interactive multi-player game, played via the Internet or modem connection to one of the participating computers. MUD players typically have to solve puzzles, avoid traps, fight other participants and carry out various tasks to achieve their goals.

mudfish another name for the bowfin.

mudnester any of an Australian group of birds that make their nests from mud, including the apostle bird (*Struthidea cinerea*) (so called from its appearance in little flocks of about 12), the white-winged gould (*Corcorax melanorhamphos*), and the magpie lark (*Gralina cyanoleuca*).

mudpuppy any of five species of brownish salamanders, living in fresh water in North America. They all breathe in water using external gills. The species *N. maculatus* is about 20 cm/8 in long. Mudpuppies eat fish, snails, and other invertebrates. (Genus *Necturus*, family Proteidae.)

mudskipper any of a group of fishes belonging to the goby family, found in brackish water and shores in the tropics, except for the Americas. It can walk or climb over mudflats, using its strong pectoral (chest) fins as legs, and has eyes set close together on top of the head. It grows up to 30 cm/12 in long. (Genus *Periophthalmus*, family Gobiidae.)

MUDSKIPPER

There is a fish that can climb trees. The mudskipper spends three-quarters of its time out of water. Malaysian mudskippers live in mangrove swamps, where they climb among the tangled stems and roots, and sometimes into the branches.

mudstone fine-grained sedimentary rock made up of clay- to silt-sized particles (up to 0.0625 mm/0.0025 in).

mulberry any of a group of trees consisting of a dozen species, including the black mulberry (*M. nigra*). It is native to W Asia and has heart-shaped, toothed leaves and spikes of whitish flowers. It is widely cultivated for its compound fruits, which resemble raspberries. The leaves of the Asiatic white mulberry (*M. alba*) are those used in feeding silkworms. (Genus *Morus*, family Moraceae.)

mule hybrid animal, usually the offspring of a male ass and a female horse.

mulga Aboriginal name for various wattles and particularly *Acacia aneura* which covers large arid areas of inland Australia giving a characteristic greyness to the landscape and providing drought fodder for sheep.

Mullard Radio Astronomy Observatory radio observatory of the University of Cambridge, England. Its main instrument is the Ryle Telescope, eight dishes 12.8 m/42 ft wide in a line of 5 km/3 mi long, opened in 1972.

mullein any of a group of daisy-like plants belonging to the figwort family. The great mullein (*V. thapsus*) has lance-shaped leaves 30 cm/12 in or more in length, covered in woolly down, and a large spike of yellow flowers. It is found in Europe and Asia and is naturalized in North America. (Genus *Verbascum*, family Scrophulariaceae.)

mullet either of two species of fish. The red mullet (*Mullus surmuletus*) is found in the Mediterranean and warm Atlantic as far north as the English Channel. It is about 40 cm/16 in long, red with yellow stripes, and has long barbels (sensitive bristles) round the mouth. (Family Mullidae.)

The grey mullet (*Crenimugil labrosus*) lives in ponds and estuaries. It is greyish above, with horizontal dark stripes, and grows to 60 cm/24 in. (Family Mugilidae.)

multicasting in computing, sending a simultaneous message across a network to two or more workstations.

multimedia computerized method of presenting information by combining audio and video components using text, sound, and graphics (still, animated, and video sequences). For example, a multimedia database of musical instruments may allow a user not only to search and retrieve text about a particular instrument but also to see pictures of it and hear it play a piece of music. Multimedia applications emphasize interactivity between the computer and the user.

As graphics, video, and audio are extremely demanding of storage space, multimedia PCs are usually fitted with CD-ROM drives because of the high storage capacity of CD-ROM discs.

In the mid-1990s developments in compression techniques and software made it possible to incorporate multimedia elements into Internet Web sites.

multiple birth in humans, the production of more than two babies from one pregnancy. Multiple births can be caused by more than two eggs being produced and fertilized (often as the result of hormone therapy to assist pregnancy), or by a single fertilized egg dividing more than once before implantation. See also *twins*.

Multiple Mirror Telescope telescope on Mount Hopkins, Arizona, USA, opened in 1979, consisting of six 1.83 m/72 in mirrors mounted in a hexagon, the light-collecting area of which

equals that of a single mirror of 4.5 m/176 in diameter. It is planned to replace the six mirrors with a single mirror 6.5 m/256 in wide.

multiple personality disorder (MPD) psychiatric disorder wherein the patient exhibits two or more personalities. Personalities can be widely differing, with the same patient switching between the personalities of children and adults of different ages, sexes, and temperaments. Each personality is distinct, and often unaware of the others. MPD may occur as a result of child abuse, though not all psychiatrists accept that it is a genuine disorder.

multiple proportions, law of in chemistry, the principle that if two elements combine with each other to form more than one compound, then the ratio of the masses of one of them that combine with a particular mass of the other is a small whole number.

multiple sclerosis (MS) or *disseminated sclerosis* incurable chronic disease of the central nervous system, occurring in young or middle adulthood. Most prevalent in temperate zones, it affects more women than men. It is characterized by degeneration of the myelin sheath that surrounds nerves in the brain and spinal cord.

Depending on where the demyelination occurs - which nerves are affected - the symptoms of MS can mimic almost any neurological disorder. Typically seen are unsteadiness, ataxia (loss of muscular coordination), weakness, speech difficulties, and rapid involuntary movements of the eyes. The course of the disease is episodic, with frequent intervals of remission. Its cause is unknown, but it may be initiated in childhood by some environmental factor, such as infection, in genetically susceptible people. It has been shown that there is a genetic component: identical twins of MS sufferers have a 1 in 4 chance of developing the disease, compared to the 1 in 1,000 chance for the general population.

In 1993 interferon beta 1b became the first drug to be approved in the United States for treating MS. It reduces the number and severity of relapses, and slows the formation of brain lesions giving hope that it may slow down the progression of the disease.

MULTIPLE SCLEROSIS SUPPORT

Embryonic site run by the British Multiple Sclerosis Society. There is information on the society itself and resources of help to sufferers and their families.

multiplexer in telecommunications, a device that allows a transmission medium to carry a number of separate signals at the same time - enabling, for example, several telephone conversations to be carried by one telephone line, and radio signals to be transmitted in stereo.

In **frequency-division multiplexing**, signals of different frequencies, each carrying a different message, are transmitted.

Electrical frequency filters separate the message at the receiving station. In **time-division multiplexing**, the messages are broken into sections and the sections of several messages interleaved during transmission. *Pulse-code modulation* allows hundreds of messages to be sent simultaneously over a single link.

multiplication one of the four basic operations of arithmetic, usually written in the form $a \times b$ or ab , and involving repeated addition in the sense that a is added to itself b times. Multiplication obeys commutative, associative, and distributive laws (the latter over addition) and every number (except 0) has a multiplicative inverse. The number 1 is the identity for multiplication.

multisession in computing, the ability of a compact disc or other *WORM* ('write once, read many times') medium, to record information at different times. Multisession technology allows archives to be built up gradually, as in the *PhotoCD* system, where users can progressively fill up a CD as they take pictures.

multistage rocket rocket launch vehicle made up of several rocket stages (often three) joined end to end. The bottom stage fires

first, boosting the vehicle to high speed, then it falls away. The next stage fires, thrusting the now lighter vehicle even faster. The remaining stages fire and fall away in turn, boosting the vehicle's payload (cargo) to an orbital speed that can reach 28,000 kph/17,500 mph.

multitasking or **multiprogramming** in computing, a system in which one processor appears to run several different programs (or different parts of the same program) at the same time. All the programs are held in memory together and each is allowed to run for a certain period.

For example, one program may run while other programs are waiting for a peripheral device to work or for input from an operator.

The ability to multitask depends on the operating system rather than the type of computer. UNIX is one of the commonest.

multi-threading in computing, executing two or more threads, or sections, of a program at a time. Multi-threading is much faster than multiprocessing because it switches very quickly between instructions.

multi-user dungeon in computing, interactive game usually abbreviated to MUD.

multi-user shared hallucination in computing, interactive game usually abbreviated to MUSH.

multiuser system or **multiaccess system** in computing, an operating system that enables several users to access centrally-stored data and programs simultaneously over a network. Each user has a terminal, which may be local (connected directly to the computer) or remote (connected to the computer via a modem and a telephone line).

Multiaccess is usually achieved by **time-sharing**: the computer switches very rapidly between terminals and programs so that each user has sole use of the computer for only a fraction of a second but can work as if she or he had continuous access.

Multi-user systems are becoming increasingly common in the workplace, and have many advantages – such as enabling employees to refer to and update a shared corporate database.

mummy any dead body, human or animal, that has been naturally or artificially preserved. Natural mummification can occur through freezing (for example, mammoths in glacial ice from 25,000 years ago), drying, or preservation in bogs or oil seeps. Artificial mummification may be achieved by embalming (for example, the mummies of ancient Egypt) or by freeze-drying.

MUMMY

Thousands of mummified cats were discovered in an underground cavern at Ben Hassan, Egypt, in 1889. Most were sold off for use as fertilizer.

mumps or **infectious parotitis** virus infection marked by fever, pain, and swelling of one or both parotid salivary glands (situated in front of the ears). It is usually shortlived in children, although meningitis is a possible complication. In adults the symptoms are more serious and it may cause sterility in men.

Mumps is the most common cause of meningitis in children, but it follows a much milder course than bacterial meningitis, and a complete recovery is usual. Rarely, mumps meningitis may lead to deafness. An effective vaccine against mumps, measles, and rubella (MMR vaccine) is now offered for children aged 18 months.

Münchhausen's syndrome emotional disorder in which a patient feigns or invents symptoms to secure medical treatment. It is the chronic form of factitious disorder, which is more common, and probably underdiagnosed. In some cases the patient will secretly ingest substances to produce real symptoms. It was named

after the exaggerated tales of Baron Münchhausen. Some patients invent symptoms for their children, a phenomenon known as Münchhausen's by proxy.

Munsterlander breed of gundog developed as two types – large (58–62 cm/23–24 in) and small (up to 56 cm/22 in) – in the early 20th century in Westphalia, Germany. The Small Munsterlander has a white coat with a brown head and brown patches and spots on the body. The Large Munsterlander has similar markings in black and white. Both have moderately long, wavy coats, drooping ears, and long tails.

muntjac any of about six species of small deer found in SE Asia. They live mostly in dense vegetation and do not form herds. The males have short spined antlers and two sharp canine teeth forming tusks. They are sometimes called 'barking deer' because of their voices. (Genus *Muntiacus*.)

muon an elementary particle similar to the electron except for its mass which is 207 times greater than that of the electron. It has a half-life of 2 millionths of a second, decaying into electrons and neutrinos. The muon was originally thought to be a meson and is thus sometimes called a mu meson, although current opinion is that it is a lepton.

Murray cod Australian freshwater fish that grows to about 2 m/6 ft. It is named after the river in which it is found. (Species *Maccullochella macquariensis*.)

The function of muscle is to pull and not to push, except in the case of the genitals and the tongue.

LEONARDO DA VINCI Italian painter, sculptor, architect, engineer, and scientist.
The Notebooks of Leonardo da Vinci vol 1, ch 3

muscle contractile animal tissue that produces locomotion and power, and maintains the movement of body substances. Muscle is made of long cells that can contract to between one-half and one-third of their relaxed length.

Stripped (or striated) muscles are activated by motor nerves under voluntary control; their ends are usually attached via tendons to bones.

muscle The movements of the arm depend on two muscles, the biceps and the triceps. To lift the arm, the biceps shortens and the triceps lengthens. To lower the arm, the opposite occurs: the biceps lengthens and the triceps shortens.

muscle Muscles make up 35–45% of our body weight; there are over 650 skeletal muscles. Muscle cells may be up to 20 cm/0.8 in long. They are arranged in bundles, fibres, fibrils, and myofibrils.

Involuntary or smooth muscles are controlled by motor nerves of the autonomic nervous system, and are located in the gut, blood vessels, iris, and various ducts.

Cardiac muscle occurs only in the heart, and is also controlled by the autonomic nervous system.

muscovite white mica, $\text{KAl}_2\text{Si}_2\text{AlO}_{10}(\text{OH},\text{F})_2$, a common silicate mineral. It is colourless to silvery white with shiny surfaces, and like all micas it splits into thin flakes along its one perfect cleavage. Muscovite is a metamorphic mineral occurring mainly in schists; it is also found in some granites, and appears as shiny flakes on bedding planes of some sandstones.

muscular dystrophy any of a group of inherited chronic muscle disorders marked by weakening and wasting of muscle. Muscle fibres degenerate, to be replaced by fatty tissue, although the nerve supply remains unimpaired. Death occurs in early adult life.

The commonest form, Duchenne muscular dystrophy, strikes boys (1 in 3,000), usually before the age of four. The child develops a waddling gait and an inward curvature (lordosis) of the lumbar spine. The muscles affected by dystrophy and the rate of progress vary. There is no cure, but physical treatments can minimize disability. Death usually occurs before the age of 20.

MUSE (abbreviation for **multi-user shared environment**) in computing, type of MUD.

MUSH (acronym for **multi-user shared hallucination**) in computing, a MUD (multi-user dungeon) that can be altered by the players. Participants in a MUSH construct new environments or 'rooms' and devise new obstacles to challenge other players.

mushroom fruiting body of certain fungi (see *fungus*), consisting of an upright stem and a spore-producing cap with radiating gills on the underside. There are many edible species belonging to the genus *Agaricus*, including the field mushroom (*A. campestris*). See also *toadstool*.

musical instrument digital interface manufacturer's standard for digital music equipment; see *MIDI*.

music therapy use of music as an adjunct to relaxation therapy, or in psychotherapy to elicit expressions of suppressed emotions

by prompting patients to dance, shout, laugh, cry, or whatever, in response.

Music therapists are most frequently called upon to help the mentally or physically disabled; for instance, patients suffering from speech difficulties or autism may be enabled to express themselves more effectively by making musical sounds, and music can help the physically disabled to develop better motor control.

musk in botany, perennial plant whose small oblong leaves give off the musky scent from which it takes its name; it is also called **monkey flower**. The name 'musk' is also given to several other plants with a similar scent, including the musk mallow (*Malva moschata*) and the musk rose (*Rosa moschata*). (*Mimulus moschatus*, family Scrophulariaceae.)

musk deer any of three species of small deer native to the mountains of central and NE Asia. A solitary animal, the musk deer is about 80–100 cm/30–40 in, sure-footed, and has large ears and no antlers. Males have long tusklake upper canine teeth. They are hunted and farmed for their musk (a waxy substance secreted by the male from a gland in the stomach area), which is used as medicine or perfume. (Genus *Moschus*.)

musk ox ruminant (cud-chewing) mammal native to the Arctic regions of North America. It has characteristics of both sheep and oxen, is about the size of a small domestic cow, and has long brown hair. At certain seasons it has a musky smell. (Species *Oribos moschatus*, family Bovidae.)

Its underwool (*qivut*) is almost as fine as that of the vicuna, and musk-ox farms have been established in Alaska, Quebec, and Norway to harvest this wool.

muskrat North American rodent, about 30 cm/12 in long, that lives beside streams, rivers, and lakes. It has webbed hind feet, a side-to-side flattened tail, and shiny, light-brown fur. It builds up a store of food, plastering it over with mud, for winter consumption. It is hunted for its fur. (Species *Ondatra zibethicus*, family Cricetidae.)

mussel any of a group of shellfish, some of which are edible, such as the common mussel (*Mytilus edulis*) which has a blue-black

hinged shell and is found in clusters attached to rocks around the N Atlantic and American coasts. Mussels are bivalve molluscs. (Class Bivalvia, phylum Mollusca.)

Freshwater pearl mussels, such as the species *Unio margaritifera*, are found in some North American and European rivers. The larvae of the North American freshwater mussel *Lampsilis perovallata* are parasitic, living on the gills or fins of freshwater bass. The larvae of the British swan mussel (*Anodonta cygnea*) are also parasitic. *Margaritifera margaritifera* became a protected species in 1991 having suffered from pollution and from amateur fishers who, unlike professionals, are not able to extract the pearl without killing the mussel itself. The **green-lipped mussel**, found only off New Zealand, produces an extract that is used in the treatment of arthritis.

MUSSEL

The European freshwater mussel *Margaritifera margaritifera* lives for at least 90 years.

mustard any of several annual plants belonging to the cress family, with seed-bearing pods and sweet-smelling yellow flowers. Brown and white mustard are cultivated as an accompaniment to food in Europe and North America. The seeds of brown mustard (*B. juncea*) and white mustard (*Sinapis alba*) are used in the preparation of table mustard. (Genus mainly *Brassica*, family Cruciferae.)

Brown mustard replaced black mustard (*B. nigra*) in commercial mustard products during the 1950s with the introduction of mechanized harvesting. *B. nigra* is unsuitable for mechanized harvesting since its pods split open to release their seeds; those of *B. juncea* do not. Table mustard is most often used as an accompaniment to meat, although it can also be used in sauces and dressings, and with fish. **English mustard** is made from finely milled brown and white mustard seed to which ground turmeric is added for colour. French Dijon mustard contains brown mustard seed, verjuice (the juice of unripe grapes), oil, and white wine. Other varieties are made with vinegar, and may be flavoured with herbs or garlic. The seedlings of white mustard are used in salads. White mustard is also sometimes grown by farmers and ploughed back to enrich the soil. Brown mustard is grown on a large scale as an oil-seed crop throughout India, China, and S Russia.

mutation any substance that increases the rate of gene mutation. A mutagen may also act as a carcinogen.

mutation in biology, a change in the genes produced by a change in the ϕ DNA that makes up the hereditary material of all living organisms. Mutations, the raw material of evolution, result from mistakes during replication (copying) of DNA molecules. Only a few improve the organism's performance and are therefore favoured by ϕ natural selection. Mutation rates are increased by certain chemicals and by radiation.

Common mutations include the omission or insertion of a base (one of the chemical subunits of DNA); these are known as point mutations. Larger-scale mutations include removal of a whole segment of DNA or its inversion within the DNA strand. Not all mutations affect the organism, because there is a certain amount of redundancy in the genetic information. If a mutation is 'translated' from DNA into the protein that makes up the organism's structure, it may be in a nonfunctional part of the protein and thus have no detectable effect. This is known as a **neutral mutation**, and is of importance in ϕ molecular clock studies because such mutations tend to accumulate gradually as time passes. Some mutations do affect genes that control protein production or functional parts of protein, and most of these are lethal to the organism.

mutton bird any of various shearwaters and petrels that breed in burrows on Australasian islands. The young are very fat, and are killed for food and oil.

motional induction in physics, the production of an electromotive force (emf) or voltage in an electric circuit caused by a changing

ϕ magnetic flux in a neighbouring circuit. The two circuits are often coils of wire, as in a transformer, and the size of the induced emf depends largely on the numbers of turns of wire in each of the coils.

mutualism or **ϕ sybiosis** an association between two organisms of different species whereby both profit from the relationship.

myall Aboriginal word for various wattle trees such as the weeping myall *Acacia pendula* found in semi-arid areas of the E states of Australia and the coastal myall *A. glaucescens* of New South Wales and Queensland.

myasthenia gravis in medicine, an uncommon condition characterized by loss of muscle power, especially in the face and neck. The muscles tire rapidly and fail to respond to repeated nervous stimulation. ϕ Autoimmunity is the cause.

mycelium interwoven mass of threadlike filaments or ϕ hyphae, forming the main body of most fungi. The reproductive structures, or 'fruiting bodies', grow from the mycelium.

Mycenaean civilization Bronze Age civilization that flourished in Crete, Cyprus, Greece, the Aegean Islands, and W Anatolia about 3000–1000 BC. During this period, magnificent architecture and sophisticated artefacts were produced.

ϕ Mycenaean civilization was strongly influenced by the Minoan from Crete, from about 1600 BC. It continued to thrive, with its centre at Mycenae, after the decline of Crete in about 1400. It was finally overthrown by the Dorian invasions, about 1100. The system of government was by kings, who also monopolized priestly functions. The Mycenaeans have been identified with the Achaeans of Homer; they may also have been the marauding Sea Peoples of Egyptian records.

They used a form of Greek deciphered by Michael Ventris called Linear B, which has been discovered on large numbers of clay tablets containing administrative records. Their palaces were large and luxurious, and their tombs (known as beehive tombs) were massive and impressive monuments. Pottery, frescoes, and metalwork reached a high artistic level. Evidence of the civilization was brought to light by the excavations of Heinrich Schliemann at Troy, Mycenae, and Tiryns (a stronghold on the plain of Argolis) from 1870 onwards, and of Arthur Evans in Crete from 1899.

mycorrhiza mutually beneficial (mutualistic) association occurring between plant roots and a soil fungus. Mycorrhizal roots take up nutrients more efficiently than non-mycorrhizal roots, and the fungus benefits by obtaining carbohydrates from the plant or tree.

An **ectotrophic mycorrhiza** occurs on many tree species, which usually grow much better, most noticeably in the seedling stage, as a result. Typically the roots become repeatedly branched and coral-like, penetrated by hyphae of a surrounding fungal mycelium. In an **endotrophic mycorrhiza**, the growth of the fungus is mainly inside the root, as in orchids. Such plants do not usually grow properly, and may not even germinate, unless the appropriate fungus is present.

Research by UK ecologists in 1996 showed that mycorrhizal fungi provides protection against ϕ nematode worms that feed on plant roots, as well as pathogenic fungi.

myelin sheath insulating layer that surrounds nerve cells in vertebrate animals. It serves to speed up the passage of nerve impulses.

Myelin is made up of fats and proteins and is formed from up to a hundred layers, laid down by special cells, the Schwann cells.

mynah any of various tropical starlings found in SE Asia. The glossy black hill mynah (*Gracula religiosa*) of India can realistically mimic sounds and human speech. It is up to 40 cm/16 in long with yellow wattles (loose folds of skin) on the head, and a yellow bill and legs. (Family Sturnidae, order Passeriformes.)

myoglobin globular protein, closely related to ϕ haemoglobin and located in vertebrate muscle. Oxygen binds to myoglobin and is released only when the haemoglobin can no longer supply adequate oxygen to muscle cells.

myopia or *short-sightedness* defect of the eye in which a person can see clearly only those objects that are close up. It is caused either by the eyeball being too long or by the cornea and lens system of the eye being too powerful, both of which cause the images of distant objects to be formed in front of the retina instead of on it. Nearby objects are sharply perceived. Myopia can be corrected by suitable glasses or contact lenses.

myopia, low-luminance poor night vision. About 20% of people have poor vision in twilight and nearly 50% in the dark. Low-luminance myopia does not show up in normal optical tests, but in 1989 a method was developed of measuring the degree of blurring by projecting images on a screen using a weak laser beam.

myrmecophyte plant that lives in association with a colony of ants and possesses specialized organs in which the ants live. For example, *Myrmecodia*, an epiphytic plant from Malaysia, develops root tubers containing a network of cavities inhabited by ants.

Several species of *Acacia* from tropical America have specialized hollow thorns for the same purpose. This is probably a mutualistic (mutually beneficial) relationship, with the ants helping to protect the plant from other insect pests and in return receiving shelter.

myrrh gum/resin produced by several small trees belonging to the bursera family, especially *C. myrrha*, found in Ethiopia and

Arabia. In ancient times it was used for incense and perfume and in embalming dead bodies. (Genus *Commiphora*, family Burseraceae.)

myrtle any of a group of Old World evergreen shrubs belonging to the myrtle family. The commonly cultivated Mediterranean myrtle (*M. communis*) has oval opposite leaves and white flowers followed by purple berries, all of which are fragrant. (Genus *Myrtus*, family Myrtaceae.)

mystery reproductive syndrome (MRS) viral disease of pigs that causes sows to lose up to 10% of their litter. It was first seen in the USA in 1987 and in Europe in 1991. The symptoms are flu-like.

myxoedema thyroid-deficiency disease developing in adult life, most commonly in middle-aged women. The symptoms include loss of energy and appetite, weight gain, inability to keep warm, mental dullness, and dry, puffy skin. It is reversed by giving the thyroid hormone thyroxine. See also hypothyroidism.

myxomatosis contagious, usually fatal, virus infection of rabbits which causes much suffering. It has been deliberately introduced in the UK and Australia since the 1950s to reduce the rabbit population.

N

n in mathematics, variable used to denote an indefinite number.

nacre another name for mother-of-pearl.

nadir the point on the celestial sphere vertically below the observer and hence diametrically opposite the zenith. The term is used metaphorically to mean the low point of a person's fortunes.

naevus mole, or patch of discoloration on the skin which has been present from birth. There are many different types of naevi, including those composed of a cluster of small blood vessels, such as the 'strawberry mark' (which usually disappears early in life), and the 'port-wine stain'.

A naevus of moderate size is harmless, and such marks can usually be disguised cosmetically unless they are extremely disfiguring, when they can sometimes be removed by cutting out, burning with an electric needle, freezing with carbon dioxide snow, or by argon laser treatment. In rare cases a mole may be a precursor of a malignant melanoma. Any changes in a mole, such as enlargement, itching, soreness, or bleeding, should be reported to a doctor.

naaware in computing, another name for guiltware.

nail in biology, a hard, flat, flexible outgrowth of the digits of primates (humans, monkeys, and apes). Nails are composed of keratin.

name server (abbreviated from *domain name server*) on the Internet, a type of *server* which matches an Internet Protocol address to a *domain* name and vice versa.

Humans remember names, but computers work with numbers. Domain name servers translate between the two, so that a human can type an email address such as janedoe@anywhere.com and the computer can route the message correctly.

NAND gate type of logic gate.

nano- prefix used in SI units of measurement, equivalent to a one-billionth part (10^{-9}). For example, a nanosecond is one-billionth of a second.

nanotechnology experimental technology using individual atoms or molecules as the components of minute machines, measured by the nanometre, or millionth of a millimetre. Nanotechnology research in the 1990s focused on testing molecular structures and refining ways to manipulate atoms using a scanning tunnelling microscope. The ultimate aim is to create very small computers and molecular machines which could perform vital engineering or medical tasks.

The scanning electron microscope can be used to see and position single atoms and molecules, and to drill holes a nanometre (billionth of a metre) across in a variety of materials. The instrument can be used for ultraviolet etching; the entire 28 volumes of the *Encyclopedia Britannica* could be engraved on the head of a pin. In the USA a complete electric motor has been built, which is less than 0.1 nm across with a top speed of 600,000 rpm. It is etched out of silicon, using the ordinary methods of chip manufacturers.

naphtha the mixtures of hydrocarbons obtained by destructive distillation of petroleum, coal tar, and shale oil. It is a raw material for the petrochemical and plastics industries. The term was originally applied to naturally occurring liquid hydrocarbons.

naphthalene $C_{10}H_8$ solid, white, shiny, aromatic hydrocarbon obtained from coal tar. The smell of moth-balls is due to their naphthalene content. It is used in making indigo and certain azo dyes, as a mild disinfectant, and as an insecticide.

Napier, John (1550-1617)

8th Laird of Merchiston
Scottish mathematician who invented logarithms in 1614 and 'Napier's bones', an early mechanical calculating device for multiplication and division.

It was Napier who first used and then popularized the decimal point to separate the whole number part from the fractional part of a number.

Mary Evans Picture Library

narcissism in psychology, an exaggeration of normal self-respect and self-involvement which may amount to mental disorder when it precludes relationships with other people.

narcissus any of a group of bulbous plants belonging to the amaryllis family. Species include the daffodil, jonquil, and narcissus. All have flowers with a cup or trumpet projecting from the centre. (Genus *Narcissus*, family Amaryllidaceae.)

narcotic pain-relieving and sleep-inducing drug. The term is usually applied to heroin, morphine, and other opium derivatives, but may also be used for other drugs which depress brain activity, including anaesthetic agents and hypnotics.

narwhal toothed whale found only in the Arctic Ocean. It grows to 5 m/16 ft long, has a grey and black body, a small head, and short flippers. The male has a single spiral tusk growing straight out in front of its upper lip that can measure up to 2.7 m/9 ft long. (Species *Monodon monoceros*, family Monodontidae.)

NASA acronym for *National Aeronautics and Space Administration*, US government agency for spaceflight and aeronautical research, founded in 1958 by the National Aeronautics and Space Act. Its headquarters are in Washington DC and its main installation is at the Kennedy Space Center in Florida. NASA's early planetary and lunar programmes included Pioneer spacecraft from 1958, which gathered data for the later crewed missions, the most famous of which took the first people to the Moon in *Apollo 11* on 16-24 July 1969.

In the early 1990s, NASA moved towards lower-budget 'Discovery missions', which should not exceed a budget of \$150 million (excluding launch costs), nor a development period of three years.

nastic movement plant movement that is caused by an external stimulus, such as light or temperature, but is directionally independent of its source, unlike tropisms. Nastic movements occur as a result of changes in water pressure within specialized cells or differing rates of growth in parts of the plant.

Examples include the opening and closing of crocus flowers following an increase or decrease in temperature (thermonasty), and the opening and closing of evening-primrose *Oenothera* flowers on exposure to dark and light (photnasty).

The leaf movements of the Venus flytrap *Dionaea muscipula* following a tactile stimulus, and the rapid collapse of the leaflets of the sensitive plant *Mimosa pudica* are examples of haptonomy. Sleep movements, where the leaves or flowers of some plants adopt a different position at night, are described as nyctinasty. Other movement types include hydronasty, in response to a change in the atmospheric humidity, and chemonasty, in response to a chemical stimulus.

nasturtium any of a group of plants that includes watercress (*N. officinale*), a perennial aquatic plant of Europe and Asia, grown as a salad crop. Belonging to a different family altogether, the South American trailing nasturtiums include the cultivated species *T. majus*, with orange, scarlet, or yellow flowers, and *T. minus*, which has smaller flowers. (Genus *Nasturtium*, family Cruciferae; South American genus *Tropaeolum*, family Tropaeaceae.)

National Cash Register Company (NCR) US company founded in 1884 in Dayton, Ohio, by John H Patterson (1844-1922), originally as a business manufacturing 'thief-catchers' (devices to stop cashiers and sales clerks robbing tills). By 1910, largely due to Patterson's aggressive sales force, his factory was producing 90% of the USA's cash registers, and the company still retains its lead today.

National Computing Centre (NCC) UK centre set up in 1966 to offer advice and technical assistance to businesses on every aspect of information technology. The NCC is also the world's largest provider of escrow services for source code, a service necessary for businesses using custom-built software from a single supplier. It is based in Manchester.

National Education and Research Network in computing, communications backbone usually abbreviated to NERN.

natural grid the network of cables, carried overhead on pylons or buried under the ground, that connects consumers of electrical power to power stations, and interconnects the power stations. It ensures that power can be made available to all customers at any time, allowing demand to be shared by several power stations, and particular power stations to be shut down for maintenance work from time to time.

National Information Infrastructure (NII) in computing, US network, often referred to as the information superhighway, that embraces every component of the Internet - from the satellites that carry the data to the PCs and telephone links that Americans use to access the Net. The NII was a 1995 US government initiative, the implementation of which was left to the private sector. The project aims to give all Americans access to the country's information and computing resources.

National Institute of Standards and Technology (NIST) US body that plays an important role in setting computing and communications standards. NIST's Advanced Technology Program, which gives financial assistance to companies developing technologically advanced products during the research and development period, has played a considerable role in nurturing the US computer industry.

National Physical Laboratory (NPL) research establishment, set up in 1900 at Teddington, England, under the control of the Department of Industry; the chair of the visiting committee is the president of the Royal Society. In 1944 it began work on a project to construct a digital computer, called the ACE (Automatic Computing Engine), one of the first ever built. It was completed in 1950, embodying many of the ideas of British mathematician Alan Turing. It was privatized in 1995.

National Rivers Authority (NRA) UK government agency launched in 1989. It had responsibility for managing water resources, investigating and regulating pollution, and taking over flood controls and land drainage from the former ten regional water authorities of England and Wales. In April 1996 the NRA was replaced by the Environment Agency, having begun to establish a reputation for being supportive to wildlife projects and tough on polluters.

Following a judicial review of the authority 1991 for allegedly failing to carry out its statutory duty to protect rivers and seas from pollution, river quality improved by 26% 1993-96.

native companion another name for the *ð*broлга, so called because these birds are often seen in pairs.

native metal or **free metal** any of the metallic elements that occur in nature in the chemically uncombined or elemental form (in addition to any combined form). They include bismuth, cobalt, copper, gold, iridium, iron, lead, mercury, nickel, osmium, palladium, platinum, ruthenium, rhodium, tin, and silver. Some are commonly found in the free state, such as gold; others occur almost exclusively in the combined state, but under unusual conditions do occur as native metals, such as mercury. Examples of native non-metals are carbon and sulphur.

Natural Environment Research Council (NERC) UK organization established by royal charter 1965 to undertake and support research in the earth sciences, to give advice both on exploiting natural resources and on protecting the environment, and to support education and training of scientists in these fields of study.

Research areas include geothermal energy, industrial pollution, waste disposal, satellite surveying, acid rain, biotechnology, atmospheric circulation, and climate. Research is carried out principally within the UK but also in Antarctica and in many developing countries. It comprises 13 research bodies.

natural frequency the frequency at which a mechanical system will vibrate freely. A pendulum, for example, always oscillates at the same frequency when set in motion. More complicated systems, such as bridges, also vibrate with a fixed natural frequency. If a varying force with a frequency equal to the natural frequency is applied to such an object the vibrations can become violent, a phenomenon known as resonance.

natural gas mixture of flammable gases found in the Earth's crust (often in association with petroleum). It is one of the world's three main fossil fuels (with coal and oil). Natural gas is a mixture of hydrocarbons, chiefly methane (80%), with ethane, butane, and propane. Natural gas is usually transported from its source by pipeline, although it may be liquefied for transport and storage and is, therefore, often used in remote areas where other fuels are scarce and expensive. Prior to transportation, butane and propane are removed and liquefied to form 'bottled gas'.

Natural History Museum British museum containing departments of zoology, entomology, geology, mineralogy, palaeontology, and botany. Based in London from 1856, the museum is housed in a building designed by Alfred Waterhouse and erected 1873-80 in South Kensington, London; it has no administrative connection with the British Museum. In 1985 the Natural History Museum was merged with the Geological Museum.

natural logarithm in mathematics, the exponent of a number expressed to base e, where e represents the irrational number 2.71828...

Natural logarithms are also called Napierian logarithms, after their inventor, the Scottish mathematician John Napier.

natural number one of the set of numbers used for counting. Natural numbers comprise all the positive integers, excluding zero.

natural radioactivity radioactivity generated by those radioactive elements that exist in the Earth's crust. All the elements from polonium (atomic number 84) to uranium (atomic number 92) are radioactive.

Radioisotopes of some lighter elements are also found in nature (for example potassium-40). See background radiation.

natural selection the process whereby gene frequencies in a population change through certain individuals producing more descendants than others because they are better able to survive and reproduce in their environment.

The accumulated effect of natural selection is to produce adaptations such as the insulating coat of a polar bear or the spadefoot forelimbs of a mole. The process is slow, relying firstly on random variation in the genes of an organism being produced by mutation and secondly on the genetic recombination of sexual reproduction. It was recognized by Charles Darwin and English naturalist Alfred Russel Wallace as the main process driving evolution.

nature the living world, including plants, animals, fungi, and all microorganisms, and naturally formed features of the landscape, such as mountains and rivers.

Whatever Nature has in store for mankind, unpleasant it may be, man must accept, for ignorance is never better than knowledge.

ENRICO FERMI Italian-born US physicist.
In *Laura Fermi Atoms in the Family* 1954

nature-nurture controversy or **environment-heredity controversy** long-standing dispute among philosophers and psychologists over the relative importance of environment, that is, upbringing, experience, and learning ('nurture'), and heredity, that is, genetic inheritance ('nature'), in determining the make-up of an organism, as related to human personality and intelligence.

One area of contention is the reason for differences between individuals: for example, in performing intelligence tests. The environmentalist position assumes that individuals do not differ significantly in their inherited mental abilities and that subsequent differences are due to learning, or to differences in early experiences. Opponents insist that certain differences in the capacities of individuals (and hence their behaviour) can be attributed to inherited differences in their genetic make-up.

nature reserve area set aside to protect a habitat and the wildlife that lives within it, with only restricted admission for the public. A nature reserve often provides a sanctuary for rare species. The world's largest is Etosha Reserve, Namibia; area 99,520 sq km/38,415 sq mi.

naturopathy in alternative medicine, facilitating of the natural self-healing processes of the body. Naturopaths are the general practitioners (GPs) of alternative medicine and often refer clients to other specialists, particularly in manipulative therapies, to complement their own work of seeking, through diet, the prescription of natural medicines and supplements, and lifestyle counselling, to restore or augment the vitality of the body and thereby its optimum health.

nautical mile unit of distance used in navigation, an internationally agreed-on standard (since 1959) equalling the average length of one minute of arc on a great circle of the Earth, or 1,852 m/6,076.12 ft. The term formerly applied to various units of distance used in navigation.

nautiloid fossil cephalopod mollusc with a straight or coiled chambered shell, and gently curved transverse septa. They range from Upper Cambrian to Recent periods. Nautilus is the only living representative.

classification Nautiloids comprise the subclass Nautiloidea in class Cephalopoda, phylum Mollusca.

nautilus sea animal related to octopuses and squids, with many short, grasping tentacles surrounding a sharp beak, but different in that it has an outer shell. It is a cephalopod, a type of mollusc, and is found in the Indian and Pacific oceans. The well-known *pearl nautilus* (*N. pompilius*) has a chambered spiral shell about 20 cm/8 in in diameter. Its body occupies the outer chamber. (Genus *Nautilus*, class Cephalopoda.)

Paper nautilus is another name for the Cargonaut, a type of orotop.

Nautilus the name of the world's first nuclear-powered submarine, launched by the USA in 1954; it sailed under the icecap to the North Pole.

navel or **umbilicus** small indentation in the centre of the abdomen of mammals, marking the site of attachment of the umbilical cord, which connects the fetus to the placenta.

navigate in computing, to find your way around hyperspace or a hypertext document, especially when using a browser.

BACTERIA

The freshwater bacterium *Aquaspirillum magnetotacticum* uses the Earth's magnetic field to navigate. The bacteria in the northern hemisphere travel north (downwards) if dislodged from the mud at the bottom of rivers and lakes; those in the southern hemisphere head south.

navigation the science and technology of finding the position, course, and distance travelled by a ship, plane, or other craft. Traditional methods include the magnetic compass and sextant. Today the gyrocompass is usually used, together with highly sophisticated electronic methods, employing beacons of radio signals, such as Decca, Loran, and Omega. Satellite navigation uses satellites that broadcast time and position signals.

The US global positioning system (GPS) was introduced in 1992. When complete, it will feature 24 Navstar satellites that will enable users (including eventually motorists and walkers) to triangulate their position (from any three satellites) to within 15 m/50 ft.

In 1992, 85 nations agreed to take part in trials of a new navigation system which makes use of surplus military space technology left over from the Cold War. The new system, known as FANS or Future Navigation System, will make use of the 24 Russian Glonass satellites and the 24 US GPS satellites. Small computers will gradually be fitted to civil aircraft to process the signals from the satellite, allowing aircraft to navigate with pinpoint accuracy anywhere in the world. The signals from at least three satellites will guide the craft to within a few metres of accuracy. FANS will be used in conjunction with four Inmarsat satellites to provide worldwide communications between pilots and air-traffic controllers.

If sailing in unfamiliar waters, remember:

navigation, biological the ability of animals or insects to navigate. Although many animals navigate by following established routes or known landmarks, many animals can navigate without such aids; for example, birds can fly several thousand miles back to their nest site, over unknown terrain.

Such feats may be based on compass information derived from the position of the Sun, Moon, or stars, or on the characteristic patterns of Earth's magnetic field.

Biological navigation refers to the ability to navigate both in long-distance migrations and over shorter distances when foraging (for example, the honey bee finding its way from the hive to a nectar site and back). Where reliant on known landmarks, birds may home on features that can be seen from very great distances (such as the cloud caps that often form above isolated mid-ocean islands). Even smells can act as a landmark. Aquatic species like salmon are believed to learn the characteristic taste of the river where they hatch and return to it, often many years later. Brain

cells in some birds have been found to contain ζ magnetite and may therefore be sensitive to the Earth's magnetic field.

navigation map in computing, specialized tool to help users find their way around a Web site. Colourful graphics overlay a hidden grid, like that on a conventional map, containing χ ypertext links. Users navigate by placing their cursor on an image and clicking the mouse, sending a "map reference" back to the Web site which activates a link. Navigation maps give the designer more control over how the page will appear on the screen, and are more attractive than conventional links.

NBS abbreviation for *National Bureau of Standards*, the US federal standards organization, on whose technical standards all US weights and measures are based.

NDA in computing, abbreviation for nondisclosure agreement.

near point the closest position to the eye to which an object may be brought and still be seen clearly. For a normal human eye the near point is about 25 cm; however, it gradually moves further away with age, particularly after the age of 40.

nebula cloud of gas and dust in space. Nebulae are the birth-places of stars, but some nebulae are produced by gas thrown off from dying stars (see ϕ lanetary nebula; ϕ supernova). Nebulae are classified depending on whether they emit, reflect, or absorb light.

An emission nebula, such as the ϕ Orion nebula, glows brightly because its gas is energized by stars that have formed within it. In a reflection nebula, starlight reflects off grains of dust in the nebula, such as surround the stars of the ϕ Pleiades cluster. A dark nebula is a dense cloud, composed of molecular hydrogen, which partially or completely absorbs light behind it. Examples include the Coalsack nebula in ϕ Crux and the Horsehead nebula in Orion.

neck structure between the head and the trunk in animals. In the back of the neck are the upper seven vertebrae of the spinal column, and there are many powerful muscles that support and move the head. In front, the neck region contains the ϕ pharynx and ϕ trachea, and behind these the oesophagus. The large arteries (carotid, temporal, maxillary) and veins (jugular) that supply the brain and head are also located in the neck. The ϕ larynx (voice box) occupies a position where the trachea connects with the pharynx, and one of its cartilages produces the projection known as Adam's apple. The ϕ thyroid gland lies just below the larynx and in front of the upper part of the trachea.

necrosis death or decay of tissue in a particular part of the body, usually due to bacterial poisoning or loss of local blood supply.

nectar sugary liquid secreted by some plants from a nectary, a specialized gland usually situated near the base of the flower. Nectar often accumulates in special pouches or spurs, not always in the same location as the nectary. Nectar attracts insects, birds, bats, and other animals to the flower for ϕ pollination and is the raw material used by bees in the production of honey.

nectarine smooth, shiny-skinned variety of ϕ peach, usually smaller than other peaches and with firmer flesh. It arose from a natural variation of the original form.

needlefish any of a group of bony marine fishes with an elongated body and long jaws lined with many sharp teeth. They live in warm, tropical seas. (Family Belontiidae.)

Néel temperature the temperature at which the ζ susceptibility of an antiferromagnetic material has a maximum value; see also ϕ magnetism.

nematode any of a group of unsegmented ϕ worms that are pointed at both ends, with a tough, smooth outer skin. They include many free-living species found in soil and water, including the sea, but a large number are parasites, such as the roundworms and pinworms that live in humans, or the eelworms that attack plant roots. They differ from ϕ flatworms in that they have two openings to the gut (a mouth and an anus). (Phylum Nematoda.)

Most nematode species are found in deep-sea sediment. Around 13,000 species are known, but a 1995 study by the Natural History Museum, London, based on the analysis of sediment from 17 seabed sites worldwide, estimated that nematodes may make up as much as 75% of all species, with there being an estimated 100 million species. Some are anhydrobiotic, which means they can survive becoming dehydrated, entering a state of suspended animation until they are rehydrated.

nemesis theory theory of animal extinction, suggesting that a sister star to the Sun caused the extinction of the dinosaurs and other groups of animals.

The theory holds that the movement of this as yet undiscovered star disrupts the ϕ Ort cloud of comets every 26 million years, resulting in the Earth suffering an increased bombardment from comets at these times. The theory was proposed in 1984 to explain the newly discovered layer of iridium - an element found in comets and meteorites - in rocks dating from the end of dinosaur times. However, many palaeontologists deny any evidence for a 26-million-year cycle of extinctions.

neo-Darwinism the modern theory of ϕ evolution, built up since the 1930s by integrating the 19th-century English scientist Charles ϕ Darwin's theory of evolution through natural selection with the theory of genetic inheritance founded on the work of the Austrian biologist Gregor ϕ Mendel.

Neo-Darwinism asserts that evolution takes place because the environment is slowly changing, exerting a selection pressure on the individuals within a population. Those with characteristics that happen to adapt to the new environment are more likely to survive and have offspring and hence pass on these favourable characteristics. Over time the genetic make-up of the population changes and ultimately a new species is formed.

neodymium yellowish metallic element of the lanthanide series, symbol Nd, atomic number 60, relative atomic mass 144.24. Its rose-coloured salts are used in colouring glass, and neodymium is used in lasers.

It was named in 1885 by Austrian chemist Carl von Welsbach (1858–1929), who fractionated it away from didymium (originally thought to be an element but actually a mixture of rare-earth metals consisting largely of neodymium, praseodymium, and cerium).

neon Greek *neos* 'new' colourless, odourless, nonmetallic, gaseous element, symbol Ne, atomic number 10, relative atomic mass 20.183. It is grouped with the inert gases, is nonreactive, and forms no compounds. It occurs in small quantities in the Earth's atmosphere.

Tubes containing neon are used in electric advertising signs, giving off a fiery red glow; it is also used in lasers. Neon was discovered by Scottish chemist William Ramsay and the Englishman Morris Travers.

Neopilina deep-sea 'living fossil' occurring at great depths and feeding exclusively on radiolarians (marine protozoans).

classification *Neopilina* is in class Monoplacophora, phylum Mollusca.

neoplasm Greek *'new growth'* any lump or tumour, which may be benign or malignant (cancerous).

neoprene synthetic rubber, developed in the USA in 1931 from the polymerization of chloroprene. It is much more resistant to heat, light, oxidation, and petroleum than is ordinary rubber.

neoteny in biology, the retention of some juvenile characteristics in an animal that seems otherwise mature. An example is provided by the axolotl, a salamander that can reproduce sexually although still in its larval form.

neper unit used in telecommunications to express a ratio of powers and currents. It gives the attenuation of amplitudes as the natural logarithm of the ratio.

nephritis or *Bright's disease* general term used to describe inflammation of the kidney. The degree of illness varies, and it may be acute (often following a recent streptococcal infection), or chronic, requiring a range of treatments from antibiotics to dialysis or transplant.

nephron microscopic unit in vertebrate kidneys that forms urine. A human kidney is composed of over a million nephrons. Each nephron consists of a knot of blood capillaries called a glomerulus, contained in the Bowman's capsule, and a long narrow tubule enmeshed with yet more capillaries. Waste materials and water pass from the bloodstream into the tubule, and essential minerals and some water are reabsorbed from the tubule back into the bloodstream. The remaining filtrate (urine) is passed out from the body.

Neptune in astronomy, the eighth planet in average distance from the Sun. It is a giant gas (hydrogen, helium, methane) planet, with a mass 17.2 times that of Earth. It has the highest winds in the Solar System.

nephron The kidney (left) contains more than a million filtering units, or nephrons (right), consisting of the glomerulus, Bowman's capsule, and the loop of Henle. Blood flows through the glomerulus – a tight knot of fine blood vessels from which water and metabolic wastes filter into the tubule. This filtrate flows through the convoluted tubule and loop of Henle where most of the water and useful molecules are reabsorbed into the blood capillaries. The waste materials are passed to the collecting tubule as urine.

NEPTUNE

Detailed description of the planet Neptune. It includes a chronology of the exploration of the planet, along with statistics and information on its rings, moons, and satellites. Supported by a good selection of images.

1989, of which Proteus (diameter 415 km/260 mi) is larger than Nereid (300 km/200 mi).

rings there are four faint rings: Galle, Le Verrier, Arago, and Adams (in order from Neptune). Galle is the widest at 1,700 km/1,060 mi. Leverrier and Arago are divided by a wide diffuse particle band called the plateau.

Neptune was located 1846 by German astronomers Johan Galle and Heinrich d'Arrest (1822–1875) after calculations by English astronomer John Couch Adams and French mathematician Urbain Leverrier had predicted its existence from disturbances in the movement of Uranus. *Voyager 2*, which passed Neptune in Aug 1989, revealed various cloud features, notably an Earth-sized oval storm cloud, the Great Dark Spot, similar to the Great Red Spot on Jupiter, but images taken by the Hubble Space Telescope in 1994 show that the Great Dark Spot has disappeared. A smaller dark spot DS2 has also gone.

neptunium silvery, radioactive metallic element of the actinide series, symbol Np, atomic number 93, relative atomic mass 237.048. It occurs in nature in minute amounts in pitchblende and other uranium ores, where it is produced from the decay of neutron-bombarded uranium in these ores. The longest-lived isotope, Np-237, has a half-life of 2.2 million years. The element can be produced by bombardment of U-238 with neutrons and is chemically highly reactive.

It was first synthesized in 1940 by US physicists E McMillan (1907–) and P Abelson (1913–), who named it after the planet Neptune (since it comes after uranium as the planet Neptune comes after Uranus).

Neptunium was the first transuranic element to be synthesized.

NERC abbreviation for Natural Environment Research Council.

nerd in computing, slang term for someone who seems to spend more time interacting with computers than with human beings. The term was originally an abusive one, applied to weedy, diffident but studious US high school students by their more sporty and outgoing colleagues.

Nernst, (Walther) Hermann (1864–1941)

German physical chemist who won a Nobel prize in 1920 for work on heat changes in chemical reactions. He proposed in 1906 the principle known as the Nernst heat theorem or the third law of thermodynamics: chemical changes at the temperature of absolute zero involve no change of entropy (disorder).

transferring data at the rate of one gigabit per second. It was designed for computer research, and is not accessible to the public.

nerve bundle of nerve cells enclosed in a sheath of connective tissue and transmitting nerve impulses to and from the brain and spinal cord. A single nerve may contain both motor and sensory nerve cells, but they function independently.

nerve cell or **neuron** elongated cell, the basic functional unit of the nervous system that transmits information rapidly between different parts of the body. Each nerve cell has a cell body, containing the nucleus, from which trail processes called dendrites, responsible for receiving incoming signals. The unit of information is the nerve impulse, a travelling wave of chemical and electrical changes involving the membrane of the nerve cell. The cell's longest process, the axon, carries impulses away from the cell body.

The impulse involves the passage of sodium and potassium ions across the nerve-cell membrane. Sequential changes in the permeability of the membrane to positive sodium (Na^+) ions and potassium (K^+) ions produce electrical signals called action potentials. Impulses are received by the cell body and passed, as a pulse of electric charge, along the axon. The axon terminates at the synapse, a specialized area closely linked to the next cell (which may be another nerve cell or a specialized effector cell such as a muscle). On reaching the synapse, the impulse releases a chemical neurotransmitter, which diffuses across to the neighbouring cell and there stimulates another impulse or the action of the effector cell.

Nerve impulses travel quickly – in humans, they may reach speeds of 160 m/525 ft per second.

nerve cell The anatomy and action of a nerve cell. The nerve cell or neuron consists of a cell body with the nucleus and projections called dendrites which pick up messages. An extension of the cell, the axon, connects one cell to the dendrites of the next. When a nerve cell is stimulated, waves of sodium (Na^+) and potassium (K^+) ions carry an electrical impulse down the axon.

nervous breakdown popular term for a reaction to overwhelming psychological stress. There is no equivalent medical term. People said to be suffering from a nervous breakdown may be suffering from a neurotic illness, such as depression or anxiety, or a psychotic illness, such as schizophrenia.

nervous system the system of interconnected nerve cells of most invertebrates and all vertebrates. It is composed of the central and autonomic nervous systems. It may be as simple as the nerve net of coelenterates (for example, jellyfishes) or as complex as the mammalian nervous system, with a central nervous system comprising brain and spinal cord and a peripheral nervous system connecting up with sensory organs, muscles, and glands.

human nervous system The human nervous system represents the product of millions of years of evolution, particularly in the degree of encephalization or brain complexity. It can be divided into central and peripheral parts for descriptive purposes, although there is both anatomical and functional continuity between the two parts. The central nervous system consists of the brain and the spinal cord. The peripheral nervous system is not so clearly subdivided, but its anatomical parts are: (1) the spinal nerves; (2) the cranial nerves; and (3) the autonomic nervous system.

nest place chosen or constructed by a bird or other animal for incubation of eggs, hibernation, and shelter. Nests vary enormously, from saucerlike hollows in the ground, such as the scrapes of hares, to large and elaborate structures, such as the 4-m/13-ft diameter mounds of the megapode birds.

birds' nests Birds that nest in slight depressions in the ground, such as terns and plovers, lay eggs that so closely resemble the ground that they generally escape detection. A slightly more elaborate nest is the burrow, such as that occupied by the sand-martin, kingfisher, or puffin. In many cases these underground nests are made in burrows left by rabbits or voles.

Many birds and some animals make their nests in the hollows of trees; the female of the Bornean rhinoceros hornbill is sealed up by the male for many weeks, until her chicks are almost ready to leave the nest. The mud nests of the swallow family and other birds are built mainly with mud; some of these weigh over 2 kg/4.5 lb. Among the crudest nests that are made with collected material, such as sticks, leaves, blades of grass or hair, are those of the wood-pigeon, which are so loosely put together that the eggs are visible through them.

Swallows, martins, sparrows, and flycatchers prefer houses as nesting sites; the thrushes, finches, and linnets use evergreen bushes and hedges. Most species construct nests that are highly distinctive.

other nest-builders Amongst the fish, good examples of nest-builders are the three-spined stickleback *Gasterosteus aculeatus* and the Siamese fighting fish *Betta splendens*. The stickleback's nest is anchored to the river bed and constructed of algae and other aquatic plants stuck together by a secretion from the fish's kidneys. The nest of fighting fish is a floating bubble nest anchored to a piece of plant material into which the eggs are placed by the male after courtship.

Amongst the insects, nest-builders include the social insects, the ants, bees, and wasps, and their nests or hives, and the huge termite nests, up to 3 m/10 ft tall, found in the tropics.

Of the mammals, good examples are those of the harvest mouse (*Micromys minutus*) and the red squirrel (*Sciurus vulgaris*). The harvest mouse nest is a kind of ball made of interlaced leaves of

grass that generally belong to the same plants that support it above the ground. The red squirrel's nest is composed of a layer of twigs with a layer of moss or bark fragments. The whole thing is usually placed at the base of a large branch.

Net abuse in computing, action that upsets participants in USENET. Common forms include spamming (advertising), cross-posting (sending the same message to several groups), scams (financial frauds), and attempts to rig or prevent discussions. In theory, Internet Service Providers (ISPs) can punish Net abuse by blocking access to the Net, but in practice this sanction is very rarely invoked as the offender merely finds a new ISP.

Netcom in computing, major US-based Internet Service Provider (ISP), founded in 1988 to provide college students with off-campus access to university computer facilities. In 1996 the company claimed to be the world's largest ISP, with some 500,000 subscribers.

Netfind in computing, search engine designed to locate personal e-mail addresses. Users supply an individual's name and a possible domain name, and Netfind searches a database of domain names, offering users a series of choices to help narrow down the range of options.

netiquette (derived from *Internet etiquette*) behaviour guidelines evolved by users of the Internet. The rules of netiquette include: no messages typed in upper case (considered to be the equivalent of shouting); new users, or new members of a newsgroup, should read the frequently asked questions (FAQ) file before asking a question; no advertising via USENET newsgroups.

Users who contravene netiquette can expect to receive electronic mail flames (angry messages) pointing out the error of their ways. The Internet community is fiercely protective of netiquette.

net police (or *net cops*) in computing, USENET readers who monitor and 'punish' postings which they find offensive or believe to be in breach of netiquette. Many unmoderated (see moderator) newsgroups are policed by these self-appointed guardians, whose attempts to enforce their vision of the group sometimes make them a target for 'punishment' themselves.

Netscape in computing, US software company that supplies Navigator, a World Wide Web browser, which is usually referred to as Netscape. (Netscape Communications was founded in 1994 as Mosaic Communications, and called its browser Netscape. The names were changed in deference to the University of Illinois, where the Mosaic browser was written.)

Netscape gained widespread popularity by giving its browser away free for non-commercial use. Most of the company's revenues now come from sales of Netscape Communicator – a suite of software that includes a copy of Navigator – Web servers and intranet software with powerful groupware features. In 1996, it unveiled Netscape ONE (Open Network Environment), designed to help developers to create new online applications.

Net, the abbreviation for the Internet. The term is often used to denote the entire community of people with computer access to the Internet.

nettle any of a group of weedy plants with stinging hairs on oval, tooth-edged leaves; the hairs contain nerve poisons that penetrate the skin and cause a rash. The flowers are small and greenish, carried on spikes emerging at the same point where the leaves join the stem. The common nettle (*U. dioica*) grows on waste ground in Europe and North America, where it was introduced. (Genus *Urtica*, family Urticaceae.)

NETTLE

The hairs on stinging nettle leaves operate like mini hypodermic syringes. When the leaf is touched, the pressure in the hair falls as the fragile tip is broken away and a dose of nerve toxin is released.

network Local area networks can be connected together in a ring circuit or in a star arrangement. In the ring arrangement, signals from a terminal or peripheral circulate around the ring to reach the terminal or peripheral addressed. In the star arrangement, signals travel via a central controller. In a bus network all elements are connected off a single cable that is terminated at each end.

nettle rash popular name for the skin disorder *urticaria*.

Network leading local area network operating system, supplied by Novell.

network in computing, a method of connecting computers so that they can share data and peripheral devices, such as printers. The main types are classified by the pattern of the connections – star or ring network, for example – or by the degree of geographical spread allowed; for example, local area networks (LANs) for communication within a room or building, and wide area networks (WANs) for more remote systems. Internet is the computer network that connects major English-speaking institutions throughout the world, with around 12 million users. Janet (joint academic network), a variant of Internet, is used in Britain. SuperJanet, launched in 1992, is an extension of this that can carry 1,000 million bits of information per second.

network computer (NC) simple computer consisting essentially of a microprocessor, a RAM chip and a monitor. NCs are designed to function as part of a network, connected to a central server via the Internet or an intranet, downloading software (especially object oriented programs) as required.

The absence of internal storage makes them much cheaper to buy and maintain than PCs, and they are easier to manage and upgrade, as all the software is stored in one place. Some commentators believe that the NC will eventually replace the networked PC as the standard computer setup for business, especially for tasks previously performed using dumb terminals.

network interface card (NIC) in computing, item of computer hardware that allows computers to be connected to a computer network.

network operating system (NOS) in computing, software designed to enable a LAN or other network to operate. The main task of every NOS is to tell both the central file server and the workstations connected to it how to communicate with each other.

network A wide area network is used to connect remote computers via telephone lines or satellite links. The ISDN (Integrated Services Digital Network) telecommunications network allows high-speed transfer of digital data.

Network operating systems may also include security and backup features, remote access facilities, and a centralized database.

neuralgia sharp or burning pain originating in a nerve and spreading over its area of distribution. Trigeminal neuralgia, a common form, is a severe pain on one side of the face.

neural network artificial network of processors that attempts to mimic the structure of nerve cells (neurons) in the human brain. Neural networks may be electronic, optical, or simulated by computer software.

A basic network has three layers of processors: an input layer, an output layer, and a 'hidden' layer in between. Each processor is connected to every other in the network by a system of 'synapses'; every processor in the top layer connects to every one in the hidden layer, and each of these connects to every processor in the output layer. This means that each nerve cell in the middle and bottom layers receives input from several different sources; only when the amount of input exceeds a critical level does the cell fire an output signal.

The chief characteristic of neural networks is their ability to sum up large amounts of imprecise data and decide whether they match a pattern or not. Networks of this type may be used in developing robot vision, matching fingerprints, and analysing fluctuations in stock-market prices. However, it is thought unlikely by scientists that such networks will ever be able accurately to imitate the human brain, which is very much more complicated; it contains around 10 billion nerve cells, whereas current artificial networks contain only a few hundred processors.

neurohormone chemical secreted by nerve cells and carried by the blood to target cells. The function of the neurohormone is to act as a messenger; for example, the neurohormone ADH (antidiuretic hormone) is secreted in the pituitary gland and carried to the kidney, where it promotes water reabsorption in the kidney tubules.

neurology medical speciality concerned with the study and treatment of disorders of the brain, spinal cord, and peripheral nerves.

neuron another name for a nerve cell.

neurosis in psychology, a general term referring to emotional disorders, such as anxiety, depression, and phobias. The main disturbance tends to be one of mood; contact with reality is relatively unaffected, in contrast to psychosis.

neurotransmitter chemical that diffuses across a synapse, and thus transmits impulses between nerve cells, or between nerve

Neural Networks

by Peter Lafferty

Neural networks – strictly artificial neural networks – represent a radically different approach to computing. They are called neural networks because they are loosely modelled on the networks of neurons – nerve cells – that make up brains. Neural networks are characterized by their ability to learn, and can be described as trainable pattern recognizers. The study and use of neural networks is sometimes called neurocomputing.

Brains perform remarkable computational feats: recognizing music from just a few seconds of a recording, or faces seen only once before – accomplishments that defeat even the most modern computers. Yet brains stumble with arithmetic and make errors with simple logic. The reason for these anomalies might be found in the differences between brain and computer architecture – their internal structure and operating mechanisms.

Conventional computers possess distinct processing and memory units, controlled by programs, but animal nervous systems and neural networks are instead made up of highly interconnected webs of simple processing units. They have no specific memory locations, information instead being stored as patterns of interconnections between the processing units. Neural networks are not programmed, but are trained by example. They can, therefore, learn things that cannot easily be stated in programs, making them invaluable in a wide range of applications.

Although neurocomputing might seem a recent development, research started at around the same time as the early work on computers. In the 1940s scientists devised simple electrical networks, crudely modelled neural circuits, which could perform simple logical computations.

More sophisticated networks, called perceptrons, followed in the 1950s – the ancestors of modern neural networks. Perceptrons were just simple networks of amplifiers, but they could learn to recognize patterns. This generated tremendous excitement; however, significant limits to their abilities were soon discovered. Marvin Minsky and Seymour Papert of the Massachusetts Institute of Technology, USA, proved that certain problems could never be solved by perceptrons. When they published their results, research into neural networks effectively ceased for over a decade. At the end of the mid 1970s, however, theoretical breakthroughs made it possible for more complex neural networks to be developed, and by the mid 1980s they had become sufficiently sophisticated for general applications.

Neural networks are of interest to computer technologists because they have the potential to offer solutions to a range of problems that have proved difficult to solve using conventional computing approaches. These problems include pattern recognition, machine learning, time-series forecasting, machine vision and robot control. Underpinning all this is their ability to learn.

In a famous example, a neural network was trained to recognize speech – with eerily realistic results. The network, called NET-talk, was developed by T J Sejnowski and C R Rosenberg at Johns Hopkins University in the USA. It was linked to a computer that could produce synthetic speech, so its progress could be heard. After producing formless noise for a few hours, it started babbling like a baby. Overnight training improved its performance so that it could read text with a 95% accuracy. No conventionally programmed computer could do this.

cells and effector organs (for example, muscles). Common neurotransmitters are noradrenaline (which also acts as a hormone) and acetylcholine, the latter being most frequent at junctions between nerve and muscle. Nearly 50 different neurotransmitters have been identified.

neutral equilibrium the state of equilibrium possessed by a body that will stay at rest if moved into a new position; it will neither move back to its original position nor move on any further. A sphere placed on a horizontal surface is an example. See *stability*.

neutralization in chemistry, a process occurring when the excess acid (or excess base) in a substance is reacted with added base (or added acid) so that the resulting substance is neither acidic nor basic.

In theory neutralization involves adding acid or base as required to achieve pH 7. When the colour of an indicator is used to test for neutralization, the final pH may differ from pH 7 depending upon the indicator used. It will also differ from 7 in reactions between strong acids and weak bases and weak acids and strong bases, as the salt formed will have acid or basic properties respectively.

neutral oxide oxide that has neither acidic nor basic properties (see *oxide*). Neutral oxides are only formed by nonmetals. Examples are carbon monoxide, water, and nitrogen(I) oxide.

neutral solution solution of pH 7, in which the concentrations of $H^+(aq)$ and $OH^-(aq)$ ions are equal.

neutrino in physics, a particle of the lepton class, having a mass too close to zero to be measured. The most familiar type, the antiparticle of the electron neutrino, is emitted in the beta decay of a nucleus. The other two are the muon and tau neutrinos.

neutron one of the three main subatomic particles, the others being the proton and the electron. The neutron is a composite particle, being made up of three quarks, and therefore belongs to the

baryon group of the hadrons. Neutrons have about the same mass as protons but no electric charge, and occur in the nuclei of all atoms except hydrogen. They contribute to the mass of atoms but do not affect their chemistry.

For instance, the isotopes of a single element differ only in the number of neutrons in their nuclei but have identical chemical properties. Outside a nucleus, a free neutron is unstable, decaying with a half-life of 11.6 minutes into a proton, an electron, and an antineutrino. The neutron was discovered by the British chemist James Chadwick in 1932.

neutron beam machine nuclear reactor or accelerator producing a stream of neutrons, which can 'see' through metals. It is used in industry to check molecular radiation in metal under stress.

neutron bomb or enhanced radiation weapon small hydrogen bomb for battlefield use that kills by radiation, with minimal damage to buildings and other structures.

neutron number (symbol N) the number of neutrons possessed by an atomic nucleus. Isotopes are atoms of the same element possessing different neutron numbers.

neutron star very small, 'superdense' star composed mostly of neutrons. They are thought to form when massive stars explode as supernovae, during which the protons and electrons of the star's atoms merge, owing to intense gravitational collapse, to make neutrons. A neutron star may have the mass of up to three Suns, compressed into a globe only 20 km/12 mi in diameter.

NEUTRON STAR

Neutron stars are so condensed that a fragment the size of a sugar cube would weigh as much as all the people on Earth put together.

Neutrino: Discovery

by Peter Lafferty

Discovering the neutrino

Most fundamental particles are discovered experimentally. Some are predicted by theory, but are often not taken seriously until detected. The neutrino is an exception. Postulated in 1930, its existence was taken as an act of faith for 25 years.

There were good reasons for predicting the neutrino's existence. Unexplained energy losses in certain radioactive decays (called beta decay) suggested the laws of conservation of energy and angular momentum were invalid at subatomic level. The great Danish theoretical physicist Niels Bohr maintained these laws held only on average, not for each individual process. Austrian physicist Wolfgang Pauli explained it more simply: in beta decay, there was a previously undiscovered neutral particle carrying away the missing energy and momentum. He called it a 'neutron'. Italian physicist Enrico Fermi introduced the alternative term 'neutrino': Italian for 'little neutral one'. He constructed a successful theory of beta decay based on the neutrino's existence.

Reines and Cowan's explosive suggestion

Experimental observation of neutrinos proved difficult. They pass easily through solid material, penetrating lead 965 million million km/600 million million mi thick without being absorbed. This makes them extremely hard to detect. In the 1950s, US physicists Frederick Reines and Clyde Cowan put forward a far-fetched scheme using a nuclear weapon as neutrino source. Cowan described the proposed scheme several years later:

'We would dig a shaft near the centre of the explosion about 10 ft in diameter and about 150 ft deep. We would put a tank, 10 ft in diameter and 75 ft long on end at the bottom of the shaft. We would then suspend a detector from the top of the tank, along with its recording apparatus, and back-fill the shaft about the tank.'

'As the time for the explosion approached, we would start vacuum pumps and evacuate the tank as highly as possible. Then, when the countdown reached zero, we would break the suspension with a small explosive, allowing the detector to fall freely in the vacuum. For about two seconds, the falling detector would be seeing neutrinos and recording the pulses from them while the earth shook from the blast passed harmlessly by, rattling the tank mightily but not disturbing our falling detector. When all was relatively quiet, the detector would reach the bottom of the tank, landing on a thick pile of foam rubber and feathers.'

'We would return to the site of the shaft in a few days (when surface radioactivity had died away sufficiently), dig down to the tank, recover the detector and discover the truth about neutrinos.'

The crucial experiment

Before the spectacular experiment could be set up, Reines and Cowan realized that, with suitable modifications, they could utilize the much smaller neutrino flux from a nuclear reactor. They set up their experiment next to the Savannah River nuclear plant's reactor. The detector comprised a tank containing cadmium chloride dissolved in water. A neutrino passing through the tank reacts with protons in the water, producing a positron and a neutron. The positron combines with electrons, producing gamma rays. The neutron also produces gamma rays by reacting with the cadmium. When a gamma ray falls on a scintillation detector it produces a flash of light, detected using a photomultiplier and showing that a neutrino has passed through the tank.

At first, there were about 1.63 'events' (or signals) per hour with the reactor operating and 0.4 with it shut down. Subsequent experiments with various adjustments raised the rate to nearly three events per hour. The next task was to confirm that these signals were produced by neutrinos. This involved eliminating all other possible sources: principally neutrons, gamma rays, electrons, and protons from the reactor.

The water was in two plastic tanks, holding 200 1/40 gal, between large scintillation counters, and surrounded by 110 photomultipliers, with lead walls and floor 10 cm/4 in thick, and roof and doors 20 cm/8 in thick to eliminate radiation from the reactor. To prove the lead's effectiveness, tests were done with additional shields. One experiment involved packing wet sawdust in bags round the detectors to reduce spurious neutron flow. There was no appreciable change in signal, and so it was concluded that it was not due to radiation produced outside the detectors. The neutrino had indeed been detected.

Modern neutrino detection

Nowadays, neutrinos from space are routinely detected by underground 'telescopes' similar to the Reines and Cowan set-up. Some modern neutrino telescopes comprise large tanks of ultrapure water, weighing up to 3000 tonnes. The tank, in a mine, has walls lined with photoelectric detectors. An alternative type of telescope uses dry-cleaning fluid (carbon tetrachloride); when it captures a neutrino, it produces radioactive argon whose presence may be detected by analysis of the liquid. There are large-scale neutrino detectors in Japan, Russia, Italy, and the USA. In Feb 1987, when a supernova exploded in the Large Magellanic Cloud, these instruments detected neutrinos from the explosion 170,000 light-years away.

If its mass is any greater, its gravity will be so strong that it will shrink even further to become a black hole. Being so small, neutron stars can spin very quickly. The rapidly flashing radio stars called pulsars are believed to be neutron stars. The flashing is caused by a rotating beam of radio energy similar in behaviour to a lighthouse beam of light.

newbie in computing, insulting term for a new user of a USENET newsgroup, whose naive or off-topic comments irritate established members of the group. A classic newbie *faux pas* is to post a ques-

Newfoundland breed of large, gentle dog said to have originated in Newfoundland, Canada. Males can grow to 70 cm/27.5 in tall, and weigh 65 kg/145 lb; the females are slightly smaller. They have a dense, flat coat, usually dull black, and an oily, water-repellent undercoat, and they are excellent swimmers.

Newfoundlands that are black and white or brown and white are called Landseers.

New General Catalogue catalogue of star clusters and nebulae compiled by the Danish astronomer John Louis Emil Dreyer (1852-1926) and published in 1888. Its main aim was to revise, correct, and expand upon the *General Catalogue* compiled by English astronomer John Herschel, which appeared in 1864.

new media in computing, general term for CD-ROM, the World Wide Web, and other electronic media, including multimedia.

Most publishing companies now have a 'new media' division which manages a Web site and studies how best to compete and exploit the company's assets in the electronic future.

Newcomen, Thomas (1663-1729)

English inventor of an early steam engine. His 'fire engine' of 1712 was used for pumping water from mines until James Watt invented one with a separate condenser.

newsgroup discussion group on the Internet's USENET. Newsgroups are organized in seven broad categories: **comp.** – computers and programming; **news.** – newsgroups themselves; **rec.** – sports and hobbies; **sci.** – scientific research and ideas; **talk.** – discussion groups; and **misc.** – everything else. In addition, there are alternative hierarchies such as the wide-ranging and anarchic **alt.** (alternative). Within these categories there is a hierarchy of sub-divisions.

newsreader in computing, program that gives access to USENET newsgroups, interpreting the standard commands understood by news servers in a simple, user-friendly interface. Popular newsreaders include **rn** for UNIX, **Turnpike** and **Agent** for PCs and **NewsReader** for Macintosh. It is also possible to access USENET with a web browser such as **Netscape Navigator**.

news server computer that stores USENET messages for access by users. Most Internet Service Providers (ISPs) offer a news server as part of the service.

newt small salamander found in Europe, Asia, NW Africa, and North America. (Family Salamandridae, order Urodela.)

NEWT

If a young newt loses one of its limbs it can grow another. Unfortunately, the ability to do this declines with age.

new technology collective term applied to technological advances made in such areas as telecommunications, nuclear energy, space satellites, and computers.

New Technology Telescope optical telescope that forms part of the European Southern Observatory, La Silla, Chile; it came into operation in 1991. It has a thin, lightweight mirror, 3.38 m/11.75 ft across, which is kept in shape by computer-adjustable supports to produce a sharper image than is possible with conventional mirrors. Such a system is termed **active optics**.

newton SI unit (symbol N) of force. One newton is the force needed to accelerate an object with mass of one kilogram by one metre

Newton, Isaac (1642–1727)

English physicist and mathematician who laid the foundations of physics as a modern discipline. During 1665–66, he discovered the binomial theorem, differential and integral calculus, and that white light is composed of many colours. He developed the three standard laws of motion and the universal law of gravitation, set out in *Philosophiæ naturalis principia mathematica* 1687 (usually referred to as the *Principia*). Knighted 1705.

Newton's greatest achievement was to demonstrate that scientific principles are of universal application. He clearly defined

the nature of mass, weight, force, inertia, and acceleration.

In 1679 Newton calculated the Moon's motion on the basis of his theory of gravity and also found that his theory explained the laws of planetary motion that had been derived by German astronomer Johannes Kepler on the basis of observations of the planets.

ISAAC NEWTON English physicist and mathematician.
Letter to Robert Hooke, Feb 1675

Newtonian physics physics based on the concepts of the English scientist Isaac Newton, before the formulation of quantum theory or relativity theory.

Newtonian telescope in astronomy, a simple reflecting telescope in which light collected by a parabolic primary mirror is directed to a focus at the side of the tube by a flat secondary mirror placed at 45 degrees to the optical axis. It is named after Isaac Newton, who constructed such a telescope in 1668.

Newton's laws of motion in physics, three laws that form the basis of Newtonian mechanics. (1) Unless acted upon by an unbalanced force, a body at rest stays at rest, and a moving body continues moving at the same speed in the same straight line. (2) An unbalanced force applied to a body gives it an acceleration proportional to the force (and in the direction of the force) and inversely proportional to the mass of the body. (3) When a body A exerts a force on a body B, B exerts an equal and opposite force on A; that is, to every action there is an equal and opposite reaction.

Newton's rings in optics, an interference phenomenon seen (using white light) as concentric rings of spectral colours where light passes through a thin film of transparent medium, such as the wedge of air between a large-radius convex lens and a flat glass plate. With monochromatic light (light of a single wavelength), the rings take the form of alternate light and dark bands. They are caused by interference (interaction) between light rays reflected from the plate and those reflected from the curved surface of the lens.

NeXTStep operating system and development environment, originally created for the NeXT workstation, but later made available for other computers, including the IBM PC. NeXTStep is based on UNIX but contains a high level of object orientation. Apple is using NeXTStep (more accurately, OpenStep) as the basis for its next-generation Macintosh operating system, codenamed Rhapsody 1997.

NeXT Technology Inc US computer manufacturer founded by Steve Jobs in 1985. NeXT's first product was an advanced workstation, the NeXT Cube, aimed at the higher education market. It sold poorly and NeXT abandoned hardware manufacturing to become a software company, Next Software Inc. This was taken over by Apple Computer for \$400 million at the end of 1996.

niacin one of the 'B group' vitamins; see δ nicotinic acid.

niche in ecology, the 'place' occupied by a species in its habitat, including all chemical, physical, and biological components, such as what it eats, the time of day at which the species feeds, temperature, moisture, the parts of the habitat that it uses (for example, trees or open grassland), the way it reproduces, and how it behaves.

It is believed that no two species can occupy exactly the same niche, because they would be in direct competition for the same resources at every stage of their life cycle.

Nichrome trade name for a series of alloys containing mainly nickel and chromium, with small amounts of other substances such as iron, magnesium, silicon, and carbon. Nichrome has a high melting point and is resistant to corrosion. It is therefore used in electrical heating elements and as a substitute for platinum in the δ flame test.

nickel hard, malleable and ductile, silver-white metallic element, symbol Ni, atomic number 28, relative atomic mass 58.71. It occurs in igneous rocks and as a free metal (δ native metal), occasionally occurring in fragments of iron-nickel meteorites. It is a component of the Earth's core, which is held to consist principally of iron with some nickel. It has a high melting point, low electrical and thermal conductivity, and can be magnetized. It does not tarnish and therefore is much used for alloys, electroplating, and for coinage.

It was discovered in 1751 by Swedish mineralogist Axel Cronstedt (1722-1765) and the name given as an abbreviated form of *kopparnickel*, Swedish 'false copper', since the ore in which it is found resembles copper but yields none.

nickname in computing, an alternative δ user-id, as used by participants in δ MUDs, Internet Relay Chat and other interactive setups.

nicotine $C_{10}H_{14}N_2$ δ alkaloid (nitrogenous compound) obtained from the dried leaves of the tobacco plant *Nicotiana tabacum* and used as an insecticide. A colourless oil, soluble in water, it turns brown on exposure to the air.

Nicotine in its pure form is one of the most powerful poisons known. It is the component of cigarette smoke that causes physical addiction. It is named after a 16th-century French diplomat, Jacques Nicot, who introduced tobacco to France.

nicotinic acid or **niacin** water-soluble δ vitamin ($C_6H_5N.COOH$) of the B complex, found in meat, fish, and cereals; it can also be formed in small amounts in the body from the essential amino acid tryptophan. Absence of nicotinic acid from the diet leads to the disease δ pellagra.

nightingale songbird belonging to the thrush family; it sings with remarkable beauty by night as well as during the day. About 16.5 cm/6.5 in. long, it is dull brown with a reddish-brown rounded tail; the breast is dull greyish-white, tinting to brown. It migrates in summer to Europe and winters in Africa. It feeds on insects, small animals, and occasionally fruit. It has a huge musical repertoire, built from about 900 melodic elements. (Species *Luscinia megarhynchos*, family Muscicapidae.)

The female is slightly smaller than the male, but the plumage is very similar. The nest is often built on the ground, made of dry grass and leaves, and four to six olive-green eggs are laid in it. The male's song continues until the young are hatched.

The **thrush nightingale** (*L. luscinia*) of eastern Europe, is a louder but less sweet songster. Both species also sing in their winter ranges in Africa.

nightjar any of about 65 species of night-hunting birds. They have wide, bristly mouths for catching flying insects. Their distinctive calls have earned them such names as 'whippoorwill' and

'church-will's-widow'. Some US species are called nighthawks. (Family Caprimulgidae, order Caprimulgiformes.)

The name 'nighthawk' most commonly refers to the Chordeiles species of North America, including *Chordeiles minor* which breeds widely as far north as southern Alaska, and migrates south to Argentina.

nightshade any of several plants in the nightshade family. They include the annual herbaceous black nightshade (*S. nigrum*), with white flowers similar to those of the potato plant and black berries; the perennial shrubby bittersweet or woody nightshade (*S. dulcamara*), with purple, potato-like flowers and scarlet berries; and, belonging to a different genus, deadly nightshade or δ belladonna (*A. belladonna*). (Genera *Solanum* and *Atropa*, family Solanaceae.)

NII in computing, abbreviation for δ National Information Infrastructure.

nilgai large antelope native to India. The bull has short conical horns and is bluish-grey. The female is brown. (Species *Boselaphus tragocamelus*.)

Nintendo Japanese δ games console and software manufacturer. In 1996, the company introduced the N64 - the first 64-bit games console - using technology from workstation manufacturer Silicon Graphics Inc. Nintendo's most successful game is *Super Mario Brothers*.

niobium soft, grey-white, somewhat ductile and malleable, metallic element, symbol Nb, atomic number 41, relative atomic mass 92.906. It occurs in nature with tantalum, which it resembles in chemical properties. It is used in making stainless steel and other alloys for jet engines and rockets and for making superconductor magnets.

Niobium was discovered in 1801 by English chemist Charles Hatchett (1765-1847), who named it columbium (symbol Cb), a name that is still used in metallurgy. In 1844 it was renamed after Niobe by German chemist Heinrich Rose (1795-1864) because of its similarity to tantalum (Niobe is the daughter of Tantalus in Greek mythology).

NIST in computing, abbreviation for δ National Institute of Standards and Technology.

nit egg case of the δ louse, which is glued to the base of the host's hair.

nitrate salt or ester of nitric acid, containing the NO_3^- ion. Nitrates are used in explosives, in the chemical and pharmaceutical industries, in curing meat (see δ nitrite), and as fertilizers. They are the most water-soluble salts known and play a major part in the nitrogen cycle. Nitrates in the soil, whether naturally occurring or from inorganic or organic fertilizers, can be used by plants to make proteins and nucleic acids. However, runoff from fields can result in δ nitrate pollution.

nitrate pollution the contamination of water by nitrates. Increased use of artificial fertilizers and land cultivation means that higher levels of nitrates are being washed from the soil into rivers, lakes, and aquifers. There they cause an excessive enrichment of the water (δ eutrophication), leading to a rapid growth of algae, which in turn darkens the water and reduces its oxygen content. The water is expensive to purify and many plants and animals die. High levels are now found in drinking water in arable areas. These may be harmful to newborn babies, and it is possible that they contribute to stomach cancer, although the evidence for this is unproven.

nitre or **saltpetre** potassium nitrate, KNO_3 , a mineral found on and just under the ground in desert regions; used in explosives. Nitre occurs in Bihar, India, Iran, and Cape Province, South Africa. The salt was formerly used for the manufacture of gunpowder, but the supply of nitre for explosives is today largely met by making the salt from nitrate (also called Chile saltpetre, $NaNO_3$). Saltpetre is a δ preservative and is widely used for curing meats.

nitric acid or **aqua fortis** HNO_3 fuming acid obtained by the oxidation of ammonia or the action of sulphuric acid on potassium

nitrate. It is a highly corrosive acid, dissolving most metals, and a strong oxidizing agent. It is used in the nitration and esterification of organic substances, and in the making of sulphuric acid, nitrates, explosives, plastics, and dyes.

nitric oxide or nitrogen monoxide (NO) colourless gas released when metallic copper reacts with nitric acid and when nitrogen and oxygen combine at high temperatures. It is oxidized to nitrogen dioxide on contact with air. Nitric oxide has a wide range of functions in the body. It is involved in the transmission of nerve impulses and the protection of nerve cells against stress. It is released by macrophages in the immune system in response to viral and bacterial infection or to the proliferation of cancer cells. It is also important in the control of blood pressure.

nitrification process that takes place in soil when bacteria oxidize ammonia, turning it into nitrates. Nitrates can be absorbed by the roots of plants, so this is a vital stage in the nitrogen cycle.

nitrite salt or ester of nitrous acid, containing the nitrite ion (NO_2^-). Nitrites are used as preservatives (for example, to prevent the growth of botulism spores) and as colouring agents in cured meats such as bacon and sausages.

nitrocellulose alternative name for cellulose nitrate.

nitrogen Greek *nitron* 'native soda', sodium or potassium *nitrate* colourless, odourless, tasteless, gaseous, nonmetallic element, symbol N, atomic number 7, relative atomic mass 14.0067. It forms almost 80% of the Earth's atmosphere by volume and is a constituent of all plant and animal tissues (in proteins and nucleic acids). Nitrogen is obtained for industrial use by the liquefaction and fractional distillation of air. Its compounds are used in the manufacture of foods, drugs, fertilizers, dyes, and explosives.

Nitrogen has been recognized as a plant nutrient, found in manures and other organic matter, from early times, long before the complex cycle of nitrogen fixation was understood. It was isolated in 1772 by English chemist Daniel Rutherford (1749-1819) and named in 1790 by French chemist Jean Chaptal (1756-1832).

nitrogen cycle the process of nitrogen passing through the ecosystem. Nitrogen, in the form of inorganic compounds (such as nitrates) in the soil, is absorbed by plants and turned into organic compounds (such as proteins) in plant tissue. A proportion of this nitrogen is eaten by herbivores, with some of this in turn being passed on to the carnivores, which feed on the herbivores. The

nitrogen is ultimately returned to the soil as excrement and when organisms die and are converted back to inorganic form by decomposers.

Although about 78% of the atmosphere is nitrogen, this cannot be used directly by most organisms. However, certain bacteria and cyanobacteria (see blue-green algae) are capable of nitrogen fixation. Some nitrogen-fixing bacteria live mutually with leguminous plants (peas and beans) or other plants (for example, alder), where they form characteristic nodules on the roots. The presence of such plants increases the nitrate content, and hence the fertility, of the soil.

... the aim of science is not things themselves, as the dogmatists in their simplicity imagine, but the relations between things; outside those relations there is no reality knowable.

JULES HENRI POINCARÉ French mathematician.
Science and Hypothesis 1905

nitrogen fixation the process by which nitrogen in the atmosphere is converted into nitrogenous compounds by the action of microorganisms, such as cyanobacteria (see blue-green algae) and bacteria, in conjunction with certain legumes. Several chemical processes duplicate nitrogen fixation to produce fertilizers; see nitrogen cycle.

nitrogen oxide any chemical compound that contains only nitrogen and oxygen. All nitrogen oxides are gases. Nitrogen monoxide and nitrogen dioxide contribute to air pollution. See also nitrous oxide.

Nitrogen oxide was discovered during the 1980s to act as a chemical messenger in small quantities within the human body, despite being toxic at higher concentrations, and its rapid reaction with oxygen. The medical condition of septic shock is linked to overproduction by the body of nitrogen oxide. Nitrogen oxide has an unpaired electron, which can be removed to produce the nitrosyl ion, NO^+ . **nitrogen monoxide** NO, or nitric oxide, is a colourless gas released when metallic copper reacts with concentrated nitric acid. It is also produced when nitrogen and oxygen combine at high temperature. On contact with air it is oxidized to nitrogen dioxide. **Nitrogen dioxide** nitrogen(IV) oxide, NO_2 , is a brown, acidic, pungent gas that is harmful if inhaled and contributes to the formation

nitrogen cycle The nitrogen cycle is one of a number of cycles during which the chemicals necessary for life are recycled. The carbon, sulphur, and phosphorus cycles are others. Since there is only a limited amount of these chemicals in the Earth and its atmosphere, the chemicals must be continuously recycled if life is to go on.

of H_2O acid rain, as it dissolves in water to form nitric acid. It is the most common of the nitrogen oxides and is obtained by heating most nitrate salts (for example lead(II) nitrate, $\text{Pb}(\text{NO}_3)_2$). If liquefied, it gives a colourless solution (N_2O_4). It has been used in rocket fuels.

nitroglycerine $\text{C}_3\text{H}_5(\text{ONO}_2)_3$ flammable, explosive oil produced by the action of nitric and sulphuric acids on glycerol. Although poisonous, it is used in cardiac medicine. It explodes with great violence if heated in a confined space and is used in the preparation of dynamite, cordite, and other high explosives.

It was invented by the Italian Ascanio Sobrero in 1846, and is unusual among explosives in that it is a liquid. Nitroglycerine is an effective explosive because it has low activation energy, and produces little smoke when burned. However, it was initially so reactive it was virtually unusable. Alfred Nobel's innovation was to purify nitroglycerine (using water, with which it is immiscible, to dissolve the impurities), and thereby make it more stable.

nitrous acid HNO_2 weak acid that, in solution with water, decomposes quickly to form nitric acid and nitrogen dioxide.

nitrous oxide or **dinitrogen oxide** N_2O colourless, nonflammable gas that, used in conjunction with oxygen, reduces sensitivity to pain. In higher doses it is an anaesthetic. Well tolerated, it is often combined with other anaesthetic gases to enable them to be used in lower doses. It may be self-administered; for example, in childbirth. It is a greenhouse gas; about 10% of nitrous oxide released into the atmosphere comes from the manufacture of nylon. It used to be known as 'laughing gas'.

NNTP (abbreviation for **Network News Transfer Protocol**) in computing, set of standard procedures by which USENET news is distributed across the Internet. NNTP governs both the way e-mailed messages travel between news servers and the way newsreaders retrieve news from servers.

nobelium synthesized, radioactive, metallic element of the actinide series, symbol No, atomic number 102, relative atomic mass 259. It is synthesized by bombarding curium with carbon nuclei.

It was named in 1957 after the Nobel Institute in Stockholm, Sweden, where it was claimed to have been first synthesized. Later evaluations determined that this was in fact not so, as the successful 1958 synthesis at the University of California at Berkeley produced a different set of data. The name was not, however, challenged. In 1992 the International Unions for Pure and Applied Chemistry and Physics (IUPAC and IUPAP) gave credit to Russian scientists in Dubna for the discovery of nobelium.

Nobel, Alfred Bernhard (1833–1896)

Swedish chemist and engineer. He invented dynamite in 1867, gelignite in 1875, and ballistite, a smokeless gunpowder, in 1887. Having amassed a large fortune from the manufacture of explosives and the exploitation of the Baku oilfields in Azerbaijan, near the Caspian Sea, he left this in trust for the endowment of five Nobel prizes.

Mary Evans Picture Library

Nobel prize annual international prize, first awarded in 1901 under the will of Alfred Nobel, Swedish chemist, who invented dynamite. The interest on the Nobel endowment fund is divided

annually among the persons who have made the greatest contributions in the fields of physics, chemistry, medicine, literature, and world peace. The first four are awarded by academic committees based in Sweden, while the peace prize is awarded by a committee of the Norwegian parliament. A sixth prize, for economics, financed by the Swedish National Bank, was first awarded in 1969. The prizes have a large cash award and are given to organizations – such as the United Nations peacekeeping forces, which received the Nobel Peace Prize in 1988 – as well as individuals.

noble gas alternative name for **inert gas**.

noble gas structure the configuration of electrons in noble or inert gases (helium, neon, argon, krypton, xenon, and radon).

This is characterized by full electron shells around the nucleus of an atom, which render the element stable. Any ion, produced by the gain or loss of electrons, that achieves an electronic configuration similar to one of the inert gases is said to have a noble gas structure.

NO CARRIER in computing, error message returned by a modem when the telephone line drops unexpectedly because of line noise or other interruptions.

node in computing, any device connected to a network, such as a router, a bridge, a hub, and a server. See also **ghost**.

node in physics, a position in a standing wave pattern at which there is no vibration. Points at which there is maximum vibration are called **antinodes**. Stretched strings, for example, can show nodes when they vibrate. Guitarists can produce special effects (harmonics) by touching a sounding string lightly to produce a node.

nodule in geology, a lump of mineral or other matter found within rocks or formed on the seabed surface; mining technology is being developed to exploit them.

noise unwanted sound. Permanent, incurable loss of hearing can be caused by prolonged exposure to high noise levels (above 85 decibels). Over 55 decibels on a daily outdoor basis is regarded as an unacceptable level.

In scientific and engineering terms, a noise is any random, unpredictable signal.

noise pollution Noise is a recognized form of pollution, but is difficult to measure because the annoyance or discomfort caused varies between individuals. If the noise is in a narrow frequency band, temporary hearing loss can occur even though the level is below 85 decibels or exposure is only for short periods. Lower levels of noise are an irritant, but seem not to increase fatigue or affect efficiency to any great extent. Loss of hearing is a common complaint of people working on factory production lines or in the construction and road industry. Minor psychiatric disease, stress-related ailments including high blood pressure, and disturbed sleep patterns are regularly linked to noise, although the causal links are in most cases hard to establish. Loud noise is a major pollutant in towns and cities.

electronic noise Electronic noise takes the form of unwanted signals generated in electronic circuits and in recording processes by stray electrical or magnetic fields, or by temperature variations. In electronic recording and communication systems, white noise frequently appears in the form of high frequencies, or hiss. The main advantages of digital systems are their relative freedom from such noise and their ability to recover and improve noise-affected signals.

nomadic pastoralism farming system where animals (cattle, goats, camels) are taken to different locations in order to find fresh pastures. It is practised in the developing world; out of an estimated 30–40 million (1990) nomadic pastoralists worldwide, most are in central Asia and the Sahel region of W Africa. Increasing numbers of cattle may lead to overgrazing of the area and desertification.

The increasing enclosure of land has reduced the area available for nomadic pastoralism and, as a result, this system of farming is under threat. The movement of farmers in this way contrasts with sedentary agriculture.

nondisclosure agreement (NDA) in computing, agreement signed with suppliers by manufacturers, programmers, journalists, and others, in exchange for detailed information or copies of new products in advance of their public launch. For example, a manufacturer might sign an NDA to get a copy of a new operating system in order to have compatible hardware ready for the program's launch. NDAs are often required in order to participate in beta (pre-launch) tests of important pieces of software.

nonlinear video editing in computing, video editing method that processes compressed video data stored on a hard disc. This makes it much easier for editors to find their way around the material, and enables them to commence editing at any point in the tape – hence the name.

Editors use a computer to rearrange the material and produce an Edit Decision List (EDL) bearing all information on cuts, fades, and other effects. The EDL can then be used to create an automated final edit using the original tapes. The main video editing programs are Avid VideoShop for the Apple Macintosh and Tektronix Lightworks for PCs.

nonmetal one of a set of elements (around 20 in total) with certain physical and chemical properties opposite to those of metals. Nonmetals accept electrons (see *electronegativity*) and are sometimes called electronegative elements.

nonrenewable resource natural resource, such as coal or oil, that takes thousands or millions of years to form naturally and can therefore not be replaced once it is consumed. The main energy sources used by humans are nonrenewable; renewable resources, such as solar, tidal, and geothermal power, have so far been less exploited.

Nonrenewable resources have a high carbon content because their origin lies in the photosynthetic activity of plants millions of years ago. The fuels release this carbon back into the atmosphere as carbon dioxide. The rate at which such fuels are being burnt is thus resulting in a rise in the concentration of carbon dioxide in the atmosphere.

nonvolatile memory in computing, memory that does not lose its contents when the power supply to the computer is disconnected.

noradrenaline in the body, a catecholamine that acts directly on specific receptors to stimulate the sympathetic nervous system. Released by nerve stimulation or by drugs, it slows the heart rate mainly by constricting arterioles (small arteries) and so raising blood pressure. It is used therapeutically to treat shock.

NOR gate in electronics, a type of logic gate.

normal distribution in statistics, a distribution widely used to model variation in a set of data which is symmetrical about its mean value. It can be expressed in the form:

$$f(x) = 1/\sigma\sqrt{2\pi} \exp\{-1/2(x-\mu)^2/\sigma^2\}$$

where $f(x)$ is the relative frequency of data value x , σ is the standard deviation, μ is the mean, \exp is the exponential function, and π is a mathematical constant. The curve resulting when $f(x)$ is

plotted against x is called the **normal distribution curve**.

An example of normal distribution can be found in the intelligence quotients (IQ) found in human populations, distributed around a mean value of 100. The distribution is also known as the Gaussian distribution after German mathematician Karl Gauss.

normal distribution curve the bell-shaped curve that results when a normal distribution is represented graphically by plotting the distribution $f(x)$ against x . The curve is symmetrical about the mean value.

detail of olfactory epithelium

nose The structure of the nose. The organs of smell are confined to a small area in the roof of the nasal cavity. The olfactory cells are stimulated when certain molecules reach them. Smell is one of our most subtle senses: tens of thousands of smells can be distinguished. By comparison, taste, although closely related to smell, is a crude sensation. All the subtleties of taste depend upon smell.

Northrop US aircraft and military manufacturing company founded in 1939 by John K Northrop (1895–1981), an aircraft designer who had been a cofounder of Lockheed. Northrop makes uncrewed target aircraft and aircraft parts for other companies, and built the Black Widow night fighter used in World War II.

Norwich terrier small compact breed of terrier. It has a hard and wiry coat, that is close-lying and straight, and is coloured red, black, and tan; red grizzle; or grizzle and tan. Its head is rather foxlike, the muzzle being rather short and the skull wide between the erect ears. The legs are short, straight, and strong; the tail is traditionally docked. The height is usually 25 cm/10 in and the weight 5–6 kg/11–13 lb.

nose in humans, the upper entrance of the respiratory tract; the organ of the sense of smell. The external part is divided down the middle by a septum of cartilage. The nostrils contain plates of cartilage that can be moved by muscles and have a growth of stiff hairs at the margin to prevent foreign objects from entering. The whole nasal cavity is lined with a mucous membrane that warms and moistens the air as it enters and ejects dirt. In the upper parts of the cavity the membrane contains 50 million olfactory receptor cells (cells sensitive to smell).

nostril in vertebrates, the opening of the nasal cavity, in which cells sensitive to smell are located. (In fish, these cells detect water-borne chemicals, so they are effectively organs of taste.) In vertebrates with lungs, the nostrils also take in air. In humans, and most other mammals, the nostrils are located on the snout.

notebook computer in computing, a small battery-powered portable about A4 in size and the thickness of a book. The first notebook computers, such as the Epson HX-20 and Tandy 100, became available in the early 1980s, with the first PC-compatible notebook, the Toshiba T1100, following in 1985. In the 1990s, the notebook format became the standard for portable PCs and Apple PowerBooks. Some manufacturers also offer smaller portable PCs called subnotebooks. See also *laptop computer*.

NOT gate or **inverter gate** in electronics, a type of logic gate.

notochord the stiff but flexible rod that lies between the gut and the nerve cord of all embryonic and larval chordates, including the

vertebrates. It forms the supporting structure of the adult lancelet, but in vertebrates it is replaced by the vertebral column, or spine.

nova (plural *novae*) faint star that suddenly erupts in brightness by 10,000 times or more, remains bright for a few days, and then fades away and is not seen again for very many years, if at all. Novae are believed to occur in close binary star systems, where gas from one star flows to a companion (white dwarf). The gas ignites and is thrown off in an explosion at speeds of 1,500 kps/930 mps or more. Unlike a supernova, the star is not completely disrupted by the outburst. After a few weeks or months it subsides to its previous state; it may erupt many more times.

Although the name comes from the Latin 'new', photographic records show that such stars are not really new, but faint stars undergoing an outburst of radiation that temporarily gives them an absolute magnitude in the range –6 to –10, at least 100,000 times brighter than the Sun. They fade away, rapidly at first and then more slowly over several years. Two or three such stars are detected in our Galaxy each year, but on average one is sufficiently close to us to become a conspicuous naked-eye object only about once in ten years. Novae very similar to those appearing in our own Galaxy have also been observed in other galaxies.

Novell US network operating system specialist. Novell's NetWare operating system for IBM-compatible PCs dominates the market for local area networks and is used as an industry standard.

NSFnet (shorthand for *National Science Foundation Network*) in computing, network funded by the US National Science Foundation, and an important part of the Internet backbone. In 1993 the National Science Foundation started building a very high speed Backbone Network Service (vBNS) to connect five government supercomputing centres at speeds of up to 2.5 gigabits per second – fast enough to transmit the entire contents of several public libraries every second.

NTP abbreviation for *normal temperature and pressure*, the former name for STP (standard temperature and pressure).

NTSC (abbreviation for *National Television Standards Committee*) in computing, the US television standard signal format. Sometimes believed to stand for 'Never Twice the Same Colour'.

nuclear energy A pressurized water nuclear power station. Water at high pressure is circulated around the reactor vessel where it is heated. The hot water is pumped to the steam generator where it boils in a separate circuit; the steam drives the turbines coupled to the electricity generator. This is the most widely used type of reactor. More than 20 countries have pressurized water reactors.

nuclear energy or **atomic energy** energy released from the inner core, or nucleus, of the atom. Energy produced by nuclear fission (the splitting of uranium or plutonium nuclei) has been harnessed since the 1950s to generate electricity, and research continues into the possible controlled use of nuclear fusion (the fusing, or combining, of atomic nuclei).

In nuclear power stations, fission takes place in a nuclear reactor. The nuclei of uranium or, more rarely, plutonium are induced to split, releasing large amounts of heat energy. The heat is then removed from the core of the reactor by circulating gas or water, and used to produce the steam that drives alternators and turbines to generate electrical power. Unlike fossil fuels, such as coal and oil, which must be burned in large quantities to produce energy, nuclear fuels are used in very small amounts and supplies are therefore unlikely to be exhausted in the foreseeable future. However, the use of nuclear energy has given rise to concern over safety. Anxiety has been heightened by accidents such as the one at Chernobyl, Ukraine, in 1986. There has also been mounting

concern about the production and disposal of toxic nuclear waste, which may have an active life of several thousand years, and the cost of maintaining nuclear power stations and decommissioning them at the end of their lives.

nuclear fusion process whereby two atomic nuclei are fused, with the release of a large amount of energy. Very high temperatures and pressures are thought to be required in order for the process to happen. Under these conditions the atoms involved are stripped of all their electrons so that the remaining particles, which together make up a plasma, can come close together at very high speeds and overcome the mutual repulsion of the positive charges on the atomic nuclei. At very close range the strong nuclear force will come into play, fusing the particles together to form a larger nucleus. As fusion is accompanied by the release of large amounts of energy, the process might one day be harnessed to form the basis of commercial energy production. Methods of achieving controlled fusion are therefore the subject of research around the world.

Fusion is the process by which the Sun and the other stars produce their energy.

nuclear notation method used for labelling an atom according to the composition of its nucleus. The atoms or isotopes of a particular element are represented by the symbol A_ZX where A is the mass number of their nuclei, Z is their atomic number, and X is the chemical symbol for that element.

nuclear physics study of the properties of the nucleus of the atom, including the structure of nuclei; nuclear forces; the interactions between particles and nuclei; and the study of radioactive decay. The study of elementary particles is particle physics.

NUCLEAR ENERGY: FREQUENTLY ASKED QUESTIONS

<http://www-formal.stanford.edu/jmc/progress/nuclear-faq.html>

Answers to the most commonly asked questions about nuclear energy, particularly with a view to sustaining human progress. It contains many links to related pages and is a personal opinion that openly asks for comment from visitors.

When we have found how the nuclei of atoms are built up we shall have found the greatest secret of all – except life. We shall have found the basis of everything – of the earth we walk on, of the air we breathe, of the sunshine, of our physical body itself, of everything in the world, however great or however small – except life.

nuclear reaction reaction involving the nuclei of atoms. Atomic nuclei can undergo changes either as a result of radioactive decay, as in the decay of radium to radon (with the emission of an alpha particle) or as a result of particle bombardment in a machine or device, as in the production of cobalt-60 by the bombardment of cobalt-59 with neutrons.

Nuclear fission and nuclear fusion are examples of nuclear reactions. The enormous amounts of energy released arise from the mass-energy relation put forward by Einstein, stating that $E = mc^2$ (where E is energy, m is mass, and c is the velocity of light).

In nuclear reactions the sum of the masses of all the products (on the atomic mass unit scale) is less than the sum of the masses of the reacting particles. This lost mass is converted to energy according to Einstein's equation.

nuclear reactor device for producing nuclear energy in a controlled manner. There are various types of reactor in use, all using nuclear fission. In a gas-cooled reactor, a circulating gas under pressure (such as carbon dioxide) removes heat from the core of the reactor, which usually contains natural uranium. The efficiency of the fission process is increased by slowing neutrons in the core by using a moderator such as carbon. The reaction is controlled with neutron-absorbing rods made of boron. An advanced gas-cooled reactor (AGR) generally has enriched uranium as its fuel. A water-cooled reactor, such as the steam-generating heavy water (deuterium oxide) reactor, has water circulating through the hot core. The water is converted to steam, which drives turbo-alternators for generating electricity. The most widely used reactor is the pressurized-water reactor (PWR), which contains a sealed system of pressurized water that is heated to form steam in heat exchangers in an external circuit. The fast reactor has no moderator and uses fast neutrons to bring about fission. It uses a mixture of plutonium and uranium oxide as fuel. When operating, uranium is converted to plutonium, which can be extracted and used later as fuel. It is also called the fast breeder because it produces more plutonium than it consumes. Heat is removed from the reactor by a coolant of liquid sodium.

Public concern over the safety of nuclear reactors has been intensified by explosions and accidental release of radioactive materials. The safest system allows for the emergency cooling of a reactor by automatically flooding an overheated core with water. Other concerns about nuclear power centre on the difficulties of reprocessing nuclear fuel and disposing safely of nuclear waste, and the cost of maintaining nuclear power stations and of decommissioning them at the end of their lives. The break up of the former USSR raised concerns about the ability of the new nation states to safely manage ageing reactors. In 1989, the UK government decided to postpone the construction of new nuclear power stations; in the USA, no new stations have been commissioned in over a decade. Rancho Seco, near Sacramento, California, was the first nuclear power station to be closed, by popular vote, in 1989. Sweden is committed to decommissioning its reactors. Some countries, such as France, are pressing ahead with their nuclear programmes.

It was reported in 1997 that there were 443 nuclear power plants in 31 countries, representing a net growth of 15 since the 1992 Rio Earth Summit, and a further 36 were under construction. This compares with a total of just over 100 reactors generating electricity in 15 countries in 1972. Nuclear power generates around 17% of the world's electricity.

Major accidents resulting in the release of large quantities of radiation occurred at Three Mile Island in the USA in 1979 and Chernobyl, Ukraine, in 1986.

nuclear safety measures to avoid accidents in the operation of nuclear reactors and in the production and disposal of nuclear weapons and of nuclear waste. There are no guarantees of the safety of any of the various methods of disposal.

Nuclear accidents Windscale (now Sellafield), Cumbria, England. In 1957, fire destroyed the core of a reactor, releasing large quantities of radioactive fumes into the atmosphere.

Ticonderoga, 130 km/80 mi off the coast of Japan. In 1965 a US Navy Skyhawk jet bomber fell off the deck of this ship, sinking in 4,900 m/16,000 ft of water. It carried a one-megaton hydrogen bomb. The accident was only revealed in 1989.

Three Mile Island, Harrisburg, Pennsylvania, USA. In 1979, a combination of mechanical and electrical failure, as well as operator error, caused a pressurized water reactor to leak radioactive matter.

Church Rock, New Mexico, USA. In July 1979, 380 million litres/100 million gallons of radioactive water containing uranium leaked from a pond into the Rio Puerco, causing the water to become over 6,500 times as radioactive as safety standards allow for drinking water.

Chernobyl, Ukraine. In April 1986 there was an explosive leak, caused by overheating, from a nonpressurized boiling-water reactor, one of the largest in Europe. The resulting clouds of radioactive material spread as far as the UK. 31 people were killed in the explosion, and thousands of square kilometres of land were contaminated by fallout. By June 1992, seven times as many children in the Ukraine and Belarus were contracting thyroid cancer as before the accident, the incidence of leukemia was rising, and it was estimated that more than 6,000 people had died as a result of the accident, and that the death toll in the Ukraine alone would eventually reach 40,000.

Toms, Siberia, Russia. In April 1993 a tank exploded at a uranium reprocessing plant, sending a cloud of radioactive particles into the air.

nuclear waste the radioactive and toxic by-products of the nuclear-energy and nuclear-weapons industries. Nuclear waste may have an active life of several thousand years. Reactor waste is of three types: high-level spent fuel, or the residue when nuclear fuel has been removed from a reactor and reprocessed; intermediate, which may be long- or short-lived; and low-level, but bulky, waste from reactors, which has only short-lived radioactivity. Disposal, by burial on land or at sea, has raised problems of safety, environmental pollution, and security.

The issue of nuclear waste is becoming the central controversy threatening the future of generating electricity by nuclear energy. The dumping of nuclear waste at sea officially stopped in 1983, when a moratorium was agreed by the members of the London Dumping Convention (a United Nations body that controls disposal of wastes at sea). covertly, the USSR continued dumping, and deposited thousands of tonnes of nuclear waste and three faulty reactors in the sea during 1964–86. The USSR and the Russian Federation between them dumped an estimated 12 trillion becquerels of radioactivity in the sea 1959–93. Russia has no way of treating nuclear waste and in 1993 announced its intention of continuing to dump it in the sea, in violation of international conventions, until 1997. Twenty reactors from Soviet nuclear-powered ships were dumped off the Arctic and Pacific coasts 1965–93, and some are leaking. Fish-spawning grounds off Norway are threatened by plutonium from abandoned Soviet nuclear warheads.

nucleic acid complex organic acid made up of a long chain of nucleotides, present in the nucleus and sometimes the cytoplasm of the living cell. The two types, known as DNA (deoxyribonucleic acid) and RNA (ribonucleic acid), form the basis of heredity. The nucleotides are made up of a sugar (deoxyribose or ribose), a phosphate group, and one of four purine or pyrimidine bases. The order of the bases along the nucleic acid strand contains the genetic code.

nucleolus in biology, a structure found in the nucleus of eukaryotic cells. It produces the RNA that makes up the ribosomes, from instructions in the DNA.

nucleon in particle physics, either a δ proton or a δ neutron, when present in the atomic nucleus. **Nucleon number** is an alternative name for the δ mass number of an atom.

nucleon number or **mass number** (symbol A) the sum of the numbers of protons and neutrons in the nucleus of an atom. With the proton number, it is used in nuclear notation – for example, in the symbol $^{14}_6\text{C}$ representing the isotope carbon-14, the lower number is the δ proton number, and the upper is the nucleon number.

nucleotide organic compound consisting of a purine (adenine or guanine) or a pyrimidine (thymine, uracil, or cytosine) base linked to a sugar (deoxyribose or ribose) and a phosphate group. δ DNA and δ RNA are made up of long chains of nucleotides.

TO REMEMBER CLASSES OF NUCLEOTIDES:

IN DNA THERE ARE FOUR NUCLEOTIDES (CYTOSINE, THYMINE, ADENINE, GUANINE) DIVIDED INTO TWO CLASSES (PYRIMIDINES AND PURINES). THE EASIEST WAY TO REMEMBER WHICH CLASS THEY BELONG TO IS THAT THE PYRIMIDINES CONTAIN THE LETTER Y (CYTOSINE AND THYMINE)

nucleus in astronomy, the compact central core of a δ galaxy, often containing powerful radio, X-ray and infrared sources. Active galaxies have extremely energetic nuclei.

nucleus in biology, the central, membrane-enclosed part of a eukaryotic cell, containing the chromosomes.

nucleus in physics, the positively charged central part of an δ atom, which constitutes almost all its mass. Except for hydrogen nuclei, which have only protons, nuclei are composed of both protons and neutrons. Surrounding the nuclei are electrons, of equal and opposite charge to that of the protons, thus giving the atom a neutral charge.

The nucleus was discovered by New Zealand physicist Ernest Rutherford in 1911 as a result of experiments in passing alpha particles through very thin gold foil.

nucleide in physics, a species of atomic nucleus characterized by the number of protons (Z) and the number of neutrons (N). Nucleides with identical δ proton number but differing δ neutron number are called δ isotopes.

nuée ardente a rapidly flowing, glowing white-hot cloud of ash and gas emitted by a volcano during a violent eruption. The ash and other pyroclastics in the lower part of the cloud behave like an ash flow. In 1902 a nuée ardente produced by the eruption of Mount Pelee in Martinique swept down the volcano in a matter of seconds and killed 28,000 people in the nearby town of St Pierre.

null character character with the δ ASCII value 0. A null character is used by some programming languages, most notably C, to mark the end of a character string.

null-modem special cable that is used to connect the δ serial interfaces of two computers, so as to allow them to exchange data.

null string in computing, a string, usually denoted by '-', containing nothing or a δ null character. A null string is used in some programming languages to denote the last of a series of values.

numbat or **banded anteater** Australian δ marsupial anteater. It is brown with white stripes on the back and has a long tubular tongue to gather termites and ants. The body is about 25 cm/10 in long, and the tongue can be extended 10 cm/4 in. It is different from other marsupials in that it has no pouch. (Species *Myrmecobius fasciatus*.)

number symbol used in counting or measuring. In mathematics, there are various kinds of numbers. The everyday number system is the decimal ('preceding by tens') system, using the base ten. δ Real numbers include all rational numbers (integers, or whole numbers, and fractions) and irrational numbers (those not

expressible as fractions). δ Complex numbers include the real and imaginary numbers (real-number multiples of the square root of -1). The δ binary number system, used in computers, has two as its base. The δ natural numbers, 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9, give a counting system that, in the decimal system, continues 10, 11, 12, 13, and so on. These are whole numbers (integers), with fractions represented as, for example, $\frac{1}{2}$, $\frac{3}{4}$, or as decimal fractions (0.25, 0.5, 0.75). They are also rational numbers. Irrational numbers cannot be represented in this way and require symbols, such as $\sqrt{2}$, π , and e. They can be expressed numerically only as the (inexact) approximations 1.414, 3.142, and 2.718 (to three places of decimals) respectively. The symbols π and e are also examples of transcendental numbers, because they (unlike $\sqrt{2}$) cannot be derived by solving a δ polynomial equation (an equation with one δ variable quantity) with rational δ coefficients (multiplying factors). Complex numbers, which include the real numbers as well as imaginary numbers, take the general form $a + bi$, where $i = \sqrt{-1}$ (that is, $i^2 = -1$), and a is the real part and bi the imaginary part.

evolution of number systems The ancient Egyptians, Greeks, Romans, and Babylonians all evolved number systems, although none had a δ zero, which was introduced from India by way of Arab mathematicians in about the 8th century AD and allowed a place-value system to be devised on which the decimal system is based. Other number systems have since evolved and have found applications. For example, numbers to base two (binary numbers), using only 0 and 1, are commonly used in digital computers to represent the two-state 'on' or 'off' pulses of electricity. Binary numbers were first developed by German mathematician Gottfried Leibniz in the late 17th century.

Numbers constitute the only universal language.

number theory in mathematics, the abstract study of the structure of number systems and the properties of positive integers (whole numbers). For example, the theories of factors and prime numbers fall within this area, as do the work of mathematicians Giuseppe Peano (1858–1932), Pierre de Fermat, and Karl Gauss.

numerator the number or symbol that appears above the line in a vulgar fraction. For example, the numerator of $\frac{5}{6}$ is 5. The numerator represents the fraction's dividend and indicates how many of the equal parts indicated by the denominator (number or symbol below the line) comprise the fraction.

nursing care of the sick, the very young, the very old, and the disabled. Organized training originated in 1836 in Germany, and was developed in Britain by the work of Florence Nightingale, who, during the Crimean War, established standards of scientific, humanitarian care in military hospitals. Nurses give day-to-day care and carry out routine medical and surgical duties under the supervision of medical staff.

In ancient times very limited care was associated with some temples, and in Christian times nursing became associated with the religious orders until the Reformation brought it into secular hands in Protestant countries. Many specialities and qualifications now exist in Western countries, standards being maintained by professional bodies and boards.

nut any dry, single-seeded fruit that does not split open to release the seed, such as the chestnut. A nut is formed from more than one carpel, but only one seed becomes fully formed, the remainder aborting. The wall of the fruit, the pericarp, becomes hard and woody, forming the outer shell.

Examples of true nuts are the acorn and hazelnut. The term also describes various hard-shelled fruits and seeds, including almonds and walnuts, which are really the stones of δ drupe, and brazil nuts and shelled peanuts, which are seeds. The kernels of most nuts provide a concentrated, nutritious food, containing vitamins, minerals, and enzymes, about 50% fat, and 10–20% protein, although

Nucleus: Early Experiments to Determine Structure

The most incredible event

What is an atom? Until about 100 years ago, scientists were pretty confident in regarding atoms as the permanent bricks of which the whole universe was built. All the changes of the universe amounted to nothing more drastic than simple rearrangements of permanent, indestructible atoms. Atoms seemed like the bricks in a child's box of toys, which could be used to build many different buildings in turn.

Chipped bricks ...

This comfortable picture was changed by the investigations of British physicist Joseph John Thomson (1856-1940) into cathode rays. Thomson showed conclusively that not only could atomic 'bricks' be chipped, but that the fragments produced were identical, no matter what atom they came from. They were of equal weight or mass, and carried the same negative electrical charge. The fragments were called electrons.

Thomson's experiments enabled him to calculate the ratio of the mass of the electron to its charge: it was about 1,000 times smaller than the value that had already been calculated for a hydrogen ion in the electrolysis of liquids. This was the proof, announced in April 1897, that electrons were fundamental particles of matter, far smaller than any atom. But atoms could not consist of negatively charged electrons alone. Particles with like electrical charge repel one another and, anyway, atoms are electrically neutral.

Thomson, who built up the Cavendish Laboratory at Cambridge into a great research school, was succeeded as professor by New Zealand physicist Ernest Rutherford (1871-1937), his pupil and one of the greatest pioneers of subatomic physics. Rutherford, while professor of physics at Manchester University, had shown that [alpha]-particles were doubly ionized helium atoms, using a Geiger-Müller counter. His assistant, German physicist Hans Wilhelm Geiger (1882-1945), with a colleague Walther Müller, invented this instrument, which is still used to measure ionizing radiation.

... And indestructible tissue paper?

Rutherford's idea for attacking the problem of the nature of an atom was to study the scattering of [alpha]-particles passing through thin metal foils. This painstaking work was carried out by Geiger in 1910 with his colleague Marsden, with astonishing results. They found that most of the particles were only slightly deflected as they passed through the foil. But a very small proportion, about 1 in 8,000, were widely deflected. Rutherford described this result as '... quite the most incredible event that has ever happened to me in my life ... It was almost as if you fired a 15 inch shell at a piece of tissue paper and it came back and hit you.'

The nuclear atom

Rutherford concluded when he published the results in 1911 that almost all the mass of the atom was concentrated in a very small region and that most of the atom was 'empty space'. This crucial experiment established the idea of the nuclear atom. The obstacle that deflected the [alpha]-particles could only be the missing positive charges of the atom. These were carried by the minute central nucleus. The electrons, Rutherford supposed, must be in motion around the nucleus, otherwise they would be drawn to it.

The number of positive charges in the nucleus equalled the number of electrons, and so accounted for the electrical neutrality of the atom. The proton, later discovered as part of the nucleus, carried an equal but opposite charge to the electron. But on theoretical grounds, Rutherford's planetary model of the atom was unstable. Since electrons are charged particles, an atom ought to radiate energy by virtue of their motion. Danish theoretical physicist Niels Bohr (1885-1962), who was Rutherford's pupil, provided the theory that accounted for the stability of the atom. He showed that electrons must reside in 'stationary' orbits, in which they did not radiate energy.

a few, such as chestnuts, are high in carbohydrates and have only a moderate protein content of 5%. Nuts also provide edible and industrial oils. Most nuts are produced by perennial trees and shrubs. Whereas the majority of nuts are obtained from plantations, considerable quantities of pecans and brazil nuts are still collected from the wild. World production in the mid-1980s was about 4 million tonnes per year.

nut and bolt common method of fastening pieces of metal or wood together. The nut consists of a small block (usually metal) with a threaded hole in the centre for screwing on to a threaded rod or pin (bolt or screw). The method came into use at the turn of the 19th century, following Henry Maudslay's invention of a precision screw-cutting lathe.

nutrition the strategy adopted by an organism to obtain the chemicals it needs to live, grow, and reproduce. Also, the science of food, and its effect on human and animal life, health, and disease. Nutrition involves the study of the basic nutrients required to sustain life, their bioavailability in foods and overall diet, and the effects upon them of cooking and storage. It is also concerned with dietary deficiency diseases.

There are six classes of nutrients: water, carbohydrates, proteins, fats, vitamins, and minerals.

water Water is involved in nearly every body process. Animals and humans will succumb to water deprivation sooner than to starvation.

carbohydrates Carbohydrates are composed of carbon, hydrogen and oxygen. The major groups are starches, sugars, and cellulose and related material (or 'roughage'). The prime function of the carbohydrates is to provide energy for the body; they also serve as efficient sources of glucose, which the body requires for brain func-

proteins Proteins are made up of smaller units, amino acids. The primary function of dietary protein is to provide the amino acids required for growth and maintenance of body tissues. Both vegetable and animal foods are protein sources.

fats Fats serve as concentrated sources of energy, and protect vital organs such as the kidneys and skeleton. Saturated fats derive primarily from animal sources; unsaturated fats from vegetable sources such as nuts and seeds.

vitamins Vitamins are essential for normal growth, and are either fat-soluble or water-soluble. Fat-soluble vitamins include A, essential to the maintenance of mucous membranes, particularly the conjunctiva of the eyes; D, important to the absorption of calcium; E, an anti-oxidant; and K, which aids blood clotting. Water-soluble

vitamins are the B complex, essential to metabolic reactions, and C, for maintaining connective tissue.

minerals Minerals are vital to normal development; calcium and iron are particularly important as they are required in relatively large amounts. Minerals required by the body in trace amounts include chromium, copper, fluoride, iodine, iron, magnesium, manganese, molybdenum, phosphorus, potassium, selenium, sodium, and zinc.

nylon synthetic long-chain polymer similar in chemical structure to protein. Nylon was the first all-synthesized fibre, made from petroleum, natural gas, air, and water by the Du Pont firm in 1938. It is used in the manufacture of moulded articles, textiles, and medical sutures. Nylon fibres are stronger and more elastic than silk and are relatively insensitive to moisture and mildew. Nylon is used for hosiery and woven goods, simulating other materials such as silks and furs; it is also used for carpets.

The Invention of Nylon

by Paul Meehan

Introduction

During the late 1920s, the Du Pont chemical company committed itself to a long-term programme of 'basic research', with particular emphasis on the development of new synthetic materials. In 1928, Wallace Hume Carothers (1896-1937), a young Harvard chemist, was appointed to lead the fledgling project. Within four years Carothers' team had developed and marketed neoprene, the first successful synthetic rubber; during the next decade numerous new materials were patented, culminating with the commercial release of nylon in October 1938, 18 months after Carothers' tragic death.

Polymer chemistry

By 1925, Du Pont had recognized the importance of the development of new materials; cheaper and better alternatives to expensive products such as silk were in great demand. Wallace Carothers, educated in Illinois and a teacher of chemistry at three Southern Universities, was plucked from Harvard to head Du Pont's research facility at Wilmington, Delaware, in 1928. The main goal of Carothers' team was to prepare and investigate organic compounds of high molecular weight; the group was then to develop ways in which each product's properties could be tailored to suit their desired final applications. This particular field, relatively unexplored at the time, was known as polymer chemistry; this branch of science was revolutionized by Carothers and his colleagues during the course of the next decade.

Carothers' first major contribution was the implementation of a technique known as 'condensation polymerization'. In this process, two compounds containing reactive groups at each end were combined in equimolar amounts to form a third complex, with the elimination of water as a by-product. The new complex, also containing reactive end-groups, could be further reacted, leading to the stepwise formation of a large polymeric material. The addition of a tiny amount of a 'termination agent', typically a monoacid or monamine, halted the reaction, and prevented the generation of compounds of extremely high molecular weight, which would prove unmanageable. The final product could then be treated by one of several simple processes to produce polymers with specific properties.

Within three years the team had developed neoprene, the first commercially produced synthetic rubber. This was launched to great success in 1932. Subsequent experiments with polyesters proved moderately successful, but the company's overriding desire was to develop products which would emulate the properties of silk. For this

reason Carothers turned to polyamide production. The reaction between dibasic acids and diamines generated a polymeric salt. Subsequent heating of this salt formed the polyamide resin. This process produced the series of products which would ultimately revolutionize materials science and make Du Pont's fortune - the nylons.

Nylon development

Upon production, the polyamides were treated by a process known as 'melt-spinning'. During this process, the hot, molten polymer is passed into a stream of cold air, whereupon it solidifies into a filament; depending on the final intended use of the product, this filament can range in size from finer than a human hair to thick bristles, akin to those used in toothbrushes. The filaments are then stretched, a process known as 'drawing', to make the component molecules pack more closely; this increase in the order, or crystallinity, of the material provides increased strength and elasticity in the resulting fibre. Nylon can be drawn to four times its original length.

Although nylon was the name given to the class of polyamide compounds produced by this process, commercial nylon is formed from the reaction between hexamethylenediamine and adipic acid; each component contains six carbon atoms, hence the systematic name nylon-6,6. The nylons as a group are strong, tough materials, adaptable to moulding. Although nylon has since been used in a huge variety of commercial applications, such as mechanical parts, carpets and home furnishings, the initial and most famous use of nylon was in ladies hosiery.

Commercial success

Carothers' life was blighted by a history of personal suffering; alcoholism and recurrent bouts of clinical depression ultimately led to his suicide, shortly after his 41st birthday in 1937. However, the development of nylon established his greatness as a chemical pioneer. When Charles Stine unveiled nylon to an unsuspecting world in New York, New York, on October 27th, 1938, the product was greeted by near-hysteria; on their first day of sales, a remarkable 5 million pairs of nylon stockings were bought by the public. Du Pont presently sells over 3 billion pounds worth of nylon annually, confirming the durability and importance of the product. However, Du Pont's legacy of success transcends nylon production. Carothers' research team pioneered modern polymer chemistry and sparked the materials revolution which has galvanized the chemical industry in the second half of the 20th century.

obesity condition of being overweight (generally, 20% or more above the desirable weight for one's sex, build, and height). Obesity increases susceptibility to disease, strains the vital organs, and reduces life expectancy; it is usually remedied by controlled weight loss, healthy diet, and exercise.

In 1994 US researchers discovered a gene in mice, *ob*, which controls the production of leptin, a protein involved in appetite control; defects in this gene cause obesity. Research during 1995 showed that obese mice lost weight dramatically after a 4-week treatment with the protein. An almost identical gene is found in humans, but obese humans have been found to have too much leptin rather than too little, as was the case in mice, so leptin injections will not cure obesity in humans.

object-oriented programming (OOP) computer programming based on 'objects', in which data are closely linked to the procedures that operate on them. For example, a circle on the screen might be an object: it has data, such as a centre point and a radius, as well as procedures for moving it, erasing it, changing its size, and so on.

The technique originated with the Simula and Smalltalk languages in the 1960s and early 1970s, but it has now been incorporated into many general-purpose programming languages, including Java.

It used two transmitters based in the UK: one tracked the bomber, guiding it on a course across the target. The other also tracked the bomber and ordered it to drop its bombs at the computed bomb-release point. Since accuracy was of a very high order, bombing became very accurate, and the system was used by the Pathfinder force to drop marker bombs for the rest of a bombing force.

observation in science, the perception of a phenomenon – for example, examining the Moon through a telescope, watching mice to discover their mating habits, or seeing how a plant grows.

Traditionally, observation was seen as entirely separate from theory, free from preconceptions and therefore lending support to the idea of scientific objectivity. However, as the preceding examples show, observations are ordered according to a pre-existing theory; for instance, one cannot observe mating behaviour without having decided what mating behaviour might look like. In addition, many observations actually affect the behaviour of the observed (for instance, of mating mice).

When I am obliged to give up observation and experiment I shall die.

The modern observatory dates from the invention of the telescope. Observatories may be ground-based, carried on aircraft, or sent into orbit as satellites, in space stations, and on the space shuttle.

The erection of observatories was revived in W Asia about AD 1000, and extended to Europe. The observatory built on the island of Hven (now Ven) in Denmark in 1576 for Tycho Brahe (1546-1601) was elaborate, but survived only to 1597. Later, observatories were built in Paris in 1667, *Greenwich* (the *Royal Greenwich Observatory*) in 1675, and Kew, England. Most early observatories were near towns, but with the advent of big telescopes, clear skies with little background light, and hence high, remote sites, became essential.

Obesity, a Question of Inheritance

by Hilary Neve

At present, it is not possible to answer the question 'is obesity influenced by genetic factors?', as the roles of inherited (or genetic) factors in the development and maintenance of obesity are not yet understood fully, and the conclusions reported in many studies vary. They range from 'little genetic influence' to 'strong genetic influence', and depend on the specific factor investigated. This is because obesity itself is not merely just a simple disorder, but is in fact a complex mix of several varied disorders, each of which may be influenced by both genetic and nongenetic factors, and with interaction between different genes, and between genes and the environment.

Definition of Obesity

An individual is considered to be obese when they have a Body Mass Index (BMI) in excess of 30. The BMI is calculated by taking the individual's weight in kilograms and dividing this by the height in metres. Obesity occurs when energy intake exceeds the actual energy expended, so the unused energy is stored as body fat. A BMI of over 30 is a hazard to health and well being, and is now common enough in the Western world to constitute one of the most important medical and public health problems, putting the individual at high risk of degenerative disease or even death, and these risks increase as the BMI increases.

Obesity has been attributed to numerous causes including excessive intake, reactive eating due to stress or anxiety, low resting metabolic rate influencing the caloric value of energy expenditure, environmental effects, family behaviour problems, and genetic factors. Other influences include human biology, endocrine alterations, society, culture, and physical activity. It is a complex issue.

Genetic Influence

An individual's genetic composition (their genotype) has a specific influence on their sex, height, eye colour, and skeleton, and may also influence their body and muscular mass, as well as body fat and how this is regionally distributed. The variation in body fat distribution may also result from a complex interaction of physical, environmental, and social features, as well as from the genotype. Each gene may have a varying or specific influence with many genes each exerting a small effect, or perhaps a single rarer gene that plays a larger role over time, with inherited differences in the likelihood of developing obesity.

Each genotype may have its own particular influence, with a single gene defect influencing obesity, or it may exert several independent (polygenic) influences, including regulation of energy expenditure (or metabolism). For example, there may be a form of thrifty genotype that has developed over time, and which influences the more efficient use of energy intake. The body fat itself may consist mainly of enlarged fat cells, or there may be a larger number of smaller fat cells, each of which may have a specific genotype influence. Perhaps there is no particular gene that influences the development and/or maintenance of obesity, but probably several genes and aspects of human physiology that determine many aspects of weight, appetite, satiety, metabolism, and a predisposition to physical activity. Families may have shared genes, and they often share the same environment and particular eating patterns – also influential factors that need to be examined separately. With regard to body fat variation, the additive genetic effect on the amount of subcutaneous fat is considered to be quite

low, but has been reported as highest for fat mass and regional distribution of the fat, which suggests that the genotype may be more influential on the visceral fat than the subcutaneous store. From the limited data available it appears that the genotype could account for up to 40 percent of the individual differences in the resting metabolic rate, the thermic effect of food, and the energy cost of light exercise, which would explain why some people become obese.

Studies

Studies of obesity in families show there is possibly a familial influence; for example, in a series of studies of the families of obese children, it was found that a child with one obese parent was at greater risk of developing obesity, but surprisingly also that those with two obese parents were at a lesser risk! This shows how complex this issue is and demonstrates the need for much more investigation.

Studies of adopted children and both their biological and adoptive parents suggest that inheritance plays an important role in the risk of developing obesity. Research has shown that there was no relationship between the BMI of the child and the adoptive parents, but that the BMI of the biological parents actually increased with that of the child whose weight was increasing.

Further evidence for the effect of the genotype and its influence has come from work examining the body weight of twins, where nearly two-thirds of the variability in BMI was attributed to genetic factors. The body weight of twins of the same sex (monozygotic) has been found to have identical genetic features and is more similar than the body weight of twins of different sexes (dizygotic). The genetic features of dizygotic twins are similar to those of other siblings.

Obesity appears to be more prevalent in the families of obese patients seeking surgical treatment for their condition than in a group of nonobese patients treated with other abdominal surgery. In approximately 10 percent of the families of the patients seeking help, more than one other member sought treatment. The incidence of obesity in the families of these patients was compared with that in a group of nonobese patients, and it was found that there were significantly more obese family members in the obese group. These included mothers and daughters, fathers and daughters, sisters and brothers, all with a BMI of over 35. This would suggest a genetic influence, and a need for further investigations into these factors.

There are also certain inherited syndromes where obesity is one of the characteristics. These include, in particular, Prader-Willi Syndrome, where children develop a ravenous appetite and a variety of food-seeking behaviours, with parents fighting a losing battle to control the child's intake. The Bardet-Biedl Syndrome is transmitted via an autosomal recessive trait, with obesity occurring in up to 80 percent of the cases.

There appears to be some single and polygenic influence on the transmission of obesity, although the genetic influence is more important in determining body fat distribution, and studies show that it may run in families, but one needs to examine separately the influences of the environment and the genes. The search for genetic members of the various obesity phenotypes does not appear to have been initiated to any extent as yet, but it appears likely to be increased in the future, as searches for influences on obesity continue.

Ocean Drilling Program (ODP, formerly the *Deep-Sea Drilling Project 1968–85*) research project initiated in the USA to sample the rocks of the ocean crust. Initially under the direction of Scripps Institution of Oceanography, the project was planned and administered by the Joint Oceanographic Institutions for Deep Earth Sampling (JOIDES). The operation became international in 1975, when Britain, France, West Germany, Japan, and the USSR also became involved.

Boreholes were drilled in all the oceans using the JOIDES ships *Glomar Challenger* and *Resolution*. Knowledge of the nature and history of the ocean basins was increased dramatically. The technical difficulty of drilling the seabed to a depth of 2,000 m/6,500 ft was overcome by keeping the ship in position with side-thrusting propellers and satellite navigation, and by guiding the drill using a radiolocation system. The project is intended to continue until 2005.

oceanography study of the oceans. Its subdivisions deal with each ocean's extent and depth, the water's evolution and composition, its physics and chemistry, the bottom topography, currents and wind effects, tidal ranges, the biology, and the various aspects of human use.

Oceanography involves the study of water movements – currents, waves, and tides – and the chemical and physical properties of the seawater. It deals with the origin and topography of the ocean floor – ocean trenches and ridges formed by plate tectonics, and continental shelves from the submerged portions of the continents. Computer simulations are widely used in oceanography to plot the possible movements of the waters, and many studies are carried out by remote sensing.

ocean ridge mountain range on the seabed indicating the presence of a constructive plate margin (where tectonic plates are moving apart and magma rises to the surface; see plate tectonics). Ocean ridges, such as the Mid-Atlantic Ridge, consist of many segments offset along transform faults, and can rise thousands of metres above the surrounding seabed.

Ocean ridges usually have a rift valley along their crests, indicating where the flanks are being pulled apart by the growth of the plates of the lithosphere beneath. The crests are generally free of sediment; increasing depths of sediment are found with increasing distance down the flanks.

ocean trench deep trench in the seabed indicating the presence of a destructive margin (produced by the movements of plate tectonics). The subduction or dragging downwards of one plate of the lithosphere beneath another means that the ocean floor is pulled down. Ocean trenches are found around the edge of the Pacific Ocean and the NE Indian Ocean; minor ones occur in the Caribbean and near the Falkland Islands.

Ocean trenches represent the deepest parts of the ocean floor, the deepest being the Mariana Trench which has a depth of 11,034 m/36,201 ft. At depths of below 6 km/3.6 mi there is no light and very high pressure; ocean trenches are inhabited by crustaceans, coelenterates (for example, sea anemones), polychaetes (a type of worm), molluscs, and echinoderms.

octahedron, regular An octahedron is a solid figure which has eight faces, each of which is an equilateral triangle.

octal number system number system to the base eight, used in computing. The highest digit that can appear in the octal system is seven. Whereas normal decimal, or base-ten, numbers may be considered to be written under column headings based on the number ten, octal, or base-eight, numbers can be thought of as written under column headings based on the number eight. The octal number 567 is therefore equivalent to the decimal number 375, since $(5 \times 64) + (6 \times 8) + (7 \times 1) = 375$.

The octal number system is sometimes used by computer programmers as an alternative to the ϕ hexadecimal number system.

octane rating numerical classification of petroleum fuels indicating their combustion characteristics.

The efficient running of an internal combustion engine depends on the ignition of a petrol-air mixture at the correct time during the cycle of the engine. Higher-rated petrol burns faster than lower-rated fuels. The use of the correct grade must be matched to the engine.

Octans faint constellation in the southern hemisphere, represented as an octant. It contains the southern celestial pole. The closest naked-eye star to the south celestial pole is fifth-magnitude Sigma Octantis.

octet rule in chemistry, rule stating that elements combine in a way that gives them the electronic structure of the nearest ϕ inert gas. All the inert gases except helium have eight electrons in their outermost shell, hence the term octet.

octopus soft-bodied sea animal with a round or oval body and eight slender arms (tentacles) in a ring surrounding its mouth. They are solitary creatures, living alone in rocky dens. They feed on crabs and other small animals. There are about 50 different species of octopus living in all the oceans of the world. Some are small, having bodies only 8 cm/3 in long, but the largest deep-sea species can grow to lengths of 20 m/64 ft.

behaviour Octopuses can change colour to blend in with their surroundings and can swim using their arms or by a form of jet propulsion by squirting out water from their bodies. The octopus has rows of suckers along the length of each arm (or tentacle) which, as well as helping it swim and crawl around the ocean floor, allows it to search in cracks and crevices and grab prey. The octopus is a carnivore (flesh-eater), usually feeding on crabs, shrimps, and mussels, but the larger species of octopus have been known to hunt small sharks and dogfish. They trap the prey in their arms

and drag it towards their powerful beaklike jaws. Once it has bitten its prey, the octopus injects it with a poisonous saliva to kill it. Sometimes, when frightened or to avoid enemies, they squirt out a black ink from their bodies which hides them and allows them to escape. If they lose an arm, they can grow another in its place. Octopuses are highly intelligent with two well developed eyes, similar to those of vertebrates (animals with backbones). They breathe using gills as fish do, but are unique in that they have three hearts. **classification** Octopuses belong to the phylum Mollusca (ϕ molluscs), class Cephalopoda (ϕ cephalopods), subclass Coleoidea. They belong to the genus *Octopus* and there are about 50 known species including the common octopus (*O. vulgaris*), which may reach 2 m/6 ft in length; the Australian blue-ringed octopus (genus *Flapalochlaena*) that can kill a human being in 15 minutes as a result of its venomous bite; and the giant deep-sea octopus (*Architeuthis dux*) that can grow to 20 m/64 ft.

odd number any number not divisible by 2, thus odd numbers form the infinite sequence 1, 3, 5, 7, ... Every square number n^2 is the sum of the first n odd numbers. For example, $49 = 7^2 = 1 + 3 + 5 + 7 + 9 + 11 + 13$.

oedema any abnormal accumulation of fluid in tissues or cavities of the body; waterlogging of the tissues due to excessive loss of ϕ lasma through the capillary walls.

It may be generalized (the condition once known as dropsy) or confined to one area, such as the ankles.

Oedema may be mechanical – the result of obstructed veins or heart failure – or it may be due to increased permeability of the capillary walls, as in liver or kidney disease or malnutrition. Accumulation of fluid in the abdomen, a complication of cirrhosis, is known as ascites.

Oedipus complex in psychology, the unconscious antagonism of a son to his father, whom he sees as a rival for his mother's affection. For a girl antagonism to her mother, as a rival for her father's affection, the term is Electra complex. The terms were coined by Sigmund Freud.

Freud saw this as a universal part of childhood development, which in most children is resolved during late childhood. Contemporary theory places less importance on the Oedipus/Electra complex than did Freud and his followers.

OEM in computing, abbreviation for ϕ original equipment manufacturer.

oersted c.g.s. unit (symbol Oe) of ϕ magnetic field strength, now replaced by the SI unit ampere per metre. The Earth's magnetic field is about 0.5 oersted; the field near the poles of a small bar magnet is several hundred oersteds; and a powerful ϕ electromagnet can have a field strength of 30,000 oersteds.

oesophagus muscular tube by which food travels from mouth to stomach. The human oesophagus is about 23 cm/9 in long. It extends downwards from the ϕ arynx, immediately behind the windpipe. It is lined with a mucous membrane which secretes lubricant fluid to assist the downward movement of food (ϕ peristalsis).

oestrogen any of a group of hormones produced by the ϕ varities of vertebrates; the term is also used for various synthetic hormones that mimic their effects. The principal oestrogen in mammals is oestradiol. Oestrogens control female sexual development, promote the growth of female secondary sexual characteristics, stimulate egg production, and, in mammals, prepare the lining of the uterus for pregnancy.

Oestrogens are used therapeutically for some hormone disorders and to inhibit lactation; they also form the basis of oral contraceptives. US researchers in 1995 observed that oestrogen plays a role in the healing of damaged blood vessels. It has also been found that women recover more quickly from strokes if given a low oestrogen dose.

oestrus in mammals, the period during a female's reproductive cycle (also known as the oestrus cycle or menstrual cycle) when mating is most likely to occur. It usually coincides with ovulation.

office automation introduction of computers and other electronic equipment, such as fax machines, to support an office routine. Increasingly, computers are used to support administrative tasks such as document processing, filing, mail, and schedule management; project planning and management accounting have also been computerized.

office suite in computing, set of bundled programs designed especially for business use. An office suite will typically contain a spreadsheet, scheduling and presentation software, a word processor, a database, and e-mail facilities. The programs are set up to work individually and in concert, so that the user can (for example) create a report with charts created from a spreadsheet, and then e-mail the document to a list of clients selected from the database. Popular office suites include Lotus SmartSuite and Microsoft Office.

offline in computing, not connected, so that data cannot be transferred, for example, to a printer. The opposite of *on line*.

offline browser in computing, program that downloads and copies Web pages onto a computer so that they can be viewed without being connected to the Internet. By taking advantage of off-peak hours, when telephone charges are low and the network responds faster, offline browsers are a thrifty way of using the World Wide Web.

offline editing in video and film, process of editing a scratch copy of the footage rather than the expensively created footage itself. Once the edit has been finalized, the real footage is edited by a machine.

offline reader in computing, program that downloads information from newsgroups, FTP servers or other Internet resources, storing it locally on a hard disc so that it can be read without running up a large telephone bill.

offset printing the most common method of printing, which uses smooth (often rubber) printing plates. It works on the principle of lithography: that grease and water repel one another.

The printing plate is prepared using a photographic technique, resulting in a type image that attracts greasy printing ink. On the printing press the plate is wrapped around a cylinder and wetted and inked in turn. The ink adheres only to the type area, and this image is then transferred via an intermediate blanket cylinder to the paper.

ogive in statistics, the curve on a graph representing cumulative frequency.

ohm SI unit (symbol Ω) of electrical resistance (the property of a conductor that restricts the flow of electrons through it).

It was originally defined with reference to the resistance of a column of mercury, but is now taken as the resistance between two points when a potential difference of one volt between them produces a current of one ampere.

Ohm, Georg Simon (1789–1854)

German physicist who studied electricity and discovered the fundamental law that bears his name. The SI unit of electrical resistance, the ohm, is named after him, and the unit of conductance (the inverse of resistance) was formerly called the mho, which is 'ohm' spelled backwards.

Mary Evans Picture Library

Ohm's law law that states that the current flowing in a metallic conductor maintained at constant temperature is directly proportional to the potential difference (voltage) between its ends. The law was discovered by German physicist Georg Ohm in 1827.

If a current of I amperes flows between two points in a conductor across which the potential difference is V volts, then V/I is a constant called the resistance R ohms between those two points. Hence:

$$V/I = R \text{ or } V = IR$$

Not all conductors obey Ohm's law; those that do are called **ohmic conductors**.

TO REMEMBER ONE EXPRESSION OF THIS:

VAMPIRES ARE RARE.

VOLTS = AMPS \times RESISTANCE

oil flammable substance, usually insoluble in water, and composed chiefly of carbon and hydrogen. Oils may be solids (fats and waxes) or liquids. The three main types are: essential oils, obtained from plants; fixed oils, obtained from animals and plants; and mineral oils, obtained chiefly from the refining of petroleum.

Essential oils are volatile liquids that have the odour of their plant source and are used in perfumes, flavouring essences, and in aromatherapy. Fixed oils are mixtures of lipids, of varying consistency, found in both animals (for example, fish oils) and plants (in nuts and seeds); they are used as foods and as lubricants, and in the making of soaps, paints, and varnishes. Mineral oils are composed of a mixture of hydrocarbons, and are used as fuels and lubricants.

Eight of the 14 top-earning companies in the USA in 1990 (led by Exxon with \$7 billion in sales) were in the global petroleum industry.

oil beetle another name for the blister beetle.

oil, cooking fat that is liquid at room temperature, extracted from the seeds or fruits of certain plants and used for frying, salad dressings, and sauces and condiments such as mayonnaise and mustard. Plants used for cooking oil include sunflower, olive, maize (corn), soya, peanut, and rape. Vegetable oil is a blend of more than one type of oil. Most oils are hot-pressed and refined, a process that leaves them without smell or flavour. Cold-pressed, unrefined oils keep their flavour. Oils are generally low in cholesterol and contain a high proportion of polyunsaturated or monounsaturated fatty acids, although all except soya and corn oil become saturated when heated.

TO REMEMBER THE ORDER OF OHMIC VALUES IN RESISTORS:

BILLY BROWN RELIES ON YOUR GUN BUT PREFERS GOOD WHISKEY.

BLACK / BROWN / RED / ORANGE / YELLOW / GREEN / BLUE /
PURPLE / GREY / WHITE

ohmic heating method of heating used in the food-processing industry, in which an electric current is passed through foodstuffs to sterilize them before packing. The heating effect is similar to that obtained by microwaves in that electrical energy is transformed into heat throughout the whole volume of the food, not just at the surface.

Ohmic heating is suitable for foods containing chunks of meat or fruit. It is an alternative to in-can sterilization and has been used to produce canned foods such as meat chunks, prawns, baked beans, fruit, and vegetables.

oil crop plant from whose seeds vegetable oils are pressed. Cool temperate areas grow rapeseed and linseed; warm temperate regions produce sunflowers, olives, and soya beans; tropical regions produce groundnuts (peanuts), palm oil, and coconuts.

Some of the major vegetable oils, such as soya bean oil, peanut oil, and cottonseed oil, are derived from crops grown primarily for other purposes. Most vegetable oils are used as both edible oils and as ingredients in industrial products such as soaps, varnishes, printing inks, and paints.

oil palm African *Öpal* tree, the fruit of which yields valuable oils, used as food or processed into margarine, soaps, and livestock feeds. (*Elaeis guineensis*.)

oil refinery industrial complex where crude oil is processed into different products. The light volatile parts of the oil form petroleum, while the heavier parts make bitumen and petrochemicals. Oil refineries are often located at deep-water ports or near their industrial markets. They need flat land and water for cooling.

oilseed rape either of two plants; see *Örape*.

oil spill oil released by damage to or discharge from a tanker or oil installation. An oil spill kills all shore life, clogging up the feathers of birds and suffocating other creatures. At sea toxic chemicals leach into the water below, poisoning sea life. Mixed with dust, the oil forms globules that sink to the seabed, poisoning sea life there as well. Oil spills are broken up by the use of detergents but such chemicals can themselves damage wildlife. The annual spillage of oil is 8 million barrels a year. At any given time tankers are carrying 500 million barrels.

In March 1989 the *Exxon Valdez* (belonging to the Exxon Corporation) spilled oil in Alaska's Prince William Sound, covering 12,400 sq km/4,800 sq mi and killing at least 34,400 sea birds, 10,000 sea otters, and up to 16 whales. The incident led to the US Oil Pollution Act of 1990, which requires tankers operating in US waters to have double hulls.

The world's largest oil spill was in the Persian Gulf in 1991 as a direct result of hostilities during the Gulf War. Around 6–8 million barrels of oil were spilled, polluting 675 km/420 mi of Saudi coastline. In some places, the oil was 30 cm/12 in deep in the sand.

In 1994 in the Komi region of N Russia, a broken pipeline leaking into the Pechora River was estimated to have caused one of the biggest oil spills since 1989.

okapi ruminant (cud-chewing) mammal related to the giraffe, although with a much shorter neck and legs, found in the tropical rainforests of central Africa. Its purplish brown body, creamy face, and black and white stripes on the legs and hindquarters provide excellent camouflage. Okapis have remained virtually unchanged for millions of years. (Species *Okapia johnstoni*, family Giraffidae.)

The okapi was unknown to Europeans until 1901; now only a few hundred are thought to survive.

okra plant belonging to the Old World hibiscus family. Its red-and-yellow flowers are followed by long, sticky, green fruits known as ladies' fingers or bhindi. The fruits are cooked in soups and stews. (*Hibiscus esculentus*, family Malvaceae.)

Olbers' paradox question put forward 1826 by Heinrich Olbers, who asked: If the universe is infinite in extent and filled with stars, why is the sky dark at night? The answer is that the stars do not live infinitely long, so there is not enough starlight to fill the universe. A wrong answer, frequently given, is that the expansion of the universe weakens the starlight.

Old English sheepdog breed of herding dog. It is grey or blue-grey, with white on its head, chest, and legs, and is about 62 cm/24 in at the shoulder. Its long, thick, rough hair grows abundantly over its face. It was formerly used widely in S England by shepherds and drovers, and its tail was traditionally docked to a stump to show that it was a working dog and so exempt from taxation. It is therefore sometimes known as a bobtail.

OLE in computing, abbreviation for *Öbject* linking and embedding

oleander or **rose bay** evergreen Mediterranean shrub belonging to the dogbane family, with pink or white flowers and aromatic

leaves that produce and release the poison oleandrin. (*Nerium oleander*, family Apocynaceae.)

olefin common name for *Öalkene*.

Oligocene third epoch of the Tertiary period of geological time, 35.5–3.25 million years ago. The name, from Greek, means 'a little recent', referring to the presence of the remains of some modern types of animals existing at that time.

oligodendrocyte type of glial cell surrounding the neurones in the brain and spinal cord. They produce the insulating *Ömyelin* sheath surrounding the nerve axon.

oligosaccharide *Ö*carbohydrate comprising a few *Ö*monosaccharide units linked together. It is a general term used to indicate that a carbohydrate is larger than a simple di- or trisaccharide but not as large as a polysaccharide.

olive evergreen tree belonging to the olive family. Native to Asia but widely cultivated in Mediterranean and subtropical areas, it grows up to 15 m/50 ft high and has twisted branches and lance-shaped silvery leaves that grow opposite each other. The white flowers are followed by small green oval fruits that turn bluish-black when ripe. They are preserved in brine or oil; dried; or pressed to make olive oil. (*Olea europaea*, family Oleaceae.)

The oil, which is a pale, greenish yellow, is widely consumed; it is also used in soaps and ointments, and as a lubricant.

olivenite basic copper arsenate, $\text{Cu}_2\text{AsO}_4(\text{OH})$, occurring as a mineral in olive-green prisms.

olivine greenish mineral, magnesium iron silicate, $(\text{Mg},\text{Fe})_2\text{SiO}_4$. It is a rock-forming mineral, present in, for example, peridotite, gabbro, and basalt. Olivine is called peridot when pale green and transparent, and used in jewellery.

olm cave-dwelling aquatic *Ö*salamander. Olms are found in underground caves along the Adriatic seaboard in Italy, Croatia, and Yugoslavia. The adult is permanently larval in form, about 25 cm/10 in long, almost blind, with external gills and under-developed limbs. See *Öneoteny*. (Species *Proteus anguinus*, family Proteidae.)

The olm is the only European member of its family; the other members are the North American *Ö*mudpuppies.

The olm can survive for 12 years without eating. It can also withstand subzero temperatures.

omega Ω a symbol for the mass density of the universe. If Ω is less than 1.0 the universe will expand forever; if it is more than 1.0 the gravitational pull of its mass will be strong enough to reverse its expansion and cause its eventual collapse. The value of Ω is estimated as probably being between 0.1 and 1.0.

Omega navigation system long-range radio-based aid to navigation, giving world-wide coverage. There are eight Omega transmitting stations, located in Norway, Liberia, Hawaii, Réunion, Argentina, Australia, USA, and Japan. The very-low-frequency signals from the transmitters are detected by a ship's navigation receiver, and slight differences (phase differences) between the signals indicate the position of the receiver. The system is accurate to within 4 km/2.5 mi during the day and 7 km/4 mi at night. See also *Ö*Decca navigation system.

omnivore animal that feeds on both plant and animal material. Omnivores have digestive adaptations intermediate between those of *Ö*herbivores and *Ö*carnivores, with relatively unspecialized digestive systems and gut microorganisms that can digest a variety of foodstuffs.

OMR abbreviation for optical mark recognition.

onager wild ass found in W Asia. Onagers are sandy brown, lighter underneath, and about the size of a small horse. (Species *Equus hemionus*.)

onchocerciasis or **river blindness** disease found in tropical Africa and Central America. It is transmitted by bloodsucking black

flies, which infect the victim with parasitic filarial worms (genus *Onchocerca*), producing skin disorders and intense itching; some invade the eyes and may cause blindness.

It is treated with antiparasitic drugs known as filaricides.

oncogene gene carried by a virus that induces a cell to divide abnormally, giving rise to a cancer. Oncogenes arise from mutations in genes (proto-oncogenes) found in all normal cells. They are usually also found in viruses that are capable of transforming normal cells to tumour cells. Such viruses are able to insert their oncogenes into the host cell's DNA, causing it to divide uncontrollably. More than one oncogene may be necessary to transform a cell in this way.

In 1989 US scientists J Michael Bishop and Harold Varmus were jointly awarded the Nobel Prize for Physiology or Medicine for their concept of oncogenes, although credit for the discovery was claimed by a French cancer specialist, Dominique Stehelin.

oncology medical speciality concerned with the diagnosis and treatment of neoplasms, especially cancer.

ONCOLINK - THE UNIVERSITY OF PENNSYLVANIA CANCER CENTRE RESOURCE

<http://cancer.med.upenn.edu/>

As the title of this page says, a broad resource of cancer-related information for sufferers and their families. It includes sections on 'causes, screening, and prevention', 'clinical trials', and 'conferences and meetings'.

onco-mouse mouse that has a human oncogene (gene that can cause certain cancers) implanted into its cells by genetic engineering. Such mice are used to test anticancer treatments and were patented within the USA by Harvard University in 1988, thereby protecting its exclusive rights to produce the animal and profit from its research.

onion plant belonging to the lily family, whose bulb has a strong, distinctive smell and taste. Cultivated from ancient times, it may have originated in Asia. The bulb is edible; its pale concentric layers of leaf bases contain an oil that is released into the air when the onion is cut open, causing the eyes to water. Onions are used extensively in cooking. (*Allium cepa*, family Liliaceae.)

The onion is a biennial plant, the common variety producing a bulb in the first season and seeds in the second.

online in computing, connected, so that data can be transferred, for example, to a printer or from a network. The opposite of offline.

Technology ... the knack of so arranging the world that we don't have to experience it.

online help in computing, guidance and assistance in using a program which is given by the software itself, instead of a manual or a customer services representative over the telephone.

online service in computing, commercial service like America Online (AOL), CompuLink Information eXchange (CIX), or CompuServe, which offers proprietary conferencing and other services to subscribers on top of access to the Internet.

online system in computing, originally a system that allows the computer to work interactively with its users, responding to each instruction as it is given and prompting users for information when necessary. Since almost all the computers used now work this way,

'online system' is now used to refer to large database, electronic mail, and conferencing systems accessed via a dial-up modem. These often have tens or hundreds of users from different places - sometimes from different countries - 'on line' at the same time.

on-site warranty in computing, after-sales service offered free by many hardware manufacturers for a limited period after purchase - usually one year. An on-site warranty entitles purchasers to a visit from a peripatetic engineer in case of problems.

ontogeny process of development of a living organism, including the part of development that takes place after hatching or birth. The idea that 'ontogeny recapitulates phylogeny' (the development of an organism goes through the same stages as its evolutionary history), proposed by the German scientist Ernst Heinrich Haeckel, is now discredited.

Onychophora phylum of invertebrates found in rainforest leaf-litter. See velvet worm.

onyx semiprecious variety of chalcedonic silica (SiO₂) in which the crystals are too fine to be detected under a microscope, a state known as cryptocrystalline. It has straight parallel bands of different colours: milk-white, black, and red.

Sardonyx, an onyx variety, has layers of brown or red carnelian alternating with lighter layers of onyx. It can be carved into cameos.

oocyte in medicine, an immature ovum. Only a fraction of the oocytes produced in the ovary survive until puberty and not all of these undergo meiosis to become an ovum that can be fertilized by a sperm.

oolite limestone made up of tiny spherical carbonate particles, called ooliths, cemented together. Ooliths have a concentric structure with a diameter up to 2 mm/0.08 in. They were formed by chemical precipitation and accumulation on ancient sea floors.

The surface texture of ooliths is rather like that of fish roe. The late Jurassic limestones of the British Isles are mostly oolitic in nature.

Oort cloud spherical cloud of comets beyond Pluto, extending out to about 100,000 astronomical units (1.5 light years) from the Sun. The gravitational effect of passing stars and the rest of our Galaxy disturbs comets from the cloud so that they fall in towards the Sun on highly elongated orbits, becoming visible from Earth. As many as 10 trillion comets may reside in the Oort cloud, named after Dutch astronomer Jan Oort who postulated it in 1950.

oosphere another name for the female gamete, or oöovum, of certain plants such as algae.

ooze sediment of fine texture consisting mainly of organic matter found on the ocean floor at depths greater than 2,000 m/6,600 ft. Several kinds of ooze exist, each named after its constituents.

Siliceous ooze is composed of the silica shells of tiny marine plants (diatoms) and animals (radiolarians). Calcareous ooze is formed from the calcite shells of microscopic animals (foraminifera) and floating algae (coccoliths).

opah or **moonfish** large marine hony fish. These fish may be up to 2 m/6.6 ft long and weigh approximately 200 kg/440 lb. They are widely distributed in warm seas, and feed on squids, crustaceans, and small fish.

classification Opahs are genus *Lampris*, family Lampridae, order Lampriformes.

opal form of hydrous silica (SiO₂.nH₂O), often occurring as stalactites and found in many types of rock. The common opal is translucent, milk-white, yellow, red, blue, or green, and lustrous. Precious opal is opalescent, the characteristic play of colours being caused by close-packed silica spheres diffracting light rays within the stone.

Opal is cryptocrystalline, that is, the crystals are too fine to be detected under an optical microscope. Opals are found in Hungary; New South Wales, Australia (black opals were first discovered there in 1905); and Mexico (red fire opals).

Oparin, Alexandr Ivanovich (1894–1980)

Russian biochemist who in the 1920s developed one of the first of the modern theories about the origin of life on Earth, postulating a primeval soup of biomolecules.

opencast mining or *open-pit mining* or *strip mining* mining at the surface rather than underground. Coal, iron ore, and phosphates are often extracted by opencast mining. Often the mineral deposit is covered by soil, which must first be stripped off, usually by large machines such as walking draglines and bucket-wheel excavators. The ore deposit is then broken up by explosives.

One of the largest excavations in the world has been made by opencast mining at the Bingham Canyon copper mine in Utah, USA, measuring 790 m/2,590 ft deep and 3.7 km/2.3 mi across.

open cluster or *galactic cluster* in astronomy, a loose cluster of young stars. More than 1,200 open clusters have been catalogued, each containing between a dozen and several thousand stars. They are of interest to astronomers because they represent samples of stars that have been formed at the same time from similar material. Examples include the ϕ Pleades and the ϕ Hyades. See also *globular cluster* and *star cluster*.

Open Group in computing, multivendor industry body formed in February 1996 through the merger of X/Open and the ϕ Open Software Foundation. One of its functions is to test and brand with an X mark products that conform to open systems standards.

open-hearth furnace method of steelmaking, now largely superseded by the ϕ basic-oxygen process. It was developed in 1864 in England by German-born William and Friedrich Siemens, and improved by Pierre and Emile Martin in France in the same year. In the furnace, which has a wide, saucer-shaped hearth and a low roof, molten pig iron and scrap are packed into the shallow hearth and heated by overhead gas burners using preheated air.

Open Software Foundation (OSF) in computing, software house created in 1988 by several major industry players (including Bull, DEC, Hewlett-Packard, IBM and Philips) to engineer a standard operating system and user interface for the ϕ UNIX platform. The OSF joined with ϕ X/Open to form The Open Group 1996.

open systems systems that conform to ϕ Open Systems Interconnection or ϕ POSIX standards. ϕ UNIX was the original basis of open systems and most non-proprietary open systems still use this operating system.

The term is also used more loosely to describe any system that can communicate with other systems and to describe other standards, such as ϕ MS-DOS and ϕ Windows. Open systems were developed partly to make better communication possible, but also to reduce users' dependence on (and lock-in to) suppliers of proprietary systems.

Open Systems Interconnection (OSI) in computing, ϕ International Standards Organization standard, defining seven layers of communication protocols. Although OSI is an international standard, existing protocols, such as ϕ TCP/IP and IBM's ϕ Sysplex Network Architecture are more commonly used in commercial systems.

operating system (OS) in computing, a program that controls the basic operation of a computer. A typical OS controls the peripheral devices such as printers, organizes the filing system, provides a means of communicating with the operator, and runs other programs.

Many operating systems were written to run on specific computers, but some are available from third-party software houses and will run on machines from a variety of manufacturers. Examples include Microware's OS/9, Microsoft's MS-DOS and UNIX.

UNIX (developed at AT&T's Bell Laboratories) is the standard on workstations, minicomputers, and supercomputers; it is also used on desktop PCs and mainframes.

operational amplifier or *op-amp* electronic circuit that is used as a basic building block in electronic design. Operational amplifiers are used in a wide range of electronic measuring instruments. The name arose because they were originally designed to carry out mathematical operations and solve equations.

The voltage gain of an inverting operational amplifier is equal to the ratio of the resistance of the feedback resistor to the resistance of the input resistor.

operculum The thick calcareous plate that forms the operculum is clearly visible in this picture of a land winkle *Pomatias elegans*.
Premaphotos Wildlife

operculum small cap covering the spore-producing body of many mosses. It is pushed aside when the spores are mature and ready to be ejected.

operon group of genes that are found next to each other on a chromosome, and are turned on and off as an integrated unit. They usually produce enzymes that control different steps in the same biochemical pathway. Operons were discovered in 1961 (by the French biochemists François Jacob and Jacques Monod) in bacteria.

They are less common in higher organisms where the control of metabolism is a more complex process.

Ophiuchus large constellation along the celestial equator (see ϕ celestial sphere), known as the serpent bearer because the constellation (ϕ Serpens) is wrapped around it. The Sun passes through Ophiuchus each December, but the constellation is not part of the zodiac. Ophiuchus contains ϕ Barnard's star.

ophthalmia neonatorum form of ϕ conjunctivitis mostly contracted during delivery by an infant whose mother is infected with ϕ gonorrhoea. It can lead to blindness unless promptly treated.

ophthalmology medical speciality concerned with diseases of the eye and its surrounding tissues.

opiate, endogenous naturally produced chemical in the body that has effects similar to morphine and other opiate drugs; a type of neurotransmitter.

Examples include ϕ endorphins and ϕ encephalins.

opium drug extracted from the unripe seeds of the opium poppy (*Papaver somniferum*) of SW Asia. An addictive narcotic, it contains several alkaloids, including **morphine**, one of the most powerful natural painkillers and addictive narcotics known, and **codeine**, a milder painkiller.

Heroin is a synthetic derivative of morphine and even more powerful as a drug. Opium is still sometimes given as a tincture, dissolved in alcohol and known as **laudanum**. Opium also contains the highly poisonous alkaloid **thebaine**.

opossum any of a family of marsupials (mammals that carry their young in a pouch) native to North and South America. Most opossums are tree-living, nocturnal animals, with prehensile tails that can be used as an additional limb, and hands and feet well adapted for grasping. They range from 10 cm/4 in to 50 cm/20 in in length and are insectivorous, carnivorous, or, more commonly, omnivorous. (Family Didelphidae.)

The name is also popularly applied to some of the similar-looking phalangers found in Australia.

opposition in astronomy, the moment at which a body in the Solar System lies opposite the Sun in the sky as seen from the Earth and crosses the meridian at about midnight.

Although the inferior planets cannot come to opposition, it is the best time for observation of the superior planets as they can then be seen all night.

optical aberration see aberration, optical.

optical activity in chemistry, the ability of certain crystals, liquids, and solutions to rotate the plane of polarized light as it passes through them. The phenomenon is related to the three-dimensional arrangement of the atoms making up the molecules concerned. Only substances that lack any form of structural symmetry exhibit optical activity.

optical character recognition (OCR) in computing, a technique for inputting text to a computer by means of a document reader. First, a scanner produces a digital image of the text; then character-recognition software makes use of stored knowledge about the shapes of individual characters to convert the digital image to a set of internal codes that can be stored and processed by computer.

Oppenheimer, J(ulius) Robert (1904–1967)

US physicist. As director of the Los Alamos Science Laboratory 1943–45, he was in charge of the development of the atom bomb (the Manhattan Project). When later he realized the dangers

of radioactivity, he objected to the development of the hydrogen bomb, and was alleged to be a security risk in 1953 by the US Atomic Energy Commission (AEC).

Investigating the equations describing the energy states of the atom, Oppenheimer showed in 1930 that a positively charged particle with the mass of an electron could exist. This particle was detected in 1932 and called the positron.

OCR originally required specially designed characters but current devices can recognize most standard typefaces and even handwriting. OCR is used, for example, by gas and electricity companies to input data collected on meter-reading cards, and by personal digital assistants to recognize users' handwriting.

optical computer computer in which both light and electrical signals are used in the central processing unit. The technology is still not fully developed, but such a computer promises to be faster and less vulnerable to outside electrical interference than one that relies solely on electricity.

twisted pair cable

coaxial cable

fibre optic cable

optical fibre The major differences in construction between twisted pair (telephone), coaxial (Ethernet), and fibre optic cable.

optical disc in computing, a storage medium in which laser technology is used to record and read large volumes of digital data. Types include $\text{\textcircled{C}}$ CD-ROM, $\text{\textcircled{W}}$ ORM, and erasable optical disc.

optical emission spectrometry another term for emission spectroscopy.

optical fibre very fine, optically pure glass fibre through which light can be reflected to transmit images or data from one end to the other. Although expensive to produce and install, optical fibres can carry more data than traditional cables, and are less susceptible to interference. Standard optical fibre transmitters can send up to 10 billion bits of information per second by switching a laser beam on and off.

Optical fibres are increasingly being used to replace metal communications cables, the messages being encoded as digital pulses of light rather than as fluctuating electric current. Current research is investigating how optical fibres could replace wiring inside computers.

Bundles of optical fibres are also used in endoscopes to inspect otherwise inaccessible parts of machines or of the living body (see endoscopy). See illustration on page 539.

optical illusion scene or picture that fools the eye. An example of a natural optical illusion is that the Moon appears bigger when it is on the horizon than when it is high in the sky, owing to the $\text{\textcircled{r}}$ efraction of light rays by the Earth's atmosphere.

optical instrument instrument that makes use of one or more lenses or mirrors, or of a combination of these, in order to change the path of light rays and produce an image. Optical instruments such as magnifying glasses, $\text{\textcircled{m}}$ icroscopes, and $\text{\textcircled{t}}$ elesopes are used to provide a clear, magnified image of the very small or the very distant. Others, such as $\text{\textcircled{c}}$ ameras, photographic enlargers, and film $\text{\textcircled{p}}$ rojectors, may be used to store or reproduce images.

optical mark recognition (OMR) in computing, a technique that enables marks made in predetermined positions on computer-input forms to be detected optically and input to a computer. An optical mark reader shines a light beam onto the input document and is able to detect the marks because less light is reflected back from them than from the paler, unmarked paper.

optic nerve large nerve passing from the eye to the brain, carrying visual information. In mammals, it may contain up to a million nerve fibres, connecting the sensory cells of the retina to the optical centres in the brain. Embryologically, the optic nerve develops as an outgrowth of the brain.

optics branch of physics that deals with the study of $\text{\textcircled{l}}$ ight and vision – for example, shadows and mirror images, lenses, microscopes, telescopes, and cameras. For all practical purposes light rays travel in straight lines, although Albert $\text{\textcircled{E}}$ instein demonstrated that they may be 'bent' by a gravitational field. On striking a surface they are reflected or refracted with some absorption of energy, and the study of this is known as geometrical optics.

optoelectronics branch of electronics concerned with the development of devices (based on the $\text{\textcircled{s}}$ emiconductor gallium arsenide) that respond not only to the $\text{\textcircled{e}}$ lectrons of electronic data transmission, but also to $\text{\textcircled{p}}$ hotons.

In 1989, scientists at IBM in the USA built a gallium arsenide microprocessor ('chip') containing 8,000 transistors and four photodetectors. The densest optoelectronic chip yet produced, this can detect and process data at a speed of 1 billion bits per second.

opuntia any $\text{\textcircled{c}}$ actus belonging to the same group of plants as the prickly pear. They all have showy flowers and fleshy, jointed stems. (Genus *Opuntia*, family Cactaceae.)

orange round orange-coloured juicy citrus fruit of several species of evergreen trees, which bear white blossom and fruits at the same time. Thought to have originated in SE Asia, orange trees are commercially cultivated in Spain, Israel, the USA, Brazil, South Africa, and elsewhere. The sweet orange (*C. sinensis*) is the one commonly eaten fresh; the Jaffa, blood, and navel orange are varieties of this species. (Genus *Citrus*, family Rutaceae.)

Tangerines and mandarins belong to a related species (*C. reticulata*). The sour or Seville orange (*C. aurantium*) is the bitter orange used in making marmalade. Oranges yield several essential oils.

orang-utan large ape found only in Borneo and Sumatra. Up to 1.65 m/5.5 ft in height, it is covered with long, red-brown hair and lives a largely solitary life in the trees, feeding mainly on fruit. Now an endangered species, it is officially protected because its habitat is being systematically destroyed by $\text{\textcircled{d}}$ eforestation. Less than 30,000 animals remain. (Species *Pongo pygmaeus*.)

There are two subspecies: *P. p. pygmaeus* found in Borneo, and the smaller *P. p. abelii* on the island of Sumatra. Their rate of reproduction is very slow, with an eight-year gap between births. Orang-utans are slow-moving and have been hunted for food, as well as by animal collectors. The name means 'man of the forest'.

ORANG-UTAN – QUINTESSENTIAL FOREST DWELLER

http://www.lpzoo.com/ark/orang_article.html

Well-written profile of the orang-utan. Among the interesting facts in this account of the behaviour, diet, and social life of the orang-utan is that they eat some 400 different kinds of food and that they are not solitary browsers but need to know that the company of other orang-utans is available. There is a picture, a map of the orang-utan's range, and even a bibliography.

orbit path of one body in space around another, such as the orbit of Earth around the Sun, or the Moon around Earth. When the two bodies are similar in mass, as in a $\text{\textcircled{b}}$ inary star, both bodies move around their common centre of mass. The movement of objects in orbit follows Johann $\text{\textcircled{K}}$ epler's laws, which apply to artificial satellites as well as to natural bodies.

As stated by the laws, the orbit of one body around another is an ellipse. The ellipse can be highly elongated, as are comet orbits around the Sun, or it may be almost circular, as are those of some planets. The closest point of a planet's orbit to the Sun is called **perihelion**; the most distant point is **aphelion**. (For a body orbiting the Earth, the closest and furthest points of the orbit are called **perigee** and **apogee**.)

orbital, atomic region around the nucleus of an atom (or, in a molecule, around several nuclei) in which an electron is likely to be found. According to quantum theory, the position of an electron is uncertain; it may be found at any point. However, it is more likely to be found in some places than in others, and it is these that make up the orbital.

An atom or molecule has numerous orbitals, each of which has a fixed size and shape. An orbital is characterized by three numbers, called quantum numbers, representing its energy (and hence size), its angular momentum (and hence shape), and its orientation. Each orbital can be occupied by one or (if their spins are aligned in opposite directions) two electrons.

TO REMEMBER THE ORDER OF ATOMIC ORBITALS:

SPIN PAIRS DON'T FORM – GO HIGHER.

THE PAULI SELECTION RULE STATES THAT TWO ELECTRONS OF LIKE SPIN MAY NOT BE PRESENT IN ANY ORBITAL IF THEY HAVE THE SAME SET OF QUANTUM NUMBERS. SINCE THE ELECTRONIC ORBITALS IN ATOMS ARE LISTED BY THE LETTERS S, P, D, F, G, H, IN ORDER OF ASCENDING ENERGY, THIS MNEMONIC ACTS AS A USEFUL REMINDER.

orbital The shapes of atomic orbitals. An atomic orbital is a picture of the 'electron cloud' that surrounds the nucleus of an atom. There are four basic shapes for atomic orbitals: spherical, dumbbell, clover-leaf, and complex (shown at bottom left).

orca another name for ϕ killer whale.

orchid any plant of a large family that contains at least 15,000 species and 700 genera, distributed throughout the world except in the coldest areas, and most numerous in damp equatorial regions. The flowers are the most highly evolved of the plant kingdom; they have three ϕ sepals and three petals and sometimes grow singly, but more usually appear with other flowers on spikes, growing up one side of the main stem, or all around the main stem, which may be upright or drooping. (Family Orchidaceae.)

order in biological classification, a group of related ϕ families. For example, the horse, rhinoceros, and tapir families are grouped in the order Perissodactyla, the odd-toed ungulates, because they all have either one or three toes on each foot. The names of orders are not shown in italic (unlike genus and species names) and by convention they have the ending '-formes' in birds and fish; '-a' in mammals, amphibians, reptiles, and other animals; and '-ales' in fungi and plants. Related orders are grouped together in a ϕ class.

ORCHID

The flowers of bee orchids resemble female bees so completely that they have the same shape, the same smell, and even the same degree of hairiness.

ordered pair in mathematics, any pair of numbers whose order makes a difference to their meaning. Coordinates are an ordered pair because the point (2,3) is not the same as the point (3,2). Vulgar fractions are ordered pairs because the top number gives the quantity of parts while the bottom gives the number of parts into which the unit has been divided.

ordinal number in mathematics, one of the series first, second, third, fourth, Ordinal numbers relate to order, whereas ϕ cardinal numbers (1, 2, 3, 4, ...) relate to quantity, or count.

ordinate in coordinate geometry, the y ϕ coordinate of a point; that is, the vertical distance of the point from the horizontal or x -axis. For example, a point with the coordinates (3,4) has an ordinate of 4. See ϕ abscissa.

Ordnance Survey (OS) official body responsible for the mapping of Britain. It was established 1791 as the Trigonometrical Survey

ORCHID HOUSE

<http://sciserv2.uwaterloo.ca/orchids.html>

Everything you could ever want to know about orchids can be found here. There is a very good introductory 'frequently asked questions' section, as well as information for the more experienced horticulturist. There is even an orchid-related short story and some pictures of orchids accompanied by soothing music.

to continue work initiated in 1784 by Scottish military surveyor General William Roy (1726-1790). Its first accurate maps appeared in 1830, drawn to a scale of 1 in to the mile (1:63,000). In 1858 the OS settled on a scale of 1:2,500 for the mapping of Great Britain and Ireland (higher for urban areas, lower for uncultivated areas). Subsequent revisions and editions include the 1:50,000 Landranger series of 1971-86. In 1989, the OS began using a computerized system for the creation and continuous revision of maps. Customers can now have maps drafted to their own specifications, choosing from over 50 features (such as houses, roads, and vegetation). Since 1988 the OS has had a target imposed by the government to recover all its costs from sales.

Ordovician period of geological time 510-439 million years ago; the second period of the ϕ Palaeozoic era. Animal life was confined to the sea: reef-building algae and the first jawless fish are characteristic.

The period is named after the Ordovices, an ancient Welsh people, because the system of rocks formed in the Ordovician period was first studied in Wales.

ore body of rock, a vein within it, or a deposit of sediment, worth mining for the economically valuable mineral it contains. The term is usually applied to sources of metals. Occasionally metals are found uncombined (native metals), but more often they occur as compounds such as carbonates, sulphides, or oxides. The ores often contain unwanted impurities that must be removed when the metal is extracted.

Commercially valuable ores include bauxite (aluminium oxide, Al_2O_3) hematite (iron(III) oxide, Fe_2O_3), zinc blende (zinc sulphide, ZnS), and rutile (titanium dioxide, TiO_2).

Hydrothermal ore deposits are formed from fluids such as saline water passing through fissures in the host rock at an elevated

temperature. Examples are the 'porphyry copper' deposits of Chile and Bolivia, the submarine copper-zinc-iron sulphide deposits recently discovered on the East Pacific Rise, and the limestone lead-zinc deposits that occur in the southern USA and in the Pennines of Britain.

Other ores are concentrated by igneous processes, causing the ore metals to become segregated from a magma – for example, the chromite and platinum-metal-rich bands within the Bushveld, South Africa. Erosion and transportation in rivers of material from an existing rock source can lead to further concentration of heavy minerals in a deposit – for example, Malaysian tin deposits.

Weathering of rocks in situ can result in residual metal-rich soils, such as the nickel-bearing laterites of New Caledonia.

oregano any of several perennial herbs belonging to the mint family, especially the aromatic *O. vulgare*, also known as wild marjoram. It is native to the Mediterranean countries and W Asia and naturalized in the Americas. Oregano is extensively used to season Mediterranean cooking. (Genus *Origanum*, family Labiatae.)

orfe freshwater fish belonging to the carp family. It grows up to 50 cm/1.7 ft in length, and feeds on small aquatic animals. The species is generally greyish-black, but an ornamental variety is orange. It lives in rivers and lakes of Europe and NW Asia. (Species *Leuciscus idus*, family Cyprinidae.)

organ in biology, part of a living body, such as the liver or brain, that has a distinctive function or set of functions.

Man is a mind betrayed, not served, by his organs.

EDMOND AND JULES DE GONCOURT French writers.
The Goncourt Journals 30 July 1861

organelle discrete and specialized structure in a living cell; organelles include mitochondria, chloroplasts, lysosomes, ribosomes, and the nucleus.

Organic chemistry just now is enough to drive one mad. It gives one the impression of a primeval, tropical forest full of the most remarkable things, a monstrous and boundless thicket, with no way of escape, into which one may well dread to enter.

FRIEDRICH WÖHLER German chemist.
Letter to Berzelius 28 Jan 1835

organic chemistry branch of chemistry that deals with carbon compounds. Organic compounds form the chemical basis of life and are more abundant than inorganic compounds. In a typical organic compound, each carbon atom forms bonds covalently with each of its neighbouring carbon atoms in a chain or ring, and additionally with other atoms, commonly hydrogen, oxygen, nitrogen, or sulphur.

The basis of organic chemistry is the ability of carbon to form long chains of atoms, branching chains, rings, and other complex structures. Compounds containing only carbon and hydrogen are known as hydrocarbons.

TO REMEMBER THE PREFIXES FOR NAMING CARBON CHAINS:

MET ETHEL PROPERLY BUT MY PANTS HAD HOLES

METH, ETH, PROP, BUT, PENT, HEX, HEPT (METHANE CAN ALSO BE REMEMBERED BY ME - ONE PERSON)

organic chemistry Common organic-molecule groupings. Organic chemistry is the study of carbon compounds, which make up over 90% of all chemical compounds. This diversity arises because carbon atoms can combine in many different ways with other atoms, forming a wide variety of loops and chains.

organic compound in chemistry, a class of compounds that contain carbon. The original distinction between organic and inorganic compounds was based on the belief that the molecules of living systems were unique, and could not be synthesized in the laboratory. Today it is routine to manufacture thousands of organic chemicals both in research and in the drug industry. Certain simple compounds of carbon, such as carbonates, oxides of carbon, carbon disulphide, and carbides are usually treated in inorganic chemistry.

organic farming farming without the use of synthetic fertilizers (such as nitrates and phosphates) or pesticides (herbicides, insecticides, and fungicides) or other agrochemicals (such as hormones, growth stimulants, or fruit regulators). Food produced by genetic engineering cannot be described as organic.

In place of artificial fertilizers, compost, manure, seaweed, or other substances derived from living things are used (hence the name 'organic'). Growing a crop of a nitrogen-fixing plant such as

lucerne, then ploughing it back into the soil, also fertilizes the ground. Some organic farmers use naturally occurring chemicals such as nicotine or pyrethrum to kill pests, but control by non-chemical methods is preferred. Those methods include removal by hand, intercropping (planting with companion plants which deter pests), mechanical barriers to infestation, crop rotation, better cultivation methods, and biological control. Weeds can be controlled by hoeing, mulching (covering with manure, straw, or black plastic), or burning off. Organic farming methods produce food with minimal pesticide residues and greatly reduce pollution of the environment. They are more labour intensive, and therefore more expensive, but use less fossil fuel. Soil structure is greatly improved by organic methods, and recent studies show that a conventional farm can lose four times as much soil through erosion as an organic farm, although the loss may not be immediately obvious.

organizer in embryology, a part of the embryo that causes changes to occur in another part, through induction, thus 'organizing' development and differentiation.

OR gate in electronics, a type of logic gate.

origin in mathematics, the point where the x axis meets the y axis. The coordinates of the origin are (0,0).

original equipment manufacturer (OEM) in computing, company that manufactures equipment or, illogically, has equipment manufactured for it by another company. The abbreviation is often used as a verb, as in: 'IBM OEMs PCs from Acer' (in other words, Acer makes PCs with IBM badges for IBM to sell).

orimulsion fuel made by mixing bitumen and water that can be burnt in the same way as heavy oil. It is cheap to make but the smoke produced has a high sulphur content.

oriole any of several brightly coloured songbirds belonging to two families: New World orioles belong to the family Icteridae, and Old World orioles are members of the family Oriolidae. They eat insects, seeds, and fruit.

Orion in astronomy, a very prominent constellation in the equatorial region of the sky (see celestial sphere), identified with the hunter of Greek mythology.

The bright stars Alpha (Betelgeuse), Gamma (Bellatrix), Beta (Rigel), and Kappa Orionis mark the shoulders and legs of Orion. Between them the belt is formed by Delta, Epsilon, and Zeta, three second-magnitude stars equally spaced in a straight line. Beneath the belt is a line of fainter stars marking Orion's sword. One of these, Theta, is not really a star but the brightest part of the Orion nebula. Nearby is one of the most distinctive dark nebulae, the Horsehead.

Orion nebula luminous cloud of gas and dust 1,500 light years away, in the constellation Orion, from which stars are forming. It is about 15 light years in diameter, and contains enough gas to make a cluster of thousands of stars.

At the nebula's centre is a group of hot young stars, called the Trapezium, which make the surrounding gas glow. The nebula is visible to the naked eye as a misty patch below the belt of Orion.

ormolu French or moulu 'ground gold' alloy of copper, zinc, and sometimes tin, used for furniture decoration.

ornithology study of birds. It covers scientific aspects relating to their structure and classification, and their habits, song, flight, and value to agriculture as destroyers of insect pests. Worldwide scientific banding (or the fitting of coded rings to captured specimens) has resulted in accurate information on bird movements and distribution. There is an International Council for Bird Preservation with its headquarters at the Natural History Museum, London.

ornithophily pollination of flowers by birds. Ornithophilous flowers are typically brightly coloured, often red or orange. They

produce large quantities of thin, watery nectar, and are scentless because most birds do not respond well to smell. They are found mostly in tropical areas, with hummingbirds being important pollinators in North and South America, and the sunbirds in Africa and Asia.

orogeny or **orogenesis** the formation of mountains. It is brought about by the movements of the rigid plates making up the Earth's crust and uppermost mantle (described by plate tectonics). Where two plates collide at a destructive margin rocks become folded and lifted to form chains of mountains (such as the Himalayas).

Processes associated with orogeny are faulting and thrusting (see fault), folding, metamorphism, and plutonism (see plutonic rock). However, many topographical features of mountains – cirques, u-shaped valleys – are the result of non-orogenic processes, such as weathering, erosion, and glaciation. Oostasy (uplift due to the buoyancy of the Earth's crust) can also influence mountain physiography.

orrery mechanical device for demonstrating the motions of the heavenly bodies. Invented about 1710 by George Graham, it was named after his patron, the 4th Earl of Orrery. It is the forerunner of the planetarium.

orris root underground stem of a species of iris grown in S Europe. It is violet-scented and is used in perfumery and herbal medicine.

orthochromatic photographic film or paper of decreased sensitivity, which can be processed with a red safelight. Using it, blue objects appear lighter and red ones darker because of increased blue sensitivity.

orthodontics branch of dentistry concerned with dentition, and with treatment of any irregularities, such as correction of malocclusion (faulty position of teeth).

orthopaedics Greek *orthos* 'straight'; *pais* 'child' medical speciality concerned with the correction of disease or damage in bones and joints.

The first orthopaedic hospital was founded 1780 at Orbe in Switzerland by Jean Vessel. The first in England was founded 1817.

ortolan songbird belonging to the bunting family, common in Europe and W Asia, migrating to Africa in the winter. It is about 15 cm/6 in long and reddish-brown with black streaks on top, pinkish-buff below, and has an olive-green head and chest and a yellow throat; the female is paler with small dark streaks on the chest. The nest is built in the undergrowth, on the ground, or on banks. Long considered a delicacy among gourmets, it has become rare and is now a protected species. (Species *Emberiza hortulana*, family Emberizidae, order Passeriformes.)

oryx any of a group of large antelopes native to Africa and Asia. The Arabian oryx (*O. leucorhynchus*), at one time extinct in the wild, has been successfully reintroduced into its natural habitat using stocks bred in captivity. (Genus *Oryx*, family Bovidae.)

In 1997 the oryx reintroduction project was threatened because of poaching. The population was reduced to 370 compared with 410 in 1996.

The scimitar-horned oryx (*O. tao*) of the Sahara is also rare. The Beisa oryx (*O. beisa*) in E Africa and gemsbok (*O. gazella*) in the Kalahari are more common. In profile the two long horns appear as one, which may have given rise to the legend of the unicorn.

OS/2 single-user computer operating system produced jointly by Microsoft Corporation and IBM for use on personal computers, particularly when attached to large IBM computers. Its main features were reliability – useful for running file servers – and a powerful object-oriented graphical user interface, Workplace Shell.

OS/2 was announced in 1987 but sales were dismal. Microsoft abandoned it in 1992 to concentrate on Windows. IBM abandoned attempts to sell it on the mass market 1997, but supports its use as a corporate and network computer operating system.

oscillating universe in astronomy, a theory that states that the gravitational attraction of the mass within the universe will

eventually slow down and stop the expansion of the universe. The outward motions of the galaxies will then be reversed, eventually resulting in a 'Big Crunch' where all the matter in the universe would be contracted into a small volume of high density. This could undergo a further Big Bang, thereby creating another expansion phase. The theory suggests that the universe would alternately expand and collapse through alternate Big Bangs and Big Crunches.

oscillation one complete to-and-fro movement of a vibrating object or system. For any particular vibration, the time for one oscillation is called its period and the number of oscillations in one second is called its frequency. The maximum displacement of the vibrating object from its rest position is called the amplitude of the oscillation.

oscillator any device producing a desired oscillation (vibration). There are many types of oscillator for different purposes, involving various arrangements of thermionic valves or components such as transistors, inductors, capacitors, and resistors.

An oscillator is an essential part of a radio transmitter, generating the high-frequency carrier signal necessary for radio communication. The frequency is often controlled by the vibrations set up in a crystal (such as quartz).

oscillograph instrument for displaying or recording rapidly changing oscillations, electrical or mechanical.

oscilloscope or *cathode-ray oscilloscope* (CRO) instrument used to measure electrical voltages that vary over time and to display the waveforms of electrical oscillations or signals, by means of the deflection of a beam of electrons. Readings are displayed graphically on the screen of a cathode-ray tube.

OSI abbreviation for Open Systems Interconnection.

osier any of several willow trees and shrubs, cultivated for their useful branches which are used in basket making; in particular, *S. viminalis*. (Genus *Salix*.)

osmium Greek *osme* 'odour' hard, heavy, bluish-white, metallic element, symbol Os, atomic number 76, relative atomic mass 190.2. It is the densest of the elements, and is resistant to tarnish and corrosion. It occurs in platinum ores and as a free metal (see native metal) with iridium in a natural alloy called osmirdium, containing traces of platinum, ruthenium, and rhodium. Its uses include pen points and light-bulb filaments; like platinum, it is a useful catalyst.

It was discovered in 1803 and named in 1804 by English chemist Smithson Tennant (1761-1815) after the irritating smell of one of its oxides.

osmoregulation process whereby the water content of living organisms is maintained at a constant level. If the water balance is disrupted, the concentration of salts will be too high or too low, and vital functions, such as nerve conduction, will be adversely affected.

In mammals, loss of water by evaporation is counteracted by increased intake and by mechanisms in the kidneys that enhance the rate at which water is resorbed before urine production. Both these responses are mediated by hormones, primarily those of the adrenal cortex (see adrenal gland).

osmosis movement of solvent (usually water) through a semipermeable membrane separating solutions of different concentrations. The solvent passes from a less concentrated solution to a more concentrated solution until the two concentrations are equal. Applying external pressure to the solution on the more concentrated side arrests osmosis, and is a measure of the osmotic pressure of the solution.

Many cell membranes behave as semipermeable membranes, and osmosis is a vital mechanism in the transport of fluids in living organisms - for example, in the transport of water from the roots up the stems of plants.

osprey bird of prey, sometimes called 'fish hawk' because it

osmosis Apparatus for measuring osmotic pressure. In 1877 German physicist Wilhelm Pfeffer used this apparatus to make the first ever measurement of osmotic pressure and show that osmotic pressure varies according to temperature and the strength of the solute (dissolved substance).

plunges feet first into the water to catch fish. It is dark brown above and a striking white below, and measures 60 cm/2 ft with a 2 m/6 ft wingspan. The nest is often built in trees near the seashore or lakeside, and two or three white eggs, blotched with crimson, are laid. Ospreys occur on all continents except Antarctica and have faced extinction in several areas. (Species *Pandion haliaetus*, family Pandionidae, order Falconiformes.)

ossification or *osteogenesis* process whereby bone is formed in vertebrate animals by special cells (osteoblasts) that secrete layers of extracellular matrix on the surface of the existing cartilage. Conversion to bone occurs through the deposition of calcium phosphate crystals within the matrix.

osteology part of the science of anatomy, dealing with the structure, function, and development of bones.

osteomyelitis infection of bone, with spread of pus along the marrow cavity.

Now quite rare, it may follow from a compound fracture (where broken bone protrudes through the skin), or from infectious disease elsewhere in the body. It is more common in children whose bones are not yet fully grown.

The symptoms are high fever, severe illness, and pain over the limb. If the infection is at the surface of the bone it may quickly form an abscess; if it is deep in the bone marrow it may spread into the circulation and lead to blood poisoning. Most cases can be treated with immobilization, antibiotics, and surgical drainage.

osteopathy system of alternative medical practice that relies on physical manipulation to treat mechanical stress. It was developed over a century ago by US physician Andrew Taylor Still, who maintained that most ailments can be prevented or cured by techniques of spinal manipulation.

Osteopaths are generally consulted to treat problems of the musculo-skeletal structure such as back pain, and many doctors refer

Well-organized site dedicated to increasing public understanding of osteopathy. The theory behind the osteopaths' belief in the body's innate healing power and some of the healing techniques are fully explained. There is also an account of the origins and development of osteopathy and a selection of case histories attest to its success.

patients to them for such treatments. Although in the UK the wider applicability of their skills is not generally recognized, osteopathic doctors in the USA are also fully licensed to practice conventional medicine.

osteoporosis disease in which the bone substance becomes porous and brittle. It is common in older people, affecting more women than men. It may be treated with calcium supplements and etidronate. Approximately 1.7 million people worldwide, mostly women, suffer hip fractures, mainly due to osteoporosis. A single gene was discovered in 1993 to have a major influence on bone thinning.

Osteoporosis may occur in women whose ovaries have been removed, unless hormone-replacement therapy (HRT) is instituted; it may also occur in Cushing's syndrome and as a side effect of long-term treatment with corticosteroids. Early menopause in women, childlessness, small body build, lack of exercise, heavy drinking, smoking, and hereditary factors may be contributory factors.

ostrich large flightless bird. There is only one species, found in Africa. The male may be about 2.5 m/8 ft tall and weigh 135 kg/300 lb, and is the largest living bird. It has exceptionally strong legs and feet (two-toed) that enable it to run at high speed, and are also used in defence. It lives in family groups of one cock with several hens, each of which lays about 14 eggs. (Species *Struthio camelus*, order Struthioniformes.)

The adult male's body is covered with black feathers, the plumes of the wings and tail being white; females and young males have grey feathers. The bill is wide and flat, the small head has large eyes, and the long neck has a sparse covering of downy feathers. The male incubates the eggs at night, but the female may sit on them during the day. Their eggs are the smallest in relation to the adult's body size of any bird. Ostriches eat mainly plant material and they can survive for a long time without water.

otitis inflammation of the ear. *Otitis externa*, occurring in the outer ear canal, is easily treated with antibiotics. Inflamed conditions of the middle ear (*otitis media*) or inner ear (*otitis interna*) are more serious, carrying the risk of deafness and infection of the brain. Treatment is with antibiotics or, more rarely, surgery.

otolith or **ear stone** tiny calcareous deposit found in the ears of fishes, which are in contact with the sensory cushions supplied by the acoustic nerves. Their function is as an organ of balance.

otosclerosis overgrowth of bone in the middle ear causing progressive deafness. This inherited condition is gradual in onset, developing usually before middle age. It is twice as common in women as in men.

The middle ear cavity houses the sound-conduction mechanism called the ossicular chain, consisting of three tiny bones (ossicles) that magnify vibrations received at the eardrum for onward transmission to the inner ear. In otosclerosis, extraneous growth of

spongy bone immobilizes the chain, preventing the conduction of sound. Surgery is necessary to remove the diseased bone and reconstruct the ossicular chain.

otter any of various aquatic carnivores belonging to the weasel family, found on all continents except Australia. Otters have thick brown fur, short limbs, webbed toes, and long, compressed tails. They are social, playful, and agile.

otterhound breed of large dog developed during the Middle Ages from various French and British hound breeds to hunt otters. It is an excellent swimmer and has a rough, dense coat, longer than that of most hounds but in a similar range of colours. It grows to about 65 cm/26 in.

Otto cycle alternative name for the four-stroke cycle, introduced by the German engineer Nikolaus Otto (1832–1891) in 1876. It improved on existing piston engines by compressing the fuel mixture in the cylinder before it was ignited.

Otto, Nikolaus August (1832–1891)

German engineer who in 1876 patented an effective internal-combustion engine and described the four-stroke cycle.

ounce another name for the snow leopard.

ounce unit of mass, one-sixteenth of a pound (avoirdupois, equal to 437.5 grains (28.35 g); also one-twelfth of a pound troy, equal to 480 grains.

outback the inland region of Australia. Its main inhabitants are Aborigines, miners (including opal miners), and cattle ranchers. Its harsh beauty has been recorded by such artists as Sidney Nolan.

outlier in statistics, a highly atypical data value that distorts the mean within a sample.

outline font font in which the outline of each character is defined by a mathematical formula, making the font scalable to any size. Outline fonts can be output using the resolution of the output device, unlike bit map fonts, which can be output at only one size and one resolution. The most common forms of outline fonts are **PostScript** and **TrueType**.

output device in computing, any device for displaying, in a form intelligible to the user, the results of processing carried out by a computer.

Otto four-stroke cycle

Otto cycle The four-stroke cycle of a modern petrol engine. The cycle is called the Otto cycle after German engineer Nikolaus Otto, who introduced it in 1876. It improved on earlier engine cycles by compressing the fuel mixture before it was ignited.

ouzel or *ousel* ancient name for the blackbird. The **ring ouzel** (*Turdus torquatus*) is similar to a blackbird, but has a white band across the breast. It is found in Europe in mountainous and rocky country. Water ouzel is another name for the dipper.

ovary in female animals, the organ that generates the ovum. In humans, the ovaries are two whitish rounded bodies about 25 mm/1 in by 35 mm/1.5 in, located in the lower abdomen to either side of the uterus. Every month, from puberty to the onset of the menopause, an ovum is released from the ovary. This is called ovulation, and forms part of the menstrual cycle. In botany, an ovary is the expanded basal portion of the carpel of flowering plants, containing one or more ovules. It is hollow with a thick wall to protect the ovules. Following fertilization of the ovum, it develops into the fruit wall or pericarp.

The ovaries of female animals secrete the hormones responsible for the secondary sexual characteristics of the female, such as smooth, hairless facial skin and enlarged breasts. An ovary in a half-grown human fetus contains 5 million eggs, and so the unborn baby already possesses the female genetic information for the next generation.

In botany, the relative position of the ovary to the other floral parts is often a distinguishing character in classification; it may be either inferior or superior, depending on whether the petals and sepals are inserted above or below.

OverDrive chip in computing, a plug-in replacement for an Intel microprocessor, designed to speed up the PC in which it is used. Intel OverDrive chips are expensive but are cheaper than buying a new PC and offer a simpler upgrade path than replacing the computer's motherboard.

overfishing fishing at rates that exceed the sustained-yield cropping of fish species, resulting in a net population decline. For example, in the North Atlantic, herring has been fished to the verge of extinction and the cod and haddock populations are severely depleted. In the developing world, use of huge factory ships, often by fisheries from industrialized countries, has depleted stocks for local people who cannot obtain protein in any other way. See also **ifishing** and **fisheries**.

Ecologists have long been concerned at the wider implications of overfishing, in particular the devastation wrought on oceanic food chains. The United Nations Food and Agriculture Organization estimates that worldwide overfishing has damaged oceanic ecosystems to such an extent that potential catches are on average reduced by 20%. With better management of fishing programmes the fishing catch could in principle be increased; it is estimated that, annually, 20 million tonnes of fish are discarded from fishing vessels at sea, because they are not the species sought.

According to an estimate by the Food and Agriculture Organization in 1993, nine of the world's 17 main fishing grounds were suffering a potentially catastrophic decline in some species. In 1994 approximately 17% of fishing waters off the coast of New England, USA, was closed in an attempt to restore dwindling stocks. The area affected covered 17,000 sq km/6,600 sq mi and lay within the Georges Bank region of the Atlantic Ocean.

overflow error in computing, an error that occurs if a number is outside the computer's range and is too large to deal with.

overlay in computing, set of specialized data for use with a larger database. A database of a particular country's geography, for example, that includes roads, towns, and natural features such as rivers and lakes might come with overlays that can be displayed or turned off at the user's command, such as the distribution of speed cameras.

overtone note that has a frequency or pitch that is a multiple of the fundamental frequency, the sounding body's natural frequency. Each sound source produces a unique set of overtones, which gives the source its quality or timbre.

oviparous method of animal reproduction in which eggs are laid by the female and develop outside her body, in contrast to ovoviviparous and viviparous. It is the most common form of reproduction.

ovoviviparous method of animal reproduction in which fertilized eggs develop within the female (unlike oviparous), and the embryo gains no nutritional substances from the female (unlike viviparous).

It occurs in some invertebrates, fishes, and reptiles.

ovulation in female animals, the process of releasing egg cells (ova) from the ovary. In mammals it occurs as part of the menstrual cycle.

ovule structure found in seed plants that develops into a seed after fertilization. It consists of an embryo sac containing the female gamete (ovum or egg cell), surrounded by nutritive tissue, the nucellus. Outside this there are one or two coverings that provide protection, developing into the testa, or seed coat, following fertilization.

In angiosperms (flowering plants) the ovule is within an ovary, but in gymnosperms (conifers and their allies) the ovules are borne on the surface of an ovuliferous (ovule-bearing) scale, usually within a cone, and are not enclosed by an ovary.

ovum (plural *ova*) female gamete (sex cell) before fertilization. In animals it is called an egg, and is produced in the ovaries. In plants, where it is also known as an egg cell or oosphere, the ovum is produced in an ovule. The ovum is nonmotile. It must be fertilized by a male gamete before it can develop further, except in cases of **apartenogenesis**.

owl any of a group of mainly nocturnal birds of prey found worldwide. They have hooked beaks, heads that can turn quickly and far round on their very short necks, and forward-facing immobile eyes, surrounded by 'facial discs' of rayed feathers; they fly silently and have an acute sense of hearing. Owls comprise two families: typical owls (family Strigidae), of which there are about 120 species, and barn owls (family Tytonidae), of which there are 10 species. (Order Strigiformes.)

They feed mainly on rodents, but sometimes also eat reptiles, fish, and insects, and some species have been seen feeding on carrion. All species lay white eggs, and begin incubation as soon as the first egg is laid. They regurgitate indigestible remains of their prey in pellets (castings).

ox castrated male of domestic cattle, used in developing countries for ploughing and other agricultural work. Also the extinct wild ox or **aurochs** of Europe, and surviving wild species such as **buffaloes** and **yaks**.

oxalic acid (COOH)₂·2H₂O white, poisonous solid, soluble in water, alcohol, and ether. Oxalic acid is found in rhubarb, and its salts (oxalates) occur in wood sorrel (genus *Oxalis*, family Oxalidaceae) and other plants. It also occurs naturally in human body cells. It is used in the leather and textile industries, in dyeing and bleaching, ink manufacture, metal polishes, and for removing rust and ink stains.

oxbow lake curved lake found on the flood plain of a river. Oxbows are caused by the loops of meanders being cut off at times of flood and the river subsequently adopting a shorter course. In the USA, the term bayou is often used.

oxidation in chemistry, the loss of electrons, gain of oxygen, or loss of hydrogen by an atom, ion, or molecule during a chemical reaction.

Oxidation may be brought about by reaction with another compound (oxidizing agent), which simultaneously undergoes reduction, or electrically at the anode (positive electrode) of an electrolytic cell.

TO REMEMBER THE DIFFERENCE BETWEEN OXIDATION AND REDUCTION WITH RELATION TO ELECTRONS:

OILRIG

OXIDATION IS LOSS; REDUCTION IS GAIN

oxidation number Roman numeral often seen in a chemical name, indicating the valency of the element immediately before the number. Examples are lead(II) nitrate, manganese(IV) oxide, and potassium manganate(VII).

oxide compound of oxygen and another element, frequently produced by burning the element or a compound of it in air or oxygen.

oxbow lake The formation of an oxbow lake. As a river meanders across a flood plain, the outer bends are gradually eroded and the water channel deepens; as the loops widen, the neck of the loop narrows and finally gives way, allowing the water to flow in a more direct route, isolating the old water channel and forming an oxbow lake.

Oxides of metals are normally ϕ bases and will react with an acid to produce a ϕ salt in which the metal forms the cation (positive ion). Some of them will also react with a strong alkali to produce a salt in which the metal is part of a complex anion (negative ion; see ϕ amphoteric). Most oxides of nonmetals are acidic (dissolve in water to form an ϕ acid). Some oxides display no pronounced acidic or basic properties.

oxide film thin film of oxide formed on the surface of some metals as soon as they are exposed to the air. This oxide film makes the metal much more resistant to a chemical attack. The considerable lack of reactivity of aluminium to most reagents arises from this property.

The thickness of the oxide film can be increased by ϕ anodizing the aluminium.

oxidizing agent substance that will oxidize another substance (see oxidation).

In a redox reaction, the oxidizing agent is the substance that is itself reduced. Common oxidizing agents include oxygen, chlorine, nitric acid, and potassium manganate(VII).

oxlip plant closely related to the ϕ cowslip.

oxpecker or *tick-bird* either of two species of African birds belonging to the starling family. They climb around on the bodies of large mammals, feeding on ticks and other parasites and on cattle earwax. They are usually seen in groups of seven or eight, attending a herd of buffaloes or antelopes, and may help to warn the host of approaching dangers. (Species *Buphagus africana*, family Sturnidae, order Passeriformes.)

Both species have dingy brown plumage, a tawny undersurface and tail, and large laterally flattened colourful bills – one species has a red bill, the other a red and yellow bill.

oxyacetylene torch gas torch that burns ethyne (acetylene) in pure oxygen, producing a high-temperature flame (3,000°C/5,400°F). It is widely used in welding to fuse metals. In the cutting torch, a jet of oxygen burns through metal already melted by the flame.

oxyfuel fuel enriched with oxygen to decrease carbon monoxide (CO) emissions. Oxygen is added in the form of chemicals such as methyl tertiary butyl ether (MTBE) and ethanol.

Cars produce CO when there is insufficient oxygen present to convert all the carbon in the petrol to CO₂. This occurs mostly at low temperatures, such as during the first five minutes of starting the engine and in cold weather. CO emissions are reduced by the

addition of oxygen-rich chemicals. The use of oxyfuels in winter is compulsory in 35 US cities. There are fears, however, that MTBE can cause health problems, including nausea, headaches, and skin rashes.

oxygen Greek *oxys* 'acid'; *genes* 'forming' colourless, odourless, tasteless, nonmetallic, gaseous element, symbol O, atomic number 8, relative atomic mass 15.9994. It is the most abundant element in the Earth's crust (almost 50% by mass), forms about 21% by volume of the atmosphere, and is present in combined form in water and many other substances. Oxygen is a by-product of ϕ otosynthesis and the basis for ϕ respiration in plants and animals.

Oxygen is very reactive and combines with all other elements except the ϕ inert gases and fluorine. It is present in carbon dioxide, silicon dioxide (quartz), iron ore, calcium carbonate (limestone). In nature it exists as a molecule composed of two atoms (O₂); single atoms of oxygen are very short-lived owing to their reactivity. They can be produced in electric sparks and by the Sun's ultraviolet radiation in space, where they rapidly combine with molecular oxygen to form ozone (an allotrope of oxygen).

Oxygen is obtained for industrial use by the fractional distillation of liquid air, by the electrolysis of water, or by heating manganese (IV) oxide with potassium chlorate. It is essential for combustion, and is used with ethyne (acetylene) in high-temperature oxyacetylene welding and cutting torches.

The element was first identified by English chemist Joseph Priestley in 1774 and independently in the same year by Swedish chemist Karl Scheel. It was named by French chemist Antoine Lavoisier in 1777.

oxygen debt physiological state produced by vigorous exercise, in which the lungs cannot supply all the oxygen that the muscles need.

Oxygen is required for the release of energy from food molecules (aerobic ϕ respiration). Instead of breaking food molecules down fully, muscle cells switch to a form of partial breakdown that does not require oxygen (anaerobic respiration) so that they can continue to generate energy. This partial breakdown produces ϕ lactic acid, which results in a sensation of fatigue when it reaches certain levels in the muscles and the blood. Once the vigorous muscle movements cease, the body breaks down the lactic acid, using up extra oxygen to do so. Panting after exercise is an automatic mechanism to 'pay off' the oxygen debt.

oyster edible shellfish with a rough, irregular hinged shell, found on the sea bottom in coastal areas. Oysters are bivalve ϕ hellmuses; the upper valve (shell) is flat, the lower hollow, like a bowl, and the

two are hinged by an elastic ligament. The mantle, a protective layer of skin, lies against the shell, shielding the inner body, which includes the organs for breathing, digesting food, and reproduction. Oysters commonly change their sex once a year, sometimes more often; females can release up to a million eggs during a spawning period. (Family Ostreidae.)

Oysters have been considered a delicacy since ancient times. Among the species commercially exploited for food today are the North American eastern oyster (*Crassostrea virginica*) of the Atlantic coast and the European oyster (*Ostrea edulis*). The former is oviparous (eggs are discharged straight into the water) and the latter is larviparous (eggs and larvae remain in the mantle cavity for a period before release). Oyster farming is increasingly practised, the beds being specially cleansed for the easy setting of the free-swimming larvae (known as 'spats'), and the oysters later properly spaced for growth and fattened.

Valuable oysters are not obtained from members of the true oyster family; they occur in pearl oysters (family Pteriidae). There are also tree oysters (family Isognomonidae) and thorny oysters (family Spondyliidae).

oyster catcher any of several quite large, chunky shorebirds, with a long, heavy bill which is flattened at the sides and used to prise open the shells of oysters, mussels, and other shellfish. (Family Haematopodidae, order Charadriiformes.)

oz abbreviation for ounce.

Ozalid process trademarked copying process used to produce positive prints from drawn or printed materials or film, such as printing proofs from film images. The film is placed on top of chemically treated paper and then exposed to ultraviolet light. The image is developed dry using ammonia vapour.

ozone O_3 highly reactive pale-blue gas with a penetrating odour. Ozone is an allotrope of oxygen (see allotropy), made up of three atoms of oxygen. It is formed when the molecule of the stable form of oxygen (O_2) is split by ultraviolet radiation or electrical discharge. It forms the ozone layer in the upper atmosphere, which protects life on Earth from ultraviolet rays, a cause of skin cancer.

ozone depleter any chemical that destroys the ozone in the stratosphere. Most ozone depleters are chemically stable compounds containing chlorine or bromine, which remain unchanged for long enough to drift up to the upper atmosphere. The best known are chlorofluorocarbons (CFCs), but many other ozone depleters are known, including halons, used in some fire extinguishers; methyl chloroform and carbon tetrachloride, both solvents; some CFC substitutes; and the pesticide methyl bromide.

CFCs accounted for approximately 75% of ozone depletion in 1995, whereas methyl chloroform (atmospheric concentrations of which had markedly decreased during 1990-94) accounted for an estimated 12.5%. The ozone depletion rate overall is now decreasing as international agreements to curb the use of ozone-depleting chemicals begin to take effect. In 1996 there was a decrease in ozone depleters in the lower atmosphere. This trend is expected to continue into the stratosphere over the next few years.

ozone layer thin layer of the gas ozone in the upper atmosphere that shields the Earth from harmful ultraviolet rays. A continent-sized hole has formed over Antarctica as a result of damage to the ozone layer. This has been caused in part by chlorofluorocarbons (CFCs), but many reactions destroy ozone in the stratosphere: nitric oxide, chlorine, and bromine atoms are implicated.

It is believed that the ozone layer is depleting at a rate of about 5% every 10 years over northern Europe, with depletion extending south to the Mediterranean and southern USA. However, ozone depletion over the polar regions is the most dramatic manifestation of a general global effect. Ozone levels over the Arctic in spring 1997 fell over 10% since 1987, despite the reduction in the concentration of CFCs and other industrial compounds which destroy the ozone when exposed to sunlight. It is thought that this may be because of an expanding vortex of cold air forming in the lower stratosphere above the Arctic, leading to increased ozone loss. It is expected that an Arctic hole as large as that over Antarctica could remain a threat to the northern hemisphere for several decades.

The hole in the ozone layer reached record dimensions in October 1997, with ozone depleted from an area of 22 million sq km.

CHEMISTRY OF THE OZONE LAYER

<http://pooh.chem.wm.edu/chemWWW/courses/chem105/projects/group2/page1.html>

Interesting step-by-step introduction to the ozone layer for those wishing to understand the chemistry of ozone depletion, the role of chlorofluorocarbons, the consequences of increased radiation for life on earth, and actions to tackle the problem.

The information may be readily understood by those with a basic knowledge of chemistry.

P

PA (abbreviation for *public-address system*) amplification set-up for music or speech, usually employed in auditoriums or commercial venues.

paca large, tailless, nocturnal, burrowing rodent, related to the agoutis. The paca, about 60 cm/2 ft long, is native to Central and South America. (Genus *Cuniculus*, family Dasypodidae.)

pacemaker or *sinoatrial node* (SA node) in vertebrates, a group of muscle cells in the wall of the heart that contracts spontaneously and rhythmically, setting the pace for the contractions of the rest of the heart. The pacemaker's intrinsic rate of contraction is increased or decreased, according to the needs of the body, by stimulation from the autonomic nervous system. The term also refers to a medical device implanted under the skin of a patient whose heart beats inefficiently. It delivers minute electric shocks to stimulate the heart muscles at regular intervals and restores normal heartbeat.

The latest pacemakers are powered by radioactive isotopes for long life and weigh no more than 15 g/0.5 oz.

Pacific Ocean world's largest ocean, extending from Antarctica to the Bering Strait; area 166,242,500 sq km/64,170,000 sq mi; average depth 4,188 m/13,749 ft; greatest depth of any ocean 11,034 m/36,210 ft in the Mariana Trench.

That great sea, miscalled the Pacific.

packet in computing, unit of data sent across a network. As well as the actual substance of the message, every packet carries error-control information and details of its origin and its final target, enabling a router to send it on to the intended recipient. This means that packets belonging to the same file can travel via different routes over the network, to be automatically reassembled in the correct sequence when they arrive at their destination. All traffic on the Internet consists of packets. See also TCP/IP and X.25.

packet radio in computing, the use of amateur (ham) radio, instead of telephones, to communicate between computers. A terminal node controller (TNC) replaces the modem, a radio transceiver takes the place of the telephone, and the phone system is replaced by radio waves. Packet radio, which works on several different frequencies, has a complete network of its own, complete with satellite links and terrestrial relays. It cannot be used to access the Internet, but it can be connected through the Internet.

packet switching in computing, a method of transmitting data between computers connected in a network. A complete packet consists of the data being transmitted and information about which computer is to receive the data.

The packet travels around the network until it reaches the correct destination, just like a letter sent via the postal system (which is also a packet switching system). Packet switched networks are robust because different packets can take different routes to the same destination. In theory, the network should be able to survive particular circuits (connections) being bombed. The Internet, as a

US Defense Department project, was originally designed as a packet switched network to withstand the effects of a nuclear strike.

paediatrics or *pediatrics* medical speciality concerned with the care of children.

paedomorphosis in biology, an alternative term for neoteny.

page-description language in computing, a control language used to describe the contents and layout of a complete printed page. Page-description languages are frequently used to control the operation of laser printers. The most popular page-description languages are Adobe Postscript and Hewlett-Packard Printer Control Language.

page printer computer printer that prints a complete page of text and graphics at a time. Page printers use electrostatic techniques, very similar to those used by photocopiers, to form images of pages, and range in size from small laser printers designed to work with microcomputers to very large machines designed for high-volume commercial printing.

paging method of increasing a computer's apparent memory capacity. See virtual memory.

pain sense that gives an awareness of harmful effects on or in the body. It may be triggered by stimuli such as trauma, inflammation, and heat. Pain is transmitted by specialized nerves and also has psychological components controlled by higher centres in the brain. Drugs that control pain are known as painkillers or analgesics.

A pain message to the brain travels along the sensory nerves as electrical impulses. When these reach the gap between one nerve and another, biochemistry governs whether this gap is bridged and may also either increase or decrease the attention the message receives or modify its intensity in either direction. The main type of pain transmitter is known simply as 'substance P', a neuropeptide concentrated in a certain area of the spinal cord. Substance P has been found in fish, and there is also evidence that the same substances that cause pain in humans (for example, bee venom) cause a similar reaction in insects and arachnids (for instance, spiders).

Since the sensation of pain is transmitted by separate nerves from that of fine touch, it is possible in diseases such as syringomyelia to have no sense of pain in a limb, yet maintain a normal sense of touch. Such a desensitized limb is at great risk of infection from unnoticed cuts and abrasions.

painkiller agent for relieving pain. Types of painkiller include analgesics such as aspirin and aspirin substitutes, morphine, codeine, paracetamol, and synthetic versions of the natural inhibitors, the enkephalins and endorphins, which avoid the side effects of the others.

Topical nerve irritants are also used in salves, such as camphor and eucalyptus; they cause the nerve endings to react to them, bringing increased blood flow to the areas and alleviating localized and joint pain.

paint any of various materials used to give a protective and decorative finish to surfaces or for making pictures. A paint consists of a pigment suspended in a vehicle, or binder, usually with added solvents. It is the vehicle that dries and hardens to form an adhesive film of paint. Among the most common kinds are cellulose paints (or lacquers), oil-based paints, emulsion (water-based) paints, and special types such as enamels and primers.

types of paint Lacquers consist of a synthetic resin (such as an acrylic resin or cellulose acetate) dissolved in a volatile organic solvent, which evaporates rapidly to give a very quick-drying paint. A typical oil-based paint has a vehicle of a natural drying oil (such as linseed oil), containing a prime pigment of iron, lead, titanium, or zinc oxide, to which coloured pigments may be added. The finish - gloss, semimatt, or matt - depends on the amount of inert pigment (such as clay or silicates). Oil-based paints can be thinned with, and brushes cleaned in, a solvent such as turpentine or white spirit (a petroleum product). **Emulsion paints**, sometimes called latex paints, consist of pigments dispersed in a water-based emulsion of a polymer (such as polyvinyl chloride (PVC) or acrylic resin). They

can be thinned with water, which can also be used to wash the paint out of brushes and rollers. Enamels have little pigment, and they dry to an extremely hard, high-gloss film. Primers for the first coat on wood or metal, on the other hand, have a high pigment content (as do undercoat paints). Aluminium or bronze powder may be used for priming or finishing objects made of metal.

painted lady brownish-red and black butterfly that migrates to Britain from North Africa. The caterpillar feeds on thistles and other plants.

classification The painted lady *Vanessa cardui* is in family Nymphalidae, order Lepidoptera, class Insecta, phylum Arthropoda.

paint program in computing, program that enables users to 'paint' a picture on their computer screens, using a variety of brushes, spray-guns, and colours.

Paintshop Pro in computing, popular graphics or 'paint' program for Microsoft Windows created by US software house JASC Inc. It is distributed as shareware.

PAL (abbreviation for *Phase Alternation by Line*) video standard used in Britain, other parts of Europe, and China. It has a higher definition and different screen format from the US NTSC standard. Running a television program written for PAL on an NTSC system can result in the bottom of the screen image being cut off.

Palaeocene Greek 'old' + 'recent' first epoch of the Tertiary period of geological time, 65–56.5 million years ago. Many types of mammals spread rapidly after the disappearance of the great reptiles of the Mesozoic. Flying mammals replaced the flying reptiles, swimming mammals replaced the swimming reptiles, and all the ecological niches vacated by the reptiles were adopted by mammals.

palaeomagnetism science of the reconstruction of the Earth's ancient magnetic field and the former positions of the continents from the evidence of remnant magnetization in ancient rocks; that is, traces left by the Earth's magnetic field in igneous rocks before they cool. Palaeomagnetism shows that the Earth's magnetic field has reversed itself – the magnetic north pole becoming the magnetic south pole, and vice versa – at approximate half-million-year intervals, with shorter reversal periods in between the major spans.

Starting in the 1960s, this known pattern of magnetic reversals was used to demonstrate seafloor spreading or the formation of new ocean crust on either side of mid-oceanic ridges. As new material hardened on either side of a ridge, it would retain the imprint of the magnetic field, furnishing datable proof that material was spreading steadily outward. Palaeomagnetism is also used to demonstrate continental drift by determining the direction of the magnetic field of dated rocks from different continents.

palaeoniscid member of a primitive order of freshwater ray-finned fish. They had a spindle-shaped body, scales of a characteristic structure known as ganoid, and a heterocercal (asymmetrical) tail. They lived from Devonian to Jurassic times, but were most abundant in the Carboniferous period.

classification Palaeoniscids are in class Osteichthyes.

There are approximately 37 families in this group, with a wide distribution, fossils having been found in the British Isles, South Africa, Australia, and North America. The shape of the fishes suggests that they were fast swimming predators, initially freshwater with later members moving into the seas.

Cheirolepis canadensis, from the Upper Devonian era, is an example of the group.

palaeontology in geology, the study of ancient life, encompassing the structure of ancient organisms and their environment, evolution, and ecology, as revealed by their fossils. The practical aspects of palaeontology are based on using the presence of different fossils to date particular rock strata and to identify rocks that were laid down under particular conditions; for instance, giving rise to the formation of oil.

The use of fossils to trace the age of rocks was pioneered in Germany by Johann Friedrich Blumenbach (1752–1830) at Göttingen, followed by Georges Cuvier and Alexandre Brongniart in France in 1811.

The term palaeontology was first used in 1834, during the period when the first dinosaur remains were discovered.

Palaeozoic era of geological time 570–245 million years ago. It comprises the Cambrian, Ordovician, Silurian, Devonian, Carboniferous, and Permian periods. The Cambrian, Ordovician, and Silurian constitute the Lower or Early Palaeozoic; the Devonian, Carboniferous, and Permian make up the Upper or Late Palaeozoic. The era includes the evolution of hard-shelled multicellular life forms in the sea; the invasion of land by plants and animals; and the evolution of fish, amphibians, and early reptiles. The earliest identifiable fossils date from this era.

The climate at this time was mostly warm with short ice ages. The continents were very different from the present ones but, towards the end of the era, all were joined together as a single world continent called Pangea.

palate in mammals, the roof of the mouth. The bony front part is the hard palate, the muscular rear part the soft palate. Incomplete fusion of the two lateral halves of the palate (cleft palate) causes interference with speech.

palisade cell cylindrical cell lying immediately beneath the upper epidermis of a leaf. Palisade cells normally exist as one closely packed row and contain many chloroplasts. During the hours of daylight palisade cells are photosynthetic, using the energy of the sun to create carbohydrates from water and carbon dioxide.

palladium lightweight, ductile and malleable, silver-white, metallic element, symbol Pd, atomic number 46, relative atomic mass 106.4.

It is one of the so-called platinum group of metals, and is resistant to tarnish and corrosion. It often occurs in nature as a free metal (see native metal) in a natural alloy with platinum. Palladium is used as a catalyst, in alloys of gold (to make white gold) and silver, in electroplating, and in dentistry.

It was discovered in 1803 by British physicist William Wollaston (1766–1828), and named after the asteroid Pallas (found 1802).

palliative in medicine, any treatment given to relieve symptoms rather than to cure the underlying cause. In conditions that will resolve of their own accord (for instance, the common cold) or that are incurable, the entire treatment may be palliative.

palm any of a group of large tree-like plants with a single tall stem that has a thick cluster of large palmate (five-lobed) leaves or pinnate leaves (leaflets either side of the stem) at the top. Most of the numerous species are tropical or subtropical. Some, such as the coconut, date, sago, and oil palms, are important economically. (Family Palmae.)

pampas grass any of a group of large grasses native to South America, especially *C. argentea*, which is grown in gardens and has tall leaves and large clusters of feathery white flowers growing around the tips of the flower-bearing stems. (Genus *Cortaderia*.)

panchromatic in photography, a term describing highly sensitive black-and-white film made to render all visible spectral colours in correct grey tones. Panchromatic film is always developed in total darkness.

Large amount of detailed information on the subject in a carefully structured and carefully cross-referenced site. You can explore palaeontology through the three areas of phylogeny, geology, and evolution.

palisade cell Palisade cells are closely packed, columnar cells, lying in the upper surfaces of leaves. They contain many chloroplasts (where photosynthesis takes place) and are well adapted to receive and process the components necessary for photosynthesis – carbon dioxide, water, and sunlight. For instance, their vertical arrangement means that there are few cross-walls to interfere with the passage of sunlight.

hormone secretin, it releases enzymes into the duodenum that digest starches, proteins, and fats. In humans, it is about 18 cm/7 in long, and lies behind and below the stomach. It contains groups of cells called the islets of Langerhans, which secrete the hormones insulin and glucagon that regulate the blood sugar level.

panda one of two carnivores of different families, native to NW China and Tibet. The giant panda *Ailuropoda melanoleuca* has black-and-white fur with black eye patches and feeds mainly on bamboo shoots, consuming about 8 kg/17.5 lb of bamboo per day. It can grow up to 1.5 m/4.5 ft long, and weigh up to 140 kg/300 lb. It is an endangered species. The lesser, or red, panda *Ailurus fulgens*, of the raccoon family, is about 50 cm/1.5 ft long, and is black and chestnut, with a long tail.

Pandas' bamboo diet is of low nutritional value, being about 90% water. This makes it impossible for them to hibernate, since although they spend about 12 hours of every day eating, they cannot accumulate the necessary reserves of fat. There is some dispute about whether they should be included in the bear family or the raccoon family, or classified as a family of their own.

Destruction of the giant pandas' natural habitats threatens to make them extinct in the wild, and they are the focus of conservation efforts; there were only 1,200 giant pandas in 1996.

Pangaea or **Pangea** Greek 'all-land' single land mass, made up of all the present continents, believed to have existed between 300 and 200 million years ago; the rest of the Earth was covered by the Panthalassa ocean. Pangaea split into two land masses – Laurasia in the north and Gondwanaland in the south – which subsequently broke up into several continents. These then drifted slowly to their present positions (see continental drift).

The existence of a single 'supercontinent' was proposed by German meteorologist Alfred Wegener in 1912.

pangolin or **scaly anteater** toothless mammal of tropical Africa and SE Asia. They are long-tailed and covered with large, overlapping scales, except on the muzzle, sides of the head, throat, chest, and belly. They have an elongated skull and a long, extensible tongue. Pangolins measure 30–100 cm/12–39 in long, exclusive of the prehensile tail, which is about twice as long as the body.

Some are arboreal and others are terrestrial. All live on ants and termites. Pangolins comprise the order Pholidota. There is only one genus (*Manis*) and family Manidae, with seven species.

The lower gums of the mouth form two thickened horny ridges separated by a groove along which the cylindrical wormlike tongue slips in and out. The feet are strongly clawed, especially on the third toe of the forefoot, which is used in burrowing and in climbing. The extreme tip of the tail is free from scales and padded with thick skin. To deter predators a powerful stench is emitted by the entire surface of the skin, and its bony overlapping scales protect it when it rolls up into a ball.

pansy cultivated plant derived from the European wild pansy (*Viola tricolor*) and including many different varieties and strains. The flowers are usually purple, yellow, or cream, or a mixture of these colours, and there are many highly developed varieties bred for size, colour, or special markings. Several of the 400 different species are scented. (Family Violaceae.)

Panthallassa ocean that covered the surface of the Earth not occupied by the world continent Pangaea between 300 and 200 million years ago.

panther another name for the leopard.

Pantone Matching System trade name for a standard set of colours used in graphics and printing, precisely graded and numbered using a universal system. Colours shown on monitors and computer printers are not reliable enough for most designers, so print graphics programs usually include the facility to specify the desired Pantone colours.

panthothenic acid water-soluble vitamin ($C_9H_{17}NO_2$) of the B complex, found in a wide variety of foods. Its absence from the diet can lead to dermatitis, and it is known to be involved in the breakdown of fats and carbohydrates.

papaya tropical evergreen tree, native from Florida to South America. Varieties are grown throughout the tropics. The edible fruits are like melons, with orange-coloured flesh and large numbers of blackish seeds in the centre; they can weigh up to 9 kg/20 lb. (*Carica papaya*, family Caricaceae.)

The fruit juice and the tree sap contain papain, an enzyme used to tenderize meat and help digestion.

paper thin, flexible material made in sheets from vegetable fibres (such as wood pulp) or rags and used for writing, drawing, printing, packaging, and various household needs. The name comes from papyrus, a form of writing material made from water reed, used in ancient Egypt. The invention of true paper, originally made of pulped fishing nets and rags, is credited to Tsai Lun, Chinese minister of agriculture, in AD 105.

Paper came to the West with Arabs who had learned the secret from Chinese prisoners of war in Samarkand in 768. It spread from Morocco to Moorish Spain and to Byzantium in the 11th century.

YOU CAN MAKE PAPER

<http://www.beakman.com/paper/paper.html>

Fun and environmentally conscious project aiming to teach children about paper and how to make their own home-made paper. Friendly chatting follows the step-by-step instructions. The site also offers an interactive on cellular phones, gravity, smoking and our lungs, relativity, magnets, and more. Children (and adults) can post their questions to a query box.

paper Today's fully automatic papermaking machines can be 200 m/640 ft long and produce over 1,000 m/3,200 ft of paper in a minute. The most common type of papermaking machine is the Fourdrinier, named after two British stationer brothers who invented it in 1803. Their original machine deposited the paper on pieces of felt, after which it was finished by hand.

then to the rest of Europe. All early paper was handmade within frames.

With the spread of literacy there was a great increase in the demand for paper. Production by hand of single sheets could not keep pace with this demand, which led to the invention, by Louis Robert (1761–1828) in 1799, of a machine to produce a continuous reel of paper. The process was developed and patented in 1801 by François Didot, Robert's employer. Today most paper is made from wood pulp on a Fourdrinier machine, then cut to size; some high grade paper is still made from esparto or rag. Paper products absorb 35% of the world's annual commercial wood harvest; recycling avoids some of the enormous waste of trees, and most papermakers plant and replant their own forests of fast-growing stock.

paper nautilus another name for the çargonaut.

pappus (plural *pappi*) standard European sizes for paper, designated by a letter (A, B, or C) and a number (0–6). The letter indicates the size of the basic sheet at manufacture; the number is how many times it has been folded. A4 is obtained by folding an A3 sheet, which is half an A2 sheet, in half, and so on.

papillon French 'butterfly' breed of French toy spaniel that has pricked ears with plumes of hair, giving its head a butterfly-like appearance. It is less than 28 cm/11 in tall, and its fine, wavy, long coat is mainly white with coloured patches, especially on the ears.

pappus (plural *pappi*) in botany, a modified çcalyx comprising a ring of fine, silky hairs, or sometimes scales or small teeth, that persists after fertilization. Pappi are found in members of the daisy

family (Compositae) such as the dandelions *Taraxacum*, where they form a parachutelike structure that aids dispersal of the fruit.

Pap test or *Pap smear* common name for çcervical smear.

parabola in mathematics, a curve formed by cutting a right circular cone with a plane parallel to the sloping side of the cone. A parabola is one of the family of curves known as çconic sections. The graph of $y = x^2$ is a parabola.

It can also be defined as a path traced out by a point that moves in such a way that the distance from a fixed point (focus) is equal to its distance from a fixed straight line (directrix); it thus has an çeccentricity of 1.

The trajectories of missiles within the Earth's gravitational field approximate closely to parabolas (ignoring the effect of air resistance). The corresponding solid figure, the paraboloid, is formed by rotating a parabola about its axis. It is a common shape for head-light reflectors, dish-shaped microwave and radar aerials, and radiotelescopes, since a source of radiation placed at the focus of a paraboloidal reflector is propagated as a parallel beam.

paracetamol analgesic, particularly effective for musculoskeletal pain. It is as effective as aspirin in reducing fever, and less irritating to the stomach, but has little anti-inflammatory action. An overdose can cause severe, often irreversible or even fatal, liver and kidney damage.

parachute any canopied fabric device strapped to a person or a package, used to slow down descent from a high altitude, or returning spent missiles or parts to a safe speed for landing, or sometimes to aid (through braking) the landing of a plane or mis-

parabola The parabola is a curve produced when a cone is cut by a plane. It is one of a family of curves called conic sections, which also includes the circle, ellipse, and hyperbole. These curves are produced when the plane cuts the cone at different angles and positions.

sile. Modern designs enable the parachutist to exercise considerable control of direction, as in skydiving.

Leonardo da Vinci sketched a parachute design, but the first descent, from a balloon at a height of 670 m/2,200 ft over Paris, was not made until 1797 by André-Jacques Garnerin (1769–1823). The first descent from an aircraft was made by Capt Albert Berry in 1912 from a height of 457 m/1,500 ft over Missouri.

A parachute is typically folded into a pack from which it is released by a rip cord or other device. It originally consisted of some two dozen panels of silk (later nylon) in a circular canopy with shroud lines to a harness. Modern parachutes are variously shaped, often small and rectangular.

In **parascending** the parachuting procedure is reversed, the canopy (parafoil) to which the person is attached being towed behind a vehicle to achieve an ascent.

paradigm all those factors, both scientific and sociological, that influence the research of the scientist. The term, first used by the US historian of science Thomas Kuhn, has subsequently spread to social studies and politics.

Nevertheless, paradigm changes do cause scientists to see the world of their research-engagement differently. In so far as their only recourse to that world is through what they see and do, we may want to say that after a revolution scientists are responding to a different world.

THOMAS SAMUEL KUHN US philosopher and historian of science.

paradisefish small freshwater fish found in ditches and paddy fields in Asia.

As in the related fighting fish (*Betta*), the males, when in breeding colours, are very pugnacious.

classification The paradisefish *Macropodus opercularis* is in the family Anabantidae, order Perciformes, class Osteichthyes.

paraffin common name for alkane, any member of the series of hydrocarbons with the general formula C_nH_{2n+2} . The lower mem-

bers are gases, such as methane (marsh or natural gas). The middle ones (mainly liquid) form the basis of petrol, kerosene, and lubricating oils, while the higher ones (paraffin waxes) are used in ointment and cosmetic bases.

parakeet any of various small long-tailed cparrots, order Psittaciformes, with a moderate beak. They include the ring-necked parakeets, genus *Psittacula*, which are very common in India and Africa, and ccockatiels, and cbudgerigars, natives of Australia. The king parakeet is about the size of a magpie and has a red head and breast and green wings.

paraldehyde common name for cethanal trimer.

parallax the change in the apparent position of an object against its background when viewed from two different positions. In astronomy, nearby stars show a shift owing to parallax when viewed from different positions on the Earth's orbit around the Sun. A star's parallax is used to deduce its distance from the Earth.

Nearer bodies such as the Moon, Sun, and planets also show a parallax caused by the motion of the Earth. **Diurnal parallax** is caused by the Earth's rotation.

parallax in cvirtual reality, the distance between the viewer's left and right eyes in the virtual world.

This difference is what creates the impression of depth. Right and left images of distant objects look the same; but left and right images of nearby objects look markedly different owing to the difference of perspective. Manipulating this variable in a virtual world helps make objects look large or small.

parallax The parallax of a star, the apparent change of its position during the year, can be used to find the star's distance from the Earth. The star appears to change its position because it is viewed at a different angle in July and January. By measuring the angle of parallax, and knowing the diameter of the Earth's orbit, simple geometry can be used to calculate the distance to the star.

parallel circuit electrical circuit in which the components are connected side by side. The current flowing in the circuit is shared by the components. The division of the current across each conductor is in the ratio of their resistances.

parallel device in computing, a device that communicates binary data by sending the bits that represent each character simultaneously along a set of separate data lines, unlike a cserial device.

parallel circuit In a parallel circuit, the components are connected side by side, so that the current is split between two or more parallel paths or conductors.

parallel lines and parallel planes in mathematics, straight lines or planes that always remain a constant distance from one another no matter how far they are extended. This is a principle of Euclidean geometry. Some non-Euclidean geometries, such as elliptical and hyperbolic geometry, however, reject Euclid's parallel axiom.

parallelogram in mathematics, a quadrilateral (four-sided plane figure) with opposite pairs of sides equal in length and parallel, and opposite angles equal. The diagonals of a parallelogram bisect each other. Its area is the product of the length of one side and the perpendicular distance between this and the opposite side. In the special case when all four sides are equal in length, the parallelogram is known as a rhombus, and when the internal angles are right angles, it is a rectangle or square.

(i) opposite sides and angles are equal

(ii) diagonals bisect each other at O

(iii) area of a parallelogram $l \times h$

parallelogram Some properties of a parallelogram.

parallelogram of forces The diagram shows how the parallelogram of forces can be used to calculate the resultant (combined effect) of two different forces acting together on an object. The two forces are represented by two lines drawn at an angle to each other. By completing the parallelogram (of which the two lines are sides), a diagonal may be drawn from the original angle to the opposite corner to represent the resultant force vector.

parallelogram of forces in physics and applied mathematics, a method of calculating the resultant (combined effect) of two different forces acting together on an object. Because a force has both magnitude and direction it is a vector quantity and can be represented by a straight line. A second force acting at the same point in a different direction can be represented by another line drawn at an angle to the first. By completing the parallelogram (of which the two lines are sides) a diagonal may be drawn from the original angle to the opposite corner to represent the resultant force vector.

parallel processing emerging computer technology that allows more than one computation at the same time. Although in the 1980s this technology enabled only a small number of computer processor units to work in parallel, in theory thousands or millions of processors could be used at the same time.

Parallel processing, which involves breaking down computations into small parts and performing thousands of them simultaneously, rather than in a linear sequence, offers the prospect of a vast improvement in working speed for certain repetitive applications.

parallel running in computing, a method of implementing a new computer system in which the new system and the old system are run together for a short while. The old system is therefore available to take over from its replacement should any faults arise. An alternative method is *hot* running.

paralysis loss of voluntary movement due to failure of nerve impulses to reach the muscles involved. It may result from almost any disorder of the nervous system, including brain or spinal cord injury, poliomyelitis, stroke, and progressive conditions such as a tumour or multiple sclerosis. Paralysis may also involve loss of sensation due to sensory nerve disturbance.

paramagnetic material material that is weakly pulled towards a strong magnet. The effect is caused by unpaired electrons in the atoms of the material, which cause the atoms to act as weak magnets. A paramagnetic material has a fairly low magnetic susceptibility that is inversely proportional to temperature. See magnetism.

Paramecium genus of protozoa. It is unicellular and has a large nucleus (macronucleus) and one or more small nuclei (micronuclei), and an arrangement of cilia (hairlike organs) by which it moves about.

There are also two contractile vacuoles which function alternately and act as osmotic organs; water is constantly absorbed by osmosis, and these vacuoles collect and forcibly expel it. *Paramecium* directs a current of water into its mouth by the movements of its cilia. The cilia also move the animal through the water.

Reproduction is by fission and by conjugation. In the former

case, first the smaller nucleus, then the larger, become constricted and divide into two by oblique division, and the missing organs in either part are quickly regenerated. Frequent multiplication by fission diminishes the vitality of the organism and is succeeded by conjugation, when two individuals exchange part of the substance of their nuclear apparatus. When conditions become unfavourable the animals enclose themselves in cysts.

classification *Paramecium* belongs to the subclass Hymenostomatia, class Oligohymenophora, phylum Ciliophora.

parameter variable factor or characteristic. For example, length is one parameter of a rectangle; its height is another. In computing, it is frequently useful to describe a program or object with a set of variable parameters rather than fixed values.

For example, if a programmer writes a routine for drawing a rectangle using general parameters for the length, height, line thickness, and so on, any rectangle can be drawn by this routine by giving different values to the parameters.

Similarly, in a word-processing application that stores parameters for font, page layout, type of justification, and so on, these can be changed by the user.

paranoia mental disorder marked by delusions of grandeur or persecution. In popular usage, paranoia means baseless or exaggerated fear and suspicion.

In **chronic paranoia**, patients exhibit a rigid system of false beliefs and opinions, believing themselves, for example, to be followed by the secret police, to be loved by someone at a distance, or to be of great importance or in special relation to God. There are no hallucinations and patients are in other respects normal.

In **paranoid states**, the delusions of persecution or grandeur are present but not systematized.

In **paranoid (schizophrenia)**, the patient suffers from many unsystematized and incoherent delusions, is extremely suspicious, and experiences hallucinations and the feeling that external reality has altered.

paranormal not within the range of, or explicable by, established science. Paranormal phenomena include extrasensory perception (ESP) which takes in clairvoyance, precognition, and telepathy; telekinesis, the movement of objects from one position to another by human mental concentration; and mediumship, supposed contact with the spirits of the dead, usually via an intermediate 'guide' in the other world. *Parapsychology* is the study of such phenomena.

Paranormal phenomena are usually attributed to the action of an unknown factor, *opsis*.

There have been many reports of sporadic paranormal phenomena, the most remarkable being reports by one person, or occasionally more, of apparitions or hallucinatory experiences associated with another person's death.

paraplegia paralysis of the lower limbs, involving loss of both movement and sensation; it is usually due to spinal injury.

parapsychology Greek *para* 'beyond' study of (paranormal) phenomena, which are generally subdivided into two types: extrasensory perception (ESP), or the paracognitive; and psychokinesis (PK), telekinesis, or the parapsychical - movement of an object without the use of physical force or energy.

Most research into parapsychology has been experimental. The first Society for Psychical Research was established in London in 1882 by scientists, philosophers, classical scholars, and spiritualists. Despite continued scepticism within the scientific establishment, a chair of parapsychology was established in 1984 at Edinburgh University, endowed by the Hungarian author Arthur Koestler.

paraquat $\text{CH}_3(\text{C}_6\text{H}_4\text{N})_2\text{CH}_3 \cdot 2\text{CH}_3\text{SO}_4$ (technical name 1,1-dimethyl-4,4-dipyridylum) nonselective herbicide (weedkiller). Although quickly degraded by soil microorganisms, it is deadly to human beings if ingested.

parasite organism that lives on or in another organism (called the host) and depends on it for nutrition, often at the expense of the host's welfare. Parasites that live inside the host, such as liver flukes and tapeworms, are called **endoparasites**; those that live on the exterior, such as fleas and lice, are called **ectoparasites**.

parathyroid one of a pair of small endocrine glands. Most tetrapod vertebrates, including humans, possess two such pairs, located behind the thyroid gland. They secrete parathyroid hormone, which regulates the amount of calcium in the blood.

parenchyma plant tissue composed of loosely packed, more or less spherical cells, with thin cellulose walls. Although parenchyma often has no specialized function, it is usually present in large amounts, forming a packing or ground tissue. It usually has many intercellular spaces.

parental care in biology, the time and energy spent by a parent in order to rear its offspring to maturity. Among animals, it ranges from the simple provision of a food supply for the hatching young at the time the eggs are laid (for example, many wasps) to feeding and protection of the young after hatching or birth, as in birds and mammals. In the more social species, parental care may include the teaching of skills - for example, female cats teach their kittens to hunt.

parental generation in genetic crosses, the set of individuals at the start of a test, providing the first set of gametes from which subsequent generations (known as the F1 and F2) will arise.

parity of a number, the state of being either even or odd. In computing, the term refers to the number of 1s in the binary codes used to represent data. A binary representation has even parity if it contains an even number of 1s and odd parity if it contains an odd number of 1s.

For example, the binary code 1000001, commonly used to represent the character 'A', has even parity because it contains two 1s, and the binary code 1000011, commonly used to represent the character 'C', has odd parity because it contains three 1s. A parity bit (0 or 1) is sometimes added to each binary representation to give all the same parity so that a validation check can be carried out each time data are transferred from one part of the computer to another. So, for example, the codes 1000001 and 1000011 could have parity bits added and become 01000001 and 11000011, both with even parity. If any bit in these codes should be altered in the course of processing the parity would change and the error would be quickly detected.

parity check a form of validation of data.

Parkes site in New South Wales of the Australian National Radio Astronomy Observatory, featuring a radio telescope of 64 m/210 ft aperture, run by the Commonwealth Scientific and Industrial Research Organization. It received a NASA-funded upgrade in 1996 to enable it to track the space probe *Galileo*.

Parkinson's disease or **parkinsonism** or **paralysis agitans** degenerative disease of the brain characterized by a progressive loss of mobility, muscular rigidity, tremor, and speech difficulties. The condition is mainly seen in people over the age of 50.

Parkinson's disease destroys a group of cells called the *substantia nigra* ('black substance') in the upper part of the brainstem. These cells are concerned with the production of a neurotransmitter known as dopamine, which is essential to the control of voluntary movement. The almost total loss of these cells, and of their chemical product, produces the disabling effects. A defective gene responsible for 1 in 20 cases was identified in 1992.

The disease occurs in two forms: **multiple system atrophy** (MSA), which is a failure of the central nervous system and accounts for 1 in 5 cases; and **pure autonomic failure** (PAF), a deficit in the peripheral nerves. Symptoms, particularly in the early

PARKINSON'S DISEASE: HOPE THROUGH RESEARCH

<http://www.ninds.nih.gov/healinfo/disorder/parkinson/pdhttr.htm>

Extensive background information on Parkinson's disease. Amongst other issues, it discusses the causes and symptoms of the disorder, the diagnostic methods used and the treatments and medications that are available, the role of surgery in the treatment of the disease, and that of diet and exercise as ways of achieving alleviation of its symptoms.

stages, can be identical. In 1997, an estimated 1.5 million Americans and over 120,000 Britons were suffering with Parkinson's.

The introduction of the drug L-dopa in the 1960s seemed at first the answer to Parkinson's disease. However, it became evident that long-term use brings considerable problems. At best, it postpones the terminal phase of the disease. Brain grafts with dopamine-producing cells were pioneered in the early 1980s, and attempts to graft Parkinson's patients with fetal brain tissue have been made. This experimental surgery brought considerable improvement to some PAF patients, but is ineffective in the MSA form. In 1989 a large US study showed that the drug deprenyl may slow the rate at which disability progresses in patients with early Parkinson's disease.

parrot tropical bird found mainly in Australia and South America. These colourful birds have been valued as pets in the Western world for many centuries. Parrots have the ability to imitate human speech. They are mainly vegetarian, and range in size from the 8.5 cm/3.5 in pygmy parrot to the 100 cm/40 in Amazon parrot. The smaller species are commonly referred to as *çparakeets*. The plumage is often very colourful, and the call is usually a harsh screech. In most species the sexes are indistinguishable. Several species are endangered. Parrots are members of the family Psittacidae, of the order Psittaciformes.

Parrots all have powerful hooked bills and feet adapted for tree climbing. The bill, with its elongated tip, is well adapted in most parrots for tearing up fruit and cracking nuts, and in a number of species the tongue is highly specialized for extracting honey by means of a brushlike tip.

The talent for imitating human speech is marked in the grey parrot *Psittacus erithacus* of Africa. Alex, a 20-year-old African grey taking part in a long-term language project at the University of Arizona during 1996, can count up to six, name 100 objects and describe their colour, texture, and shape. Parrots were among the first items to be traded between natives and European settlers and merchants.

unusual parrots The *çkakapo* of New Zealand is flightless and usually lives on the ground, though it can still climb trees. The *çkea*, another New Zealand parrot, differs from the rest of the group in having developed carnivorous habits.

Illustrated guide to the parrot including information about genus,

parrot fish or **parrot wrasse** member of a family of marine bony fish. The teeth of this group have fused to form extremely hard beaks that are able to bite off pieces of coral; these, with seaweed and molluscs, form the principal food. The fish are all brilliantly coloured, and some may grow up to 1 m/3.3 ft in length.

classification Parrot fish comprise the family Scaridae, order Perciformes, class Osteichthyes.

parse in computing, software facility for breaking down a data stream into individual pieces of information that can be acted upon. On the World Wide Web, for example, data entered by a user can be sent to a database program for storage and later analysis; the ability to do this depends on being able to feed the right bit of data into the right record field.

parsec in astronomy, a unit (symbol pc) used for distances to stars and galaxies. One parsec is equal to 3.2616 *çlight* years, 2.063 x 10⁵ astronomical units, and 3.086 x 10¹³ km.

It is the distance at which a star would have a *çparallax* (apparent shift in position) of one second of arc when viewed from two points the same distance apart as the Earth's distance from the Sun; or the distance at which one astronomical unit subtends an angle of one second of arc.

parsley herb belonging to the carrot family, cultivated for flavouring and garnishing in cookery and for its nutrient value, being rich in vitamin C and minerals. It can grow up to 45 cm/1.5 ft high and has aromatic, curled or flat pinnate leaves (leaflets either side of the stem) and delicate open clusters of yellow flowers. It is a biennial plant. (*Petroselinum crispum*, family Umbelliferae.)

parsnip temperate biennial plant belonging to the carrot family, found in Europe and Asia, and cultivated for its tapering, creamy-white, aromatic root, which is much used as a winter vegetable. (*Pastinaca sativa*, family Umbelliferae.)

parthenocarp in botany, the formation of fruits without seeds. This phenomenon, of no obvious benefit to the plant, occurs naturally in some plants, such as bananas. It can also be induced in some fruit crops, either by breeding or by applying certain plant hormones.

parthenogenesis development of an ovum (egg) without any genetic contribution from a male. Parthenogenesis is the normal means of reproduction in a few plants (for example, dandelions) and animals (for example, certain fish). Some sexually reproducing species, such as aphids, show parthenogenesis at some stage in their life cycle to accelerate reproduction to take advantage of good conditions.

parthenogenesis During spring and summer female aphids such as the *Macrosiphum chlodkovskyi* produce a continuous succession of offspring by parthenogenesis, but mate and lay eggs before the onset of winter. Premaphotos Wildlife

particle detector one of a number of instruments designed to detect subatomic particles and track their paths; they include the cloud chamber, bubble chamber, spark chamber, and multiwire chamber.

The earliest particle detector was the cloud chamber, which contains a super-saturated vapour in which particles leave a trail of droplets, in much the same way that a jet aircraft leaves a trail of vapour in the sky. A bubble chamber contains a superheated liquid in which a particle leaves a trail of bubbles. A spark chamber contains a series of closely-packed parallel metal plates, each at a high voltage. As particles pass through the chamber, they leave a visible spark between the plates. A modern multiwire chamber consists of an array of fine, closely-packed wires, each at a high voltage. As a particle passes through the chamber, it produces an electrical signal in the wires. A computer analyses the signal and reconstructs the path of the particles. Multiwire detectors can be used to detect X-ray and gamma rays, and are used as detectors in positron emission tomography (PET).

particle physics study of the particles that make up all atoms, and of their interactions. More than 300 subatomic particles have now been identified by physicists, categorized into several classes according to their mass, electric charge, spin, magnetic moment, and interaction. Subatomic particles include the elementary particles (quarks, leptons, and gauge bosons), which are believed to be indivisible and so may be considered the fundamental units of matter; and the hadrons (baryons, such as the proton and neutron, and mesons), which are composite particles, made up of two or three quarks. The proton, electron, and neutrino are the only stable particles (the neutron being stable only when in the atomic nucleus). The unstable particles decay rapidly into other particles, and are known from experiments with particle accelerators and cosmic radiation. See atomic structure.

Pioneering research took place at the Cavendish laboratory, Cambridge, England. In 1897 English physicist Joseph John Thomson discovered that all atoms contain identical, negatively charged particles (electrons), which can easily be freed. By 1911 New Zealand physicist Ernest Rutherford had shown that the electrons surround a very small, positively-charged nucleus. In the case of hydrogen, this was found to consist of a single positively charged particle, a proton. The nuclei of other elements are made up of protons and uncharged particles called neutrons.

1932 saw the discovery of a particle (whose existence had been predicted by British theoretical physicist Paul Dirac in 1928) with the mass of an electron, but an equal and opposite charge – the positron. This was the first example of antimatter; it is now believed that all particles have corresponding antiparticles. In 1934 Italian-born US physicist Enrico Fermi argued that a hitherto unsuspected particle, the neutrino, must accompany electrons in beta-emission.

particles and fundamental forces By the mid-1930s, four types of fundamental force interacting between particles had been identified. The electromagnetic force acts between all particles with electric charge, and is thought to be related to the exchange between these particles of gauge bosons called photons, packets of electromagnetic radiation.

In 1935 Japanese physicist Hideki Yukawa suggested that the strong nuclear force (binding protons and neutrons together in the nucleus) was transmitted by the exchange of particles with a mass about one-tenth of that of a proton; these particles, called pions (originally pi mesons), were found by British physicist Cecil Powell in 1946. Yukawa's theory was largely superseded from 1973 by the theory of quantum chromodynamics, which postulates that the strong nuclear force is transmitted by the exchange of gauge bosons called gluons between the quarks and antiquarks making up protons and neutrons. Theoretical work on the weak nuclear force began with Enrico Fermi in the 1930s. The existence of the gauge bosons that carry this force, the W and Z particles, was confirmed in 1983 at CERN, the European nuclear research organization. The fourth fundamental force, gravity, is experienced by all matter; the postulated carrier of this force has been named the graviton.

leptons The electron, muon, tau, and their neutrinos comprise the leptons – light particles with half-integral spin that 'feel' the weak nuclear and electromagnetic force but not the strong force. The muon (found by US physicist Carl Anderson in cosmic radiation in 1937) produces the muon neutrino when it decays; the tau, a surprise discovery of the 1970s, produces the tau neutrino when it decays.

mesons and baryons The hadrons (particles that 'feel' the strong nuclear force) were found in the 1950s and 1960s. They are classified into mesons, with whole-number or zero spins, and baryons (which include protons and neutrons), with half-integral spins. It was shown in the early 1960s that if hadrons of the same spin are represented as points on suitable charts, simple patterns are formed. This symmetry enabled a hitherto unknown baryon, the omega-minus, to be predicted from a gap in one of the patterns; it duly turned up in experiments.

quarks In 1964, US physicists Murray Gell-Mann and George Zweig suggested that all hadrons were built from three 'flavours' of a new particle with half-integral spin and a charge of magnitude either $\frac{1}{3}$ or $\frac{2}{3}$ that of an electron; Gell-Mann named the particle the quark.

Mesons are quark-antiquark pairs (spins either add to one or cancel to zero), and baryons are quark triplets. To account for new mesons such as the psi (J) particle the number of quark flavours had risen to six by 1985.

If I could remember the names of all these particles I'd be a botanist.

particle size in chemistry the size of the grains that make up a powder. The grain size has an effect on certain properties of a substance.

Finely divided powders have a greater surface area for contact; they therefore react more quickly, dissolve more readily, and are of increased efficiency as catalysts compared with their larger-sized counterparts.

particle, subatomic in physics, a particle that is smaller than an atom; see particle physics.

partridge any of various medium-sized ground-dwelling fowl of the family Phasianidae, order Galliformes, that also includes pheasants, quail, and chickens. Partridges are Old World birds, some of which have become naturalized in North America.

Partridges pair very early in the year, the males, like the males of most gallinaceous species, being very pugnacious. The nest is made with a minimum of trouble on the ground in fields or hedgerows, and contains 10–20 olive brown eggs. The hen hatches them, but the male is attentive to her during incubation. The young are fed chiefly on ant pupae, and other insects when these are not available; these and snails and slugs form a considerable proportion of the food of older birds, but in addition grain and other seeds are consumed in great quantity when obtainable. The young remain with their parents for some months, forming coveys of about 20 birds. In the morning and evening they search the stubble and pastures for food, but during the day they hide wherever safe cover may be found.

PASCAL (French acronym for *program appliqué à la sélection et la compilation automatique de la littérature*) a high-level computer-programming language. Designed by Niklaus Wirth (1934–) in the 1960s as an aid to teaching programming, it is still widely used as such in universities, and as a good general-purpose programming language. Most professional programmers, however, now use C or C++. Pascal was named after 17th-century French mathematician Blaise Pascal.

pascal SI unit (symbol Pa) of pressure, equal to one newton per square metre. It replaces bars and millibars (10^5 Pa equals one bar). It is named after the French mathematician Blaise Pascal.

In the field of observation, chance only favours those minds which have been prepared.

Pascal, Blaise (1623–1662)

French philosopher and mathematician. He contributed to the development of hydraulics, calculus, and the mathematical theory of probability.

mathematics Pascal's work in mathematics widened general understanding of conic sections, introduced an algebraic notational system that rivalled that of Descartes and made use of the arithmetical triangle (called Pascal's triangle) in the study of probabilities.

Together with Fermat, Pascal studied two specific problems of probability: the first concerned the probability that a player will obtain a certain face of a dice in a given number of throws; and the second was to determine the portion of the stakes returnable to each player of several if a game is interrupted. Pascal used the

arithmetical triangle to derive combinatorial analysis. Pascal's triangle is a triangular array of numbers in which each number is the sum of the pair of numbers above it. In general the n th ($n = 0, 1, 2, \dots$) row of the triangle gives the binomial coefficients n^r , with $r = 0, 1, \dots, n$.

In 1657–59, Pascal also perfected his 'theory of indivisibles' – the forerunner of integral calculus –, which enabled him to study prob-

lems involving infinitesimals, such as the calculations of areas and volumes.

hydrostatics Pascal's principle and hydraulics Pascal's work in hydrostatics involved repeating the experiment by Italian physicist Evangelista Torricelli to prove that air pressure supports a column of mercury. He confirmed that a vacuum must exist in the space at the top of the tube, and set out to prove that the column of mercury is held up by the weight of air exerted on the container of liquid at the base of the tube. Pascal suggested that at high altitudes there would be less air above the tube and that the column would be lower. Poor health prevented him from undertaking the experiment himself, so he entrusted it to his brother-in-law who obtained the expected results using a mercury column in the mountains of the Puy de Dôme in 1648. This led rapidly to investigations of the use of the mercury barometer in weather forecasting.

Pascal then turned to a study of pressure in liquids and gases, and found that pressure is transmitted equally in all directions throughout a fluid and is always exerted perpendicular to any surface in or containing the fluid. Propounded in a treatise on hydrostatics in 1654, Pascal's principle is fundamental to applications of hydrostatics and governs the operation of hydraulic machines, such as the hydraulic press and jack.

calculating machine Between 1642 and 1645, Pascal constructed a machine to carry out the processes of addition and subtraction, and then organized the manufacture and sale of these first calculating machines. At least seven of these 'computers' still exist. One was presented to Queen Christina of Sweden in 1652.

Pascal's triangle triangular array of numbers (with 1 at the apex), in which each number is the sum of the pair of numbers above it. It is named after French mathematician Blaise Pascal, who used it in his study of probability. When plotted at equal distances along a horizontal axis, the numbers in the rows give the binomial probability distribution (with equal probability of success and failure) of an event, such as the result of tossing a coin.

Pascal's triangle In Pascal's triangle, each number is the sum of the two numbers immediately above it, left and right – for example, 2 is the sum of 1 and 1, and 4 is the sum of 3 and 1. Furthermore, the sum of each row equals a power of 2 – for example, the sum of the 3rd row is $4 = 2^2$; the sum of the 4th row is $8 = 2^3$.

paspalum grass of the genus *Paspalum*, especially *P. dilatatum*, native to S America and now one of the most widespread grasses in the higher-rainfall areas of Australia. It is a useful pasture grass in subtropical coastal areas, but a weed of crops, citrus orchards, and lawns.

pasqueflower plant belonging to the buttercup family. A low-growing hairy perennial, it has feathery leaves and large purple bell-shaped flowers that are upright at first, then droop. Found in Europe and Asia, it grows on grassland on limy soil. (*Pulsatilla vulgaris*, family Ranunculaceae.)

passion flower any of a group of tropical American climbing plants. They have distinctive flowers consisting of a saucer-shaped petal base, a fringed corona or circle of leafy outgrowths inside the ring of petals, and a central stalk bearing five pollen-producing stamens and three pollen-receiving stigmas. The flowers can be yellow, greenish, purple, or red. Some species produce edible fruit. (Genus *Passiflora*, family Passifloraceae.)

Parts of the flower were said by Jesuit missionaries to South America to resemble symbols of Christ's crucifixion, for example the crown of thorns, the five wounds, and the three nails; hence the name, referring to the suffering, or passion, of Christ on the cross.

Pasteur, Louis (1822–1895)

French chemist and microbiologist who discovered that fermentation is caused by microorganisms and developed the germ theory of disease. He also created a vaccine for rabies, which led to the foundation of the Pasteur Institute in Paris in 1888.

stereoisomers Pasteur first gained recognition through his early work on the optical activity of stereo isomers. In 1848 he presented a paper to the Paris Academy of Sciences in which he reported that there are two molecular forms of tartaric acid, one that rotates plane polarized light to the right and another (a mirror image of the first) that rotates it to the left. In addition, he showed that one form can be assimilated by living microorganisms whereas its optical antipode cannot.

fermentation A query from an industrialist about wine- and beer-making prompted Pasteur's research into fermentation. Using a microscope he found that properly aged wine contains small spherical globules of yeast cells whereas sour wine contains elongated yeast cells. He proved that fermentation does not require oxygen, yet it involves living microorganisms, and that, to produce the correct type of fermentation (alcohol-producing rather than lactic acid-producing), it is necessary to use the correct type of yeast. Pasteur also realized that, after wine has formed, it must be gently heated to about 50°C/122°F – pasteurized – to kill the yeast and thereby prevent souring during the ageing process.

spontaneous generation and the germ theory of disease Pasteur then turned his attention to spontaneous generation, a problem that had once again become a matter of controversy. Pasteur showed that dust in the air contains spores of living organisms that reproduce when introduced into a nutrient broth. Then he boiled the broth in a container with a U-shaped tube that allowed air to reach the broth but trapped dust in the U-bend. He found that the broth remained free of living organisms, disproving the theory of spontaneous generation.

In the mid-1860s, the French silk industry was seriously threatened by a disease that killed silkworms and Pasteur was commissioned by the government to investigate the disease. He announced in 1868 that he had found a minute parasite that

infects the silkworms, and recommended that all infected silkworms be destroyed. His advice was followed and the disease eliminated. This stimulated his interest in infectious diseases and, from the results of his previous work on fermentation, spontaneous generation, and the silkworm disease, Pasteur developed the germ theory of disease. This theory was probably the most important single medical discovery of all time, because it provided both a practical method of combating disease by disinfection and a theoretical foundation for further research.

the prevention of disease Continuing his research into disease, in 1881 Pasteur developed a method for reducing the virulence of certain pathogenic microorganisms. By heating a preparation of anthrax bacilli he attenuated their virulence but found that they still brought about the full immune response when injected into sheep. Using a similar method, Pasteur then inoculated fowl against chicken cholera, following the work of Edward Jenner (who first vaccinated against cowpox in 1796).

In 1882, Pasteur began what proved to be his most spectacular research: the prevention of rabies. He demonstrated that the causative microorganism (actually a virus, although the existence of viruses was not known at that time) infects the nervous system and then, using the dried tissues of infected animals, he succeeded in obtaining an attenuated form of the virus suitable for the inoculation of human beings. The culmination of this work came on 6 July 1885, when Pasteur used his vaccine to save the life of a young boy who had been bitten by a rabid dog. The success of this experiment brought Pasteur even greater acclaim and led to the establishment of the Pasteur Institute in 1888.

More germs are transmitted when shaking hands than when kissing. Louis Pasteur, the pioneer of hygienic methods, refused to shake hands with acquaintances for fear of infection.

pasteurization treatment of food to reduce the number of microorganisms it contains and so protect consumers from disease. Harmful bacteria are killed and the development of others is delayed. For milk, the method involves heating it to 72°C/161°F for 15 seconds followed by rapid cooling to 10°C/50°F or lower. The process also kills beneficial bacteria and reduces the nutritive property of milk.

The experiments of Louis Pasteur on wine and beer in the 1850s and 1860s showed how heat treatment slowed the multiplication of bacteria and thereby the process of souring. Pasteurization of milk made headway in the dairy industries of Scandinavia and the USA before 1900 because of the realization that it also killed off bacteria associated with the diseases of tuberculosis, typhoid, diphtheria, and dysentery.

patch in computing, modification or update made to a program, consisting of a short segment of additional code. Developers often correct bugs or fine-tune software by releasing a patch which rewrites existing codes and adds new material.

patchouli soft-wooded E Indian shrub belonging to the mint family; the leaves are the source of the perfume patchouli. (*Pogostemon heyneanus*, family Labiateae.)

patella or **kneecap** flat bone embedded in the knee tendon of birds and mammals, which protects the joint from injury.

pathogen Greek 'disease producing' in medicine, any microorganism that causes disease. Most pathogens are *parasites*, and the diseases they cause are incidental to their search for food or shelter inside the host. Nonparasitic organisms, such as soil bacteria or those living in the human gut and feeding on waste foodstuffs, can also become pathogenic to a person whose immune system or liver is damaged. The larger parasites that can cause disease, such as nematode worms, are not usually described as pathogens.

pathology medical speciality concerned with the study of disease processes and how these provoke structural and functional changes in the body.

Pauli exclusion principle in physics, a principle of atomic structure. See *exclusion principle*.

Pauli, Wolfgang (1900–1958)

Austrian-born Swiss physicist who originated the exclusion principle: in a given system no two fermions (electrons, protons, neutrons, or other elementary particles of half-integral spin) can be characterized by the same set of quantum numbers. He also predicted the existence of neutrinos. He won the Nobel Prize for Physics in 1945.

The exclusion principle, announced 1925, involved adding a fourth quantum number to the three already used (n , l , and m). This number, s , would represent the spin of the electron and would have two possible values. The principle also gave a means of determining the arrangement of electrons into shells around the nucleus, which explained the classification of elements into related groups by their atomic number.

Pauling, Linus Carl (1901–1994)

US theoretical chemist and biologist. His ideas on chemical bonding are fundamental to modern theories of molecular structure. He also investigated the properties and uses of vitamin C as related to human health. He won the Nobel Prize for Chemistry in 1954 and the Nobel Peace Prize in 1962, having campaigned for a nuclear-test ban. Work Pauling's work on the nature of the chemical bond included much new information about interatomic distances. Applying his knowledge of molecular structure to proteins in blood, he discovered that many proteins have structures held together with hydrogen bonds, giving them helical shapes.

He was a pioneer in the application of quantum-mechanical principles to the structures of molecules, relating them to interatomic distances and bond angles by X-ray and electron diffraction, magnetic effects, and thermochemical techniques. In 1928, Pauling introduced the concept of hybridization of bonds. This provided a clear, basic insight into the framework structure of all carbon compounds; that is, of the whole of organic chemistry. He also studied electronegativity of atoms and polarization (movement of electrons) in chemical bonds. Electronegativity values can be used to show why certain substances, such as hydrochloric acid, are acid, whereas others, such as sodium hydroxide, are alkaline. Much of this work was consolidated in his book *The Nature of the Chemical Bond* 1939.

Because they are platform-independent, PDF files are a good way to send documents over the Internet.

pea climbing leguminous plant (see legume) with pods of round green edible seeds, grown since prehistoric times for food. The pea is a popular vegetable and is eaten fresh, canned, frozen, or dried. The sweet pea (*Lathyrus odoratus*) of the same family is grown for its scented red, purple, pink, and white butterfly-shaped flowers; it is a popular cottage garden plant. (Edible pea *Pisum sativum*, family Leguminosae.)

PeaceNet computer network dedicated to the cause of world peace and social justice. PeaceNet carries specialist news and information services which are used by many human rights and disarmament organizations. Compare GreenNet.

peach yellow-reddish round edible fruit of the peach tree, which is cultivated for its fruit in temperate regions and has oval leaves

and small, usually pink, flowers. The fruits have thick velvety skins; nectarines are a smooth-skinned variety. (*Prunus persica*, family Rosaceae.)

peacock technically, the male of any of various large pheasants, order Galliformes. The name is most often used for the common peacock *Pavo cristatus*, a bird of the pheasant family, native to S Asia. It is rather larger than a pheasant. The male has a large fan-shaped tail, brightly coloured with blue, green, and purple 'eyes' on a chestnut background, that is raised during courtship displays. The female (peahen) is brown with a small tail.

The hen lays 4–8 eggs in the spring, and incubation takes 30 days. She remains with her chicks eight months. The green peacock, *P. muticus*, native to SE Asia, breeds freely with the common peacock. A third species, *Afroparus congensis*, was discovered in the late 1930s in the Congo forests. These are much smaller than the common peacock and do not have erectile tail coverts.

peacock butterfly butterfly measuring about 5 cm/2 in across the wings, which are a dull deep or brownish-red, and each of which bears an 'eye' rather like those in the peacock's tail.

classification The peacock butterfly *Vanessa* is in family Nymphalidae, order Lepidoptera, class Insecta, phylum Arthropoda.

The butterfly hibernates between the winter, and in early spring lays its eggs on stinging nettles; they hatch into black and yellow caterpillars, with six rows of black spines and a series of white dots arranged transversely on each segment.

peanut or **groundnut** or **monkey nut** South American vinelike annual plant. After flowering, the flower stalks bend and force the pods into the earth to ripen underground. The nuts are a staple food in many tropical countries and are widely grown in the southern USA. They provide a valuable edible oil and are the basis for a large number of processed foods. (*Arachis hypogaea*, family Leguminosae.)

pear succulent, gritty-textured edible fruit of the pear tree, native to temperate regions of Europe and Asia. White flowers precede the fruits, which have a greenish-yellow and brown skin and taper towards the stalk. Pear trees are cultivated for their fruit which are eaten fresh or canned; a wine known as perry is made from pear juice. (*Pyrus communis*, family Rosaceae.)

pearl shiny, hard, rounded abnormal growth composed of nacre (or mother-of-pearl), a chalky substance. Nacre is secreted by many molluscs, and deposited in thin layers on the inside of the shell around a parasite, a grain of sand, or some other irritant body. After several years of the mantle (the layer of tissue between the shell and the body mass) secreting this nacre, a pearl is formed.

Although commercially valuable pearls are obtained from freshwater mussels and oysters, most precious pearls come from the various species of the family Pteriidae (the pearl oysters) found in tropical waters off N and W Australia, off the Californian coast, in the Persian Gulf, and in the Indian Ocean. Because of their rarity, large mussel pearls of perfect shape are worth more than those from oysters.

Artificial pearls were first cultivated in Japan in 1893. A tiny bead of shell from a clam, plus a small piece of membrane from another pearl oyster's mantle (to stimulate the secretion of nacre) is inserted in oysters kept in cages in the sea for three years, and then the pearls are harvested.

peat fibrous organic substance found in bogs and formed by the incomplete decomposition of plants such as sphagnum moss. N Asia, Canada, Finland, Ireland, and other places have large deposits, which have been dried and used as fuel from ancient times. Peat can also be used as a soil additive.

Peat bogs began to be formed when glaciers retreated, about 9,000 years ago. They grow at the rate of only a millimetre a year, and large-scale digging can result in destruction both of the bog and of specialized plants growing there. The destruction of peat bogs is responsible for diminishing fish stocks in coastal waters; the run off from the peatlands carries high concentrations of iron, which affects the growth of the plankton on which the fish feed.

pecan nut-producing hickory tree (*C. illinoensis* or *C. pecan*), native to the central USA and N Mexico and now widely cultivated. The trees grow to over 45 m/150 ft, and the edible nuts are smooth-shelled, the kernel resembling a smooth, oval walnut. (Genus *Carya*, family Juglandaceae.)

peccary one of two species of the New World genus *Tayassu* of piglike hoofed mammals. A peccary has a gland in the middle of its back which secretes a strong-smelling substance. Peccaries are blackish in colour, covered with bristles, and have tusks that point downwards. Adults reach a height of 40 cm/16 in, and a weight of 25 kg/60 lb.

peck obsolete unit of dry measure, equalling eight quarts or a quarter bushel (9.002 litres).

pectoral relating to the upper area of the thorax associated with the muscles and bones used in moving the arms or forelimbs, in vertebrates. In birds, the *pectoralis major* is the very large muscle used to produce a powerful downbeat of the wing during flight.

pedestrianization the closing of an area to traffic, making it more suitable for people on foot. It is now common in many town shopping centres, since cars and people often obstruct one another. This restricts accessibility and causes congestion. Sometimes service vehicles (such as buses and taxis) are allowed access.

pedicel the stalk of an individual flower, which attaches it to the main floral axis, often developing in the axil of a bract.

pedometer small portable instrument for counting the number of steps taken, and measuring the approximate distance covered by a person walking. Each step taken by the walker sets in motion a swinging weight within the instrument, causing the mechanism to rotate, and the number of rotations are registered on the instrument face.

peepul another name for the *dhobo* tree.

peer-to-peer networking in computing, method of file sharing in which computers are linked to each other as opposed to being linked to a central file server.

pegasid or **sea moth** or **sea robin** marine fish of the family Pegasidae, the only family within the order Pegasiformes. Pegasids are 5–15 cm/2–6 in long with armoured bodies and large winklelike pectoral fins. There are five species and they are found only in the Indo-Pacific.

Pegasids are under threat due to demands for their use in Chinese medicine as a treatment for respiratory diseases and cancers.

Pegasus in astronomy, a constellation of the northern hemisphere, near Cygnus, and represented as the winged horse of Greek mythology.

pegmatite extremely coarse-grained igneous rock of any composition found in veins; pegmatites are usually associated with large granite masses.

pekan or **fisher marten** North American marten (carnivorous mammal) *Martes pennanti* about 1.2 m/4 ft long, with a doglike face, and brown fur with white patches on the chest. It eats porcupines.

pekingese breed of small long-haired dog first bred at the Chinese court as the 'imperial lion dog'. It has a flat skull and flat face, is typically less than 25 cm/10 in tall, and weighs less than 5 kg/11 lb.

Peking man Chinese representative of an early species of human, found as fossils, 500,000–750,000 years old, in the cave of Choukoutien in 1927 near Beijing (Peking). Peking man used chipped stone tools, hunted game, and used fire. Similar varieties of early human have been found in Java and E Africa.

Their classification is disputed: some anthropologists classify them as *Homo erectus*, others as *Homo sapiens pithecanthropus*.

pelargonium (commonly called *geranium*) any of a group of shrubby, tender flowering plants belonging to the geranium family.

grown extensively for their colourful white, pink, scarlet, and black-purple flowers. They are the familiar summer bedding and pot 'geraniums'. Ancestors of the garden hybrids came from southern Africa. (Genus *Pelargonium*, family Geraniaceae.)

pelican The pale pink pouch beneath the large bill is clearly visible in these Australian black-backed pelicans. When not fishing, they spend much of the day in shallow water, preening to keep their feathers well oiled. Premaphotos Wildlife

pelican large water bird of family Pelecanidae, order Pelecaniformes, remarkable for the pouch beneath the bill, which is used as a fishing net and temporary store for catches of fish. Some species grow up to 1.8 m/6 ft and have wingspans of 3 m/10 ft.

The legs are short and the feet large, with four webbed toes; the tail is short and rounded, and the neck long. The wings are long and expansive, and the birds are capable of rapid flight. The species are widely distributed, frequenting the seashore and margins of lakes, and feeding almost exclusively on fish, which are deposited in the pouch for subsequent digestion.

pellagra chronic disease mostly seen in subtropical countries in which the staple food is maize. It is caused by deficiency of nicotinic acid (one of the B vitamins), which is contained in protein foods, beans and peas, and yeast. Symptoms include diarrhoea, skin eruptions, and mental disturbances.

pellitory-of-the-wall plant belonging to the nettle family, found growing in cracks in walls and rocks and also on banks in W and S Europe; it is widely cultivated in gardens. The stems are up to 1 m/3 ft tall and reddish, the leaves are lance-shaped, and the greenish male and female flowers grow separately but on the same plant. (*Parietaria judaica*, family Urticaceae.)

Peltier effect in physics, a change in temperature at the junction of two different metals produced when an electric current flows through them. The extent of the change depends on what the conducting metals are, and the nature of change (rise or fall in temperature) depends on the direction of current flow. It is the reverse of the Seebeck effect. It is named after the French physicist Jean Charles Peltier (1785-1845) who discovered it in 1834.

pelvis in vertebrates, the lower area of the abdomen featuring the bones and muscles used to move the legs or hindlimbs. The pelvic girdle is a set of bones that allows movement of the legs in relation to the rest of the body and provides sites for the attachment of relevant muscles.

pen hand-held implement for writing. Pens have existed since ancient Egyptian times. Quill pens were developed by the Romans, and the technology remained unchanged until the 18th-century development of the steel nib. The fountain pen, which ensured a steady supply of ink, was invented in the 1880s. Today the dominant types of pen are the ballpoint, which became widespread in the 1940s and 1950s, and the felt-tip pen, dating from the 1960s.

pen-based computer computer (usually portable), for which input is by means of a pen or stylus, rather than a keyboard. It incorporates handwriting recognition software, although prior to the release of the Apple Newton and similar models, this had effectively meant using separate characters rather than 'joined-up' writing.

pendulum weight (called a 'bob') swinging at the end of a rod or cord. The regularity of a pendulum's swing was used in making the first really accurate clocks in the 17th century. Pendulums can be used for measuring the acceleration due to gravity (an important constant in physics).

Specialized pendulums are used to measure velocities (ballistic pendulum) and to demonstrate the Earth's rotation (Foucault's pendulum).

penetration technology the development of missiles that have low radar, infrared, and optical signatures and thus can penetrate an enemy's defences undetected. In 1980 the USA announced that it had developed such a piloted aircraft, known as Stealth. It comes in both fighter and bomber versions. The Stealth bomber saw action in the Gulf War.

penguin marine flightless bird, family Spheniscidae, order Sphenisciformes, mostly black and white, found in the southern hemisphere. They comprise 18 species in six genera. Males are usually larger than the females. Penguins range in size from 40 cm/1.6 ft to 1.2 m/4 ft tall, and have thick feathers to protect them from the intense cold. They are awkward on land (except on snow slopes down which they propel themselves at a rapid pace), but their wings have evolved into flippers, making them excellent swimmers. Penguins congregate to breed in 'rookeries', and often spend many months incubating their eggs while their mates are out at sea feeding. They feed on a mixture of fish, squid, and krill.

The wing is long and has no covert or quill feathers, and always remains open. The feathers are tiny, with very broad shafts and but little vane or web. The legs of the birds are placed far back, and in the water the feet are stretched out straight behind and held motionless, the wings working rapidly as if being used in flight. Moulting in penguins is general and areas of feathers are lost at once. It is usually a rapid process unlike the ordered progressive moult of flying birds. Penguins generally moult once a year, and have to stay out of the water during this time, without feeding.

The nest is often no more than a slight hollow in the ground, but some penguins, especially the Adelie penguins *Pygoscelis adeliae*, collect stones, with which they bank the nest round. One or two eggs are laid, and both birds, but chiefly the male, attend to their incubation. Both parents are very devoted to the young, one always staying to guard them, the other bringing them sea crustaceans and other small animals, which the young take by pushing their beaks far down the parent's throat.

They are very social birds, living together, and usually breed in vast colonies, always returning to the same rookery (breeding group). The young gather in groups while the parents are foraging

Penicillin: Discovery

by Julian Rowe

Chance favours the prepared mind

I think the discovery and development of penicillin may be looked on as quite one of the luckiest accidents that have occurred in medicine.' With these words, Professor Howard Florey (1898–1968), an Australian pathologist, concluded a lecture he gave in 1943 at the Royal Institution. The topic was penicillin: the first, and still perhaps overall the best of a range of natural chemotherapeutic agents called antibiotics.

Together with Ernst Chain (1906–1979), Howard Florey had made the practical exploitation of penicillin possible on a worldwide scale.

A chance discovery

The story of the discovery of penicillin started with a chance observation made by British bacteriologist Alexander Fleming (1881–1955), while he was working in 1928 in his laboratory at St Mary's Hospital in London.

Fleming was doing research on staphylococcus, a species of bacterium that can cause disease in humans and animals. In the laboratory such bacteria are grown in dishes containing a culture medium—a jelly-like substance which contains their food. Fleming noticed that one of his dishes had been accidentally contaminated with a mould. The mould could have entered the laboratory through an open window. All around where the mould was growing, the staphylococci had disappeared.

Fleming investigates the mould

Intrigued, because he had correctly concluded that the mould must contain a substance that killed the bacterium, Fleming isolated the mould and grew more of it in a culture broth. He found that the broth acquired a high antibacterial activity. He tested the action of the broth with a wide variety of pathogenic bacteria, and found that many of them were quickly destroyed.

Fleming was also able to demonstrate that the white corpuscles in human blood were not sensitive to the broth. This suggested to him that other human cells in the body would not be affected by it.

Penicillin is discovered

The mould that Fleming's acute powers of observation had noted in a single culture dish, was found to be *Penicillium notatum*. Fleming named the drug penicillin after this mould.

There the matter rested for 15 years. At the time that penicillin was discovered, it would have been extremely difficult to isolate and purify the drug using the chemical techniques then available. It would also have been quite easily destroyed by them. Without any of the pure substance, Fleming had no way of knowing its extraordinarily high antibacterial activity and its almost negligible toxicity. In fact, penicillin diluted 80,000,000 times will still inhibit the growth of staphylococcus. To translate this number of noughts into something tangible: if one drop of water is diluted 80,000,000 times it would fill over 6,000 whisky bottles.

The first practical application

Then in 1935, German–British biochemist Ernst Chain joined Professor Florey at Oxford. There in 1939 he began a survey of antimicrobial substances. One of the first he looked at was Fleming's mould. It was chosen because it was already known to be active against staphylococcus, and because, since it was difficult to purify, it represented a biochemical challenge.

A method of purification using primitive apparatus was discovered, and an experiment using penicillin to treat infected mice was carried out with remarkable success. Eventually, enough penicillin was made to treat the first human patient in the terminal stage of a generalized infection. The patient showed an astonishing, although temporary, recovery. Five more seriously ill patients were successfully treated.

Because these patients had already failed to respond to sulphonamide drugs, the value of penicillin was now clearly apparent. For although sulphonamides are much more toxic to bacteria than to leucocytes (white blood cells), they do have some poisonous action on the whole human organism.

The new lifesaver

England, then in the midst of World War II, had insufficient resources to manufacture the new wonder drug on a sufficiently large scale. Florey went to the USA to try to interest the large pharmaceutical companies in penicillin. As a result of an outstanding effort, enough penicillin was produced in time to treat all the battle casualties of the Normandy landings in 1944. The use of penicillin in wartime saved countless lives, as it has continued to do ever since.

for food. When the parents return, the chicks often have to chase for food, with the stronger chick being fed first. They spend much time preening themselves and each other (allopreening).

It was estimated in 1997 that the penguin population fell 20% in 10 years. Zoologists blame over-fishing, particularly by large trawling fleets.

penicillin any of a group of antibacterial (bacteria killing) compounds obtained from filtrates of moulds of the genus *Penicillium* (especially *P. notatum*) or produced synthetically. Penicillin was the first antibiotic to be discovered (by Alexander Fleming); it kills a broad spectrum of bacteria, many of which cause disease in humans.

The use of the original type of penicillin is limited by the increasing resistance of pathogens and by allergic reactions in patients. Since 1941, numerous other antibiotics of the penicillin family have been discovered which are more selective against, or resistant to, specific microorganisms.

penis male reproductive organ containing the urethra, the channel through which urine and semen are voided. It transfers sperm to the female reproductive tract to fertilize the ovum. In mammals, the penis is made erect by vessels that fill with blood, and in most

mammals (but not humans) is stiffened by a bone.

Snakes and lizards have a paired structure that serves as a penis; other reptiles have a single organ. A few birds, mainly ducks and geese, also have a type of penis, as do snails, barnacles, and some other invertebrates. Many insects have a rigid, nonerectile male organ, usually referred to as an intromittent organ.

penrynol European perennial plant belonging to the mint family, with oblong leaves and clusters or whorls of purplish flowers growing around the stem at intervals. It is found in wet places on sandy soil. (*Mentha pulegium*, family Labiatae.)

pentadactyl limb typical limb of the mammals, birds, reptiles, and amphibians. These vertebrates (animals with backbone) are all descended from primitive amphibians whose immediate ancestors

were fleshy-finned fish. The limb which evolved in those amphibians had three parts: a 'hand/foot' with five digits (fingers/toes), a lower limb containing two bones, and an upper limb containing one bone.

This basic pattern has persisted in all the terrestrial vertebrates, and those aquatic vertebrates (such as seals) which are descended from them. Natural selection has modified the pattern to fit different ways of life. In flying animals (birds and bats) it is greatly altered and in some vertebrates, such as whales and snakes, the limbs are greatly reduced or lost. Pentadactyl limbs of different species are an example of homologous organs.

pentagon five-sided plane figure. The regular pentagon has golden section proportions between its sides and diagonals. The five-pointed star formed by drawing all the diagonals of a regular pentagon is called a **pentagram**. This star has further golden sections.

pentanol $C_5H_{11}OH$ (common name *amyl alcohol*) clear, colourless, oily liquid, usually having a characteristic choking odour. It is obtained by the fermentation of starches and from the distillation of petroleum.

Pentium in computing, microprocessor produced by Intel in 1993. The Pentium followed on from the 486 processor and would have been called the 586, but Intel was unable to register numbers as a trademark. The Pentium family was extended by the Pentium Pro in 1995 and the Pentium II in 1997, and also by the addition of MMX instructions 1996. All members of the family are 32-bit chips with 64-bit data buses for faster access to memory and the FPU expansion bus.

The original Pentium had about 3.1 million transistors, the Pentium Pro about 5.5 million, and the Pentium II about 7.5 million. The slowest Pentium ran at 60 MHz, but in 1997 speeds reached 300 MHz in PCs and 450 MHz under laboratory conditions.

penumbra the region of partial shade between the totally dark part (umbra) of a shadow and the fully illuminated region outside. It occurs when a source of light is only partially obscured by a shadow-casting object. The darkness of a penumbra varies gradually from total darkness at one edge to full brightness at the other. In astronomy, a penumbra is a region of the Earth from which only a partial eclipse of the Sun or Moon can be seen.

peony any of a group of perennial plants native to Europe, Asia, and North America, remarkable for their large, round, brilliant white, pink, or red flowers. Most popular in gardens are the common peony (*P. officinalis*), the white peony (*P. lactiflora*), and the taller tree peony (*P. suffruticosa*). (Genus *Paeonia*, family Paeoniaceae.)

pepper climbing plant native to the East Indies. When gathered green, the berries are crushed to release the seeds for the spice called black pepper. When the berries are ripe, the seeds are removed and their outer skin is discarded, to produce white pepper. Chilli pepper, cayenne or red pepper, and the sweet peppers used as a vegetable come from *capsicums* native to the New World. (*Piper nigrum*, family Piperaceae.)

peppermint perennial herb of the mint family, native to Europe, with oval aromatic leaves and purple flowers. Oil of peppermint is used in medicine and confectionery. (*Mentha piperita*, family Labiatae.)

pepsin enzyme that breaks down proteins during digestion. It requires a strongly acidic environment and is present in the stomach.

peptide molecule comprising two or more amino acid molecules (not necessarily different) joined by **peptide bonds**, whereby the acid group of one acid is linked to the amino group of the other ($-CO-NH$). The number of amino acid molecules in the peptide is indicated by referring to it as a di-, tri-, or polypeptide (two, three, or many amino acids).

Proteins are built up of interacting polypeptide chains with various types of bonds occurring between the chains. Incomplete hydrolysis (splitting up) of a protein yields a mixture of peptides,

examination of which helps to determine the sequence in which the amino acids occur within the protein.

peptide bond bond that joins two peptides together within a protein. The carboxyl ($-COOH$) group on one amino acid reacts with the amino ($-NH_2$) group on another amino acid to form a peptide bond ($-CO-NH-$) with the elimination of water. Peptide bonds are broken by hydrolytic enzymes called **peptidases**.

perborate any salt formed by the action of hydrogen peroxide on borates.

Perborates contain the radical BO_3 .

percentage way of representing a number as a fraction of 100. Thus 45 percent (45%) equals $\frac{45}{100}$, and 45% of 20 is $\frac{45}{100} \times 20 = 9$.

In general, if a quantity x changes to y , the percentage change is $100(x - y)/x$. Thus, if the number of people in a room changes from 40 to 50, the percentage increase is $(100 \times 10)/40 = 25\%$. To express a fraction as a percentage, its denominator must first be converted to 100 - for example, $\frac{1}{8} = 12.5/100 = 12.5\%$. The use of percentages often makes it easier to compare fractions that do not have a common denominator.

The percentage sign is thought to have been derived as an economy measure when recording in the old counting houses; writing in the numeric symbol for $\frac{25}{100}$ of a cargo would take two lines of parchment, and hence the '100' denominator was put alongside the 25 and rearranged to '%'.

percentile in a cumulative frequency distribution, one of the 99 values of a variable that divide its distribution into 100 parts of equal frequency. In practice, only certain of the percentiles are used. They are the median (or 50th percentile), the lower and the upper quartiles (respectively, the 25th and 75th percentiles), the 10th percentile which cuts off the bottom 10% of a frequency distribution, and the 90th which cuts off the top 10%. The 5th and 95th are also sometimes used.

perch any of the largest order of spiny-finned bony fishes, the Perciformes, with some 8,000 species. This order includes the sea basses, cichlids, damselfishes, mullets, barracudas, wrasses, and gobies. Perches of the freshwater genus *Perca* are found in Europe, Asia, and North America. They have varied shapes and are usually a greenish colour. They are very prolific, spawning when about three years old, and have voracious appetites.

perch, climbing freshwater bony fish that is often found in stagnant poorly oxygenated water. It is able to breathe air and so can travel short distances on land, between water sources, by pulling itself along by its fins. Climbing perch are in the genus *Anabas*.

peregrine falcon species of falcon.

perennating organ in plants, that part of a biennial plant or herbaceous perennial that allows it to survive the winter; usually a root, tuber, rhizome, bulb, or corm.

perennial plant plant that lives for more than two years. Herbaceous perennials have aerial stems and leaves that die each autumn. They survive the winter by means of an underground storage (perennating) organ, such as a bulb or rhizome. Trees and shrubs or woody perennials have stems that persist above ground throughout the year, and may be either deciduous or evergreen. See also annual plant, biennial plant.

perfume fragrant essence used to scent the body, cosmetics, and candles. More than 100 natural aromatic chemicals may be blended from a range of 60,000 flowers, leaves, fruits, seeds, woods, barks, resins, and roots, combined by natural animal fixatives and various synthetics. Favoured ingredients include balsam, civet (from the African civet cat) hyacinth, jasmine, lily of the valley, musk (from the musk deer), orange blossom, rose, and tuberose.

Culture of the cells of fragrant plants, on membranes that are constantly bathed in a solution to carry the essential oils away for separation, is now being adopted to reduce costs.

perianth in botany, a collective term for the outer whorls of the flower, which protect the reproductive parts during development.

In most *dicotyledons* the perianth is composed of two distinct whorls, the calyx of sepals and the corolla of petals, whereas in many *monocotyledons* the sepals and petals are indistinguishable and the segments of the perianth are then known individually as tepals.

periastron in astronomy, the point at which an object travelling in an elliptical orbit around a star is at its closest to the star; the point at which it is furthest is known as the *apastron*.

pericarp wall of a fruit. It encloses the seeds and is derived from the ovary wall. In fruits such as the acorn, the pericarp becomes dry and hard, forming a shell around the seed. In fleshy fruits the pericarp is typically made up of three distinct layers. The *epicarp*, or *exocarp*, forms the tough outer skin of the fruit, while the *mesocarp* is often fleshy and forms the middle layers. The innermost layer or *endocarp*, which surrounds the seeds, may be membranous or thick and hard, as in the *drupe* (stone) of cherries, plums, and apricots.

peridotite rock consisting largely of the mineral olivine; pyroxene and other minerals may also be present. Peridotite is an ultramafic rock containing less than 45% silica by weight. It is believed to be one of the rock types making up the Earth's upper mantle, and is sometimes brought from the depths to the surface by major movements, or as inclusions in lavas.

perigee the point at which an object, travelling in an elliptical orbit around the Earth, is at its closest to the Earth. The point at which it is furthest from the Earth is the *apogee*.

perihelion the point at which an object, travelling in an elliptical orbit around the Sun, is at its closest to the Sun. The point at which it is furthest from the Sun is the *aphelion*.

perimeter or *boundary* line drawn around the edge of an area or

shape. For example, the perimeter of a rectangle is the sum of its four sides; the perimeter of a circle is known as its *circumference*.

period in chemistry, a horizontal row of elements in the periodic table. There is a gradation of properties along each period, from metallic (group I, the alkali metals) to nonmetallic (group VII, the halogens).

period another name for menstruation; see *menstrual cycle*.

period in physics, the time taken for one complete cycle of a repeated sequence of events. For example, the time taken for a pendulum to swing from side to side and back again is the period of the pendulum. The period is the reciprocal of the frequency.

predictions to be made about their behaviour.

There are striking similarities in the chemical properties of the elements in each of the vertical columns (called **groups**), which are numbered I-VII and 0 to reflect the number of electrons in the outermost unfilled shell and hence the maximum **valency**. A gradation (trend) of properties may be traced along the horizontal rows (called **periods**). Metallic character increases across a period from right to left, and down a group. A large block of elements, between

groups II and III, contains the transition elements, characterized by displaying more than one valency state.

periodontal disease (formerly known as *pyorrhoea*) disease of the gums and bone supporting the teeth, caused by the accumulation of plaque and microorganisms; the gums recede, and the teeth eventually become loose and may drop out unless treatment is sought. Bacteria can eventually erode the bone that supports the teeth, so that surgery becomes necessary.

peripatus invertebrate found in rainforest leaf-litter. See *♂velvet worm*.

peripheral device in computing, any item connected to a computer's central processing unit (CPU). Typical peripherals include keyboard, mouse, monitor and printer. Users who enjoy playing games might add a joystick or a trackball; others might connect a modem, scanner, or integrated services digital network (ISDN) terminal to their machines. *See illustration on page 565.*

periscope optical instrument designed for observation from a concealed position such as from a submerged submarine. In its basic form it consists of a tube with parallel mirrors at each end, inclined at 45° to its axis. The periscope attained prominence in naval and military operations of World War I.

The Periodic Table

by Gordon Woods

Introduction

Think how difficult it would be to assemble a jigsaw of which about 35 of the pieces were missing and roughly 20 of the 65 you had were too damaged to fit properly. Could you work out the shapes of some of the missing pieces? These are exactly the processes carried out by Mendeleyev in 1869 when he produced the first Periodic Table.

Earlier attempts

Several 19th century scientists had sought earlier to identify patterns in the properties of chemical elements linked to the weights of the atoms. Dobereiner had noticed sets of three similar elements (triads) for which the average weight of the lightest and heaviest was close to the weight of the middle one (try chlorine 35.5, bromine 80 and iodine 127). British chemist Newlands wrote the elements in order of increasing weight, noting that an element resembled the eighth following. His 'Law of Octaves' soon broke down because of missing elements from a fundamentally correct law. He was ridiculed (why not list the elements alphabetically!), flung out of 'The Royal Society', Britain's top scientific institution, only to be reinstated when it was realized that he had nearly beaten Mendeleyev.

Who was Mendeleyev?

Dmitri Ivanovich Mendeleyev was born in Tobolsk (Siberia) in 1834 and brought to St Petersburg, capital of Tsarist Russia, for his secondary education by his ambitious mother who had realized her youngest son's potential. After research throughout Europe he was appointed Chemistry Professor at St Petersburg in 1865. His first marriage foundered because of all the time he spent researching; later he married a young student. After discontent among the university students Mendeleyev took their petition to the education minister who sacked him from his professorial chair. Later both Oxford and Cambridge awarded him honorary doctorates. Aged 53 he made a solo balloon ascent to view a solar eclipse. A Periodic Table was carried aloft in his funeral procession in February 1907.

Mendeleyev's special contribution

Mendeleyev is said to have been playing patience when he suddenly visualized the arrangement of the elements in the patterns of the cards. It is certainly true that 20 years of previous education had equipped him to formulate the 'Periodic Law' which he developed for the remaining 40 years of his life. It stated that the elements display periodic (i.e. regularly repeating) properties when listed in order of increasing atomic weight.

Accurate atomic weights were needed for all 19th century element patterns. Mendeleyev correctly recalculated some values better to fit his table. However iodine and tellurium provided a problem since iodine was chemically similar to bromine yet the heavier element tellurium fitted below bromine according to the weight order. Mendeleyev's solution was to have his research assistants redefine tellurium's atomic weight to be the smaller. Thus he correctly positioned the two elements but for the wrong reason. Today we know that the elements are listed in order of increasing atomic number which only differs from the atomic weight order in three instances.

A stroke of genius was to leave spaces for elements yet to be discovered and to boldly predict properties for five such elements. Good scientists explain known information, great ones correctly predict unknown facts. Fortunately three of these missing elements were found within 20 years and their properties matched predictions to a remarkable degree.

Modern periodic tables

Note the plural. There are many different formats, some are three-dimensional but all show the elements in order of increasing atomic number. Most have vertical columns called groups and horizontal rows called periods. The underlying reason for the arrangement is the electron arrangement of the atoms of the elements. All elements in the same group have the same number of electrons in the outermost shell which governs the chemical nature of an element, hence their chemical similarity. Elements in the same period have the same number of electron shells, an extra electron being added for each increase in the atomic number.

Metals and nonmetals

Crossing from left to right elements become more nonmetallic and descending they become more metallic. Thus moving diagonally down to the right, elements are comparable in their metallic/nonmetallic nature. This can be shown by a staircase, or better, as a diagonal line through the boxes of those elements which cannot be clearly classified either as a metal or a nonmetal. For example the use of silicon in computers stems from it being a semi-conductor. Metals are conductors, nonmetals are insulators so semi-conductors are both. Science is not black and white but shades of grey.

Using the Periodic Table

The group number is given in Roman numerals above the main groups. For groups I-IV the group number is the sole valency. For groups V-VII, the main valency is (8-group number) with a less common valency of the group number from the third period onwards. Group 0 (there is no Roman numeral for zero) on the far right is called the noble gases. Their valency is regarded as 0. These elements were once called inert gases but to the astonishment of chemists Bartlett made compounds between fluorine, xenon and krypton. The Periodic Table is less helpful with transition metals which have a valency of 2 and usually other(s).

One can copy Mendeleyev's work by making predictions about 'unknown' elements. Knowing that both sodium and potassium react with water producing hydrogen and an alkali, it is reasonable to predict the same behaviour for rubidium and caesium directly below them. Since potassium is more reactive than sodium, it is likely that caesium will be the most reactive of the four. It is! When added to a bowl of water it shatters the container! Incidentally caesium is one of three elements which have different spelling in North America and the UK. Which are the others?

Are there more elements to discover?

By 1950 all the elements for which Mendeleyev had left gaps had been discovered. Some are extremely rare and were identified from the radioactive decay of other elements, sometimes in the debris of atomic bomb tests (1944-1950). However elements with atomic numbers above 92 have been created by bombarding atoms of uranium with neutrons, carbon nuclei, and other subatomic particles. These synthetic elements are all identified from their radioactivity. As the atomic number increases it becomes harder to make the elements, so less of the element exists... and it is decaying all the time. It is possible to identify 10-18 g but there is less than 1 g of the elements with atomic number greater than 100.

The discoverer of an element has the right to name it. Some chose their country (gallium, francium), or a property (chromium has compounds in many colours), or the place of discovery (such as strontium, named after the Scottish village of Strontian). Only

three places in the world have the facilities to make the synthetic elements. Both the USSR and the USA claimed initial discovery of elements 104 and 105 but each country gave them different names (for example 104 to the Russians was Kurchatovium (Ku) but to the Americans was Rutherfordium (Rf). This scientific argument was initially solved by giving them artificial temporary names, unnilquadium (a hundred and four), and unnilpentium. A committee sat for years to decide officially who were the discoverers.

Symbols and names

Element symbols are internationally agreed but the name differs with the language. This difference is only slight with elements discovered since 1850. Less reactive metals, isolated for hundreds of years may have very different names. Petrol is unleaded in the UK, bleifrei in Germany, sans plomb in France, senza piomba in

Italy, sin plomo in Spain. Note how the last three names relate to the Latin plumbum from which the symbol Pb is derived, as are plumber and plumbline.

Unusual formats

Hundreds of versions exist of the Periodic Table. For example: some show the physical state (solid, liquid or gas) of the element; in the UK only, the metal mercury and the nonmetal bromine are liquids; three-dimensional variants divide up the Periodic Table into its four blocks labelled s, p, d and f according to the shape of the outer electron cloud round the nucleus.

The Periodic Table today is the most recognizable logo of chemistry. Despite the range of formats they are all related to Mendeleev's original formulation. Element 101 is named after him but strangely he never won a Nobel prize.

a small constant permeability. When the permeability is less than 1, the material is a ϕ diamagnetic material; when it is greater than 1, it is a ϕ paramagnetic material. Ferrimagnetic materials have very large permeabilities. See also ϕ magnetism.

Permian period of geological time 290–245 million years ago, the last period of the Palaeozoic era. Its end was marked by a significant change in marine life, including the extinction of many corals and trilobites. Deserts were widespread, terrestrial amphibians and mammal-like reptiles flourished, and cone-bearing plants (gymnosperms) came to prominence. In the oceans, 49% of families and 72% of genera vanished in the late Permian. On land, 78% of reptile families and 67% of amphibian families disappeared.

permutation in mathematics, a specified arrangement of a group of objects.

It is the arrangement of a distinct objects taken b at a time in all possible orders. It is given by $a!/(a-b)!$, where '!' stands for ϕ factorial. For example, the number of permutations of four letters taken from any group of six different letters is $6!/2! = (1 \times 2 \times 3 \times 4 \times 5 \times 6)/(1 \times 2) = 360$. The theoretical number of four-letter 'words' that can be made from an alphabet of 26 letters is $26!/22! = 358,800$.

perovskite a yellow, brown or greyish-black orthorhombic mineral, CaTiO_3 , which sometimes contains cerium. Other minerals that have a similar structure are said to have the **perovskite structure**. The term also refers to MgSiO_3 with the perovskite structure, the principle mineral that makes up the Earth's lower ϕ mantle.

CaTiO_3 perovskite occurs primarily as a minor constituent of some igneous rocks in Earth's crust and mantle and in some meteorites. MgSiO_3 perovskite has the same chemical composition as pyroxene, a principal constituent of the upper mantle. But the extreme pressures in the lower mantle cause the oxygen atoms to be packed more tightly together than in pyroxene, giving rise to the perovskite form of MgSiO_3 in the lower mantle.

The perovskite structure of MgSiO_3 was discovered in diamond-anvil cell experiments in which upper mantle materials that are stable at the Earth's surface, such as the mineral pyroxene, are squeezed at high pressures to simulate the Earth's interior. Although this mineral does not occur naturally at the Earth's surface it is thought to be the most abundant mineral in the mantle, and therefore Earth's most abundant mineral.

perpendicular in mathematics, at a right angle; also, a line at right angles to another or to a plane. For a pair of ϕ skew lines in three dimensions that do not meet, there is just one common perpendicular, which is at right angles to both lines; the nearest points on the two lines are the feet of this perpendicular.

perpetual motion the idea that a machine can be designed and constructed in such a way that, once started, it will continue in motion indefinitely without requiring any further input of energy (motive power). Such a device would contradict at least one of the two laws of thermodynamics that state that (1) energy can neither be created nor destroyed (the law of conservation of energy) and

(2) heat cannot by itself flow from a cooler to a hotter object. As a result, all practical (real) machines require a continuous supply of energy, and no heat engine is able to convert all the heat into useful work.

Perseus in astronomy, a bright constellation of the northern hemisphere, near ϕ Cassiopeia. It is represented as the mythological hero; the head of the decapitated Gorgon, Medusa, is marked by ϕ Algor (Beta Persei), the best known of the eclipsing binary stars.

Perseus lies in the Milky Way and contains the Double Cluster, a twin cluster of stars called ϕ and χ Persei. They are just visible to the naked eye as two hazy patches of light close to one another.

Persian cat or **Longhair** breed of domestic longhaired cat. The modern longhair pedigree is descended from cats imported to Britain in the late 19th century from Turkey or Persia. The typical Persian has a cobby (sturdy and rounded) body, a round head and eyes, short nose, with long, luxuriant fur. They occur in many colours and colour combinations.

In the USA, most longhaired cats are classified as Persian with the colours listed as varieties; in Britain, they are called Longhairs and each colour is listed as a separate breed.

persicaria any of a group of plants belonging to the dock family, found growing in waste places and arable land, often near water. Common persicaria (*P. persicaria*) is sprawling in shape and has lance-shaped, black-spotted leaves and spikes of pink flowers. Pale persicaria (*P. lapathifolium*) is slightly larger, with pale dots on the leaves, and heads of usually white flowers. Both are found throughout much of the northern hemisphere. (Genus *Polygonum*, family Polygonaceae.)

persimmon any of a group of tropical trees belonging to the ebony family, especially the common persimmon (*D. virginiana*) of the southeastern USA. Growing up to 19 m/60 ft high, the persimmon has alternate oval leaves and yellow-green flowers. The small, sweet, orange fruits are edible. (Genus *Diospyros*, family Ebenaceae.)

The Japanese persimmon (*D. kaki*) has larger fruits and is widely cultivated.

personal computer (PC) another name for ϕ microcomputer. The term is also used, more specifically, to mean the IBM Personal Computer and computers compatible with it.

The first IBM PC was introduced in 1981; it had 64 kilobytes of random access memory (RAM) and one floppy-disc drive. It was followed in 1983 by the XT (with a hard-disc drive) and in 1984 by the AT (based on a more powerful ϕ microprocessor). Many manufacturers have copied the basic design, which is now regarded as a standard for business microcomputers. Computers designed to function like an IBM PC are IBM-compatible computers.

personal digital assistant (PDA) handheld computer designed to store names, addresses, and diary information, and to send and receive faxes and e-mail. They aim to provide a more flexible and powerful alternative to the Filofax or diary.

The market for PDAs with keyboards is being fought between the Psion Series 3 and 5 (strongest in Europe), the Sharp Zaurus range (strongest in Asia), and HPCs (Handheld PCs) running Microsoft's Windows CE operating system. However, by far the best-selling PDA in 1997 was the Palm Pilot, a very small stylus-operated machine made by US Robotics, a division of 3Com.

personal identification device (PID) device, such as a magnetic card, carrying machine readable identification, which provides authorization for access to a computer system. PIDs are often used in conjunction with a PIN.

personality individual's characteristic way of behaving across a wide range of situations. Two broad dimensions of personality are extroversion and neuroticism. A number of more specific personal traits have also been described, including psychopathy (antisocial behaviour).

personal productivity software in computing, work-oriented software such as word processors, spreadsheets, or databases.

perspective the realistic representation of a three-dimensional object in two dimensions. In a perspective drawing, vertical lines are drawn parallel from the top of the page to the bottom. Horizontal lines, however, are represented by straight lines which meet at one of two perspective points. These perspective points lie to the right and left of the drawing at a distance which depends on the view being taken of the object.

Perspex trade name for a clear, lightweight, tough plastic first produced in 1930. It is widely used for watch glasses, advertising signs, domestic baths, motorboat windcreens, aircraft canopies, and protective shields. Its chemical name is polymethylmethacrylate (PMMA). It is manufactured under other names: Lucite, Acrylite, and Rhoplex (in the USA), and Oroglas (in Europe).

perspiration excretion of water and dissolved substances from the sweat glands of the skin of mammals. Perspiration has two main functions: body cooling by the evaporation of water from the skin surface, and excretion of waste products such as salts.

Genius is one per cent inspiration and ninety-nine per cent perspiration.

THOMAS ALVA EDISON US scientist and inventor.

pertussis medical name for whooping cough, an infectious disease mainly seen in children.

Peru Current formerly known as *Humboldt Current* cold ocean current flowing north from the Antarctic along the W coast of South America to S Ecuador, then west. It reduces the coastal temperature, making the W slopes of the Andes arid because winds are already chilled and dry when they meet the coast.

pessary medical device designed to be inserted into the vagina either to support a displaced womb or as a contraceptive. The word is also used for a vaginal suppository used for administering drugs locally, made from glycerol or oil of theobromine, which melts within the vagina to release the contained substance - for example, a contraceptive, antibiotic, antifungal agent, or prostaglandin (to induce labour).

pest in biology, any insect, fungus, rodent, or other living organism that has a harmful effect on human beings, other than those that directly cause human diseases. Most pests damage crops or livestock, but the term also covers those that damage buildings, destroy food stores, and spread disease.

pesticide any chemical used in farming, gardening, or indoors to combat pests. Pesticides are of three main types: insecticides (to kill insects), fungicides (to kill fungal diseases), and herbicides (to kill plants, mainly those considered weeds). Pesticides cause a number of pollution problems through spray drift onto surrounding

areas, direct contamination of users or the public, and as residues on food.

The safest pesticides include those made from plants, such as the insecticides pyrethrum and derris.

Pyrethrins are safe and insects do not develop resistance to them. Their impact on the environment is very small as the ingredients break down harmlessly.

More potent are synthetic products, such as chlorinated hydrocarbons. These products, including DDT and dieldrin, are highly toxic to wildlife and often to human beings, so their use is now restricted by law in some areas and is declining. Safer pesticides such as malathion are based on organic phosphorus compounds, but they still present hazards to health. The aid organization Oxfam estimates that pesticides cause about 10,000 deaths worldwide every year.

Pesticides were used to deforest SE Asia during the Vietnam War, causing death and destruction to the area's ecology and lasting health and agricultural problems.

pet animal kept for companionship and occasionally for status. Research suggests that interaction with a pet induces relaxation (slower heart rate and lower blood pressure). In 16th-17th century Europe, keeping animals in this way was thought suggestive of witchcraft.

An Australian study in 1992 found that pet owners had lower cholesterol levels than non-pet owners with comparable lifestyles.

petal part of a flower whose function is to attract pollinators such as insects or birds. Petals are frequently large and brightly coloured and may also be scented. Some have a nectary at the base and markings on the petal surface, known as honey guides, to direct pollinators to the source of the nectar. In wind-pollinated plants, however, the petals are usually small and insignificant, and sometimes absent altogether. Petals are derived from modified leaves, and are known collectively as a corolla.

Some insect-pollinated plants also have inconspicuous petals, with large colourless bracts (leaflike structures) or sepals taking over their role, or strong scents that attract pollinators such as flies.

petiole in botany, the stalk attaching the leaf blade, or lamina, to the stem. Typically it is continuous with the midrib of the leaf and attached to the base of the lamina, but occasionally it is attached to the lower surface of the lamina, as in the nasturtium (a peltate leaf). Petioles that are flattened and leaflike are termed phyllodes. Leaves that lack a petiole are said to be sessile.

petit Brabançon smooth-haired form of the griffon ÇBruxelloise.

petrel any of various families of seabirds in the order Procellariiforme, including the worldwide storm petrels (family Hydrobatidae), which include the smallest seabirds (some only 13 cm/5 in long), and the diving petrels (family Pelecanoididae) of the southern hemisphere. All have a hooked bill, rudimentary hind toes, tubular nostrils, and feed by diving underwater. They include fulmars and shearwaters.

Like other ground-nesting or burrow-nesting seabirds, petrels are vulnerable to predators such as rats that take eggs and nestlings. Several island species are in danger of extinction, including the Bermuda petrel *Pterodroma cahow* and the Freira petrel of Madeira *P. madeira*.

petrochemical chemical derived from the processing of petroleum (crude oil).

Petrochemical industries are those that obtain their raw materials from the processing of petroleum and natural gas. Polymers, detergents, solvents, and nitrogen fertilizers are all major products of the petrochemical industries. Inorganic chemical products include carbon black, sulphur, ammonia, and hydrogen peroxide.

petrol mixture of hydrocarbons derived from petroleum, mainly used as a fuel for internal-combustion engines. It is colourless and highly volatile. Leaded petrol contains antiknock (a mixture of tetraethyl lead and dibromethane), which improves the combustion of petrol and the performance of a car engine. The lead from the exhaust fumes enters the atmosphere, mostly as simple lead

compounds. There is strong evidence that it can act as a nerve poison on young children and cause mental impairment. This has prompted a gradual switch to the use of **unleaded petrol** in the UK.

The changeover from leaded petrol gained momentum from 1989 owing to a change in the tax on petrol, making it cheaper to buy unleaded fuel. Unleaded petrol contains a different mixture of hydrocarbons, and has a lower octane rating than leaded petrol. Leaded petrol cannot be used in cars fitted with a catalytic converter.

In the USA, petrol is called gasoline, and unleaded petrol has been used for some years.

petrol engine the most commonly used source of power for motor vehicles, introduced by the German engineers Gottlieb Daimler and Karl Benz in 1885. The petrol engine is a complex piece of machinery made up of about 150 moving parts. It is a reciprocating piston engine, in which a number of pistons move up and down in cylinders. A mixture of petrol and air is introduced to the space above the pistons and ignited. The gases produced force the pistons down, generating power. The engine-operating cycle is repeated every four strokes (upward or downward movement) of the piston, this being known as the *four-stroke cycle*. The motion of the pistons rotate a crankshaft, at the end of which is a heavy flywheel. From the flywheel the power is transferred to the car's driving wheels via the transmission system of clutch, gearbox, and final drive.

The parts of the petrol engine can be subdivided into a number of systems. The fuel system pumps fuel from the petrol tank into the carburettor. There it mixes with air and is sucked into the engine cylinders. (With electronic fuel injection, it goes directly from the tank into the cylinders by way of an electronic monitor.) The ignition system supplies the sparks to ignite the fuel mixture in the cylinders. By means of an ignition coil and contact breaker, it boosts the 12-volt battery voltage to pulses of 18,000 volts or more. These go via a distributor to the spark plugs in the cylinders, where they create the sparks. (Electronic ignitions replace these parts.) Ignition of the fuel in the cylinders produces temperatures of 700°C/1,300°F or more, and the engine must be cooled to prevent overheating.

Most engines have a **water-cooling system**, in which water circulates through channels in the cylinder block, thus extracting the heat. It flows through pipes in a radiator, which are cooled by blown air. A few cars and most motorbikes are air-cooled, the cylin-

ders being surrounded by many fins to present a large surface area to the air. The **lubrication system** also reduces some heat, but its main job is to keep the moving parts coated with oil, which is pumped under pressure to the camshaft, crankshaft, and valve-operating gear.

petroleum or crude oil natural mineral oil, a thick greenish-brown flammable liquid found underground in permeable rocks. Petroleum consists of hydrocarbons mixed with oxygen, sulphur, nitrogen, and other elements in varying proportions. It is thought to be derived from ancient organic material that has been converted by, first, bacterial action, then heat, and pressure (but its origin may be chemical also).

From crude petroleum, various products are made by distillation and other processes; for example, fuel oil, petrol, kerosene, diesel, and lubricating oil. Petroleum products and chemicals are used in large quantities in the manufacture of detergents, artificial fibres, plastics, insecticides, fertilizers, pharmaceuticals, toiletries, and synthetic rubber.

Petroleum was formed from the remains of marine plant and animal life which existed many millions of years ago (hence it is known as a fossil fuel). Some of these remains were deposited along with rock-forming sediments under the sea where they were decomposed anaerobically (without oxygen) by bacteria which changed the fats of the sediments into fatty acids which were then changed into an asphaltic material called **kerozen**. This was then converted over millions of years into petroleum by the combined action of heat and pressure. At an early stage the organic material was squeezed out of its original sedimentary mud into adjacent sandstones. Small globules of oil collected together in the pores of the rock and eventually migrated upwards through layers of porous rock by the action of the oil's own surface tension (capillary action), by the force of water movement within the rock, and by gas pressure. This migration ended either when the petroleum emerged through a fissure as a seepage of gas or oil on to the Earth's surface, or when it was trapped in porous reservoir rocks, such as sandstone or limestone, in anticlines and other traps below impervious rock layers.

The modern oil industry originates in the discovery of oil in western Ontario in 1857 followed by Edwin Drake's discovery in Pennsylvania in 1859. Drake used a steam engine to drive a pumping tool to 21 m/68 ft below the surface where he struck oil and started an oil boom. Rapid development followed in other parts of

petroleum Refining petroleum using a distillation column. The crude petroleum is fed in at the bottom of the column where the temperature is high. The gases produced rise up the column, cooling as they travel. At different heights up the column, different gases condense to liquids called fractions, and are drawn off.

the USA, Canada, Mexico, and then Venezuela where commercial production began in 1878. Oil was found in Romania in 1860, Iran in 1908, Iraq in 1923, Bahrain in 1932, and Saudi Arabia and Kuwait in 1938.

The USA led in production until the 1960s, when the Middle East outproduced other areas, their immense reserves leading to a worldwide dependence on cheap oil for transport and industry. In 1961 the Organization of the Petroleum Exporting Countries (OPEC) was established to avoid exploitation of member countries; after OPEC's price rises in 1973, the International Energy Agency (IEA) was established in 1974 to protect the interests of oil-consuming countries. New technologies were introduced to pump oil from offshore and from the Arctic (the Alaska pipeline) in an effort to avoid a monopoly by OPEC. Global consumption of petroleum in 1993 was 23 billion barrels.

As shallow-water oil reserves dwindle, multinational companies have been developing deep-water oilfields at the edge of the continental shelf in the Gulf of Mexico. Shell has developed Mars, a 500-million barrel oilfield, in 900 m/2,940 ft of water, and the oil companies now have the technology to drill wells at up to 3,075 m/10,000 ft under the sea. It is estimated that the deep waters of Mexico could yield 8–15 million barrels in total; it could overtake the North Sea in importance as an oil source.

In Asia, the oil pipeline from Azerbaijan through Russia to the West, which is the only major pipeline from the Caspian sea, closed during Russia's conflict with Chechnya but reopened in 1997.

pollution The burning of petroleum fuel is one cause of air pollution. The transport of oil can lead to catastrophes – for example, the *Torrey Canyon* tanker lost off SW England in 1967, which led to an agreement by the international oil companies in 1968 to pay compensation for massive shore pollution. The 1989 oil spill in Alaska from the *Exxon Valdez* damaged the area's fragile environment, despite clean-up efforts. Drilling for oil involves the risks of accidental spillage and drilling-rig accidents. The problems associated with oil have led to the various alternative energy technologies.

A new kind of bacterium was developed during the 1970s in the USA, capable of 'eating' oil as a means of countering oil spills.

petrology branch of geology that deals with the study of rocks, their mineral compositions, and their origins.

Peugeot France's second-largest car manufacturer, founded in 1885 when Armand Peugeot (1849–1915) began making bicycles; the company bought the rival firm Citroën in 1974 and the European operations of the American Chrysler Company in 1978.

In 1889 Armand Peugeot produced his first steam car and in 1890 his first petrol-driven car, with a Daimler engine. Peugeot's cars did well in races and were in demand from the public, and by 1900 he was producing a range of models. In the 1930s Peugeot sporting family cars sold widely. In 1978, after the acquisition of Chrysler in Europe, the Talbot marque was reintroduced.

pewter any of various alloys of mostly tin with varying amounts of lead, copper, or antimony. Pewter has been known for centuries and was once widely used for domestic utensils but is now used mainly for ornamental ware.

peyote spineless cactus of N Mexico and the southwestern USA. It has white or pink flowers. Its buttonlike tops contain mescaline, which causes hallucinations and is used by American Indians in religious ceremonies. (*Lophophora williamsii*, family Cactaceae.)

PGP abbreviation for the encryption program P Pretty Good Privacy.

pH scale from 0 to 14 for measuring acidity or alkalinity. A pH of 7.0 indicates neutrality, below 7 is acid, while above 7 is alkaline. Strong acids, such as those used in car batteries, have a pH of about 2; strong alkalis such as sodium hydroxide are pH 13.

Acidic fruits such as citrus fruits are about pH 4. Fertile soils have a pH of about 6.5 to 7.0, while weak alkalis such as soap are 9 to 10.

phage another name for a bacteriophage, a virus that attacks bacteria.

phagocyte type of white blood cell, or leucocyte, that can engulf

a bacterium or other invading microorganism. Phagocytes are found in blood, lymph, and other body tissues, where they also ingest foreign matter and dead tissue. A macrophage differs in size and life span.

phalanger name given to members of the family Phalangeridae (possums) found in New Guinea and Sulawesi. The cuscus is an example.

phalarope any of a genus *Phalaropus* of small, elegant shorebirds in the sandpiper family (Scolopacidae). They have the habit of spinning in the water to stir up insect larvae. They are native to North America, the UK, and the polar regions of Europe.

The male phalarope is courted by the female and hatches the eggs. The female is always larger and more colourful.

phanerogam obsolete term for a plant that bears flowers or cones and reproduces by means of seeds, that is an angiosperm and gymnosperm, or a seed plant. Plants such as mosses, fungi, and ferns were known as cryptogams.

Phanerozoic Greek *phanero* 'visible' eon in Earth history, consisting of the most recent 570 million years. It comprises the Palaeozoic, Mesozoic, and Cenozoic eras. The vast majority of fossils come from this eon, owing to the evolution of hard shells and internal skeletons. The name means 'interval of well-displayed life'.

pharaoh hound breed of hunting dog known from tomb paintings to have existed in ancient Egypt. It has a long head, large pricked ears, and short red coat with small white markings on the muzzle, chest, toes, and tail tip. Wiry in build, it grows to about 56 cm/22 in tall.

Dogs of the pharaoh hound type are thought to have been introduced into Europe in antiquity by Phoenician traders.

pharmacognosy branch of pharmacology concerned with the identification of drugs extracted from plant and animal tissues.

pharmacology study of the properties of drugs and their effects on the human body.

Ali Asuli writing ... 900 years ago divided his pharmacopeia into ... 'Diseases of the Rich' and 'Diseases of the Poor'.

pharmacy the preparation and dispensing of drugs; as an area of study, pharmacy includes an understanding of the origins, nature, and action of drugs. The place where a pharmacist dispenses drugs is also referred to as a pharmacy.

pharynx muscular cavity behind the nose and mouth, extending downwards from the base of the skull. Its walls are made of muscle strengthened with a fibrous layer and lined with mucous membrane. The internal nostrils lead backwards into the pharynx, which continues downwards into the oesophagus and (through the epiglottis) into the windpipe. On each side, a Eustachian tube enters the pharynx from the middle ear cavity.

The upper part (nasopharynx) is an airway, but the remainder is a passage for food. Inflammation of the pharynx is named pharyngitis.

phase in astronomy, the apparent shape of the Moon or a planet when all or part of its illuminated hemisphere is facing the Earth.

The Moon undergoes a full cycle of phases from new (when between the Earth and the Sun) through first quarter (when at 90° eastern elongation from the Sun), full (when opposite the Sun), and last quarter (when at 90° western elongation from the Sun).

The Moon is gibbous (more than half but less than fully illuminated) when between first quarter and full or full and last quarter. Mars can appear gibbous at quadrature (when it is at right angles to the Sun in the sky). The gibbous appearance of Jupiter is barely noticeable.

The planets whose orbits lie within that of the Earth can also undergo a full cycle of phases, as can an asteroid passing inside the Earth's orbit.

phase in chemistry, a physical state of matter: for example, ice and liquid water are different phases of water; a mixture of the two is termed a two-phase system.

phase in physics, a stage in an oscillatory motion, such as a wave motion: two waves are in phase when their peaks and their troughs coincide. Otherwise, there is a **phase difference**, which has consequences in interference phenomena and alternating current electricity.

pheasant any of various large, colourful Asiatic fowls of the family Phasianidae, order Galliformes, which also includes grouse, quail, and turkey. The typical pheasants are in the genus *Phasianus*, which has two species: the Japanese pheasant, *P. versicolor*, found in Japan, and the Eurasian ring-necked or common pheasant, *P. colchicus*, also introduced to North America. The genus is distinguished by the very long wedge-shaped tail and the absence of a crest. The plumage of the male common pheasant is richly tinted with brownish-green, yellow, and red markings, but the female is a camouflaged brownish colour. The nest is made on the ground. The male is polygamous.

Among the more exotically beautiful pheasants of other genera, often kept as ornamental birds, are the golden pheasant *Chrysolophus pictus* and Lady Amherst's pheasant *Chrysolophus amherstiae*, both from China, and the argus pheasant *Argusianus argus* of Malaysia, which has metallic spots or 'eyes' on the wings.

Reeves's pheasant *Symaticus reevesii*, a native of China, is over 2 m/6.6 ft in length, and has yellow and brown spangled plumage.

phenol member of a group of aromatic chemical compounds with weakly acidic properties, which are characterized by a hydroxyl (OH) group attached directly to an aromatic ring. The simplest of the phenols, derived from benzene, is also known as phenol and has the formula C_6H_5OH . It is sometimes called **carbolic acid** and can be extracted from coal tar.

Pure phenol consists of colourless, needle-shaped crystals, which take up moisture from the atmosphere. It has a strong and characteristic smell and was once used as an antiseptic. It is, however, toxic by absorption through the skin.

phenol The phenol molecule with its ring of six carbon atoms and a hydroxyl (OH) group attached. Phenol was first extracted from coal tar in 1834. It is used to make phenolic and epoxy resins, explosives, pharmaceuticals, perfumes, and nylon.

phenolphthalein acid-base indicator that is clear below pH 8 and red above pH 9.6. It is used in titrating weak acids against strong bases.

phenotype In genetics, visible traits, those actually displayed by an organism. The phenotype is not a direct reflection of the genotype because some alleles are masked by the presence of other, dominant alleles (see dominance). The phenotype is further

modified by the effects of the environment (for example, poor nutrition stunts growth).

phenylalanine one of the nine essential amino acids. Phenylketonuria is a rare genetic disease which results from the inability to metabolize the phenylalanine present in food.

pheromone chemical signal (such as an odour) that is emitted by one animal and affects the behaviour of others. Pheromones are used by many animal species to attract mates.

phlebitis inflammation of the wall of a vein. It is sometimes associated with varicose veins or with a blockage by a blood clot (thrombosis), in which case it is more accurately described as thrombophlebitis.

Phlebitis may occur as a result of the hormonal changes associated with pregnancy, or due to long-term use of contraceptive pills, or following prolonged immobility (which is why patients are mobilized as soon as possible after surgery). If a major vein is involved, nearly always in a leg, the part beyond the blockage swells and may remain engorged for weeks. It is very painful. Treatment is with anticoagulant drugs and sometimes surgery, depending on the cause.

phloem tissue found in vascular plants whose main function is to conduct sugars and other food materials from the leaves, where they are produced, to all other parts of the plant.

Phloem is composed of sieve elements and their associated companion cells, together with some sclerenchyma and parenchyma cell types. Sieve elements are long, thin-walled cells joined end to end, forming sieve tubes; large pores in the end walls allow the continuous passage of nutrients. Phloem is usually found in association with xylem, the water-conducting tissue, but unlike the latter it is a living tissue.

phlogiston hypothetical substance formerly believed to have been produced during combustion. The term was invented by the German chemist Georg Stahl. The phlogiston theory was replaced by the theory of oxygen gain and loss, first enunciated by the French chemist Antoine Lavoisier.

phlox any of a group of plants native to North America and Siberia. Phloxes are small with alternate leaves and clusters of showy white, pink, red, or purple flowers. (Genus *Phlox*, family Polemoniaceae.)

phobia excessive irrational fear of an object or situation – for example, agoraphobia (fear of open spaces and crowded places), acrophobia (fear of heights), and claustrophobia (fear of enclosed places). Behaviour therapy is one form of treatment.

A specific phobia is a severe dislike of a particular thing, including objects, animals or situations. Specific phobias start in childhood (particularly animal phobias) and early adulthood. They are more common in women than men.

Complex phobias have more complicated contributing factors and include agoraphobia and social phobia. These phobias are more disabling. Agoraphobia typically starts between the ages of 18 and 28. Social phobia usually onsets between 11 and 16 years.

Phobos one of the two moons of Mars, discovered 1877 by the US astronomer Asaph Hall (1829–1907). It is an irregularly shaped lump of rock, cratered by meteorite impacts. Phobos is 27 x 22 x 19 km/17 x 13 x 12 mi across, and orbits Mars every 0.32 days at a distance of 9,400 km/5,840 mi from the planet's centre. It is thought to be an asteroid captured by Mars' gravity.

Pholus or 5145 *Pholus* in astronomy, a red centaur discovered 1991.

phon unit of loudness, equal to the value in decibels of an equally loud tone with frequency 1,000 Hz. The higher the frequency, the louder a noise sounds for the same decibel value; thus an 80-decibel tone with a frequency of 20 Hz sounds as loud as 20 decibels at 1,000 Hz, and the phon value of both tones is 20. An aircraft engine has a loudness of around 140 phons.

phong shading in computing, type of shading used in animation and 3-D graphics, based on a computerized model of how light is reflected from surfaces.

phonograph the name US inventor Thomas Edison gave to his sound-recording apparatus, which developed into the record player. The word 'phonograph' is still used in the USA.

phosphate salt or ester of phosphoric acid. Incomplete neutralization of phosphoric acid gives rise to acid phosphates (see acid salts and buffer). Phosphates are used as fertilizers, and are required for the development of healthy root systems. They are involved in many biochemical processes, often as part of complex molecules, such as ATP.

phosphate analysis the regular sampling and chemical analysis of phosphorus levels in the soil around archaeological sites in order to locate concentrations of human bone and excrement, and hence areas of human activity, settlements, and burial grounds.

phospholipid any lipid consisting of a glycerol backbone, a phosphate group, and two long chains. Phospholipids are found everywhere in living systems as the basis for biological membranes.

One of the long chains tends to be hydrophobic and the other hydrophilic (that is, they interrelate with water in opposite ways). This means that phospholipids will line up the same way round when in solution.

phosphor any substance that is phosphorescent, that is, gives out visible light when it is illuminated by a beam of electrons or ultraviolet light. The television screen is coated on the inside with phosphors that glow when beams of electrons strike them. Fluorescent lamp tubes are also phosphor-coated. Phosphors are also used in Day-Glo paints, and as optical brighteners in detergents.

phosphorescence in physics, the emission of light by certain substances after they have absorbed energy, whether from visible light, other electromagnetic radiation such as ultraviolet rays or X-rays, or cathode rays (a beam of electrons). When the stimulating energy is removed phosphorescence ceases, although it may persist for a short time after (unlike fluorescence, which stops immediately).

phosphoric acid acid derived from phosphorus and oxygen. Its commonest form (H_3PO_4) is also known as orthophosphoric acid, and is produced by the action of phosphorus pentoxide (P_2O_5) on water. It is used in rust removers and for rust-proofing iron and steel.

phosphorus Greek *phosphoros* 'bearer of light' highly reactive, nonmetallic element, symbol P, atomic number 15, relative atomic mass 30.9738. It occurs in nature as phosphates (commonly in the form of the mineral apatite), and is essential to plant and animal life. Compounds of phosphorus are used in fertilizers, various organic chemicals, for matches and fireworks, and in glass and steel.

Phosphorus was first identified in 1674 by German alchemist Hennig Brand (born c. 1630), who prepared it from urine. The element has three allotropic forms: a black powder; a white-yellow, waxy solid that ignites spontaneously in air to form the poisonous gas phosphorus pentoxide; and a red-brown powder that neither ignites spontaneously nor is poisonous.

PhotoCD picture storage and viewing system developed by Kodak and Philips. The aim of Kodak's PhotoCD is to allow the user to put up to 100 photos onto compact disc; images are transferred from film to a PhotoCD disc and can then be viewed by means of Kodak's own PhotoCD player, which plugs into a television set, or by using suitable software on a multimedia PC.

PhotoCD is based on multisession Δ WORM (write-once read many times) technology. The images can be written to the disc in multiple recording sessions.

photocell or **photoelectric cell** device for measuring or detecting light or other electromagnetic radiation, since its electrical state is altered by the effect of light. In a photoemissive cell, the radiation causes electrons to be emitted and a current to flow (Δ photoelectric effect); a photovoltaic cell causes an electromotive force to be generated in the presence of light

across the boundary of two substances. A photoconductive cell, which contains a semiconductor, increases its conductivity when exposed to electromagnetic radiation.

Photocells are used for photographers' exposure meters, burglar and fire alarms, automatic doors, and in solar energy arrays.

photochemical reaction any chemical reaction in which light is produced or light initiates the reaction. Light can initiate reactions by exciting atoms or molecules and making them more reactive; the light energy becomes converted to chemical energy. Many photochemical reactions set up a chain reaction and produce free radicals.

This type of reaction is seen in the bleaching of dyes or the yellowing of paper by sunlight. It is harnessed by plants in photosynthesis and by humans in photography.

Chemical reactions that produce light are most commonly seen when materials are burned. Light-emitting reactions are used by living organisms in bioluminescence. One photochemical reaction is the action of sunlight on car exhaust fumes, which results in the production of ozone. Some large cities, such as Los Angeles, and Santiago, Chile, now suffer serious pollution due to photochemical smog.

photocopier machine that uses some form of photographic process to reproduce copies of documents or illustrations. Most modern photocopiers, as pioneered by the Xerox Corporation, use electrostatic photocopying, or xerography ('dry writing').

Additional functions of photocopiers include enlargement and reduction, copying on both sides of the sheet of paper, copying in colour, collating, and stapling.

photodiode semiconductor Δ -n junction diode used to detect light or measure its intensity. The photodiode is encapsulated in a transparent plastic case that allows light to fall onto the junction. When this occurs, the reverse-bias resistance (high resistance in the opposite direction to normal current-flow) drops and allows a larger reverse-biased current to flow through the device. The increase in current can then be related to the amount of light falling on the junction.

Photodiodes that can detect small changes in light level are used in alarm systems, camera exposure controls, and optical communication links.

photoelectric cell alternative name for Δ photocell.

photoelectric effect in physics, the emission of electrons from a substance (usually a metallic surface) when it is struck by photons (quanta of electromagnetic radiation), usually those of visible light or ultraviolet radiation.

photography process for reproducing images on sensitized materials by various forms of radiant energy, including visible light, ultraviolet, infrared, X-rays, atomic radiations, and electron beams.

Photography was developed in the 19th century; among the pioneers were Louis Daguerre in France and Fox Talbot in the UK. Colour photography dates from the early 20th century.

The most familiar photographic process depends upon the fact that certain silver compounds (called halides) are sensitive to light. A photographic film is coated with these compounds and, in a camera, is exposed to light. An image, or picture, of the scene

EXPOSURE: A BEGINNERS GUIDE TO PHOTOGRAPHY

<http://www.88.com/exposure/index.htm>

Introduction to the world of photography including a 'crash course', as well as sections with a 'few easy tricks to jazz up your pictures' and an explanation of exposure theory. To help out with the latter, there is a 'sim-cam', allowing you to experiment with f-number and shutter speed for an image and see the results without wasting a lot of film.

Photography: chronology

- 1515** Leonardo da Vinci described the camera obscura.
- 1750** The painter Canaletto used a camera obscura as an aid to his painting in Venice.
- 1790** Thomas Wedgwood in England made photograms—placing objects on leather, sensitized using silver nitrate.
- 1826** Nicéphore Niepce, a French doctor, produced the world's first photograph from nature on pewter plates with a camera obscura and an eight-hour exposure.
- 1838** As a result of his earlier collaboration with Niepce, L. J. M. Daguerre produced the first daguerreotype camera photograph.
- 1839** Daguerre was awarded an annuity by the French government and his process given to the world.
- 1840** Invention of the Petzval lens, which reduced exposure time by 90%. Herschel discovered sodium thiosulphate as a fixer for silver halides.
- 1841** Fox Talbot's calotype process was patented—the first multiphot method of photography using a negative/positive process, sensitized with silver iodide.
- 1844–46** Fox Talbot published the first photographic book, *The Pencil of Nature*.
- 1845** Hill and Adamson began to use calotypes for portraits in Edinburgh, Scotland.
- 1851** Fox Talbot used a one-thousandth of a second exposure to demonstrate high-speed photography. Invention of the wet-collodion-on-glass process and the waxed-paper negative. Photographs were displayed at the Great Exhibition in London, England.
- 1852** The London Society of Arts exhibited 779 photographs.
- 1855** Roger Fenton made documentary photographs of the Crimean War from a specially constructed caravan with portable darkroom.
- 1858** Nadar took the first aerial photographs from a balloon.
- 1859** Nadar in Paris made photographs underground using battery-powered arc lights.
- 1860** Queen Victoria was photographed by Mayall. Abraham Lincoln was photographed by Mathew Brady for political campaigning.
- 1861** The single-lens reflex plate camera was patented by Thomas Sutton. The principles of three-colour photography were demonstrated by Scottish physicist James Clerk Maxwell.
- 1870** Julia Margaret Cameron used long lenses for her distinctive portraits.
- 1871** Gelatin-silver bromide was developed.
- 1878** In the USA Eadweard Muybridge analysed the movements of animals through sequential photographs, using a series of cameras.
- 1879** The photogalvanic process was invented.
- 1880** A silver bromide emulsion was fixed with hypo. Photographs were first reproduced in newspapers in New York using the half-tone engraving process. The first twin-lens reflex camera was produced in London. Gelatin-silver chloride paper was introduced.
- 1884** George Eastman produced flexible negative film.
- 1889** The Eastman Company in the USA produced the Kodak No. 1 camera and roll film, facilitating universal, hand-held snapshots.
- 1891** The first telephoto lens. The interference process of colour photography was developed by the French doctor Gabriel Lippmann.
- 1897** The first issue of Alfred Stieglitz's *Camera Notes* in the USA.
- 1902** In Germany, Deckel invented a prototype leaf shutter and Zeiss introduced the Tessar lens.
- 1904** The autochrome colour process was patented by the Lumière brothers.
- 1905** Alfred Stieglitz opened the gallery '291' in New York promoting photography. Lewis Hine used photography to expose the exploitation of children in American factories, causing protective laws to be passed.
- 1907** The autochrome process began to be factory-produced.
- 1914** Oskar Barnack designed a prototype Leica camera for Leitz in Germany.
- 1924** Leitz launched the first 35mm camera, the Leica, delayed because of World War I. It became very popular with photojournalists because it was quiet, small, dependable, and had a range of lenses and accessories.
- 1929** Rolleiflex produced a twin-lens reflex camera in Germany.
- 1935** In the USA, Mannes and Godovsky invented Kodachrome transparency film, which produced sharp images and rich colour quality. Electronic flash was invented in the USA.
- 1936** *Life* magazine, significant for its photojournalism, was first published in the USA.
- 1938** *Picture Post* magazine was introduced in the UK.
- 1940** Multigrade enlarging paper by Ilford was made available in the UK.
- 1942** Kodachrome negative film was introduced.
- 1945** The zone system of exposure estimation was published in the book *Exposure Record* by Ansel Adams.
- 1947** Polaroid black and white instant process film was invented by Dr Edwin Land, who set up the Polaroid corporation in Boston, Massachusetts. The principles of holography were demonstrated in England by Dennis Gabor.
- 1955** Kodak introduced Tri-X, a black and white 200 ASA film.
- 1959** The zoom lens was invented by the Austrian firm of Voigtlander.
- 1960** The laser was invented in the USA, making holography possible. Polacolor, a self-processing colour film, was introduced by Polaroid, using a 60-second colour film and dye diffusion technique.
- 1963** Cibachrome, paper and chemicals for printing directly from transparencies, was made available by Ciba-Geigy of Switzerland. One of the most permanent processes, it is marketed by Ilford in the UK.
- 1966** The International Center of Photography was established in New York.
- 1969** Photographs were taken on the Moon by US astronauts.
- 1970** A charge-coupled device was invented at Bell Laboratories in New Jersey, USA, to record very faint images (for example in astronomy). *Rencontres Internationales de la Photographie*, the annual summer festival of photography with workshops, was founded in Arles, France.
- 1971** Opening of the Photographers' Gallery, London, and the Photo Archive of the Bibliothèque Nationale, Paris.
- 1972** The SX70 system, a single-lens reflex camera with instant prints, was produced by Polaroid.
- 1975** The Center for Creative Photography was established at the University of Arizona.
- 1980** Ansel Adams sold an original print, *Moonrise. Hernandez*, for \$45,000, a record price, in the USA. *Voyager 1* sent photographs of Saturn back to Earth across space.
- 1983** The National Museum of Photography, Film and Television opened in Bradford, England.
- 1985** The Minolta Corporation in Japan introduced the Minolta 7000—the world's first body-integral autofocus single-lens reflex camera.
- 1988** The electronic camera, which stores pictures on magnetic disc instead of on film, was introduced in Japan.
- 1990** Kodak introduced PhotoCD which converts 35mm camera pictures (on film) into digital form and stores them on compact disc (CD) for viewing on TV.
- 1992** Japanese company Canon introduced a camera with autofocus controlled by the user's eye. The camera focuses on whatever the user is looking at. *Girl with a Leica* by Russian photographer Aleksandr Rodchenko sold for £115,500 at Christie's, London—a world-record price for a photograph.
- 1996** Corbis, a company owned by Bill Gates, bought the exclusive rights to 2,500 photographs by Ansel Adams.

before the camera is formed on the film because the silver halides become activated (light-altered) where light falls but not where light does not fall. The image is made visible by the process of ϕ developing, made permanent by fixing, and, finally, is usually printed on paper. Motion-picture photography uses a camera that exposes a roll of film to a rapid succession of views that, when developed, are projected in equally rapid succession to provide a moving image.

photogravure ϕ rinting process that uses a plate prepared photographically, covered with a pattern of recessed cells in which the ink is held. See ϕ gravure.

photoluminescence see ϕ luminescence.

photolysis chemical reaction that is driven by light or ultraviolet radiation. For example, the light reaction of photosynthesis (the process by which green plants manufacture carbohydrates from carbon dioxide and water) is a photolytic reaction.

photometer instrument that measures luminous intensity, usually by comparing relative intensities from different sources. Bunsen's grease-spot photometer of 1844 compares the intensity of a light source with a known source by each illuminating one half of a translucent area. Modern photometers use ϕ photocells, as in a photographer's exposure meter. A photomultiplier can also be used as a photometer.

photomultiplier instrument that detects low levels of electromagnetic radiation (usually visible light or infrared radiation) and amplifies it to produce a detectable signal.

One type resembles a ϕ photocell with an additional series of coated ϕ electrodes (dynodes) between the ϕ cathode and ϕ anode. Radiation striking the cathode releases electrons (primary emission) which hit the first dynode, producing yet more electrons (ϕ secondary emission), which strike the second dynode. Eventually this produces a measurable signal up to 100 million times larger than the origi-

nal signal by the time it leaves the anode. Similar devices, called image intensifiers, are used in television camera tubes that 'see' in the dark.

photon in physics, the ϕ elementary particle or 'package' (quantum) of energy in which light and other forms of electromagnetic radiation are emitted. The photon has both particle and wave properties; it has no charge, is considered massless but possesses momentum and energy. It is one of the ϕ gauge bosons, and is the carrier of the ϕ electromagnetic force, one of the fundamental forces of nature.

According to ϕ quantum theory the energy of a photon is given by the formula $E = hf$, where h is Planck's constant and f is the frequency of the radiation emitted.

photoperiodism biological mechanism that determines the timing of certain activities by responding to changes in day length. The flowering of many plants is initiated in this way. Photoperiodism in plants is regulated by a light-sensitive pigment, **phytochrome**. The breeding seasons of many temperate-zone animals are also triggered by increasing or declining day length, as part of their ϕ biorythms.

Autumn-flowering plants (for example, chrysanthemum and soya bean) and autumn-breeding mammals (such as goats and deer) require days that are shorter than a critical length; spring-flowering and spring-breeding ones (such as radish and lettuce, and birds) are triggered by longer days.

photosphere visible surface of the Sun, which emits light and heat. About 300 km/200 mi deep, it consists of incandescent gas at a temperature of 5,800K (5,530°C/9,980°F).

Rising cells of hot gas produce a mottling of the photosphere known as **granulation**, each granule being about 1,000 km/620 mi in diameter. The photosphere is often marked by large, dark patches called ϕ sunspots.

photosynthesis Process by which green plants and some bacteria manufacture carbohydrates from water and atmospheric carbon dioxide, using the energy of sunlight. Photosynthesis depends on the ability of chlorophyll molecules within plant cells to trap the energy of light to split water molecules, giving off oxygen as a by-product. The hydrogen of the water molecules is then used to reduce carbon dioxide to simple carbohydrates.

photosynthesis process by which green plants trap light energy from the Sun. This energy is used to drive a series of chemical reactions which lead to the formation of carbohydrates. The carbohydrates occur in the form of simple sugar, or glucose, which provides the basic food for both plants and animals. For photosynthesis to occur, the plant must possess chlorophyll and must have a supply of carbon dioxide and water. Photosynthesis takes place inside chloroplasts which are found mainly in the leaf cells of plants.

The by-product of photosynthesis, oxygen, is of great importance to all living organisms, and virtually all atmospheric oxygen has originated by photosynthesis.

Chloroplasts contain the enzymes and chlorophyll necessary for photosynthesis, and the leaf structure of plants is specially adapted to this purpose.

leaf structure In the lower epidermis on the leaf underside are stomata (pores; see *stoma*), each of which is surrounded by a pair of guard cells that control their opening and closing. These guard cells contain chloroplasts. The central layer of the leaf between the layers of epidermis is called the mesophyll, and all the cells in this tissue contain chloroplasts. Running through the mesophyll are the veins, each of which contains large, thick-walled xylem vessels for carrying water, and smaller, thin-walled phloem tubes for transporting the food produced by the leaf. Most of the glucose that forms during photosynthesis is stored in the chloroplasts as starch. As plant-eating animals eat the leaves they too are dependent on plant photosynthesis to supply their basic energy needs.

chemical process The chemical reactions of photosynthesis occur in two stages. During the light reaction sunlight is used to split water (H_2O) into oxygen (O_2), protons (hydrogen ions, H^+), and electrons, and oxygen is given off as a by-product. In the dark reaction, for which sunlight is not required, the protons and electrons are used to convert carbon dioxide (CO_2) into carbohydrates ($C_6H_{12}O_6$). So the whole process can be summarized by the equation.

Photosynthesis depends on the ability of chlorophyll to capture the energy of sunlight and to use it to split water molecules. The initial charge separation occurs in less than a billionth of a second, a speed that compares with current computers.

Plant pigments Photosynthetic pigments are the plant pigments responsible for capturing light energy during photosynthesis. The primary pigment is chlorophyll, which absorbs blue and red light. Other pigments, such as carotenoids, are accessory pigments which also capture light energy and pass it on to chlorophyll. Photosynthesis by cyanobacteria was responsible for the appearance of oxygen in the Earth's atmosphere 2 billion years ago, and photosynthesis by plants maintains the oxygen levels today.

PHOTOSYNTHESIS DIRECTORY

A wealth of scientific information concerning photosynthesis, its stages and its importance from MIT in Boston, USA. The site discusses issues such as the evolution and discovery of photosynthesis, the chloroplast, and the chlorophyll, and all steps of the light and dark reactions that take place during photosynthesis. The site also offers detailed diagrams of the procedures discussed.

phototropism movement of part of a plant toward or away from a source of light. Leaves are positively phototropic, detecting the source of light and orientating themselves to receive the maximum amount.

phreaking in computing, using computer technology to make free long-distance phone calls, charge them to another account, or otherwise illegally access the telephone network. In the 1980s, phreaking was semi-respectable among hackers (see *hacking*), but

it is now less reputable – and thanks to improved security in the phone network, much more difficult. The case of Kevin Mitnick did much to bring phreaking to public attention.

phyllotaxis the arrangement of leaves on a plant stem. Leaves are nearly always arranged in a regular pattern and in the majority of plants they are inserted singly, either in a spiral arrangement up the stem, or on alternate sides. Other principal forms are opposite leaves, where two arise from the same node, and whorled, where three or more arise from the same node.

phylloxera plant-eating insect of the family Phylloxeridae, closely related to the aphids.

The grape, or vine phylloxera *Phylloxera vitifolia*, a native of North America, is a notorious pest of grapevines, forming galls on roots and leaves, which damage the plant. European vines are markedly susceptible and many French vineyards suffered from the arrival of the pest in Europe in the late 19th century, when nearly 2 million hectares of vineyards were destroyed. In 1993 infestation became apparent in Californian vineyards, threatening a loss of 20,000 hectares by the end of the century. Phylloxera is very resistant to treatment, as there are no natural enemies and it is difficult to treat with pesticide because of its depth within the soil. Phylloxera insects (hemipterans) may be destroyed by spraying with carbon disulphide or petroleum.

phylogeny historical sequence of changes that occurs in a given species during the course of its evolution. It was once erroneously associated with ontogeny (the process of development of a living organism).

TREE OF LIFE

<http://phylogeny.arizona.edu/tree/phylogeny.html>

Project designed to present information about the phylogenetic relationships and characteristics of organisms, illustrating the diversity and unity of living organisms.

phylum (plural *phyla*) major grouping in biological classification. Mammals, birds, reptiles, amphibians, fishes, and tunicates belong to the phylum Chordata; the phylum Mollusca consists of snails, slugs, mussels, clams, squid, and octopuses; the phylum Porifera contains sponges; and the phylum Echinodermata includes starfish, sea urchins, and sea cucumbers. In classifying plants (where the term 'division' often takes the place of 'phylum'), there are between four and nine phyla depending on the criteria used; all flowering plants belong to a single phylum, Angiospermata, and all conifers to another, Gymnospermata. Related phyla are grouped together in a kingdom; phyla are subdivided into classes.

There are 36 different phyla. The most recently identified is the Cyclophora described in 1995. It contains a single known species, *Symbion pandora*, that lives on lobsters.

physical change in chemistry, a type of change that does not produce a new chemical substance, does not involve large energy changes, and that can be easily reversed (the opposite of a chemical change). Boiling and melting are examples of physical change.

physical chemistry branch of chemistry concerned with examining the relationships between the chemical compositions of substances and the physical properties that they display. Most chemical reactions exhibit some physical phenomenon (change of state, temperature, pressure, or volume, or the use or production of electricity), and the measurement and study of such phenomena has led to many chemical theories and laws.

physics branch of science concerned with the laws that govern the structure of the universe, and the investigation of the properties of matter and energy and their interactions. For convenience,

Atom lasers

Quantum mechanics predicts that particles can behave like waves. The wavelength of a particle gets shorter as the particle moves faster. For atoms this wavelength is usually much smaller than the size of the atom itself. However, if the atom is moving very slowly its wavelength can become quite large and the waves of nearby atoms begin to overlap. When this happens the atoms form a new state of matter known as a Bose-Einstein condensate. This new state of matter was created for the first time by American physicists in 1995. Bose-Einstein condensates have completely different properties from the other four states of matter: solid, liquid, gas and plasma.

To form a Bose-Einstein condensate it is necessary to trap a gas of atoms and then cool them to just a fraction of a degree above absolute zero. This is done using a combination of lasers and magnetic fields. By carefully releasing the atoms from the trap it is possible to make what is known as an atom laser. In an atom laser all the atoms travel in the same direction with the same speed – just like the photons (particles of light) in a conventional laser. American physicists used sodium atoms to make the first ever atom laser in 1996. Atom lasers could be used as a tool in other physics experiments, in atomic clocks or to print tiny circuits in electronics.

Quantum information technology

Recent years have seen exciting progress in a new field of physics called quantum information technology. Quantum information technology essentially involves three subjects: quantum computation, quantum cryptography and quantum communication.

In conventional computers, information is handled as a series of bits which can either be one or zero. Quantum computation is based on the ability of quantum particles to be in two or more places at the same time. This allows information to be handled as a series of 'qubits' which can be both one and zero at the same time. Therefore quantum computers can, in theory, work much faster than ordinary computers. So far physicists have built simple quantum logic gates and developed theoretical schemes to deal with the errors that can arise during computation.

Quantum cryptography allows two people, usually called Alice and Bob, to exchange information with complete security. Researchers in Switzerland and the UK have demonstrated that quantum cryptography can be made to work over distances greater than 10 km. In quantum communication Alice and Bob use the properties of quantum mechanics to communicate in ways that are not possible classically. Both quantum cryptography and

quantum communication rely on a property of quantum mechanics called entanglement. Physicists in Austria and Italy have used entanglement to 'teleport' single photons in the laboratory.

Most work so far has concentrated on pairs of entangled photons. Entanglement means that certain properties of the photons are very closely related, even when the photons are very far apart. For example, if the polarization of the first photon is measured to be vertical, then the polarization of the second photon will instantly become horizontal. This happens even though the second photon could have had any value of polarization before the measurement on the first photon. Einstein called this 'spooky action at a distance'.

Neutrino masses

Neutrinos are the most mysterious particles in the 'Standard Model of Particle Physics'. They have no charge and are thought to have no mass; and since neutrinos only experience one of the four fundamental forces, the weak force, they are difficult to detect.

One particular mystery concerns neutrinos from the Sun. The Sun produces energy by converting 600 tonnes of hydrogen into helium every second. According to theory this should result in 65 billion solar neutrinos bombarding every sq cm/0.15 sq in of the Earth's surface every second. To test this theory physicists have built massive experiments in underground mines. However none of these experiments has been able to detect any more than half the number of neutrinos predicted by theory.

One possible explanation for this shortage is that neutrinos do in fact have mass. This would allow the electron neutrinos produced in the centre of the Sun to oscillate into either muon or tau neutrinos on their journey to the surface. Existing experiments can only detect electron neutrinos although a Canadian experiment that can detect all three types is begun in 1998.

To confirm that neutrinos do indeed oscillate, physicists are planning to send beams of muon neutrinos from high-energy accelerators to the various underground experiments. If electron neutrinos are detected in these beams it will provide conclusive evidence for oscillation and hence neutrino mass. One proposal for such an experiment would involve sending a beam from CERN in Switzerland to the Gran Sasso laboratory some 730 km/450 mi away in Italy. Similar experiments have been proposed in the USA and Japan.

Proof of neutrino mass would be a major breakthrough in particle physics. It might also help solve the 'dark matter' problem – the fact that less than 10% of the mass of the universe is visible – in astrophysics.

physics is often divided into branches such as atomic physics, nuclear physics, particle physics, solid-state physics, molecular physics, electricity and magnetism, optics, acoustics, heat, thermodynamics, quantum theory, and relativity. Before the 20th century, physics was known as *natural philosophy*.

All science is either physics or stamp collecting.

- 1800** Alessandro Volta invented the Voltaic cell.
- 1801** Interference of light was discovered by Thomas Young.
- 1808** The 'modern' atomic theory was propounded by John Dalton.
- 1811** Avogadro's hypothesis relating volumes and numbers of molecules of gases was proposed by Amedeo Avogadro.
- 1814** Fraunhofer lines in the solar spectrum were mapped by Joseph von Fraunhofer.
- 1815** Refraction of light was explained by Augustin Fresnel.
- 1820** The discovery of electromagnetism was made by Hans Oersted.
- 1821** The dynamo principle was described by Michael Faraday, the thermocouple was discovered by Thomas Seebeck.
- 1822** The laws of electrodynamics were established by André Ampère.
- 1824** Thermodynamics as a branch of physics was proposed by Sadi Carnot.
- 1827** Ohm's law of electrical resistance was established by Georg Ohm, Brownian movement resulting from molecular vibrations was observed by Robert Brown.
- 1829** The law of gaseous diffusion was established by Thomas Graham.
- 1831** Electromagnetic induction was discovered by Faraday.
- 1834** Faraday discovered self-induction.
- 1842** The principle of conservation of energy was observed by Julius von Mayer.
- c. 1847** The mechanical equivalent of heat was described by James Joule.
- 1849** A measurement of speed of light was put forward by French physicist Armand Fizeau (1819–1896).
- 1851** The rotation of the Earth was demonstrated by Jean Foucault.
- 1858** The mirror galvanometer, an instrument for measuring small electric currents, was invented by William Thomson (Lord Kelvin).
- 1859** Spectrographic analysis was made by Robert Bunsen and Gustav Kirchhoff.
- 1861** Osmosis was discovered.
- 1873** Light was conceived as electromagnetic radiation by James Maxwell.
- 1877** A theory of sound as vibrations in an elastic medium was propounded by John Rayleigh.
- 1880** Piezoelectricity was discovered by Pierre Curie.
- 1887** The existence of radio waves was predicted by Heinrich Hertz.
- 1895** X-rays were discovered by Wilhelm Röntgen.
- 1896** The discovery of radioactivity was made by Antoine Becquerel.
- 1897** Joseph Thomson discovered the electron.
- 1899** Ernest Rutherford discovered alpha and beta rays.
- 1900** Quantum theory was propounded by Max Planck; the discovery of gamma rays was made by French physicist Paul-Ulrich Villard (1860–1934).
- 1902** Oliver Heaviside discovered the ionosphere.
- 1904** The theory of radioactivity was put forward by Rutherford and Frederick Soddy.
- 1905** Albert Einstein propounded his special theory of relativity.
- 1908** The Geiger counter was invented by Hans Geiger and Rutherford.
- 1911** The discovery of the atomic nucleus was made by Rutherford.
- 1913** The orbiting electron atomic theory was propounded by Danish physicist Niels Bohr.
- 1915** X-ray crystallography was discovered by William and Lawrence Bragg.
- 1916** Einstein put forward his general theory of relativity; mass spectroscopy was discovered by William Aston.
- 1924** Edward Appleton made his study of the Heaviside layer.
- 1926** Wave mechanics was introduced by Erwin Schrödinger.
- 1927** The uncertainty principle of quantum physics was established by Werner Heisenberg.
- 1931** The cyclotron was developed by Ernest Lawrence.
- 1932** The discovery of the neutron was made by James Chadwick; the electron microscope was developed by Vladimir Zworykin.
- 1933** The positron, the antiparticle of the electron, was discovered by Carl Anderson.
- 1934** Artificial radioactivity was developed by Frédéric and Irène Joliot-Curie.
- 1939** The discovery of nuclear fission was made by Otto Hahn and Fritz Strassmann.
- 1942** The first controlled nuclear chain reaction was achieved by Enrico Fermi.
- 1956** The neutrino, an elementary particle, was discovered by Clyde Cowan and Fred Reines.
- 1960** The Mössbauer effect of atom emissions was discovered by Rudolf Mössbauer; the laser, the first maser was developed by US physicist Theodore Maiman (1927–).
- 1964** Murray Gell-Mann and George Zweig discovered the quark.
- 1967** Jocelyn Bell (now Bell Burnell) and Antony Hewish discovered pulsars (rapidly rotating neutron stars that emit pulses of energy).
- 1971** The theory of superconductivity was announced, where electrical resistance in some metals vanishes above absolute zero.
- 1979** The discovery of the asymmetry of elementary particles was made by US physicists James W. Cronin and Val I. Fitch.
- 1982** The discovery of processes involved in the evolution of stars was made by Subrahmanyan Chandrasekhar and William Fowler.
- 1983** Evidence of the existence of weakons (W and Z particles) was confirmed at CERN, validating the link between the weak nuclear force and the electromagnetic force.
- 1986** The first high-temperature superconductor was discovered, able to conduct electricity without resistance at a temperature of -938°C (-396°F).
- 1989** CERN's Large Electron Positron Collider (LEP), a particle accelerator with a circumference of 57 km/16.8 mi, came into operation.
- 1991** LEP experiments demonstrated the existence of three generations of elementary particles, each with two quarks and two leptons.
- 1995** Top quark discovered at Fermilab, the US particle-physics laboratory, near Chicago. US researchers announce the discovery of a material which is superconducting at the temperature of liquid nitrogen – a much higher temperature than previously achieved.
- 1996** CERN physicists created the first atoms of antimatter (nine atoms of antihydrogen). The Lawrence Livermore National Laboratory, California, USA, produces a laser of 1.3 petawatts (130 trillion watts).
- 1997** A new subatomic particle, an exotic meson, was possibly discovered at Brookhaven National Laboratory, Upton, New York, USA. The exotic meson is made up of either a quark, an antiquark and a gluon, or two quarks and two antiquarks. US physicists display the first atomic laser. It emits atoms that act like lightwaves.

In 1853, the English mathematician William Shanks published the value of π to 707 decimal places. The calculation had taken him 15 years and was surpassed only in 1945, when computations made on an early desk calculator showed that the last 180 decimal places he had calculated were incorrect.

π symbol π , the ratio of the circumference of a circle to its diameter. The value of π is 3.1415926... correct to seven decimal places. Common approximations to π are $\frac{22}{7}$ and 3.14, although the value 3 can be used as a rough estimation.

In mathematics you don't understand things. You just get used to them.

picric acid $C_6H_2(NO_2)_3OH$ (technical name 2,4,6-trinitrophenol) strong acid that is used to dye wool and silks yellow, for the treatment of burns, and in the manufacture of explosives. It is a yellow, crystalline solid.

PICS (abbreviation for Platform for Internet Content Selection) in computing, method of classifying data according to its content. Under PICS, the creator and the reader of a file can add descriptive electronic labels to it, making it possible for users to sort documents according to keywords on the label. The system, introduced 1996, aims to help parents to control what their children can see on the Internet, for example by blocking access to pornographic or violent material; it also enables people to highlight subjects in which they are especially interested.

PICT in computing, object-oriented file format used on the Apple Macintosh computer. The format uses QuickDraw and is supported by almost all graphics applications on the Macintosh.

pie chart method of displaying proportional information by dividing a circle up into different-sized sectors (slices of pie). The angle of each sector is proportional to the size, expressed as a percentage, of the group of data that it represents.

For example, data from a traffic survey could be presented in a pie chart in the following way:

- (1) convert each item of data to a percentage figure;
- (2) 100% will equal 360 degrees of the circle, therefore each 1% = $360/100 = 3.6$ degrees;
- (3) calculate the angle of the segment for each item of data by multiplying the percentage by 3.6, and plot this on the circle.

The diagram may be made clearer by adding colours or shadings to each group, together with a key.

pier structure built out into the sea from the coastline for use as a landing place or promenade.

piezoelectric effect property of some crystals (for example, quartz) to develop an electromotive force or voltage across opposite faces when subjected to tension or compression, and, conversely, to expand or contract in size when subjected to an electromotive force. Piezoelectric crystal oscillators are used as frequency standards (for example, replacing balance wheels in watches), and for producing ultrasound.

pig any even-toed hoofed mammal of the family Suidae. They are omnivorous, and have simple, non-ruminating stomachs and thick hides. The Middle Eastern wild boar *Sus scrofa* is the ancestor of domesticated breeds: it is 1.5 m/4.5 ft long and 1 m/3 ft high, with formidable tusks, but not naturally aggressive. The smallest member of the pig family is the pygmy hog *Sus salvanus*.

Wild pigs include the babirusa and the wart hog. The farming of domesticated pigs was practised during the Neolithic in the Middle East and China at least 11,000 years ago and the pig was a common farm animal in ancient Greece and Rome. Over 400 breeds evolved over the centuries, many of which have all but disappeared in more recent times with the development of intensive rearing systems; however, different environments and requirements have ensured the continuation of a variety of types. The Berkshire, Chester White, Poland, China, Saddleback, Yorkshire, Duroc, and Razorbuck are the main surviving breeds. Modern indoor rearing methods favour the large white breeds, such as the Chester White and the originally Swedish Landrace, over coloured varieties, which tend to be harder and can survive better outdoors. Since 1960, hybrid pigs, produced by crossing two or more breeds, have become popular for their heavy but lean carcasses.

pigeon or *dove* bird of the family Columbidae, order Columbiformes, distinguished by its large crop, which becomes glabular in the breeding season and secretes a milky fluid ('pigeon's milk') that aids digestion of food for the young. There are many species, and they are found worldwide.

New World species include the mourning doves, which live much of the time on the ground. The fruit pigeons of Australasia and the Malay regions are beautifully coloured. In the USA, there were once millions of passenger pigeons *Ectopistes migratorius*, but they have been extinct since 1914.

pigeon hawk another name for the merlin, a small falcon.

pigeon pea woody, perennial legume *Cajanus cajan*, grown as a crop in many parts of Africa, Asia, and Latin America. It constitutes about 5% of world legume production (3.5 million hectares). Pigeon peas have a growing season of 6–9 months and are either harvested dry and used mainly in dahl soup, or harvested earlier and eaten as a green vegetable. They are highly nutritious containing up to 28% protein, and 10 times more fat, 5 times more vitamin A, and 3 times more vitamin C than ordinary peas. Cultivating pigeon pea also replenishes the soil with nitrates.

pig iron or *cast iron* the quality of iron produced in a blast furnace. It contains around 4% carbon plus some other impurities.

pika or *mouse-hare* any small mammal of the family Ochotonidae, belonging to the order Lagomorpha (rabbits and hares). The single genus *Ochotona* contains about 15 species, most of which live in mountainous regions of Asia, although two species are native to North America.

Pikas have short, rounded ears, and most species are about 20 cm/8 in long, with greyish-brown fur and no visible tail. Their warning call is a sharp whistle. They are vegetarian and in late summer cut grasses and other plants and place them in piles to dry as hay, which is then stored for the winter.

Pikas can be divided into rock pikas and burrowing pikas. Rock pikas live in rocky territory alone or in pairs. Population densities are low and lifespan is about six years. Females have two or three young per year. Burrowing pikas are social animals and live in family groups at high densities in meadows or steppes, with a much shorter lifespan, of less than two years. Females have as many as twenty young per year, in several large litters.

Pikas do not hibernate, but stay mostly in their burrows, feeding on the hay piles that they have stocked up during the summer.

pike any of a family Esocidae in the order Salmoniformes, of slender, freshwater bony fish with narrow pointed heads and sharp, pointed teeth. The northern pike *Esox lucius*, of North America and Eurasia, may reach a length of 2.2 m/7 ft and a weight of 9 kg/20 lb.

Other kinds of pike include muskellunges, up to 2.2 m/7 ft long, and the smaller pickerels, both in the genus *Esox*.

pikeperch any of various freshwater members of the perch family, resembling pikes, especially the walleye *Stizostedion vitreum*, common in Europe, W Asia, and North America. It reaches over 1 m/3 ft.

pike-perch freshwater bony fish. It is common in the rivers and lakes of Europe and western Asia, and also found in North

America. It may reach as much as 1 m/3.3 ft in length. Pike-perch feed on other fish.

classification Pike-perch *Lucioperca lucioperca* are in order Perciformes, class Osteichthyes.

pilchard any of various small, oily members of the herring family, Clupeidae, especially the commercial sardine of Europe *Sardina pilchardus*, and the California sardine *Sardinops sagax*.

In March 1995 a mystery virus or toxin began causing the deaths of millions of pilchards in the oceans south of Australia, killing adults over 12 cm/4.7 in long, but not appearing to harm fish feeding on the pilchards. In April a slick of dead pilchards 40 km/25 mi long was observed off Tasmania.

Pill, the commonly used term for the contraceptive pill, based on female hormones. The combined pill, which contains synthetic hormones similar to oestrogen and progesterone, stops the production of eggs, and makes the mucus produced by the cervix hostile to sperm. It is the most effective form of contraception apart from sterilization, being more than 99% effective.

The minipill or progesterone-only pill prevents implantation of a fertilized egg into the wall of the uterus. The minipill has a slightly higher failure rate, especially if not taken at the same time each day, but has fewer side effects and is considered safer for long-term use. Possible side effects of the Pill include migraine or headache and high blood pressure. More seriously, oestrogen-containing pills can slightly increase the risk of a clot forming in the blood vessels. This risk is increased in women over 35 if they smoke. Controversy surrounds other possible health effects of taking the Pill. The evidence for a link with cancer is slight (and the Pill may protect women from some forms of cancer). Once a woman ceases to take it, there is an increase in the likelihood of conceiving identical twins.

pilotfish small marine fish *Nauclrates ductor* of the family Carangidae, which also includes pompanos. It hides below sharks, turtles, or boats, using the shade as a base from which to prey on smaller fish. It is found in all warm oceans and grows to about 36 cm/1.2 ft.

pilot running in computing, a method of implementing a new computer system in which the work is gradually transferred from the old system to the new system over a period of time. This ensures that any faults in the new system are resolved before the old system is withdrawn. An alternative method is *parallel running*.

pimento or *allspice* any of several evergreen trees belonging to the myrtle family, found in tropical parts of the New World. The dried berries of the species *P. dioica* are used as a spice (see *allspice*). Also, a sweet variety of *capsicum* pepper (more correctly spelled pimiento). (Pimento genus *Pimenta*, family Myrtaceae.)

pimpernel any of a group of plants belonging to the primrose family, comprising about 30 species mostly native to W Europe. The European scarlet pimpernel (*A. arvensis*) grows in cornfields, the small star-shaped flowers opening only in full sunshine. It is naturalized in North America. (Genus *Anagallis*, family Primulaceae.)

PIN (acronym for *personal identification number*) in banking, a unique number used as a password to establish the identity of a customer using an automatic cash dispenser. The PIN is normally encoded into the magnetic strip of the customer's bank card and is known only to the customer and to the bank's computer. Before a cash dispenser will issue money or information, the customer must insert the card into a slot in the machine (so that the PIN can be read from the magnetic strip) and enter the PIN correctly at a keyboard. This helps to prevent stolen cards from being used to obtain money from cash dispensers.

pine any of a group of coniferous, resin-producing trees with evergreen needle-shaped leaves; there are about 70–100 species of pines, making them the largest family of conifers. (Genus *Pinus*, family Pinaceae.)

The oldest living species is probably the bristlecone pine (*P. aris-tata*), native to California, of which some specimens are said to be 4,600 years old.

Pine (acronym for *program for Internet news and e-mail*) electronic mail program for UNIX and MS-DOS. Pine grew out of *elm*, an older UNIX e-mailer, and includes online help and a user-friendly text editor called Pico.

pineal body or *pineal gland* a cone-shaped outgrowth of the vertebrate brain. In some lower vertebrates, it develops a rudimentary lens and retina, which show it to be derived from an eye, or pair of eyes, situated on the top of the head in ancestral vertebrates. In fishes that can change colour to match their background, the pineal perceives the light level and controls the colour change. In birds, the pineal detects changes in daylight and stimulates breeding behaviour as spring approaches. Mammals also have a pineal gland, but it is located deeper within the brain. It secretes a hormone, melatonin, thought to influence rhythms of activity. In humans, it is a small piece of tissue attached by a stalk to the rear wall of the third ventricle of the brain.

pineapple large, juicy fruit of the pineapple plant, which belongs to the bromeliad family and is native to South and Central America but now cultivated in many other tropical areas, such as Hawaii and Queensland, Australia. The plant's mauvish flowers are produced in the second year, and afterwards join with their bracts (specialized leaves protecting the buds) to form the fleshy fruit, which looks like a giant cone. (*Ananas comosus*, family Bromeliaceae.)

For export to world markets the fruits are cut unripe and lack the sweet juiciness typical of the canned pineapple (usually the smoother-skinned Cayenne variety), which is allowed to mature fully.

pine marten species of *marten*, a small mammal.

pine siskin streaked, tan, black, and yellow (finch *Carduelis pinus* of North America, about 12 cm/5 in long.

PING (contraction of *Packet Internet Groper*) in computing, short message sent over a network by one computer to check whether another is correctly connected to it. By extension, one can 'ping' other people – for example, checking addresses on a mailing list by sending an e-mail to all members requesting an acknowledgement.

pinhole camera the simplest type of camera, in which a pinhole rather than a lens is used to form an image. Light passes through the pinhole at one end of a box to form a sharp inverted image on the inside surface of the opposite end. The image is equally sharp for objects placed at different distances from the camera because only one ray from a particular distance or direction can enter through the tiny pinhole, and so only one corresponding point of light will be produced on the image. A photographic film or plate fitted inside the box will, if exposed for a long time, record the image.

pinhole camera A pinhole camera has no lens but can nevertheless produce a sharp inverted image because only one ray from a particular point can enter the tiny pinhole aperture, and so no blurring takes place. However, the very low amount of light entering the camera also means that the film at the back must be exposed for a long time before a photographic image is produced; the camera is therefore only suitable for photographing stationary objects.

pink any of a group of annual or perennial plants that have stems with characteristic swellings (nodes) and scented flowers ranging in colour from white through pink to purple. Members of the pink family include carnations, sweet williams, and baby's breath (*Gypsophila paniculata*). (Genus *Dianthus*, family Carophyllaceae.)

Depiford pink (*D. armeria*), which has deep pink flowers with pale dots, is native to Europe and naturalized in the USA.

pinna in botany, the primary division of a ϕ pinnate leaf. In mammals, the pinna is the external part of the ear.

pinnate leaf leaf that is divided up into many small leaflets, arranged in rows along either side of a midrib, as in ash trees (*Fraxinus*). It is a type of compound leaf. Each leaflet is known as a **pinna**, and where the pinnae are themselves divided, the secondary divisions are known as pinnules.

pint imperial dry or liquid measure of capacity equal to 20 fluid ounces, half a quart, one-eighth of a gallon, or 0.568 litre. In the US, a pint is equal to 0.473 litre, while a dry pint is equal to 0.550 litre.

pinworm ϕ nematode worm *Enterobius vermicularis*, an intestinal parasite of humans.

pion or **pi meson** in physics, a subatomic particle with a neutral form (mass 135 MeV) and a positively charged form (mass 139 MeV). The charged pion decays into muons and neutrinos and the neutral form decays into gamma-ray photons. They belong to the ϕ hadron class of elementary particles.

The mass of a positive pion is 273 times that of an electron; the mass of a neutral pion is 264 times that of an electron.

Pioneer probe any of a series of US Solar-System space probes 1958-78. The probes *Pioneer 4-9* went into solar orbit to monitor the Sun's activity during the 1960s and early 1970s. *Pioneer 5*, launched in 1960, was the first of a series to study the solar wind between the planets. *Pioneer 10*, launched March in 1972, was the first probe to reach Jupiter (December 1973) and to leave the Solar System in 1983. *Pioneer 11*, launched April 1973, passed Jupiter December 1974, and was the first probe to reach Saturn (September 1979), before also leaving the Solar System.

Pioneer 10 and *11* carry plaques containing messages from Earth in case they are found by other civilizations among the stars. Pioneer Venus probes were launched May and August 1978. One orbited Venus, and the other dropped three probes onto the surface. The orbiter finally burned up in the atmosphere of Venus 1992. In 1992 *Pioneer 10* was more than 8 billion km/4.4 billion mi from the Sun. Both *10* and *Pioneer 11* were still returning data measurements of starlight intensity to Earth.

Pioneer 1, 2, and 3, launched in 1958, were intended Moon probes, but *Pioneer 2's* launch failed, and *1* and *3* failed to reach their target, although they did measure the ϕ Van Allen radiation belts. *Pioneer 4* began to orbit the Sun after passing the Moon.

pioneer species in ecology, those species that are the first to colonize and thrive in new areas. Coal tips, recently cleared woodland, and new roadsides are areas where pioneer species will quickly appear. As the habitat matures other species take over, a process known as succession.

pipefish any of various long-snouted, thin, pipe-like marine fish in the same family (Syngnathidae) as seahorses. The great pipefish *Syngnathus acus* grows up to 50 cm/1.6 ft, and the male has a brood pouch for eggs and developing young, which hatch as tiny versions of the adults in five to six weeks: there is no larval stage.

PIPEFISH

When pipefish mate it is the female who penetrates the male. She inserts her eggs into his internal pouch using her protruding ovarian duct. He then fertilizes the eggs and carries them as they develop.

pipeline any extended line of conduits for carrying water, oil, gas, or other material over long distances. Pipelines are widely used in water-supply and oil- and gas-distribution schemes. The USA has 2.4 million km/1.5 million mi of pipeline (including over 300,000 km/200,000 mi of oil pipeline). One of the longest is the Trans-Alaskan Pipeline in Alaska.

The first gas pipeline between North Africa and Europe opened in 1996, bringing gas from Algeria to Spain and eventually to France and Portugal. Financed largely by the European Union, it will help diversify the supply of gas throughout Europe and bring transport costs down. The 1,400 km/875 mi pipeline brings gas from Algeria via Morocco and the Strait of Gibraltar to the city of Cordoba in southern Spain, where it will be channelled into Spain's natural-gas network. It should supply nearly half of Spain's gas needs by 2000. Construction of the pipeline took almost five years, at a cost of \$2.3 billion. It was the most complicated project of its kind in the world, since 45 km/30 mi of the pipe had to be laid on the geologically complex floor of the Strait of Gibraltar, the site of treacherously strong currents.

Piper Alpha disaster accident aboard the North Sea oil platform Piper Alpha on 6 July 1988, in which 167 people died. The rig was devastated by a series of explosions, caused initially by a gas leakage. An official inquiry held into the disaster highlighted the vulnerability of offshore rigs.

pipette device for the accurate measurement of a known volume of liquid, usually for transfer from one container to another, used in chemistry and biology laboratories.

A pipette is a glass tube, often with an enlarged bulb, which is calibrated in one or more positions, or it may be a plastic device with an adjustable plunger, fitted with one or more disposable plastic tips.

PIPEX (contraction of *public Internet protocol exchange*) in computing, UK-based Internet provider which started operations in 1992, specializing in serving the commercial sector. The company became one of the UK's major ϕ backbone providers and was acquired by ϕ UNET 1996.

pipit any of various sparrow-sized ground-dwelling songbirds of the genus *Anthus* of the family Motacillidae, order Passeriformes.

piranha any South American freshwater fish of the genus *Serrasalmus*, in the same order as cichlids. They can grow to 60 cm/2 ft long, and have razor-sharp teeth: some species may rapidly devour animals, especially if attracted by blood.

Pisces inconspicuous zodiac constellation, mainly in the northern hemisphere between ϕ Aries and ϕ Aquarius, near ϕ Pegasus. It is represented as two fish tied together by their tails. The Girdle, a delicate ring of stars, marks the head of the western fish in Pisces. The constellation contains the vernal equinox, the point at which the Sun's path around the sky (the ecliptic) crosses the celestial equator (see ϕ celestial sphere). The Sun reaches this point around 21 March each year as it passes through Pisces from mid-March to late April. In astrology, the dates for Pisces are between about 19 Feb and 20 March (see ϕ precession).

Piscis Austrinus or **Southern Fish** constellation of the southern hemisphere near ϕ Capricornus. Its brightest star is the first-magnitude ϕ Fomalhaut.

pistachio deciduous tree of the cashew family, native to Europe and Asia, whose green nuts are eaten salted or used to enhance and flavour food, especially ice cream. (*Pistacia vera*, family Anacardiaceae.)

pistil general term for the female part of a flower, either referring to one single ϕ carpel or a group of several fused carpels.

pistol any small firearm designed to be fired with one hand.

Pistols were in use from the early 15th century.

The problem of firing more than once without reloading was tackled by using many combinations of multiple barrels, both stationary and revolving. A breech-loading, multichambered revolver from 1650 still survives; the first practical solution, however, was

Samuel Colt's six-gun 1847. Behind a single barrel, a short six-chambered cylinder was rotated by cocking the hammer and a fresh round of ammunition brought into firing position. The automatic pistol, operated by gas or recoil, was introduced in Germany in the 1890s. Both revolvers and automatics remain in widespread military use.

piston barrel-shaped device used in reciprocating engines (steam, petrol, diesel oil) to harness power. Pistons are driven up and down in cylinders by expanding steam or hot gases. They pass on their motion via a connecting rod and crank to a crankshaft, which turns the driving wheels. In a pump or compressor, the role of the piston is reversed, being used to move gases and liquids. See also internal-combustion engine.

pit bull terrier or *American pit bull terrier* variety of dog that was developed in the USA solely as a fighting dog. It usually measures about 50 cm/20 in at the shoulder and weighs roughly 23 kg/50 lb, but there are no established criteria since it is not recognized as a breed by either the American or British Kennel Clubs. Selective breeding for physical strength and aggression has created a dog unsuitable for life in the modern community.

pitch in chemistry, a black, sticky substance, hard when cold, but liquid when hot, used for waterproofing, roofing, and paving. It is made by the destructive distillation of wood or coal tar, and has been used since antiquity for caulking wooden ships.

pitch in mechanics, the distance between the adjacent threads of a screw or bolt. When a screw is turned through one full turn it moves a distance equal to the pitch of its thread. A screw thread is a simple type of machine, acting like a rolled-up inclined plane, or ramp (as may be illustrated by rolling a long paper triangle around a pencil). A screw has a mechanical advantage greater than one.

pitchblende or *uraninite* brownish-black mineral, the major constituent of uranium ore, consisting mainly of uranium oxide (UO₂). It also contains some lead (the final, stable product of uranium decay) and variable amounts of most of the naturally occurring radioactive elements, which are products of either the decay or the fissioning of uranium isotopes. The uranium yield is 50–80%; it is also a source of radium, polonium, and actinium. Pitchblende was first studied by Pierre and Marie Curie, who found radium and polonium in its residues in 1898.

pitcher plant any of various insectivorous plants, the leaves of which are shaped like a pitcher and filled with a fluid that traps and digests insects. (Genera especially *Nepenthes* and *Sarracenia*, family Sarracenaceae.)

Pitot tube instrument that measures fluid (gas and liquid) flow. It is used to measure the speed of aircraft, and works by sensing pressure differences in different directions in the airstream.

It was invented in the 1730s by the French scientist Henri Pitot (1695–1771).

pitta tropical bird of order Passeriformes, genus *Pitta*, forming the family Pittidae. Some 20 species are native to SE Asia, W Africa, and Australia. They have round bodies, big heads, are often brightly coloured, and are silent. They live on the ground and in low undergrowth, and can run from danger. They feed on insects.

pittosporum tree or shrub of the large genus *Pittosporum*, family Pittosporaceae, of Asia, Africa, and Australia. Of the Australian species, some are found in moist rainforest areas while one species grows in the dry inland. *P. undulatum* of the eastern mainland states has cream bell-shaped flowers and orange fruit.

pituitary gland major endocrine gland of vertebrates, situated in the centre of the brain. It is attached to the hypothalamus by a stalk. The pituitary consists of two lobes. The posterior lobe is an extension of the hypothalamus, and is in effect nervous tissue. It stores two hormones synthesized in the hypothalamus: α ADH and oxytocin. The anterior lobe secretes six hormones, some of which control the activities of other glands (thyroid, gonads, and adrenal cortex); others are direct-acting hormones affecting milk secretion and controlling growth.

pituri Australian shrub *Duboisia hopwoodii*, the leaves and twigs of which are used by Aborigines as a narcotic.

Pixar Hollywood animation company bought by Steve Jobs in 1986. In 1995 Pixar, together with Walt Disney, released *Toy Story*, the first ever feature-length computer-animated cartoon film.

pixel (derived from *picture element*) single dot on a computer screen. All screen images are made up of a collection of pixels, with each pixel being either off (dark) or on (illuminated, possibly in colour). The number of pixels available determines the screen's resolution. Typical resolutions of microcomputer screens vary from 320 x 200 pixels to 640 x 480 pixels, but screens with 1,024 x 768 pixels are now common for high-quality graphic (pictorial) displays.

pixel Computer screen images are made of a number of pixels ('dots'). The greater the number of pixels the greater the resolution of the image; most computer screens are set at 640 x 480 pixels, although higher resolutions are available.

PKZIP in computing, widely-used shareware file compression utility. Files created with PKZIP (often posted to *newsgroups* and *bulletin boards*) bear the suffix .zip and are said to be 'zipped'.

placebo Latin 'I will please' any harmless substance, often called a 'sugar pill', that has no active ingredient, but may nevertheless bring about improvement in the patient's condition.

The use of placebos in medicine is limited to drug trials, where a placebo is given alongside the substance being tested, to compare effects. The 'placebo effect', first named in 1945, demonstrates the control mind exerts over matter, bringing changes in blood pressure, perceived pain, and rates of healing. Recent research points to the release of certain neurotransmitters in the production of the placebo effect.

placenta organ that attaches the developing embryo or fetus to the uterus in placental mammals (mammals other than marsupials, platypuses, and echidnas). Composed of maternal and embryonic tissue, it links the blood supply of the embryo to the blood supply of the mother, allowing the exchange of oxygen, nutrients, and waste products. The two blood systems are not in direct contact, but are separated by thin membranes, with materials diffusing across from one system to the other. The placenta also produces hormones that maintain and regulate pregnancy. It is shed as part of the afterbirth.

It is now understood that a variety of materials, including drugs and viruses, can pass across the placental membrane. HIV, the virus that causes AIDS, can be transmitted in this way.

The tissue in plants that joins the ovary to the ovules is also called a placenta.

place value the value given to a digit because of its position within a number. For example, in the decimal number 2,465 the 2 represents two thousands, the 4 represents four hundreds, the 6 represents six tens, and the 5 represents five units.

plane in astronomy, a bright patch in the chromosphere above a group of sunspots, occasionally seen on images of the Sun in hydrogen light.

placenta The placenta is a disc-shaped organ about 25 cm/10 in in diameter and 3 cm/1 in thick. It is connected to the fetus by the umbilical cord.

PLAGUE

<http://www.outbreak.org/cgi-unreg/dynaserve.exe/Plague/index.html>

Basic medical details of the biological weapon version of plague viruses and bacteria. The Web site contains brief sections covering characteristics of the diseases including its toxicology, the symptoms they cause, cautions and precautions, first aid therapy for victims of the diseases, and a list of neutralization and decontamination methods.

plague term applied to any epidemic disease with a high mortality rate, but it usually refers to the bubonic plague. This is a disease transmitted by fleas (carried by the black rat) which infect the sufferer with the bacillus *Yersinia pestis*. An early symptom is swelling of lymph nodes, usually in the armpit and groin; such swellings are called 'buboes'. It causes virulent blood poisoning and the death rate is high.

Rarer but more virulent forms of plague are septicaemic and pneumonic; both still exert a formidable mortality. Outbreaks of plague still occur, mostly in poor countries, but never to the extent seen in the late Middle Ages. According to a World Health Organization report published in 1996, the incidence of plague is on the increase. It was reported in 13 states of the USA between 1984 and 1994, in comparison with just 3 states in the 1940s.

PLAGUE

In 1666, to help counter the spread of plague, the British Parliament decreed that all bodies had to be wrapped in a woollen shroud for burial. This decree provided wool-makers with a constant source of business for nearly 150 years.

plaice fish *Pleuronectes platessa* belonging to the flatfish group, abundant in the N Atlantic. It is white beneath and brownish with orange spots on the 'eyed' side. It can grow to 75 cm/2.5 ft long, and weigh about 2 kg/4.5 lb.

plain or **grassland** land, usually flat, upon which grass predominates. The plains cover large areas of the Earth's surface, especially between the deserts of the tropics and the rainforests of the Equator, and have rain in one season only. In such regions the climate belts move north and south during the year, bringing rainforest conditions at one time and desert conditions at another. Temperate plains include the North European Plain, the High Plains of the USA and Canada, and the Russian Plain also known as the steppe.

plaintext in computing, another name for ϕ cleartext.

plan in computing, file publicly accessible on UNIX systems that holds whatever information users wish to make public about themselves.

On other services such records may be called a resumé, bio, or directory entry. The purpose is generally the same, to allow users of the same system to find out a little more about the real-world identity of the people with whom they are interacting.

planarian nonparasitic flatworm. Planarians are usually small, flat, soft creatures, common both in fresh water and in the sea, where they may be found under rocks and stones in pools. Some of them are brilliantly coloured. They feed on insects, small molluscs, and worms.

The mouth is on the underside of the body, the digestive system varies from a simple bulblike pharynx to a many-branched intestine. The skin is covered with protective vibrating cilia ('hairs'). Planarians multiply sexually and also by division.

classification Planarians form the class Turbellaria, which, with Monogenea, Digenea, and Cestoda, comprise the phylum Platyhelminthes.

Planck's constant in physics, a fundamental constant (symbol h) that relates the energy (E) of one quantum of electromagnetic radiation (the smallest possible 'packet' of energy; see quantum theory) to the frequency (f) of its radiation by $E = hf$.

Its value is 6.6261×10^{-34} joule seconds.

plane in botany, any of several trees belonging to the plane family. Species include the oriental plane (*P. orientalis*), a favourite plantation tree of the Greeks and Romans, and the American plane or buttonwood (*P. occidentalis*). A hybrid of these two is the London plane (*P. x acerifolia*), with palmate, usually five-lobed leaves, which is widely planted in cities for its resistance to air pollution. (Genus *Platanus*, family Platanaceae.)

All species have hanging burlike fruits and can grow to 30 m/100 ft high.

planet Greek '*wanderer*' large celestial body in orbit around a star, composed of rock, metal, or gas. There are nine planets in the ϕ Solar System: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Neptune, Uranus, and Pluto. The inner four, called the **terrestrial planets**, are small and rocky, and include the planet Earth. The outer planets, with the exception of Pluto, are called the **major planets**, and consist of large balls of rock, liquid, and gas; the largest is Jupiter, which contains a mass equivalent to 70% of all the other planets combined. Planets do not produce light, but reflect the light of their parent star.

As seen from the Earth, all the historic planets are conspicuous

Planck, Max Karl Ernst (1858–1947)

German physicist who framed the quantum theory in 1900. His research into the manner in which heated bodies radiate energy led him to report that energy is emitted only in indivisible amounts, called 'quanta', the magnitudes of which are proportional to the frequency of the radiation. His discovery ran counter to classical physics and is held to have marked the commencement of the modern science. He was awarded the Nobel Prize for Physics in 1918.

Measurements of the frequency distribution of black body radiation by Wilhelm Wien (1864–1928) in 1893 showed the peak value

of energy occurring at a higher frequency with greater temperature. This may be observed in the varying colour produced by a glowing object. At low temperatures, it glows red but as the temperature rises the peak energy is emitted at a greater frequency, and the colour become yellow and then white.

Wien attempted to derive a radiation law that would relate the energy to frequency and temperature but discovered a radiation

law in 1896 that was valid only at high frequencies. Lord Rayleigh (1842–1919) later found a similar equation that held for radiation emitted at low frequencies. Planck was able to combine these two radiation laws, arriving at a formula for the observed energy of the radiation at any given frequency and temperature. This entailed making the assumption that the energy consists of the sum of a finite number of discrete units of energy that he called quanta, and that the energy ϵ of each quantum is given by the equation: $\epsilon = h\nu$, where ν is the frequency of the radiation and h is a constant now recognized to be a fundamental constant of nature, called Planck's constant. By directly relating the energy of a radiation to its frequency, an explanation was found for the observation that radiation of greater energy has a higher frequency distribution.

Planck's idea that energy must consist of indivisible particles, not waves, was revolutionary because it totally contravened the accepted belief that radiation consisted of waves. It soon found rapid acceptance: Albert Einstein in 1905 used Planck's quantum theory as an explanation for photoelectricity and in 1913 Danish physicist Niels Bohr successfully applied the quantum theory to the atom. This was later developed into a full system of quantum mechanics in the 1920s, when it also became clear that energy and matter have both a particle and a wave nature.

Planck's constant, a fundamental constant (symbol h), is the energy of one quantum of electromagnetic radiation divided by the frequency of its radiation.

naked-eye objects moving in looped paths against the stellar background. The size of these loops, which are caused by the Earth's own motion round the Sun, are inversely proportional to the planet's distance from the Earth.

new discoveries In 1995 Italian astronomers believed they had detected a new planet around 51 Pegasi in the constellation Pegasus. It was named 51 Pegasi B and is thought to have a mass comparable to that of Jupiter. The gravitational pull thought to be that of the planet may be caused by pulsation in the parent star.

The discovery of three further new planets was announced at the American Astronomical Society meeting in January 1996. All are outside the Solar System, but two are only about 35 light years from Earth and orbit stars visible with the naked eye. One, 70 Vir B, is in the constellation Virgo, and the other, 47 UMa B, is in Ursa Major. The third, β Pictoris, is about 50 light years away in the southern constellation Pictor.

In April 1996 another planet was discovered, orbiting Rho Cancri in the constellation Cancer. Yet another was found in June 1996, this time orbiting the star Tau Bootis. By July 1996 the total of new planets discovered since October 1995 had risen to 10.

The discovery of a new planet with an orbit which is more irregular than that of any other was discovered by US astronomers October 1996. The new planet has 1.6 times the mass of Jupiter and orbits the star 16 Cygni B. Its distance from the star 16 Cygni B varies from 90 million km to 390 million km.

planetary embryo in astronomy, one of numerous massive bodies thought to have formed from the accretion of planetesimals during the formation of the Solar System. Embryos in the region of the Earth's orbit would have been about 1,023 kg/2,251 lb in mass, and about 10–100 of them would have coalesced to make the Earth.

planetary nebula shell of gas thrown off by a star at the end of its life. Planetary nebulae have nothing to do with planets. They were named by William Herschel, who thought their rounded shape resembled the disc of a planet. After a star such as the Sun has expanded to become a red giant, its outer layers are ejected into space to form a planetary nebula, leaving the core as a white dwarf at the centre.

planimeter simple integrating instrument for measuring the area of a regular or irregular plane surface. It consists of two hinged arms: one is kept fixed and the other is traced around the boundary of the area. This actuates a small graduated wheel; the area is calculated from the wheel's change in position.

planisphere in astronomy, a graphical device for determining the aspect of the sky for any date and time in the year. It consists of two discs mounted concentrically so that the upper disc, which has an aperture corresponding to the horizon of the observer, can rotate over the lower disc, which is printed with a map of the sky centred

Discovery of the Major Planets

by Tony Jones

Other than the Earth, there are eight major planets in the solar system. Five of them – Mercury, Venus, Mars, Jupiter and Saturn – have been known since antiquity. Looking like bright stars, they reveal their true nature by moving slowly from night to night against the background of the constellations. Indeed, the word 'planet' comes from the ancient Greek for 'wanderer'.

Venus is unmistakable. Shining brilliant white, it is by far the brightest object in the sky after the Sun and Moon and is often visible in daylight. Every few months it is an arresting sight in the evening or morning sky. Jupiter, Mars and Saturn are also prominent, and Mercury may escape attention only because it is close to the Sun and never seen in darkness. These five, together with the Sun and Moon, were familiar sights in the heavens throughout recorded history and have been woven into religious and astrological myth since ancient times.

The world was taken by surprise then, when a humble music teacher discovered a new member of the Sun's family of planets in 1781. William Herschel (1738–1822) was a committed amateur astronomer and a skilled telescope maker. He had built a series of superb telescopes at his home in Bath, England. On 13 March, while conducting a survey of the night sky, he came across a curious star that appeared as a disk rather than a point of light. A few nights later it had changed position and within months the astronomical world had confirmed that Herschel's object was a new planet far beyond the orbit of Saturn, then the outermost known member of the solar system.

Herschel wanted to call it George's Star, in honour of King George III, but the name Uranus, after the Greek sky god and father of Cronos (Saturn), was eventually accepted. The King was dazzled none the less, and Herschel, the first person ever to discover a new planet, became a favourite at the royal court and soon the most influential astronomer of his day.

Uranus, though faint, is actually visible to the naked eye under good conditions. It was later found that the planet had been recorded on at least 20 occasions as far back as 1690 and mistaken for a star each time. The earlier observers had not had the benefit of Herschel's powerful telescopes which were able to discern the greenish disc of the planet.

Some years later astronomers were having problems with the orbit of Mercury, the planet closest to the Sun. Its movements could not be completely accounted for by Newton's laws of gravity. A French astronomer, Urbain Leverrier (1811–1877), proposed in 1845 that the discrepancy could be explained by the

gravitational attraction of an undiscovered planet, which he called Vulcan, orbiting within the orbit of Mercury only 30 million km from the Sun. All attempts to find Vulcan failed, and the Mercury problem remained unsolved until 1915, when Albert Einstein (1879–1955) showed that the discrepancies in the orbit were a consequence of the general theory of relativity.

Leaving astronomers to search for Vulcan, Leverrier turned his attention to Uranus which was also deviating from its predicted path. Again, he attributed the perturbation to another planet, this time beyond the orbit of Uranus, and predicted where in the sky it would be found. Johann Galle (1812–1910) at the Berlin Observatory pointed a telescope at Leverrier's position on 23 September 1846 and almost at once discovered the new planet only one degree from the predicted location. It became known as Neptune, after the Roman god of the sea.

It turned out that a young Cornish mathematician, John Couch Adams (1819–1892) had predicted the position of Neptune a year earlier but had been unable to persuade the Astronomer Royal, George Airy (1801–1892) to take it seriously. When Airy finally asked James Challis (1803–1882) at Cambridge Observatory to search for the planet, Challis saw it on two occasions more than a month before Galle but failed to recognize it.

Buoyed by this outstanding triumph of Newtonian mechanics, astronomers soon suspected that Neptune in turn was being affected by the pull of a still more distant planet. One of the scientists who attempted to calculate its position was US businessman and astronomer Percival Lowell (1855–1916). He built his own observatory in 1895 at Flagstaff in Arizona but failed to track down the mystery planet. It was not until 18 February 1930, 14 years after Lowell's death, that Clyde Tombaugh (1906–1997), an assistant at the observatory, finally stumbled across the planet. He had ignored the predictions of the mathematicians and had systematically worked his way through the zodiac, the band of sky in which the planets move, comparing pairs of photographs taken on different nights and looking for a 'star' that had moved.

The planet, which was named Pluto after the god of the underworld, was much fainter than expected and was later found on several photographs taken during earlier searches.

Though astronomers continue to discover asteroids, comets and other small bodies in the outer solar system, modern search techniques are so thorough that there is little chance of more major planets lying unseen beyond the orbit of Pluto.

on the north or south celestial pole. In use, the observer aligns the time of day marked around the edge of the upper disc with the date marked around the edge of the lower disc. The aperture then shows which stars are above the horizon.

plankton small, often microscopic, forms of plant and animal life that live in the upper layers of fresh and salt water, and are an important source of food for larger animals. Marine plankton is concentrated in areas where rising currents bring mineral salts to the surface.

plant organism that carries out photosynthesis, has cellulose cell walls and complex cells, and is immobile. A few parasitic plants have lost the ability to photosynthesize but are still considered to be plants.

Plants are autotrophs, that is, they make carbohydrates from water and carbon dioxide, and are the primary producers in all food chains, so that all animal life is dependent on them. They play a vital part in the carbon cycle, removing carbon dioxide from the atmosphere and generating oxygen. The study of plants is known as botany.

levels of complexity Many of the lower plants (the algae and bryophytes) consist of a simple body, or thallus, on which the organs of reproduction are borne. Simplest of all are the threadlike algae, for example *Spirogyra*, which consist of a chain of cells.

The seaweeds (algae) and mosses and liverworts (bryophytes) represent a further development, with simple, multicellular bodies that have specially modified areas in which the reproductive organs are carried. Higher in the morphological scale are the ferns, club mosses, and horsetails (pteridophytes). Ferns produce leaflike fronds bearing sporangia on their undersurface in which the spores are carried. The spores are freed and germinate to

produce small independent bodies carrying the sexual organs; thus the fern, like other pteridophytes and some seaweeds, has two quite separate generations in its life cycle (see *alternation of generations*).

The pteridophytes have special supportive water-conducting tissues, which identify them as vascular plants, a group which includes all seed plants, that is the gymnosperms (conifers, yews, cypresses, and ginkgos) and the angiosperms (flowering plants).

seed plants The seed plants are the largest group, and structurally the most complex. They are usually divided into three parts: root, stem, and leaves. Stems grow above or below ground. Their cellular structure is designed to carry water and salts from the roots to the leaves in the xylem, and sugars from the leaves to the roots in the phloem. The leaves manufacture the food of the plant by means of photosynthesis, which occurs in the chloroplasts they

contain. Flowers and cones are modified leaves arranged in groups, enclosing the reproductive organs from which the fruits and seeds result.

plantain any of a group of northern temperate plants. The great plantain (*P. major*) is low-growing with large oval leaves close to the ground, grooved stalks, and spikes of green flowers with purple anthers (in which the pollen matures) followed by seeds, which are used in bird food. (Genus *Plantago*, family Plantaginaceae.)

The most common introduced species is the ribwort plantain (*P. lanceolata*), native to Europe and Asia and a widespread weed in Australia, Europe, and America. Many other species are troublesome weeds.

A type of banana is also known as plantain.

plantation large farm or estate where commercial production of one crop – such as rubber (in Malaysia), palm oil (in Nigeria), or tea (in Sri Lanka) – is carried out. Plantations are usually owned by large companies, often multinational corporations, and run by an estate manager. Many plantations were established in countries under colonial rule, using slave labour.

plant classification taxonomy or classification of plants. Originally the plant kingdom included bacteria, diatoms, dinoflagellates, fungi, and slime moulds, but these are not now thought of as plants. The groups that are always classified as plants are the bryophytes (mosses and liverworts), pteridophytes (ferns, horse-tails, and club mosses), gymnosperms (conifers, yews, cypresses, and ginkgos), and angiosperms (flowering plants). The angiosperms are split into monocotyledons (for example, orchids, grasses, lilies) and dicotyledons (for example, oak, buttercup, geranium, and daisy).

The basis of plant classification was established by the Swedish naturalist Carolus Linnaeus. Among the angiosperms, it is largely based on the number and arrangement of the flower parts.

The unicellular algae, such as *Chlamydomonas*, are often now put with the protists (single-celled organisms) instead of the plants. Some classification schemes even classify the multicellular algae (seaweeds and freshwater weeds) in a new kingdom, the Protocista, along with the protists.

plant hormone substance produced by a plant that has a marked effect on its growth, flowering, leaf fall, fruit ripening, or some other process. Examples include auxin, gibberellin, ethylene, and cytokinin.

Unlike animal hormones, these substances are not produced by a particular area of the plant body, and they may be less specific in their effects. It has therefore been suggested that they should not be described as hormones at all.

plant propagation production of plants. Botanists and horticulturalists can use a wide variety of means for propagating plants. There are the natural techniques of vegetative reproduction, together with cuttings, grafting, and micropropagation. The range is wide because most plant tissue, unlike animal tissue, can give rise to the complete range of tissue types within a particular species.

plaque any abnormal deposit on a body surface, especially the thin, transparent film of sticky protein (called mucus) and bacteria on tooth surfaces. If not removed, this film forms tartar (calculus), promotes tooth decay, and leads to gum disease. Another form of plaque is a deposit of fatty or fibrous material in the walls of blood vessels causing atheroma.

Plaskett's star the most massive binary star known, consisting of two supergiants of about 40 and 50 solar masses, orbiting each other every 14.4 days. Plaskett's star lies in the constellation Monoceros and is named after Canadian astronomer John S. Plaskett (1865–1941), who identified it as a binary star and discovered its massive nature in 1922.

plasmapheresis technique for acquiring plasma from blood. Blood is withdrawn from the patient and separated into its components (plasma and blood cells) by centrifugal force in a continuous-flow cell separator. Once separated, the plasma is available for specific treatments. The blood cells are transfused back into the patient.

plasma torch cutting device used mainly in metallurgy. It works by passing a strong electric current through a rarefied gas, ionizing it to produce temperatures on impact of up to 8,000°C/4,500°F.

plasmid small, mobile piece of DNA found in bacteria and used in genetic engineering. Plasmids are separate from the bacterial chromosome but still multiply during cell growth. Their size ranges from 3% to 20% of the size of the chromosome. There is usually only one copy of a single plasmid per cell, but occasionally several are found. Some plasmids carry 'fertility genes' that enable them to move from one bacterium to another and transfer genetic information between strains. Plasmid genes determine a wide variety of bacterial properties including resistance to antibiotics and the ability to produce toxins.

plasmolysis the separation of the plant cell cytoplasm from the cell wall as a result of water loss. As moisture leaves the vacuole the total volume of the cytoplasm decreases while the cell itself, being rigid, hardly changes. Plasmolysis is induced in the laboratory by immersing a plant cell in a strongly saline or sugary solution, so that water is lost by osmosis. Plasmolysis is unlikely to occur in the wild except in severe conditions.

plaster of Paris form of calcium sulphate, obtained from gypsum; it is mixed with water for making casts and moulds.

plastic any of the stable synthetic materials that are fluid at some stage in their manufacture, when they can be shaped, and that later set to rigid or semi-rigid solids. Plastics today are chiefly derived from petroleum. Most are polymers, made up of long chains of identical molecules.

environmental influence Since plastics have afforded an economical replacement for ivory in the manufacture of piano keys and billiard balls, the industrial chemist may well have been responsible for the survival of the elephant.

Most plastics cannot be broken down by microorganisms, so cannot easily be disposed of. Incineration leads to the release of toxic fumes, unless carried out at very high temperatures.

plastic surgery surgical speciality concerned with the repair of congenital defects and the reconstruction of tissues damaged by disease or injury, including burns. If a procedure is undertaken solely for reasons of appearance, for example, the removal of bags under the eyes or a double chin, it is called cosmetic surgery.

A doctor is a man who can distinguish the possible from the impossible.

plastid general name for a cell organelle of plants that is enclosed by a double membrane and contains a series of internal membranes and vesicles. Plastids contain DNA and are produced by division of existing plastids. They can be classified into two main groups: the **chromoplasts**, which contain pigments such as carotenes and chlorophyll, and the **leucoplasts**, which are colourless; however, the distinction between the two is not always clear-cut.

Chloroplasts are the major type of chromoplast. They contain chlorophyll, are responsible for the green coloration of most plants, and perform photosynthesis. Other chromoplasts give flower petals and fruits their distinctive colour. Leucoplasts are food-storage bodies and include amyloplasts, found in the roots of many plants, which store large amounts of starch.

plate or **tectonic plate**, one of several sections of lithosphere approximately 100 km/60 mi thick and at least 200 km/120 mi across, which together comprise the outermost layer of the Earth like the pieces of the cracked surface of a hard-boiled egg.

The plates are made up of two types of crustal material: oceanic crust (sima) and continental crust (sial), both of which are underlain by a solid layer of mantle. Dense oceanic crust lies beneath Earth's oceans and consists largely of basalt. Continental crust, which underlies the continents and their continental shelves, is thicker, less dense, and consists of rocks rich in silica and aluminium.

Due to convection in the Earth's mantle (see plate tectonics) these pieces of lithosphere are in motion, riding on a more plastic layer of the mantle, called the asthenosphere. Mountains, volcanoes, earthquakes, and other geological features and phenomena all come about as a result of interaction between the plates.

plateau elevated area of fairly flat land, or a mountainous region in which the peaks are at the same height. An **intermontane plateau** is one surrounded by mountains. A **pedmont plateau** is one that lies between the mountains and low-lying land. A **continental plateau** rises abruptly from low-lying lands or the sea. Examples are the Tibetan Plateau and the Massif Central in France.

platelet tiny disc-shaped structure found in the blood, which helps it to clot. Platelets are not true cells, but membrane-bound cell fragments without nuclei that bud off from large cells in the bone marrow.

They play a vital role in blood clotting as they release blood clotting factors at the site of a cut. Over twelve clotting factors have been discovered and they produce a complex series of reactions which ultimately leads to fibrinogen, the inactive blood sealant always found in the plasma, being converted into fibrin. Fibrin aggregates into threads which form the fabric of a blood clot.

plate tectonics theory formulated in the 1960s to explain the phenomena of continental drift and seafloor spreading, and the formation of the major physical features of the Earth's surface. The Earth's outermost layer, the lithosphere, is regarded as a jigsaw puzzle of rigid major and minor plates that move relative to each other, probably under the influence of convection currents in the mantle beneath. At the margins of the plates, where they collide or move apart, major landforms such as fold mountains, volcanoes, ocean trenches, and ocean ridges are created. The rate of drift is at most 15 cm/6 in per year.

The concept of plate tectonics brings together under one unifying theory many previously unrelated phenomena observed in the Earth's crust. The size of the crust plates is variable, as they are constantly changing, but six or seven large plates now cover much of the Earth's surface, the remainder being occupied by a number of smaller plates. Each large plate may include both continental and ocean crust. As a result of seismic studies it is known that the lithosphere is a rigid layer extending to depths of 50–100 km/30–60 mi, overlying the upper part of the mantle (the asthenosphere), which is composed of rocks very close to melting point, with a low shear strength. This zone of mechanical weakness allows the

Well-illustrated site on this geological phenomenon. As well as the plentiful illustrations, this site also has a good clear manner of explaining the way the plates of the Earth's crust interact to produce seismic activity.

plate tectonics The three main types of action in plate tectonics. (top) Seafloor spreading. The upwelling of magma forces apart the crust plates, producing new crust at the joint. Rapid extrusion of magma produces a domed ridge; more gentle spreading produces a central valley. (middle) The drawing downwards of an oceanic plate beneath a continent produces a range of volcanic fold mountains parallel to the plate edge. (bottom) Collision of continental plates produces immense fold mountains, such as the Himalayas. Younger mountains are found near the coast with older ranges inland. The plates of the Earth's lithosphere are always changing in size and shape of each plate as material is added at constructive margins and removed at destructive margins. The process is extremely slow, but it means that the tectonic history of the Earth cannot be traced back further than about 200 million years.

movement of the overlying plates. The margins of the plates are defined by major earthquake zones and belts of volcanic and tectonic activity, which have been well known for many years. Almost all earthquake, volcanic, and tectonic activity is confined to the margins of plates, and shows that the plates are in constant motion.

platinum Spanish *platina* 'little silver' (*plata* 'silver') heavy, soft, silver-white, malleable and ductile, metallic element, symbol Pt, atomic number 78, relative atomic mass 195.09. It is the first of a group of six metallic elements (platinum, osmium, iridium, rhodium, ruthenium, and palladium) that possess similar traits, such as resistance to tarnish, corrosion, and attack by acid, and that often occur as free metals (native metals). They often occur in natural alloys with each other, the commonest of which is osmiridium. Both pure and as an alloy, platinum is used in dentistry, jewellery, and as a catalyst.

Platonic solid in geometry, another name for a regular polyhedron, one of five possible three-dimensional figures with all its faces the same size and shape.

Platyhelminthes invertebrate phylum consisting of the flatworms.

platypus monotreme, or egg-laying, mammal *Ornithorhynchus anatinus*, found in Tasmania and E Australia. Semiaquatic, it has small eyes and no external ears, and jaws resembling a duck's beak. It lives in long burrows along river banks, where it lays two eggs in a rough nest. It feeds on water worms and insects, and when full-grown is 60 cm/2 ft long.

According to research by Australian scientists in 1995, platypuses locate their prey by detecting the small electric fields produced by their nerve and muscle activity.

REMARKABLE PLATYPUS

<http://www.anca.gov.au/plants/manageme/platintr.htm>

Comprehensive information on the shy monotreme presented by the Australian Natural Conservation Agency. Findings of latest research into platypuses is presented, together with recommendations to help preserve the species.

Platyrrhini New World monkeys, including the the families Callitrichidae (marmosets and tamarins) and Cebidae (including capuchin, spider, and howler monkeys). The term is now rarely used.

Platyrrhines are characterized by having nostrils that are widely spaced and face sideways. Compare with the Old World Catarrhini.

PlayStation in computing, market-leading games console made by Sony.

Pleiades in astronomy, an open star cluster about 400 light years away in the constellation Taurus, represented as the Seven Sisters of Greek mythology. Its brightest stars (highly luminous, blue-white giants only a few million years old) are visible to the naked eye, but there are many fainter ones.

It is a young cluster, and the stars of the Pleiades are still surrounded by traces of the reflection nebula from which they formed, visible on long-exposure photographs.

pleiotropy process whereby a given gene influences several different observed characteristics of an organism. For example, in the fruit fly *Drosophila* the vestigial gene reduces the size of wings, modifies the halteres, changes the number of egg strings in the ovaries, and changes the direction of certain bristles. Many human syndromes are caused by pleiotropic genes, for example Marfan's syndrome where the slender physique, hypermobility of the joints, elongation of the limbs, dislocation of the lens, and susceptibility to heart disease are all caused by one gene.

Pleistocene first epoch of the Quaternary period of geological time, beginning 1.64 million years ago and ending 10,000 years ago. The polar ice caps were extensive and glaciers were abundant during the ice age of this period, and humans evolved into modern *Homo sapiens sapiens* about 100,000 years ago.

Plesetsk rocket-launching site 170 km/105 mi S of Archangel, Russia. From 1966 the USSR launched artificial satellites from here, mostly military.

plesiosaur prehistoric carnivorous marine reptile of the Jurassic and Cretaceous periods, which reached a length of 12 m/36 ft, and had a long neck and paddlelike limbs. The plesiosaurs evolved from the plesiosaurs.

pleuracanth extinct freshwater sharklike fish with a diphycceral (symmetrical) tail and a long fin down the back. They existed from Devonian to Triassic times, and were abundant in the Carboniferous period. Little is known of their ancestry.

pleurisy inflammation of the pleura, the thin, secretory membrane that covers the lungs and lines the space in which they rest. Pleurisy is nearly always due to bacterial or viral infection, but may also be a complication of other diseases.

Normally the two lung surfaces move easily on one another, lubricated by small quantities of fluid. When the pleura is inflamed, the surfaces may dry up or stick together, making breathing difficult and painful. Alternatively, a large volume of fluid may collect in the pleural cavity, the space between the two surfaces, and pus may accumulate.

Plimsoll line loading mark painted on the hull of merchant ships, first suggested by English politician Samuel Plimsoll. It shows the depth to which a vessel may be safely (and legally) loaded.

Pliocene 'almost recent' fifth and last epoch of the Tertiary period of geological time, 5.2-1.64 million years ago. The earliest hominid, the humanlike ape *Australopithecines*, evolved in Africa.

pliosaur prehistoric carnivorous marine reptile, descended from the plesiosaurs, but with a shorter neck, and longer head and jaws. It was approximately 5 m/15 ft long. In 1989 the skeleton of one of a previously unknown species was discovered in N Queensland, Australia. A hundred million years ago, it lived in the sea that once covered the Great Artesian Basin.

plotter or **graph plotter** device that draws pictures or diagrams under computer control.

Plotters are often used for producing business charts, architectural plans, and engineering drawings. Flatbed plotters move a pen up and down across a flat drawing surface, whereas roller plotters roll the drawing paper past the pen as it moves from side to side.

Plough, the in astronomy, a popular name for the most prominent part of the constellation ζ Ursa Major.

plough agricultural implement used for tilling the soil. The plough dates from about 3500 BC, when oxen were used to pull a simple wooden blade, or ard. In about 500 BC the iron ploughshare came into use. By about AD 1000 horses as well as oxen were being used to pull wheeled ploughs, equipped with a ploughshare for cutting a furrow, a blade for forming the walls of the furrow (called a coulter), and a mouldboard to turn the furrow. In the 18th century an innovation introduced by Robert Ransome (1753-1830), led to a reduction in the number of animals used to draw a plough: from 8-12 oxen, or 6 horses, to a 2- or 4-horse plough.

Steam ploughs came into use in some areas in the 1860s, superseded half a century later by tractor-drawn ploughs. The modern plough consists of many 'bottoms', each comprising a curved ploughshare and angled mouldboard. The bottom is designed so that it slices into the ground and turns the soil over.

plover any shore bird of the family Charadriidae, order Charadriiformes, found worldwide. Plovers are usually black or brown above and white below, and have short bills. The European golden plover *Pluvialis apricaria*, of heathland and sea coast, is about 28 cm/11 in long. In winter the upper parts are a sooty black with large yellow spots, and white throat and underparts, changing to black in the spring. It nests on the ground, laying four yellowish eggs blotched with brown.

The ringed plover *Charadrius hiaticula*, with a black and white face, and black band on the throat, is found on British shores, nesting in a scrape on a beach or amongst shingle. The largest of the ringed plovers is the killdeer *Charadrius vociferus*, so called because of its cry.

plug and play in computing, item of hardware or software that configures itself and the user's system automatically when first installed. Having been thus 'plugged' in, it can be used ('played' with) immediately. In the PC industry, suppliers have adopted a form of Plug and Play (PnP) developed by Microsoft and Intel in 1993.

plug-in in computing, small add-on file which enhances the operation of an application program, often by enabling it to launch, display or interpret a file created using another one. The first plug-ins were made for graphics programs in the 1980s, but the practice became very popular in the mid-1990s, when a range of plug-ins became available to enhance the multimedia capabilities of Netscape's Navigator browser. Plug-ins are often created and distributed by independent developers rather than the manufacturer of the program they extend.

plug, three-pin insulated device with three metal projections used to connect the wires in the cable of an electrical appliance

plotter A flatbed plotter, which may be used to produce plans, graphs, and other drawings. The moving arm, holding a pen of the appropriate colour, travels over the surface of the paper.

with the wires of a mains supply socket. In the UK, plugs have pins of rectangular section, and must comply with the British Standard BS 1363 laid down by the British Standards Institute. A plug must be designed carefully with regard to construction, labelling, clearance between components, accessibility of live parts, earthing (see earth), and terminal design. Before being approved, it is tested for the resistance of its insulation, temperature rise while in use, anchorage of cables, mechanical strength, and susceptibility to damage by heat and rust.

plum smooth-skinned, oval, reddish-purple or green edible fruit of the plum tree. There are many varieties, including the Victoria, czar, egg-plum, greengage, and damson; the wild sloe (*P. spinosa*), which is the fruit of the blackthorn, is closely related. Dried plums are known as prunes. (*Prunus domestica*, family Rosaceae.)

plumbago alternative name for the mineral graphite.

plumule part of a seed embryo that develops into the shoot, bearing the first true leaves of the plant. In most seeds, for example the sunflower, the plumule is a small conical structure without any leaf structure. Growth of the plumule does not occur until the cotyledons have grown above ground. This is epigeal germination. However, in seeds such as the broad bean, a leaf structure is visible on the plumule in the seed. These seeds develop by the plumule growing up through the soil with the cotyledons remaining below the surface. This is known as hypogeal germination.

Pluto in astronomy, the smallest and, usually, outermost planet of the Solar System. The existence of Pluto was predicted by calculation by Percival Lowell and the planet was located by Clyde Tombaugh in 1930. Its highly elliptical orbit occasionally takes it within the orbit of Neptune, as in 1979–99. Pluto has a mass about 0.002 of that of Earth.

mean distance from the Sun 5.8 billion km/3.6 billion mi

equatorial diameter 2,300 km/1,438 mi

rotation period 6.39 Earth days

year 248.5 Earth years

atmosphere thin atmosphere with small amounts of methane gas **surface** low density, composed of rock and ice, primarily frozen methane; there is an ice cap at Pluto's north pole

satellites one moon, Charon

PLUTO AND CHARON

plutonic rock igneous rock derived from magma that has cooled and solidified deep in the crust of the Earth; granites and gabbros are examples of plutonic rocks.

plutonium silvery-white, radioactive, metallic element of the actinide series, symbol Pu, atomic number 94, relative atomic mass 239.13. It occurs in nature in minute quantities in pitchblende and other ores, but is produced in quantity only synthetically. It has six allotropic forms (see allotropy) and is one of three fissile elements (elements capable of splitting into other elements – the others are thorium and uranium). The element has awkward physical properties and is the most toxic substance known.

plywood manufactured panel of wood widely used in building. It consists of several thin sheets, or plies, of wood, glued together with the grain (direction of the wood fibres) of one sheet at right angles to the grain of the adjacent plies. This construction gives plywood equal strength in every direction.

PLYWOOD

Many people know that Alfred Nobel, founder of the prizes that bear his name, was the inventor of dynamite. However, it is less well known that his father, Immanuel Nobel, was the inventor of plywood.

pneumatic drill drill operated by compressed air, used in mining and tunnelling, for drilling shot holes (for explosives), and in road repairs for breaking up pavements. It contains an air-operated piston that delivers hammer blows to the drill bit many times a second. The French engineer Germain Sommeiller (1815–1871) developed the pneumatic drill in 1861 for tunnelling in the Alps.

pneumatophore erect root that rises up above the soil or water and promotes gas exchange. Pneumatophores, or breathing roots, are formed by certain swamp-dwelling trees, such as mangroves, since there is little oxygen available to the roots in waterlogged conditions. They have numerous pores or lenticels over their surface, allowing gas exchange.

pneumoconiosis disease of the lungs caused by an accumulation of dust, especially from coal, asbestos, or silica. Inhaled particles make the lungs gradually fibrous and the victim has difficulty breathing. Over many years the condition causes severe disability.

pneumonectomy surgical removal of all or part of a lung.

pneumonia inflammation of the lungs, generally due to bacterial or viral infection but also to particulate matter or gases. It is characterized by a build-up of fluid in the alveoli, the clustered air sacs (at the ends of the air passages) where oxygen exchange takes place.

Symptoms include fever and pain in the chest. With widespread availability of antibiotics, infectious pneumonia is much less common than it was. However, it remains a dire threat to patients whose immune systems are suppressed (including transplant recipients and AIDS and cancer victims) and to those who are critically ill or injured. Pneumocystis pneumonia is a leading cause of death in AIDS.

pneumothorax the presence of air in the pleural cavity, between a lung and the chest wall. It may be due to a penetrating injury of the lung or to lung disease, or it may occur without apparent cause (spontaneous pneumothorax) in an otherwise healthy person. Prevented from expanding normally, the lung is liable to collapse.

p-n junction diode in electronics, another name for semiconductor diode.

pochard any of various diving ducks found in Europe and North America, especially the genus *Aythya*. They feed largely on water plants. The nest is made in long grass on the borders of lakes and pools.

pod in botany, a type of fruit that is characteristic of legumes (plants belonging to the Leguminosae family), such as peas and beans. It develops from a single carpel and splits down both sides when ripe to release the seeds.

In certain species the seeds may be ejected explosively due to uneven drying of the fruit wall, which sets up tensions within the fruit. In agriculture, the name 'legume' is used for the crops of the pea and bean family. 'Grain legume' refers to those that are grown mainly for their dried seeds, such as lentils, chick peas, and soya beans.

podzol or **podsol** type of light-coloured soil found predominantly under coniferous forests and on moorlands in cool regions where rainfall exceeds evaporation. The constant downward movement of water leaches nutrients from the upper layers, making podzols poor agricultural soils.

The leaching of minerals such as iron, lime, and alumina leads to the formation of a bleached zone, often also depleted of clay.

These minerals can accumulate lower down the soil profile to form a hard, impermeable layer which restricts the drainage of water through the soil.

poikilothermy the condition in which an animal's body temperature is largely dependent on the temperature of the air or water in which it lives. It is characteristic of all animals except birds and mammals, which maintain their body temperatures by homeothermy (they are 'warm-blooded').

Poikilotherms have behavioural means of temperature control; they can warm themselves up by basking in the sun, or shivering, and can cool themselves down by sheltering from the Sun under a rock or by bathing in water.

Poikilotherms are often referred to as 'cold-blooded animals', but this is not really correct: their internal temperatures, regulated by behavioural means, are often as high as those of birds and mammals during the times they need to be active for feeding and reproductive purposes, and may be higher, for example in very hot climates. The main difference is that their body temperatures fluctuate more than those of homeotherms.

poinsettia or **Christmas flower** winter-flowering shrub with large red leaves encircling small greenish-yellow flowers. It is native to Mexico and tropical America and is a popular houseplant in North America and Europe. (*Euphorbia pulcherrima*, family Euphorbiaceae.)

point in geometry, a basic element, whose position in the Cartesian system may be determined by its ϕ coordinates.

Mathematicians have had great difficulty in defining the point, as it has no size, and is only the place where two lines meet. According to the Greek mathematician Euclid, (i) a point is that which has no part; (ii) the straight line is the shortest distance between two points.

point and click in computing, basic method of navigating a Web page or a multimedia CD-ROM. The user points at an object using a cursor and a mouse, and clicks to activate it.

pointer any of several breeds of gun dog, bred especially to scent the position of game and indicate it by standing, nose pointed towards it, often with one forefoot raised, in silence. English pointers have smooth coats, mainly white mixed with black, tan, or dark brown. They stand about 60 cm/24 in tall, and weigh 28 kg/62 lb.

A very similar breed, the German short-haired pointer, was developed in the 19th century to point and also to pursue game.

The Weimeraner is another pointing breed.

point of sale (POS) in business premises, the point where a sale is transacted, for example, a POS terminal such as a supermarket checkout. In conjunction with electronic funds transfer, point of sale is part of the terminology of 'cashless shopping', enabling buyers to transfer funds directly from their bank accounts to the shop's.

point-of-sale terminal (POS terminal) computer terminal used in shops to input and output data at the point where a sale is transacted; for example, at a supermarket checkout. The POS terminal inputs information about the identity of each item sold, retrieves the price and other details from a central computer, and prints out a fully itemized receipt for the customer. It may also input sales data for the shop's computerized stock-control system.

A POS terminal typically has all the facilities of a normal till, including a cash drawer and a sales register, plus facilities for the direct capture of sales information - commonly, a laser scanner for reading bar codes. It may also be equipped with a device to read customers' bank cards, so that payment can be transferred electronically from the customers' bank accounts to the shop's (see ϕ EFTPOS).

Point-to-Point Protocol in computing, method of connecting a computer to the Internet; usually abbreviated to PPP.

poise c.g.s. unit (symbol P) of dynamic viscosity (the property of liquids that determines how readily they flow). It is equal to one dyne-second per square centimetre. For most liquids the centipoise (one hundredth of a poise) is used. Water at 20°C/68°F has a viscosity of 1.002 centipoise.

Poiseuille's formula in physics, a relationship describing the rate of flow of a fluid through a narrow tube. For a capillary (very narrow) tube of length l and radius r with a pressure difference p between its ends, and a liquid of viscosity η , the velocity of flow expressed as the volume per second is $\pi pr^4/8\eta$. The formula was devised in 1843 by French physicist Jean Louis Poiseuille (1799-1869).

poison or **toxin** any chemical substance that, when introduced into or applied to the body, is capable of injuring health or destroying life.

The liver removes some poisons from the blood. The majority of poisons may be divided into corrosives, such as sulphuric, nitric, and hydrochloric acids; irritants, including arsenic and copper sulphate; narcotics such as opium, and carbon monoxide; and narcotic-irritants from any substances of plant origin including carbolic acid and tobacco.

how poisons work Corrosives all burn and destroy the parts of the body with which they come into contact; irritants have an irritating effect on the stomach and bowels; narcotics affect the brainstem and spinal cord, inducing a stupor; and narcotic-irritants can cause intense irritations and finally act as narcotics.

FROG

There is a species of frog found in Colombia that produces enough poison to kill 1,500 people. Pharmacologists are keen to see if the venom of *Phylllobates terribilis* might be the basis of a new painkiller.

polar coordinates in mathematics, a way of defining the position of a point in terms of its distance r from a fixed point (the origin) and its angle θ to a fixed line or axis. The coordinates of the point are (r, θ) .

Often the angle is measured in radians, rather than degrees. The system is useful for defining positions on a plane in programming the operations of, for example, computer-controlled cloth- and metal-cutting machines.

polarimetry in astronomy, any technique for measuring the degree of polarization of radiation from stars, galaxies, and other objects.

Polaris or **Pole Star** or **North Star** bright star closest to the north celestial pole, and the brightest star in the constellation ϕ Ursa Minor. Its position is indicated by the 'pointers' in ϕ Ursa Major. Polaris is a yellow ϕ super giant about 500 light years away. It is also known as Alpha Ursae Minoris.

It currently lies within 1° of the north celestial pole; ϕ precession (Earth's axial wobble) will bring Polaris closest to the celestial pole (less than 0.5° away) in about AD 2100. Then its distance will start to increase, reaching 1° in 2205 and 47° in 28000. Other bright stars that have been, or will be close to the north celestial pole are Alpha Draconis (3000 BC), Gamma Cephei (AD 4000), Alpha Cephei (AD 7000), and ϕ Vega (AD 14000).

polarized light light in which the electromagnetic vibrations take place in one particular plane. In ordinary (unpolarized) light, the electric fields vibrate in all planes perpendicular to the direction of propagation. After reflection from a polished surface or transmission through certain materials (such as Polaroid), the electric fields are confined to one direction, and the light is said to be linearly polarized. In circularly polarized and elliptically polarized light, the electric fields are confined to one direction, but the direction rotates as the light propagates. Polarized light is used to test the strength of sugar solutions, to measure stresses in transparent materials, and to prevent glare.

polarography electrochemical technique for the analysis of oxidizable and reducible compounds in solution. It involves the diffusion of the substance to be analyzed onto the surface of a small

electrode, usually a bead of mercury, where oxidation or reduction occurs at an electric potential characteristic of that substance.

Polaroid camera instant-picture camera, invented by Edwin Land in the USA in 1947. The original camera produced black-and-white prints in about one minute. Modern cameras can produce black-and-white prints in a few seconds, and colour prints in less than a minute. An advanced model has automatic focusing and exposure.

It ejects a piece of film on paper immediately after the picture has been taken.

The film consists of layers of emulsion and colour dyes together with a pod of chemical developer. When the film is ejected the pod bursts and processing occurs in the light, producing a paper-backed print.

polar reversal change in polarity of Earth's magnetic field. Like all magnets, Earth's magnetic field has two opposing regions, or poles, one of attraction and one of repulsion, positioned approximately near geographical North and South Poles. During a period of normal polarity the region of attraction corresponds with the North Pole. Today, a compass needle, like other magnetic materials, aligns itself parallel to the magnetizing force and points to the North Pole. During a period of reversed polarity, the region of attraction would change to the South Pole and the needle of a compass would point south.

Studies of the magnetism retained in rocks at the time of their formation (like little compasses frozen in time) have shown that the polarity of the magnetic field has reversed repeatedly throughout geological time.

Polar reversals are a random process. Although the average time between reversals over the last ten million years has been 250,000 years, the rate of reversal has changed continuously over geological time. The most recent reversal was 700,000 years ago; scientists have no way of predicting when the next reversal will occur. The reversal process takes about a thousand years. Movements of Earth's molten core are thought to be responsible for the magnetic field and its polar reversals. Dating rocks using distinctive sequences of magnetic reversals is called palaeomagnetic stratigraphy.

polder area of flat reclaimed land that used to be covered by a river, lake, or the sea. Polders have been artificially drained and protected from flooding by building dykes. They are common in the Netherlands, where the total land area has been increased by nearly one-fifth since AD 1200. Such schemes as the Zuider Zee project have provided some of the best agricultural land in the country.

pole either of the geographic north and south points of the axis about which the Earth rotates. The geographic poles differ from the magnetic poles, which are the points towards which a freely suspended magnetic needle will point.

In 1985 the magnetic north pole was some 350 km/218 mi NW of Resolute Bay, Northwest Territories, Canada. It moves northwards about 10 km/6 mi each year, although it can vary in a day about 80 km/50 mi from its average position. It is relocated every decade in order to update navigational charts.

It is thought that periodic changes in the Earth's core cause a reversal of the magnetic poles (see *polar reversal*, magnetic field). Many animals, including migrating birds and fish, are believed to orient themselves partly using the Earth's magnetic field. A permanent scientific base collects data at the South Pole.

polecat Old World weasel *Mustela putorius* with a brown back and dark belly and two yellow face patches. The body is about 50 cm/20 in long and it has a strong smell from anal gland secretions. It is native to Asia, Europe, and N Africa. In North America, *skunks* are sometimes called polecats. A ferret is a domesticated polecat.

pole, magnetic see *magnetic pole*.

Pole Star another name for *Polaris*, the northern pole star. There is no bright star near the southern celestial pole.

polio (poliomyelitis) viral infection of the central nervous system affecting nerves that activate muscles. The disease used to be known as infantile paralysis. Two kinds of vaccine are available,

one injected (see *Polio*) and one given by mouth. The Americas were declared to be polio-free by the Pan American Health Organization in 1994. In 1997 the World Health Organization reported that causes of polio had dropped by nearly 90% since 1988 when the organization began its programme to eradicate the disease by the year 2000. Most cases remain in Africa and south-east Asia.

The polio virus is a common one and its effects are mostly confined to the throat and intestine, as with influenza or a mild digestive upset. There may also be muscle stiffness in the neck and back. Paralysis is seen in about 1% of cases, and the disease is life-threatening only if the muscles of the throat and chest are affected. Cases of this kind, once entombed in an 'iron lung', are today maintained on a respirator.

It is courage based on confidence, not daring, and it is confidence based on experience.

pollack marine fish *Pollachius virens* of the cod family, growing to 75 cm/2.5 ft, and found close to the shore on both sides of the N Atlantic.

pollarding type of pruning whereby the young branches of a tree are severely cut back, about 2-4 m/6-12 ft above the ground, to produce a stumpy trunk with a rounded, bushy head of thin new branches. It is similar to *coppcing*.

pollen the grains of *seed* plants that contain the male gametes. In *angiosperms* (flowering plants) pollen is produced within

pollen Pollination, the process by which pollen grains transfer their male nuclei (gametes) to the ovary of a flower. The pollen grains land on the stigma and form a pollen tube that grows down into the ovary. The male nuclei travel along the pollen tube.

anthers; in most gymnosperms (cone-bearing plants) it is produced in male cones. A pollen grain is typically yellow and, when mature, has a hard outer wall. Pollen of insect-pollinated plants (see pollination) is often sticky and spiny and larger than the smooth, light grains produced by wind-pollinated species.

The outer wall of pollen grains from both insect-pollinated and wind-pollinated plants is often elaborately sculptured with ridges or spines so distinctive that individual species or genera of plants can be recognized from their pollen. Since pollen is extremely resistant to decay, useful information on the vegetation of earlier times can be gained from the study of fossil pollen. The study of pollen grains is known as palynology.

pollen tube outgrowth from a pollen grain that grows towards the ovule, following germination of the grain on the stigma. In angiosperms (flowering plants) the pollen tube reaches the ovule by growing down through the style, carrying the male gametes

inside. The gametes are discharged into the ovule and one fertilizes the egg cell.

pollination the process by which pollen is transferred from one plant to another. The male gametes are contained in pollen grains, which must be transferred from the anther to the stigma in angiosperms (flowering plants), and from the male cone to the female cone in gymnosperms (cone-bearing plants). Fertilization (not the same as pollination) occurs after the growth of the pollen tube to the ovary. Self-pollination occurs when pollen is transferred to a stigma of the same flower, or to another flower on the same plant; cross-pollination occurs when pollen is transferred to another plant. This involves external pollen-carrying agents, such as wind (see anemophily), water (see hydrophily), insects, birds (see ornithophily), bats, and other small mammals.

Animal pollinators carry the pollen on their bodies and are attracted to the flower by scent, or by the sight of the petals. Most

Southeast Asia: Eco-Disaster 1997

by Charles Arthur

This was probably the biggest short-term eco-disaster modern humanity has ever witnessed. It began with an agricultural practice that has been followed for centuries in Indonesia. Late in August, villagers there began clearing land by setting fire to the forest. But they were joined by companies eager to create new space for rubber and palm oil plantations. Overall, hundreds of individual fires were purposely set in the expectation that the monsoon rains would quickly come and put them out, leaving the land easy to clear. A combination of events led to the fires going out of control. They were not stopped when they were small because of the commercial desire to keep them going. The peat and lignite began to burn underneath the soil, which was dry from the summer. The monsoon, nature's own fire extinguisher, was late and unusually small. Winds whipped up the flames, giving the fires new life and blowing the ashes overseas.

Smoke and haze

Singapore was one of the countries on the receiving end of the smoke and haze. Within a month of the fires starting, the sun became invisible during the day. The haze pollution index, issued daily, went above 500 – the level at which it is officially hazardous. An index of between 0 and 50 is considered 'good', between 50 and 100 is 'moderate', and 100 to 200 is 'unhealthy'.

By the end of September, Britain was preparing to evacuate diplomats' families and issued health warnings to tourists in the affected area. One journalist described the first effects of standing amidst the 'darkness at noon: an acid taste around the mouth, next a stinging sensation in the eyes and the pervasive reek of carbonized wood. After a few minutes, a tightening in the chest.'

Meanwhile, a convoy of more than 1,200 firemen set off in what turned out to be a vain attempt to fight the fires, reckoned by then to have consumed 1.5 million acres of forest. Countries affected by the smog, which was now clearly visible in satellite photographs as a swathe across the ocean and land, included Malaysia, Indonesia, Singapore, the Philippines, Brunei, and Thailand.

Human toll

The pollution then began to have a more direct effect. On the night of 26 September, two cargo ships collided, killing 29 crewmen, in the Straits of Malacca – an accident blamed on poor visibility caused by the haze. The following day, an A300B4 Airbus on a Garuda Airlines internal flight in Indonesia, from Jakarta to the city of Medan on Sumatra, crashed into a rice field in a mountainous area of northern Sumatra. The 222 passengers and 12 crew were all killed. The crash was initially blamed on the smog haze, a suspicion that intensified the next day when the visibility at Medan airport remained so poor that

relatives of the crash victims were unable to leave for it from Jakarta aboard a Boeing 747 jumbo jet that the airline had made available. However, the transcript of the conversation between the pilot and the control tower subsequently showed that the pilot mistook left for right, and turned in the wrong direction for landing. Whether this was compounded by the lowered visibility remains an open question. But in subsequent weeks the Indonesian government cancelled some domestic internal flights because, from the air, the pilots could not see the airports where they were meant to land.

By this time, two people had also died directly from smoke inhalation, while on Borneo and Sumatra, where the fires were raging, hospitals had treated at least 32,000 victims of smoke inhalation. On Borneo, which is shared between Indonesia, Malaysia, and Brunei, normal life came to a halt while people waited, and hoped, for the monsoon.

Climate change

The delay in the monsoon – which the original land-burners had expected – was pinned on a reversal in the direction of El Niño, an enormous ocean current in the Pacific which normally brings warm, wet air from the south. Instead it brought drier air and little rain. It was not only humans or plants that suffered as the fires raged. The habitats of orang-utans and other rare species in Borneo fell to the flames, and hundreds of other species, including insects, animals, and birds, faced threats to their supply of food and water, and to the valuable nesting space for their young.

At last, on 30 September, Kuala Lumpur received the first downpours – though only enough to drop its pollution index to near 100, from 155. The peak reading for the whole period was at Sarawak, in Indonesia, which recorded a level of 835. The haze did not disappear in October: Kuala Lumpur was still reporting visibility down to a few hundred metres at ground level at noon in the middle of the month. The problem persisted until November, when the monsoon arrived in full. By then, though, some of the smoke had reached northern Australia.

Lasting effects

The long-term effects of the fire are hard to predict. The ecological effects are impossible to estimate, because forest species – both animal and plant – often prove remarkably resilient to fire, recolonizing burnt areas more quickly than scientists predict. The revenues lost from tourism amounted to millions of dollars. Almost as soon as the smoke began to clear, the country was plunged into a foreign exchange crisis on the international markets, partly sparked by fears about the strength of its economy following the fires.

flowers are adapted for pollination by one particular agent only. Bat-pollinated flowers tend to smell of garlic, rotting vegetation, or fungus. Those that rely on animals generally produce nectar, a sugary liquid, or surplus pollen, or both, on which the pollinator feeds. Thus the relationship between pollinator and plant is an example of mutualism, in which both benefit. However, in some plants the pollinator receives no benefit (as in pseudocopulation), while in others, nectar may be removed by animals that do not effect pollination.

polling in computing, a technique for transferring data from a terminal to the central computer of a multiuser system. The computer automatically makes a connection with each terminal in turn, interrogates it to check whether it is holding data for transmission, and, if it is, collects the data.

pollinium group of pollen grains that is transported as a single unit during pollination. Pollinia are common in orchids.

polluter-pays principle the idea that whoever causes pollution is responsible for the cost of repairing any damage. The principle is accepted in British law but has in practice often been ignored; for example, farmers causing the death of fish through slurry pollution have not been fined the full costs of restocking the river.

pollution the harmful effect on the environment of by-products of human activity, principally industrial and agricultural processes – for example, noise, smoke, car emissions, chemical and radioactive effluents in air, seas, and rivers, pesticides, radiation, sewage (see sewage disposal), and household waste. Pollution contributes to the greenhouse effect. See also *air pollution*.

Pollution control involves higher production costs for the industries concerned, but failure to implement adequate controls may result in irreversible environmental damage and an increase in the incidence of diseases such as cancer. Radioactive pollution results from inadequate nuclear safety.

Transboundary pollution is when the pollution generated in one country affects another, for example as occurs with acid rain. Natural disasters may also cause pollution; volcanic eruptions, for example, cause ash to be ejected into the atmosphere and deposited on land surfaces.

As cruel a weapon as the cave man's club, the chemical barrage has been hurled against the fabric of life.

Pollux or **Beta Geminorum** the brightest star in the constellation Gemini, and the 17th-brightest star in the sky. Pollux is a yellow star with a true luminosity 45 times that of the Sun. It is 35 light years away.

The first-magnitude Pollux and the second-magnitude Castor, Alpha Geminorum, mark the heads of the Gemini twins. It is thought that the two stars may have changed their relative brightness since Bayer named them, as Alpha is usually assigned to the brightest star in a constellation.

polonium radioactive, metallic element, symbol Po, atomic number 84, relative atomic mass 210. Polonium occurs in nature in small amounts and was isolated from pitchblende. It is the element having the largest number of isotopes (27) and is 5,000 times as radioactive as radium, liberating considerable amounts of heat. It was the first element to have its radioactive properties recognized and investigated.

Polonium was isolated in 1898 from the pitchblende residues analyzed by French scientists Pierre and Marie Curie, and named after Marie Curie's native Poland.

polyanthus cultivated variety of primrose, with several flowers on one stalk, bred in a variety of colours. (Family Primulaceae)

polychlorinated biphenyl (PCB) any of a group of chlorinated isomers of biphenyl ($C_{12}H_{10}Cl_x$). They are dangerous industrial

chemicals, valuable for their fire-resisting qualities. They constitute an environmental hazard because of their persistent toxicity. Since 1973 their use has been limited by international agreement.

polyester synthetic resin formed by the condensation of polyhydric alcohols (alcohols containing more than one hydroxyl group) with dibasic acids (acids containing two replaceable hydrogen atoms). Polyesters are thermosetting plastics, used in making synthetic fibres, such as Dacron and Terylene, and constructional plastics. With glass fibre added as reinforcement, polyesters are used in car bodies and boat hulls.

polyethylene or **polyethene** polymer of the gas ethylene (technically called ethene, C_2H_4). It is a tough, white, translucent, waxy thermoplastic (which means it can be repeatedly softened by heating). It is used for packaging, bottles, toys, wood preservation, electric cable, pipes and tubing.

Polyethylene is produced in two forms: low-density polyethylene, made by high-pressure polymerization of ethylene gas, and high-density polyethylene, which is made at lower pressure by using catalysts. This form, first made in 1953 by German chemist Karl Ziegler, is more rigid at low temperatures and softer at higher temperatures than the low-density type. Polyethylene was first made in the 1930s at very high temperatures by ICI.

polygon in geometry, a plane (two-dimensional) figure with three or more straight-line sides. Common polygons have names which define the number of sides (for example, triangle, quadrilateral, pentagon).

These are all convex polygons, having no interior angle greater than 180° . The sum of the internal angles of a polygon having n sides is given by the formula $(2n - 4) \times 90^\circ$; therefore, the more sides a polygon has, the larger the sum of its internal angles and, in the case of a convex polygon, the more closely it approximates to a circle.

polygraph technical name for a lie detector.

PAVILION OF POLYHEDREALITY

<http://www.li.net/~george/pavilion.html>

Collection of images and instructions on how to make various polyhedrals, some from quite surprising materials.

polyhedron in geometry, a solid figure with four or more plane faces. The more faces there are on a polyhedron, the more closely it approximates to a sphere. Knowledge of the properties of polyhedra is needed in crystallography and stereochemistry to determine the shapes of crystals and molecules.

There are only five types of regular polyhedron (with all faces the same size and shape), as was deduced by early Greek

mathematicians; they are the tetrahedron (four equilateral triangular faces), cube (six square faces), octahedron (eight equilateral triangles), dodecahedron (12 regular pentagons) and icosahedron (20 equilateral triangles).

polymer compound made up of a large long-chain or branching matrix composed of many repeated simple units (**monomers**). There are many polymers, both natural (cellulose, chitin, lignin) and synthetic (polyethylene and nylon, types of plastic). Synthetic polymers belong to two groups: thermosoftening and thermosetting (see *plastic*).

The size of the polymer matrix is determined by the amount of monomer used; it therefore does not form a molecule of constant molecular size or mass.

POLYMERS AND LIQUID CRYSTALS

Online tutorial about two modern physical wonders. The site is divided into a 'virtual textbook' and a 'virtual laboratory', with corresponding explanations and experiments.

polymerase chain reaction (PCR) technique developed during the 1980s to clone short strands of DNA from the ϕ genome of an organism. The aim is to produce enough of the DNA to be able to sequence and identify it. It was developed by US biochemist Kary Mullis of San Diego in 1983.

polymerization chemical union of two or more (usually small) molecules of the same kind to form a new compound. **Addition polymerization** produces simple multiples of the same compound. **Condensation polymerization** joins molecules together with the elimination of water or another small molecule.

Addition polymerization uses only a single monomer (basic molecule); condensation polymerization may involve two or more different monomers (co-polymerization).

polymorphism in genetics, the coexistence of several distinctly different types in a ϕ population (groups of animals of one species). Examples include the different blood groups in humans, different colour forms in some butterflies, and snail shell size, length, shape, colour, and stripiness.

polymorphism in mineralogy, the ability of a substance to adopt different internal structures and external forms, in response to different conditions of temperature and/or pressure. For example, diamond and graphite are both forms of the element carbon, but they have very different properties and appearance.

Silica (SiO_2) also has several polymorphs, including quartz, tridymite, cristobalite, and stishovite (the latter a very high pressure form found in meteoritic impact craters).

polynomial in mathematics, an algebraic expression that has one or more ϕ variables (denoted by letters). A polynomial of degree

one, that is, whose highest ϕ power of x is 1, as in $2x + 1$, is called a linear polynomial; $3x^2 + 2x + 1$ is quadratic; $4x^3 + 3x^2 + 2x + 1$ is cubic.

polyp or **polypus** small 'stalked' benign tumour, usually found on mucous membrane of the nose or bowels. Intestinal polyps are usually removed, since some have been found to be precursors of cancer.

polyp Corals such as this *Galaxea fascicularis* from the Indian Ocean off Kenya, E Africa, are composed of countless individual polyps. Premaphotos Wildlife

polyp in zoology, the sedentary stage in the life cycle of a coelenterate (such as a ϕ coral or ϕ jellyfish), the other being the free-swimming medusa.

polypeptide long-chain ϕ peptide.

polyploid in genetics, possessing three or more sets of chromosomes in cases where the normal complement is two sets (ϕ diploid). Polyploidy arises spontaneously and is common in plants (mainly among flowering plants), but rare in animals. Many crop plants are natural polyploids, including wheat, which has four sets of chromosomes per cell (durum wheat) or six sets (common wheat).

Plant breeders can induce the formation of polyploids by treatment with a chemical, colchicine.

polypropylene plastic made by the polymerization, or linking together, of ϕ propene molecules ($\text{CH}_2=\text{CH}-\text{CH}_3$). It is used as a moulding material.

polysaccharide long-chain ϕ carbohydrate made up of hundreds or thousands of linked simple sugars (monosaccharides) such as glucose and closely related molecules.

polymerization In polymerization, small molecules (monomers) join together to make large molecules (polymers). In the polymerization of ethene to polyethene, electrons are transferred from the carbon-carbon double bond of the ethene molecule, allowing the molecules to join together as a long chain of carbon-carbon single bonds.

polysaccharide A typical polysaccharide molecule, glycogen (animal starch), is formed from linked glucose ($C_6H_{12}O_6$) molecules. A glycogen molecule has 100–1,000 linked glucose units.

The polysaccharides are natural polymers. They either act as energy-rich food stores in plants (starch) and animals (glycogen), or have structural roles in the plant cell wall (cellulose, pectin) or the tough outer skeleton of insects and similar creatures (chitin). See also *carbohydrate*.

polystyrene type of plastic used in kitchen utensils or, in an expanded form, in insulation and ceiling tiles. CFCs are used to produce expanded polystyrene so alternatives are being sought.

polytetrafluoroethene (PTFE) polymer made from the monomer tetrafluoroethene (CF_2CF_2). It is a thermosetting plastic with a high melting point that is used to produce 'non-stick' surfaces on pans and to coat bearings. Its trade name is Teflon.

Polythene trade name for a variety of *polyethylene*.

polyunsaturate type of *fat* or oil containing a high proportion of triglyceride molecules whose fatty acid chains contain several double bonds. By contrast, the fatty-acid chains of the triglycerides in saturated fats (such as lard) contain only single bonds. Medical evidence suggests that polyunsaturated fats, used widely in margarines and cooking fats, are less likely to contribute to cardiovascular disease than saturated fats, but there is also some evidence that they may have adverse effects on health.

The more double bonds the fatty-acid chains contain, the lower the melting point of the fat. Unsaturated chains with several double bonds produce oils, such as vegetable and fish oils, which are liquids at room temperature. Saturated fats, with no double bonds, are solids at room temperature. The polyunsaturated fats used for margarines are produced by taking a vegetable or fish oil and turning some of the double bonds to single bonds, so that the product is semi-solid at room temperature. This is done by bubbling hydrogen through the oil in the presence of a catalyst, such as platinum. The catalyst is later removed.

Monounsaturated oils, such as olive oil, whose fatty-acid chains contain a single double bond, are probably healthier than either saturated or polyunsaturated fats. Butter contains both saturated and unsaturated fats, together with *cholesterol*, which also plays a role in heart disease.

polyurethane polymer made from the monomer urethane. It is a thermoset plastic, used in liquid form as a paint or varnish, and in foam form for upholstery and in lining materials (where it may be a fire hazard).

polyvinyl chloride (PVC) type of plastic used for drainpipes, floor tiles, audio discs, shoes, and handbags. It is derived from vinyl chloride ($CH_2=CHCl$).

Swedish scientists identified a link between regular exposure to PVC and testicular cancer, in 1998, increasing the demand for a ban on PVC in commercial products.

pome type of *pseudocarp*, or false fruit, typical of certain plants belonging to the Rosaceae family. The outer skin and fleshy tissues are developed from the *receptacle* (the enlarged end of the flower stalk) after fertilization, and the five *carpels* (the true fruit) form the pome's core, which surrounds the seeds. Examples of pomes are apples, pears, and quinces.

pomegranate round, leathery, reddish-yellow fruit of the pomegranate tree, a deciduous shrub or small tree native to SW Asia but cultivated widely in tropical and subtropical areas. The fruit contains a large number of seeds that can be eaten fresh or made into wine. (*Punica granatum*, family *Punicaceae*.)

pomeranian breed of toy dog, about 15 cm/6 in high, weighing about 3 kg/6.5 lb. It has long straight hair with a neck frill, and the tail is carried over the back.

pomeron in physics, hypothetical object with energy and momentum, but no colour or electrical charge, produced when an electron strikes a proton. Pomerons were first suggested in 1958 by Russian physicist Isaac Pomeranchuk.

pompano warm-water, marine fish. It is silver and grows up to 90 cm/35 in. Pompanos are a valuable edible fish.

classification Pompanos are in the genus *Trachinotus*, in order Perciformes of class Osteichthyes.

Pompeii ancient city in Italy, near the volcano *Vesuvius*, 21 km/13 mi SE of Naples.

In AD 63 an earthquake destroyed much of the city, which had been a Roman port and pleasure resort; it was completely buried beneath volcanic ash when *Vesuvius* erupted in AD 79. Over 2,000 people were killed. Pompeii was rediscovered in 1748 and the systematic excavation begun in 1763 still continues.

pond-skater water *bug* (insect of the Hemiptera order with piercing mouth parts) that rows itself across the surface by using its middle legs. It feeds on smaller insects.

pondweed any of a group of aquatic plants that either float on the surface of the water or are submerged. The leaves of floating pondweeds are broad and leathery, whereas leaves of the submerged forms are narrower and translucent; the flowers grow in green spikes. (Genus *Potamogeton*, family *Potamogetonaceae*.)

pony small horse under 1.47 m/4.5 ft (14.2 hands) shoulder height. Although of Celtic origin, all the pony breeds have been crossed with thoroughbred and Arab stock, except for the smallest – the hardy Shetland, which is less than 105 cm/42 in shoulder height.

poodle breed of gun dog, including standard (above 38 cm/15 in at shoulder), miniature (below 38 cm/15 in), and toy (below 28 cm/11 in) varieties. The dense curly coat, usually cut into an elaborate style, is often either black or white, although greys and browns are also bred.

The poodle probably originated in Russia, was naturalized in Germany, where it was used for retrieving ducks and gained its name (from the German *pudeln*, 'to splash'), and became a luxury dog in France.

POP (acronym for *point of presence*) in computing, place where users can access a network via a telephone connection. A POP is a collection of modems and other equipment which are permanently connected to the network. Compare *cyPOP*.

POP3 (abbreviation for *Post Office Protocol*) on the Internet, one of the two most common mail protocols.

Internet Service Providers (ISPs) offer ζ SMTP, POP3, or both. The primary difference to most users is the choice of software available. SMTP is older and more flexible, but POP3 is generally simpler for those accessing the Internet via a dial-up account.

poplar any of a group of deciduous trees with characteristically broad leaves. The white poplar (*P. alba*) has a smooth grey trunk and leaves with white undersides. (Genus *Populus*, family Salicaceae.)

Other varieties are the aspen (*P. tremula*), grey poplar (*P. canescens*), and black poplar (*P. nigra*). Most species are tall; they are often grown as windbreaks in commercial orchards.

poppy any of a group of plants belonging to the poppy family. They have brightly coloured mainly red and orange flowers, often with dark centres, and yield a milky sap. Species include the crimson European field poppy (*P. rhoeas*) and the Asian opium poppy (*P. somniferum*), source of the drug ζ opium. Closely related are the California poppy (*Eschscholtzia californica*) and the yellow horned or sea poppy (*Glaucium flavum*). (Poppy genus *Papaver*, family Papaveraceae.)

population in biology and ecology, a group of animals of one species, living in a certain area and able to interbreed; the members of a given species in a ζ community of living things.

population in statistics, the universal set from which a sample of data is selected. The chief object of statistics is to find out population characteristics by taking samples.

population control measures taken by some governments to limit the growth of their countries' populations by trying to reduce birth rates. Propaganda, freely available contraception, and tax disincentives for large families are some of the measures that have been tried.

The population-control policies introduced by the Chinese government are the best known. In 1979 the government introduced a 'one-child policy' that encouraged ζ family planning and penalized couples who have more than one child. It has been only partially successful since it has been difficult to administer, especially in rural areas, and has in some cases led to the killing of girls in favour of sons as heirs.

population cycle in biology, regular fluctuations in the size of a population, as seen in lemmings, for example. Such cycles are often caused by density-dependent mortality: high mortality due to overcrowding causes a sudden decline in the population, which then gradually builds up again. Population cycles may also result from an interaction between a predator and its prey.

population genetics the branch of genetics that studies the way in which the frequencies of different ζ alleles (alternative forms of a

gene) in populations of organisms change, as a result of natural selection and other processes.

pop-up menu in computing, a menu that appears in a (new) window when an option is selected with a mouse or key-stroke sequence in a ζ graphical user ζ interface (GUI), such as Windows 95. Compare with ζ pull-down menu.

porbeagle medium-sized ζ shark.

porcupine any ζ rodent with quills on its body, belonging to either of two families: Old World porcupines (family Hystricidae), terrestrial in habit and having long black-and-white quills; or New World porcupines (family Erethizontidae), tree-dwelling, with prehensile tails and much shorter quills.

porcupine fish another name for the puffer fish.

pore in biology, a pore is a small opening in the skin that releases sweat and sebum. Sebum acts as a natural lubricant and protects the skin from the effects of moisture or excessive dryness.

pornography, Internet material of an explicitly sexual nature, whether it be text, photographs, graphics, audio, or video available on the Internet.

The amount of pornography and the ease of finding it has been exaggerated by both politicians and mass media. Nonetheless, there is material available on the Internet to offend almost everyone, and most governments are either attempting or considering some means of censorship.

porphyria group of rare genetic disorders caused by an enzyme defect. Porphyria affects the digestive tract, causing abdominal distress; the nervous system, causing psychotic disorder, epilepsy, and weakness; the circulatory system, causing high blood pressure; and the skin, causing extreme sensitivity to light. No specific treatments exist.

In porphyria the body accumulates and excretes (rather than utilizes) one or more porphyrins, the pigments that combine with iron to form part of the oxygen-carrying proteins haemoglobin and myoglobin; because of this urine turns reddish brown on standing. It is known as the 'royal disease' because sufferers are believed to have included Mary Queen of Scots, James I, and George III.

porphyry any ζ igneous rock containing large crystals in a finer matrix.

porpoise any small whale of the family Delphinidae that, unlike dolphins, have blunt snouts without beaks. Common porpoises of the genus *Phocaena* can grow to 1.8 m/6 ft long; they feed on fish and crustaceans.

port in computing, a socket that enables a computer processor to communicate with an external device. It may be an **input port**

port The two types of communications port in a microcomputer. The parallel port enables up to eight bits of data to travel through it at any one time; the serial port enables only one.

(such as a joystick port), or an **output port** (such as a printer port), or both (an **i/o port**).

Microcomputers may provide ports for cartridges, televisions and/or monitors, printers, and modems, and sometimes for hard discs and musical instruments (MIDI, the musical-instrument digital interface). Ports may be serial or parallel.

port point where goods are loaded or unloaded from a water-based to a land-based form of transport. Most ports are coastal, though inland ports on rivers also exist. Ports often have specialized equipment to handle cargo in large quantities (for example, container or roll-on/roll-off facilities).

portability in computing, the characteristic of certain programs that enables them to run on different types of computer with minimum modification. Programs written in a high-level language can usually be run on any computer that has a compiler or interpreter for that particular language.

portable computer computer that can be carried from place to place. The term embraces a number of very different computers - from those that would be carried only with some reluctance to those, such as laptop computers and notebook computers, that can be comfortably carried and used in transit.

port address on the Internet, a way for a host system to specify which server a particular application will use.

Portuguese man-of-war any of a genus *Physalia* of phylum *Coelenterata* (see *coelenterate*). They live in the sea, in colonies, and have a large air-filled bladder (or 'float') on top and numerous hanging tentacles made up of feeding, stinging, and reproductive individuals. The float can be 30 cm/1 ft long.

position vector a vector that defines the position of a point with respect to the origin.

positive integer any whole number from 0 upwards. 0 is included so that the properties of positive integers include those related to the identity for addition.

positron in physics, the antiparticle of the electron; an elementary particle having the same mass as an electron but exhibiting a positive charge. The positron was discovered in 1932 by US physicist Carl Anderson at Caltech, USA, its existence having been predicted by the British physicist Paul Dirac in 1928.

positron emission tomography (PET) an imaging technique which enables doctors to observe the metabolic activity of the human body by following the progress of a radioactive chemical that has been inhaled or injected, detecting gamma radiation given out when positrons emitted by the chemical are annihilated. The technique has been used to study a wide range of conditions, including schizophrenia, Alzheimer's disease and Parkinson's disease.

POSIX (acronym for *portable operating system interface for UNIX*) ANSI standard, developed to describe how the programming interfaces and other features of UNIX worked, in order to remove control from the developers, AT&T Bell Laboratories. Subsequently many other (proprietary) operating systems were modified in order to become POSIX-compliant, that is, they provide an open systems interface, so that they can communicate with other POSIX-compliant systems, even though the operating systems themselves are internally quite different. See also *open systems interconnection*.

possum another name for the *opossum*, a marsupial animal with a prehensile tail found in North, Central and South America. The name is also used for many of the smaller marsupials found in Australia.

post in computing, to send a message to a newsgroup or bulletin board for others to read.

POS terminal acronym for *point of sale terminal*, a cash register linked to a computer.

posting in computing, another word for article.

postmaster in computing, systems administrator in charge of a mail server. The term is especially used for people who manage the electronic mail system in a local area network (LAN) or other local network.

postmortem or *autopsy* Latin 'after death' dissection of a dead body to determine the cause of death.

postnatal depression mood change occurring in many mothers a few days after the birth of a baby, also known as 'baby blues'. It is usually a shortlived condition but can sometimes persist; one in five women suffer a lasting depression after giving birth. The most severe form of post-natal depressive illness, *puerperal psychosis*, requires hospital treatment.

In mild cases, antidepressant drugs and hormone treatment may help, although no link has been established between hormonal levels and postnatal depression. Research by UK psychologists 1996 showed that the mourning of a lost lifestyle may be a contributory factor.

PostScript in computing, a page-description language developed by Adobe that has become a standard. PostScript is primarily a language for printing documents on laser printers, but it can be adapted to produce images on other types of devices.

PostScript is an object-oriented language, meaning that it treats images, including fonts, as collections of geometrical objects rather than as *bit maps*. PostScript fonts are *outline fonts* stored in the computer memory as a set of instructions for drawing the circles, straight lines and curves that make up the outline of each character. This means they are also scalable. Given a single typeface definition, a PostScript printer can thus produce a multitude of fonts.

potash general name for any potassium-containing mineral, most often applied to potassium carbonate (K_2CO_3) or potassium hydroxide (KOH). Potassium carbonate, originally made by roasting plants to ashes in earthenware pots, is commercially produced from the mineral sylvite (potassium chloride, KCl) and is used mainly in making artificial fertilizers, glass, and soap.

The potassium content of soils and fertilizers is also commonly expressed as *potash*, although in this case it usually refers to potassium oxide (K_2O).

potassium Dutch *potassa* 'potash' soft, waxlike, silver-white, metallic element, symbol K (Latin *kaliium*), atomic number 19, relative atomic mass 39.0983. It is one of the alkali metals and has a very low density - it floats on water, and is the second lightest metal (after lithium). It oxidizes rapidly when exposed to air and reacts violently with water. Of great abundance in the Earth's crust, it is widely distributed with other elements and found in salt and mineral deposits in the form of potassium aluminium silicates.

Potassium is the main base ion of the fluid in the body's cells. Along with sodium, it is important to the electrical potential of the nervous system and, therefore, for the efficient functioning of nerve and muscle. Shortage, which may occur with excessive fluid loss (prolonged diarrhoea, vomiting), may lead to muscular paralysis; potassium overload may result in cardiac arrest. It is also required by plants for growth. The element was discovered and named in 1807 by English chemist Humphry Davy, who isolated it from potash in the first instance of a metal being isolated by electric current.

potassium-argon dating or *K-Ar dating* isotopic dating method based on the radioactive decay of potassium-40 (^{40}K) to the stable isotope argon-40 (^{40}Ar). Ages are based on the known half-life of ^{40}K , and the ratio of ^{40}K to ^{40}Ar . The method is routinely applied to rock samples about 100,000 to 30 million years old.

The method is used primarily to date volcanic layers in stratigraphic sequences with archaeological deposits, and the palaeomagnetic-reversal timescale. Complicating factors, such as sample contamination by argon absorbed from the atmosphere, and argon gas loss by diffusion out of the mineral, limit the application of this technique.

potassium dichromate $K_2Cr_2O_7$ orange, crystalline solid, soluble in water, that is a strong oxidizing agent in the presence of dilute

sulphuric acid. As it oxidizes other compounds it is itself reduced to potassium chromate (K_2CrO_4), which is green. Industrially it is used in the manufacture of dyes and glass and in tanning, photography, and ceramics.

potassium manganate(VII) $KMnO_4$ or **potassium permanganate** dark purple, crystalline solid, soluble in water, that is a strong oxidizing agent in the presence of dilute sulphuric acid. In the process of oxidizing other compounds it is itself reduced to manganese(II) salts (containing the Mn^{2+} ion), which are colourless.

potato perennial plant with edible tuberous roots that are rich in starch and are extensively eaten as a vegetable. Used by the Andean Indians for at least 2,000 years before the Spanish Conquest, the potato was introduced to Europe by the mid-16th century, and reputedly to England by the explorer Walter Raleigh. (*Solanum tuberosum*, family Solanaceae.)

In Ireland, the potato famine of 1845, caused by a parasitic fungus, resulted in many thousands of deaths from starvation, and led to large-scale emigration to the USA.

potato blight disease of the potato caused by a parasitic fungus *Phytophthora infestans*. It was the cause of the 1845 potato famine in Ireland. New strains of *P. infestans* continue to arise. The most virulent version so far is *P. infestans* US-8, which arose in Mexico 1992, spreading to N America 1994. It remained resistant to known fungicides 1996.

potential difference (pd) difference in the electrical potential (see ϕ potential, electric) of two points, being equal to the electrical energy converted by a unit electric charge moving from one point to the other. The SI unit of potential difference is the volt (V). The potential difference between two points in a circuit is commonly referred to as voltage. See also ϕ Ohm's law.

potential divider or **voltage divider** two resistors connected in series in an electrical circuit in order to obtain a fraction of the potential difference, or voltage, across the battery or electrical source. The potential difference is divided across the two resistors in direct proportion to their resistances.

potential, electric in physics, the potential at a point is equal to the energy required to bring a unit electric charge from infinity to the point. The SI unit of potential is the volt (V). Positive electric charges will flow 'downhill' from a region of high potential to a region of low potential. See ϕ potential difference.

potential energy ϕ energy possessed by an object by virtue of its relative position or state (for example, as in a compressed spring). It is contrasted with kinetic energy, the form of energy possessed by moving bodies.

potentiometer in physics, an electrical ϕ resistor that can be divided so as to compare, measure, or control voltages. In radio circuits, any rotary variable resistance (such as volume control) is referred to as a potentiometer.

A simple type of potentiometer consists of a length of uniform resistance wire (about 1 m/3 ft long) carrying a constant current provided by a battery connected across the ends of the wire. The source of potential difference (voltage) to be measured is connected (to oppose the cell) between one end of the wire, through a ϕ galvanometer (instrument for measuring small currents), to a contact free to slide along the wire. The sliding contact is moved until the galvanometer shows no deflection. The ratio of the length of potentiometer wire in the galvanometer circuit to the total length of wire is then equal to the ratio of the unknown potential difference to that of the battery.

potto arboreal, nocturnal, African prosimian primate *Perodicticus potto* belonging to the ϕ loris family. It has a thick body, strong limbs, and grasping feet and hands, and grows to 40 cm/16 in long, with horny spines along its backbone, which it uses in self-defence. It climbs slowly, and eats insects, snails, fruit, and leaves.

Other experts on ornithology are invited to contribute textual and visual material.

domesticated from the SE Asian jungle fowl *Gallus gallus* and then raised in the East as well as the West. Turkeys are New World birds, domesticated in ancient Mexico. Geese and ducks were domesticated in Egypt, China, and Europe.

Good egg-laying breeds of chicken are Leghorns, Minorcas, and Anconas; varieties most suitable for eating are Dorkings, Australorps, Brahmas, and Cornish; those useful for both purposes are Orpingtons, Rhode Island Reds, Wyandottes, Plymouth Rocks, and Jersey White Giants. Most farm poultry are hybrids, selectively crossed for certain characteristics, including feathers and down.

factory farming Since World War II, the development of battery-produced eggs and the intensive breeding of broiler fowls and turkeys has roused a public outcry against 'factory' methods of farming. The birds are often kept constantly in small cages, have their beaks and claws removed to prevent them from pecking their neighbours, and are given feed containing growth hormones and antibacterial drugs, which eventually make their way up the food chain to humans. Factory farming has led to a growing interest in deep-litter and free-range systems, although these account for only a small percentage of total production.

standard potential divider

potentiometer used as a potential divider

potential divider A potential divider is a resistor or a chain of resistors connected in series in an electrical circuit. It is used to obtain a known fraction of the total voltage across the whole resistor or chain. When a variable resistor, or potentiometer, is used as a potential divider, the output voltage can be varied continuously by sliding a contact along the resistor. Devices like this are used in electronic equipment to vary volume, tone, and brightness control.

pound imperial unit (abbreviation lb) of mass. The commonly used avoirdupois pound, also called the **imperial standard pound** (7,000 grains/0.45 kg), differs from the **pound troy** (5,760 grains/0.37 kg), which is used for weighing precious metals. It derives from the Roman *libra*, which weighed 0.327 kg.

poundal imperial unit (abbreviation pdl) of force, now replaced in the SI system by the newton. One poundal equals 0.1383 newtons.

It is defined as the force necessary to accelerate a mass of one pound by one foot per second per second.

powan British species of whitefish.

powder metallurgy method of shaping heat-resistant metals such as tungsten. Metal is pressed into a mould in powdered form and then sintered (heated to very high temperatures).

powder post beetle dark, small (2–3 mm/0.08–0.12 in long), elongate beetles, which attack both freshly-cut and old timber. Over 90 species have been described.

classification Powder post beetles are in the family Lyctidae of order Coleoptera, class Insecta, phylum Arthropoda.

The eggs are laid in the vessels in the sapwood of hardwoods. Softwoods, such as pine, are never attacked because the vessels are not of the right size, nor will heartwood be attacked as it does not have the right starch and sugar content. The life cycle takes about one year, the winter being spent in the larval condition. The larvae are commonly called woodworm.

The adults' exit holes are distinctly visible on the surface of wood, and often a very fine wood powder is noticeable around them. There are various measures which can be taken to prevent infestation: painting and varnishing the wood surface prevents the adult females from laying their eggs in the wood; and chemical treatment of the wood may help.

power in mathematics, that which is represented by an exponent or index, denoted by a superior small numeral. A number or symbol raised to the power of 2 – that is, multiplied by itself – is said to be squared (for example, 3^2 , x^2), and when raised to the power of 3, it is said to be cubed (for example, 2^3 , y^3).

power in optics, a measure of the amount by which a lens will deviate light rays. A powerful converging lens will converge parallel rays steeply, bringing them to a focus at a short distance from the lens. The unit of power is the dioptre, which is equal to the reciprocal of focal length in metres. By convention, the power of a converging (or convex) lens is positive and that of a diverging (or concave) lens negative.

power in physics, the rate of doing work or consuming energy. It is measured in watts (joules per second) or other units of work per unit time.

PowerPC in computing, microprocessor produced by IBM and Motorola, originally as a challenger to Intel, though now being directed towards industrial uses.

The PowerPC was based on IBM's multichip POWER (Performance Optimization With Enhanced Risc) architecture introduced with the RS/6000 line of UNIX workstations and servers 1990. When Apple decided to switch to PowerPC processor, its previous chip supplier, Motorola, switched from its own 88000 RISC processor to join a triumvirate backing the PowerPC. However, the group failed to make any impact on Intel and Apple's sales declined 1995–97.

PowerPoint in computing, presentation graphics program made by Microsoft and sold mainly as part of Microsoft Office.

power station building where electrical energy is generated from a fuel or from another form of energy. Fuels used include fossil fuels such as coal, gas, and oil, and the nuclear fuel uranium. Renewable sources of energy include gravitational potential energy, used to produce hydroelectric power, and wind power.

The energy supply is used to turn turbines either directly by means of water or wind pressure, or indirectly by steam pressure, steam being generated by burning fossil fuels or from the heat released by the fission of uranium nuclei. The turbines in their turn spin alternators, which generate electricity at very high voltage.

The world's largest power station is Turukhansk, on the Lower Tunguska river, Russia, with a capacity of 20,000 megawatts.

I can therefore see no justification for the introduction of a system which has no element of permanency and every element of danger to life and property.

THOMAS EDISON US Scientist and inventor.

power transmission transfer of electrical power from one location, such as a power station, to another. Electricity is conducted along cables at a high voltage (up to 500 kV on the super grid) in order to reduce the current in the wires, and hence minimize the amount of energy wasted from them as heat.

Transformers are needed to step down these voltages before power can be supplied to consumers. High voltages require special insulators to prevent current from leaking to the ground and these may clearly be seen on the pylons that carry overhead wires.

PRAIRIE NET

<http://dolphin.upenn.edu/~bdp/index.html>

Clearing house of information on the prairies. Contents include a catalogue of prairie fauna and flora, reports of conservation efforts to protect America's grasslands, and a photo gallery. There are reports of exhibitions on the prairies and links to other prairie sites.

prairie the central North American plain, formerly grass-covered, extending over most of the region between the Rocky Mountains on the west and the Great Lakes and Ohio River on the east.

prairie dog any of the North American genus *Cynomys* of burrowing rodents in the squirrel family (Sciuridae). They grow to 30 cm/12 in, plus a short 8 cm/3 in tail. Their 'towns' can contain up to several thousand individuals. Their barking cry has given them their name. Persecution by ranchers has brought most of the five species close to extinction.

PRAIRIE DOG

<http://ngp.ngpc.state.ne.us/wildlife/pdogs.html>

Well-written profile of this sociable burrowing rodent from the Nebraska wildlife. In addition to information on its diet and habitat, it looks at the ecological importance of preserving prairie dog towns.

prairie wolf another name for the coyote.

praseodymium Greek *prasios* 'leek-green' + *didymos* 'twin' silver-white, malleable, metallic element of the lanthanide series, symbol Pr, atomic number 59, relative atomic mass 140.907. It occurs in nature in the minerals monazite and bastnaesite, and its green salts are used to colour glass and ceramics. It was named in 1855 by Austrian chemist Carl von Welsbach (1858–1929).

He fractionated it from didymium (originally thought to be an element but actually a mixture of rare-earth metals consisting largely of neodymium, praseodymium, and cerium), and named it for its green salts and spectroscopic line.

prawn any of various shrimps of the suborder Natantia ('swimming'), of the crustacean order Decapoda, as contrasted with lob-

sters and crayfishes, which are able to 'walk'. Species called prawns are generally larger than species called shrimps.

praying mantis another name for *ymantis*.

preadaptation in biology, the fortuitous possession of a character that allows an organism to exploit a new situation. In many cases, the character evolves to solve a particular problem that a species encounters in its preferred habitat, but once evolved may allow the organism to exploit an entirely different situation. The ability to extract oxygen directly from the air evolved in some early fishes, probably in response to life in stagnant, deoxygenated pools; this later made it possible for their descendants to spend time on land, so giving rise eventually to the air-breathing amphibians.

Precambrian in geology, the time from the formation of Earth (4.6 billion years ago) up to 570 million years ago. Its boundary with the succeeding Cambrian period marks the time when animals first developed hard outer parts (exoskeletons) and so left abundant fossil remains. It comprises about 85% of geological time and is divided into two periods: the Archaean, in which no life existed, and the Proterozoic, in which there was life in some form.

precession slow wobble of the Earth on its axis, like that of a spinning top. The gravitational pulls of the Sun and Moon on the Earth's equatorial bulge cause the Earth's axis to trace out a circle on the sky every 25,800 years. The position of the celestial poles (see *celestial sphere*) is constantly changing owing to precession, as are the positions of the equinoxes (the points at which the celestial equator intersects the Sun's path around the sky). The precession of the equinoxes means that there is a gradual westward drift in the ecliptic – the path that the Sun appears to follow – and in the coordinates of objects on the celestial sphere.

This is why the dates of the astrological signs of the zodiac no longer correspond to the times of year when the Sun actually passes through the constellations. For example, the Sun passes through Leo from mid-Aug to mid-Sept, but the astrological dates for Leo are between about 23 July and 22 Aug.

Precession also occurs in other planets. Uranus has the Solar System's fastest known precession (264 days) determined in 1995.

precipitation in chemistry, the formation of an insoluble solid in a liquid as a result of a reaction within the liquid between two or more soluble substances. If the solid settles, it forms a *precipitate*; if the particles of solid are very small, they will remain in suspension, forming a *colloidal precipitate* (see *colloid*).

precipitation in meteorology, water that falls to the Earth from the atmosphere. It includes rain, snow, sleet, hail, dew, and frost.

precocial animals that are active and mobile from birth. Examples include antelopes, ostriches, and crocodiles.

predator any animal that hunts, kills, and eats another animal (the prey). Examples of predators include lions, who prey on antelope and zebra, and owls, who prey on mice and rats.

Predators are usually bigger and more powerful than their prey (although a stoat preys on a rabbit, which may be four or five times its size), and their population is smaller – if the predator became more widespread than the prey, the population of the predator would inevitably fall. Other relationships between species include parasitism, in which the host is not necessarily killed by the parasite, and symbiosis, in which both species benefit from the relationship.

pre-eclampsia or *toxemia of pregnancy* potentially serious condition developing in the third trimester and marked by high blood pressure and fluid retention. Arising from unknown causes, it disappears when pregnancy is over. It may progress to *eclampsia* if untreated.

prefabricated building in architecture and construction, the manufacture of large elements, such as walls, floors, and roofs, or even entire buildings, for assembly at the site. Prefabrication is widely used for constructing housing and other buildings, either to meet tight construction deadlines or, as in the UK during the

reconstruction following World War II and the housing boom of the 1960s, when there is a large demand for buildings but labour supply is limited.

history Modern prefabrication began when the Industrial Revolution brought about large-scale production of iron. From 1750, iron framing was developed for factories, as in the flax-spinning mill at Ditherington near Shrewsbury, built in 1796.

Joseph Paxton's 'Crystal Palace' of 1851 was entirely prefabricated from cast-iron and glass to meet a nine-month construction deadline. This style was further developed by Buckminster Fuller's geodesic domes in the 1960s. During the 1930s, Jean Prouvé (1901–1984) developed a system of wall components for lightweight housing and further developed the 'curtain wall' as well as other components for prefabricated construction.

Prefabrication really came into its own from 1945, when there was a shortage of labour to carry out the massive building programmes being undertaken in the wake of World War II. In the UK, entire houses and other buildings were fully made up at the factory and then delivered and assembled on site.

pregnancy in humans, the period during which an embryo grows within the womb. It begins at conception and ends at birth, and the normal length is 40 weeks. Menstruation usually stops on conception. About one in five pregnancies fails, but most of these failures occur very early on, so the woman may notice only that her period is late. After the second month, the breasts become tense and tender, and the areas round the nipples become darker. Enlargement of the uterus can be felt at about the end of the third month, and thereafter the abdomen enlarges progressively. Fetal movement can be felt at about 18 weeks; a heart-beat may be heard during the sixth month. Pregnancy in animals is called *gestation*.

complications Occasionally the fertilized egg implants not in the womb but in the fallopian tube (the tube between the ovary and the uterus), leading to an ectopic ('out of place') pregnancy. This will cause the woman severe abdominal pain and vaginal bleeding. If the growing fetus ruptures the tube, life-threatening shock may ensue. *Toxaemia* is characterized by rising blood pressure, and if left untreated, can result in convulsions leading to coma.

According to 1996 World Health Organization (WHO) figures, 585,000 women die annually from pregnancy-related causes; 99% of these deaths occur in developing countries. The highest rate of maternal death is in Sierra Leone with 1,800 deaths per 100,000 live births, compared with an average of 27 for industrialized countries.

prehistoric art art that predates written records. The history of the fine arts – painting, engraving, and sculpture – begins around 40,000 BC in the Palaeolithic period (Old Stone Age). The oldest known rock engravings are in Australia, but within the next 30,000 years art occurs on every continent. The earliest surviving artefacts in Europe date from approximately 30,000–10,000 BC, a period of hunter-gatherer cultures. Small sculptures are generally of fecund female nudes and relate to the cult of the Mother Goddess; for example, the stone *Willendorf Venus* (Kunsthistorisches Museum, Vienna) about 21,000 BC. The murals of the caves of Lascaux, France, and Altamira, Spain, depict mostly animals.

During the Neolithic period (New Stone Age) 10,000–2,000 BC, settled communities were established, which led to a greater technical and aesthetic sophistication in tools, ceramic vessels, jewellery, and human and animal figures. Human figures appear more often in wall paintings, and are skillfully composed into groups. The period 4,000–2,000 BC saw the erection of the great megalithic monuments, such as those at Carnac, France, and Stonehenge, England, and the production of ceramic pots and figurines with decorative elements that were later to be developed in Celtic art.

prehistoric life the diverse organisms that inhabited Earth from the origin of life about 3.5 billion years ago to the time when humans began to keep written records, about 3500 BC. During the course of evolution, new forms of life developed and many other forms, such as the dinosaurs, became extinct. Prehistoric life evolved over this vast timespan from simple bacteria-like cells in the oceans to algae and protozoans and complex multicellular forms such as worms, molluscs, crustaceans, fishes, insects, land plants, amphibians, reptiles, birds, and mammals. On a geological

pregnancy The development of a human embryo. Division of the fertilized egg, or ovum, begins within hours of conception. Within a week a ball of cells—a blastocyst—has developed. After the third week, the embryo has changed from a mass of cells into a recognizable shape. At four weeks, the embryo is 3 mm/0.1 in long, with a large bulge for the heart and small pits for the ears. At six weeks, the embryo is 1.5 cm/0.6 in with a pulsating heart and ear flaps. At the eighth week, the embryo is 2.5 cm/1 in long and recognizably human, with eyelids, small fingers, and toes. From the end of the second month, the embryo is almost fully formed and further development is mainly by growth. After this stage, the embryo is termed a fetus.

timescale human beings evolved relatively recently, about 4 million years ago, although the exact dating is a matter of some debate. See also *geological time*.

prehistory human cultures before the use of writing. The study of prehistory is mainly dependent on archaeology. General chronological dividing lines between prehistoric eras, or history and prehistory, are difficult to determine because communities have developed at differing rates. The Three Age System of classification (published in 1836 by the Danish archaeologist Christian Thomsen) is based on the predominant materials used by early humans for tools and weapons: *Stone Age*, *Bronze Age*, and *Iron Age*.

Human prehistory begins with the emergence of early modern hominids (see *human species*, *origins of*). *Homo habilis*, the first tool user, was in evidence around 2 million years ago, and found at such sites as Koobi Fora, Kenya and Olduvai Gorge, Tanzania.

Stone Age Stone was the main material used for tools and weapons. The Stone Age is divided into:

Old Stone Age (Palaeolithic) 3,500,000–8500 BC. Stone and bone tools were chipped into shape by early humans or hominids from Africa, Asia, the Middle East, and Europe, as well as later Neanderthal and Cro-Magnon people; the only domesticated animals were dogs. Some Asians crossed the Bering land bridge to inhabit the Americas. *Prehistoric art* was being produced 20,000 years ago in many parts of the world; for example, at Altamira in Spain, Lascaux in France, in southern Africa, and in Australia.

Middle Stone Age (Mesolithic) and **New Stone Age** (Neolithic). Bone tools and stone or flint implements were used. In Neolithic times, agriculture and the domestication of goats, sheep, and cattle began. Stone Age cultures survived in the Americas, Asia, Africa, Oceania, and Australia until the 19th and 20th centuries. **Bronze Age** Bronze tools and weapons appeared approximately 5000 BC in the Far East, and continued in the Middle East until about 1200 BC; in Europe this period lasted from about 2000 to 500 BC.

Iron Age Iron was hardened (alloyed) by the addition of carbon, so that it superseded bronze for tools and weapons; in the Old World generally from about 1000 BC.

prematurity the condition of an infant born before the full term. In obstetrics, an infant born before 37 weeks' gestation is described as premature.

Premature babies are often at risk. They lose heat quickly because they lack an insulating layer of fat beneath the skin; there may also be breathing difficulties. In hospitals with advanced technology, specialized neonatal units can save some babies born as early as 23 weeks.

premenstrual tension (PMT) or **premenstrual syndrome** medical condition caused by hormone changes and comprising a number of physical and emotional features that occur cyclically before menstruation and disappear with its onset. Symptoms include mood changes, breast tenderness, a feeling of bloatedness, and headache.

premolar in mammals, one of the large teeth toward the back of the mouth. In herbivores they are adapted for grinding. In carnivores they may be carnassials. Premolars are present in milk dentition as well as permanent dentition.

presbyopia vision defect, an increasing inability with advancing age to focus on near objects. It is caused by thickening and loss of elasticity in the lens, which is no longer able to relax to the near-spherical shape required for near vision.

prescription in medicine, an order written in a recognized form by a practitioner of medicine, dentistry, or veterinary surgery to a pharmacist for a preparation of medications to be used in treatment.

By tradition it used to be written in Latin, except for the directions addressed to the patient. It consists of (1) the superscription *recipe* ('take'), contracted to Rx; (2) the inscription or body, containing the names and quantities of the drugs to be dispensed; (3) the subscription, or directions to the pharmacist; (4) the signature, followed by directions to the patient; and (5) the patient's name, the date, and the practitioner's name.

presentation graphics in computing, program that helps users to create presentations such as visual aids, handouts, and overhead slides. Presentation graphics programs process artwork, graphics, and text to produce a series of 'slides' - images which help speakers to get their message across. Leading programs include Microsoft PowerPoint and (for multimedia presentations, incorporating moving pictures and sounds) Macromedia Director.

preservative substance (additive) added to a food in order to inhibit the growth of bacteria, yeasts, moulds, and other microorganisms, and therefore extend its shelf life. The term sometimes refers to antioxidants (substances added to oils and fats to prevent their becoming rancid) as well. All preservatives are potentially damaging to health if eaten in sufficient quantity. Both the amount used, and the foods in which they can be used, are restricted by law.

Alternatives to preservatives include faster turnover of food stocks, refrigeration, better hygiene in preparation, sterilization, and pasteurization (see food technology).

pressure in a fluid, the force that would act normally (at right angles) per unit surface area of a body immersed in the fluid. The SI unit of pressure is the pascal (Pa), equal to a pressure of one newton per square metre. In the atmosphere, the pressure declines with height from about 100 kPa at sea level to zero where the atmosphere fades into space. Pressure is commonly measured with a barometer, manometer, or Bourdon gauge. Other common units of pressure are the bar and the torr.

Absolute pressure is measured from a vacuum; gauge pressure is the difference between the absolute pressure and the local atmospheric pressure. In a liquid, the pressure at a depth h is given by pgh where p is the density and g is the acceleration of free fall.

pressure cooker closed pot in which food is cooked in water under pressure, where water boils at a higher temperature than normal boiling point (100°C/212°F) and therefore cooks food quickly. The modern pressure cooker has a quick-sealing lid and a safety valve that can be adjusted to vary the steam pressure inside.

The French scientist Denis Papin invented the pressure cooker in England in 1679.

pressure law law stating that the pressure of a fixed mass of gas at constant volume is directly proportional to its absolute temperature.

The law may be expressed as: pressure/temperature = constant or, more usefully, as: $P_1/T_1 = P_2/T_2$ where P_1 and T_1 are the initial pressure and temperature in kelvin of a gas, and P_2 and T_2 are its final pressure and temperature. See also gas laws.

pressurized water reactor (PWR) a nuclear reactor design used in nuclear power stations in many countries, and in nuclear-powered submarines. In the PWR, water under pressure is the coolant and moderator. It circulates through a steam generator, where its heat boils water to provide steam to drive power turbines.

Prestel viewdata service that provides information on the television screen via the telephone network. The service was first offered to the public by British Telecom - then a division of the General Post Office - in 1979. It never lived up to expectations and British Telecom sold off what remained in 1995.

Prestel On-Line is now a Scottish telecommunications company specializing in Internet access and content provision

Pretty Good Privacy (PGP) in computing, strong encryption program that runs on personal computers and is distributed on the Net free of charge. It was written by Phil Zimmermann and released to the Net in 1991 amid growing fears that the USA would pass a law requiring all secure communications systems to incorporate a 'back door' to make it easy for law enforcement officials to read encrypted messages.

PGP is based on the RSA algorithm and uses public-key cryptography; its source code has been released to the cryptographic

community for study and testing. Since version 1.0, its development has proceeded in multiple locations around the world to avoid conflicts with the US laws banning the export of strong encryption. A companion product, PGPfone, released in 1996, runs across the Internet to give users the equivalent of a military grade secure telephone.

prickly pear any of several cacti (see cactus) native to Central and South America, mainly Mexico and Chile, but naturalized in S Europe, N Africa, and Australia, where it is a pest. The common prickly pear (*O. vulgaris*) is low-growing, with flat, oval stem joints, bright yellow flowers, and prickly, oval fruit; the flesh and seeds of the pitted fruit have a pleasant taste. (Genus *Opuntia*, family Cactaceae.)

primary data information that has been collected at first hand. It involves measurement of some sort, whether by taking readings off instruments, sketching, counting, or conducting interviews (using questionnaires).

primary sexual characteristic the endocrine gland producing maleness and femaleness. In males, the primary sexual characteristic is the testis; in females it is the ovary. Both are endocrine glands that produce hormones responsible for secondary sexual characteristics, such as facial hair and a deep voice in males and breasts in females.

primate in zoology, any member of the order of mammals that includes monkeys, apes, and humans (together called anthropoids), as well as lemurs, bushbabies, lorises, and tarsiers (together called prosimians).

Generally, they have forward-directed eyes, gripping hands and feet, opposable thumbs, and big toes. They tend to have nails rather than claws, with gripping pads on the ends of the digits, all adaptations to the arboreal, climbing mode of life.

In 1996 a new primate genus (probably extinct) was identified by a US anthropologist from a collection of bones believed to belong to a primate. The animal has been named *Pseudopithecus martini*.

According to the Red List of endangered species published by the World Conservation Union (IUCN) for 1996, 46% of primate species are threatened with extinction.

He is proud that he has the biggest brain of all the primates, but attempts to conceal the fact that he also has the biggest penis.

DESMOND MORRIS English anthropologist.
The Naked Ape, Introduction

prime number number that can be divided only by 1 or itself, that is, having no other factors. There is an infinite number of primes, the first ten of which are 2, 3, 5, 7, 11, 13, 17, 19, 23, and 29 (by definition, the number 1 is excluded from the set of prime numbers). The number 2 is the only even prime because all other even numbers have 2 as a factor.

Over the centuries mathematicians have sought general methods (algorithms) for calculating primes, from Eratosthenes' sieve to programs on powerful computers.

The largest prime, $2^{859433}-1$ (258,716 digits long) was discovered in 1993. It is the thirty-third Mersenne prime. All Mersenne primes are in the form 2^q-1 , where q is also a prime.

primrose any of a group of plants belonging to the primrose family, with showy five-lobed flowers. The common primrose (*P. vulgaris*) is a woodland plant, native to Europe, with abundant pale yellow flowers in spring. Related to it is the cowslip. (Genus *Primula*, family Primulaceae.)

principal focus in optics, the point at which incident rays parallel to the principal axis of a lens converge, or appear to diverge, after refraction. The distance from the lens to its principal focus is its focal length.

print in computing, to transfer data to a printer, to a screen or to another file.

printed circuit board (PCB) electrical circuit created by laying (printing) 'tracks' of a conductor such as copper on one or both sides of an insulating board. The PCB was invented in 1936 by Austrian scientist Paul Eisler, and was first used on a large scale in 1948.

Components such as integrated circuits (chips), resistors and capacitors can be soldered to the surface of the board (surface-mounted) or, more commonly, attached by inserting their connecting pins or wires into holes drilled in the board. PCBs include motherboards, expansion boards, and adapters.

printed circuit board A typical microcomputer printed circuit board (PCB). The PCB contains sockets for the integrated circuits, or chips, and the connecting tracks.

printer in computing, an output device for producing printed copies of text or graphics. Types include the daisywheel printer, which produces good-quality text but no graphics; the dot matrix printer, which produces text and graphics by printing a pattern of small dots; the ink-jet printer, which creates text and graphics by spraying a fine jet of quick-drying ink onto the paper; and the laser printer, which uses electrostatic technology very similar to that used by a photocopier to produce high-quality text and graphics.

Printers may be classified as impact printers (such as daisy wheel and dot-matrix printers), which form characters by striking an inked ribbon against the paper, and nonimpact printers (such as ink-jet and laser printers), which use a variety of techniques to produce characters without physical impact on the paper.

A further classification is based on the basic unit of printing, and categorizes printers as character printers, line printers, or page printers, according to whether they print one character, one line, or a complete page at a time.

printing reproduction of multiple copies of text or illustrative material on paper, as in books or newspapers, or on an increasing variety of materials; for example, on plastic containers. The first printing used woodblocks, followed by carved wood type or moulded metal type and hand-operated presses. Modern printing is effected by electronically controlled machinery. Current printing processes include electronic phototypesetting with offset printing, and gravure print.

origins In China the art of printing from a single wooden block was known by the 6th century AD, and movable type was being used by the 11th century. In Europe printing was unknown for another three centuries, and it was only in the 15th century that movable type was reinvented, traditionally by Johannes Gutenberg in Germany. From there printing spread to Italy, France, and England, where it was introduced by William Caxton.

steam power, linotype, and monotype There was no further substantial advance until, in the 19th century, steam power replaced hand-operation of printing presses, making possible long 'runs'; hand-composition of type (each tiny metal letter was taken from the case and placed individually in the narrow stick that carried one line of text) was replaced by machines operated by a keyboard. Linotype, a hot-metal process (it produced a line of type in a solid slug) used in newspapers, magazines, and books, was invented by Ottmar Mergenthaler in 1866 and commonly used until the 1980s. The Monotype, used in bookwork (it produced a series of individual characters, which could be hand-corrected), was invented by Tolbert Lanston (1844-1913) in the USA in 1889.

Important as these developments were, they represented no fundamental change but simply a faster method of carrying out the same basic typesetting operations. The actual printing process still involved pressing the inked type on to paper, by galley press.

20th-century developments In the 1960s, letterpress began to face increasing competition from offset printing, a method that prints from an inked flat surface, and from the gravure method (used for high-circulation magazines), which uses recessed plates. The introduction of electronic phototypesetting machines, also in the 1960s, allowed the entire process of setting and correction to be done in the same way that a typist operates, thus eliminating the hot-metal composing room (with its hazardous fumes, lead scraps, and noise) and leaving only the making of plates and the running of the presses to be done traditionally.

By the 1970s some final steps were taken to plateless printing, using various processes, such as a computer-controlled laser beam, or continuous jets of ink acoustically broken up into tiny equal-sized drops, which are electrostatically charged under computer control. Pictures can be fed into computer typesetting systems by optical scanners.

print spooler in computing, utility program that stores information in a temporary file before sending it on to a printer. Print spoolers help computers to work efficiently, allowing the central processing unit (CPU) to carry on with other work while a document is being printed.

prión (acronym for *proteinaceous infectious particle*) exceptionally small microorganism, a hundred times smaller than a virus.

Composed of protein, and without any detectable amount of nucleic acid (genetic material), it is thought to cause diseases such as scrapie in sheep, and certain degenerative diseases of the nervous system in humans. How it can operate without nucleic acid is not yet known.

prism in mathematics, a solid figure whose cross section is constant in planes drawn perpendicular to its axis. A cube, for example, is a rectangular prism with all faces (bases and sides) the same shape and size.

triangular prism

cross section is the same throughout the prism's length

trapezoidal prism

pentagonal prism

prism

in optics, a triangular block of transparent material (plastic, glass, silica) commonly used to 'bend' a ray of light or split a beam into its spectral colours. Prisms are used as mirrors to define the optical path in binoculars, camera viewfinders, and periscopes. The dispersive property of prisms is used in the spectroscopy.

privacy on the Internet, generally used to mean the right to control who has access to the personal information generated by interaction with computers.

The right to privacy is one of the most hotly debated issues on the Internet, as commercial suppliers seek to gather more and more information about their customers. The most common approaches to securing the right to privacy are technological, via encryption, and legislative, via laws such as Britain's Data Protection Act. A third approach is to use services such as anonymous remailers to strip identifying information from individual messages when posting contentious or sensitive material.

privacy enhanced mail (PEM) in computing, Internet protocol that gives a degree of confidentiality to e-mail, using various public-key cryptography methods.

privet any of a group of evergreen shrubs with dark green leaves, belonging to the olive family. They include the European common privet (*L. vulgare*) with white flowers and black berries, naturalized in North America, and the native North American California privet (*L. ovalifolium*), also known as hedge privet. (Genus *Ligustrum*, family Oleaceae.)

probability likelihood, or chance, that an event will occur, often expressed as odds, or in mathematics, numerically as a fraction or decimal.

In general, the probability that n particular events will happen out of a total of m possible events is n/m . A certainty has a probability of 1; an impossibility has a probability of 0. Empirical probability is defined as the number of successful events divided by the total possible number of events.

In tossing a coin, the chance that it will land 'heads' is the same as the chance that it will land 'tails', that is, 1 to 1 or even; mathematically, this probability is expressed as $\frac{1}{2}$ or 0.5. The odds against any chosen number coming up on the roll of a fair die are 5 to 1; the probability is $\frac{1}{6}$ or 0.1666... If two dice are rolled there are $6 \times 6 = 36$ different possible combinations. The probability of a double (two numbers the same) is $\frac{6}{36}$ or $\frac{1}{6}$ since there are six doubles in the 36 events: (1,1), (2,2), (3,3), (4,4), (5,5), and (6,6).

Probability theory was developed by the French mathematicians Blaise Pascal and Pierre de Fermat in the 17th century, initially in response to a request to calculate the odds of being dealt various hands at cards. Today probability plays a major part in the mathematics of atomic theory and finds application in insurance and statistical studies.

At any rate, I am convinced that He [God] does not play dice.

proboscis monkey large, leaf-eating monkey found only in mangrove swamps in Borneo. The male's nose is bulbous and prolonged to hang below the upper lip.

classification Proboscis monkeys *Nasalis larvatus*, are in family Cercopithecidae, order Primates.

procedural programming programming in which programs are written as lists of instructions for the computer to obey in sequence. It closely matches the computer's own sequential operation.

procedure in computing, a small part of a computer program that performs a specific task, such as clearing the screen or sorting a file. A **procedural language**, such as BASIC, is one in which the programmer describes a task in terms of how it is to be done, as opposed to a **declarative language**, such as PROLOG, in which it is described in terms of the required result. See **programming**.

Careful use of procedures is an element of structured programming. In some programming languages there is an overlap between procedures, ϕ functions, and ϕ subroutines.

process control automatic computerized control of a manufacturing process, such as glassmaking. The computer receives ϕ feedback information from sensors about the performance of the machines involved, and compares this with ideal performance data stored in its control program. It then outputs instructions to adjust automatically the machines' settings.

Because the computer can monitor and reset each machine hundreds of times each minute, performance can be maintained at levels that are very close to the ideal.

processing cycle in computing, the sequence of steps performed repeatedly by a computer in the execution of a program. The computer's central processing unit (CPU) continuously works through a loop, involving fetching a program instruction from memory, fetching any data it needs, operating on the data, and storing the result in the memory, before fetching another program instruction.

There are no things, only processes.

processor in computing, another name for the central processing unit or microprocessor of a computer.

Procyon or *Alpha Canis Minoris* brightest star in the constellation Canis Minor and the eighth-brightest star in the sky. Procyon is a first-magnitude white star 11.4 light years from Earth, with a mass of 1.7 Suns. It has a white dwarf companion that orbits it every 40 years.

The name, derived from Greek, means 'before the dog', and reflects the fact that in midnorthern latitudes Procyon rises shortly before Sirius, the Dog Star. Procyon and Sirius are sometimes called 'the Dog Stars'. Both are relatively close to us and have white dwarf companions.

Prodigy in computing, online (originally, viewdata) service launched in 1988 by a partnership of IBM and leading US retailer Sears Roebuck; bought in 1996 by the global communications company International Wireless, which relaunched it as an Internet service.

Even though Prodigy has been lavishly funded, throughout its history it has lagged behind CompuServe and America Online (AOL). By 1996, it had 1.4 million subscribers, but had never marketed itself outside North America. In late 1996, Prodigy announced it would launch a Spanish-language service in Mexico.

productivity, biological in an ecosystem, the amount of material in the food chain produced by the primary producers (plants) that is available for consumption by animals. Plants turn carbon dioxide and water into sugars and other complex carbon compounds by means of photosynthesis. Their net productivity is defined as the quantity of carbon compounds formed, less the quantity used up by the respiration of the plant itself.

progesterone steroid hormone that occurs in vertebrates. In mammals, it regulates the menstrual cycle and pregnancy. Progesterone is secreted by the corpus luteum (the ruptured Graafian follicle of a discharged ovum).

prograde or *direct motion* in astronomy, the orbit or rotation of a planet, or satellite if the sense of rotation is the same as the general sense of rotation of the Solar System. On the celestial sphere, it refers to motion from west to east against the background of stars.

program in computing, a set of instructions that controls the operation of a computer. There are two main kinds: applications programs, which carry out tasks for the benefit of the user – for example, word processing; and systems programs, which control the internal workings of the computer. A utility program is a systems program that carries out specific tasks for the user. Programs can be written in any of a number of programming languages but are always translated into machine code before they can be executed by the computer.

program counter in computing, an alternative name for sequence-control register.

program documentation documentation that provides a complete technical description of a program, built up as the software is written, and is intended to support any later maintenance or development of the program.

program files in computing, files which contain the code used by a computer program.

program flow chart type of flow chart used to describe the flow of data through a particular computer program.

program loop part of a computer program that is repeated several times. The loop may be repeated a fixed number of times

(counter-controlled loop) or until a certain condition is satisfied (condition-controlled loop). For example, a counter-controlled loop might be used to repeat an input routine until exactly ten numbers have been input; a condition-controlled loop might be used to repeat an input routine until the data terminator 'XXX' is entered.

programmer job classification for computer personnel. Programmers write the software needed for any new computer system or application.

programming writing instructions in a programming language for the control of a computer. Applications programming is for end-user programs, such as accounts programs or word-processing packages. Systems programming is for operating systems and the like, which are concerned more with the internal workings of the computer.

There are several programming styles:

procedural programming, in which programs are written as lists of instructions for the computer to obey in sequence, is by far the most popular. It is the 'natural' style, closely matching the computer's own sequential operation; **declarative programming**, as used in the programming language PROLOG, does not describe how to solve a problem, but rather describes the logical structure of the problem. Running such a program is more like proving an assertion than following a procedure; **functional programming** is a style based largely on the definition of functions. There are very few functional programming languages, HOPE and ML being the most widely used, though many more conventional languages (for example C) make extensive use of functions; **object-oriented programming**, the most recently developed style, involves viewing a program as a collection of objects that behave in certain ways when they are passed certain 'messages'. For example, an object might be defined to represent a table of figures, which will be displayed on screen when a 'display' message is received.

programming language in computing, a special notation in which instructions for controlling a computer are written. Programming languages are designed to be easy for people to write and read, but must be capable of being mechanically translated (by a compiler or an interpreter) into the machine code that the computer can execute. Programming languages may be classified as high-level languages or low-level languages. See also source language.

program trading in finance, buying and selling a group of shares using a computer program to generate orders automatically whenever there is an appreciable movement in prices.

One form in use in the USA in 1989 was index arbitrage, in which a program traded automatically whenever there was a difference between New York and Chicago prices of an equivalent number of shares. Program trading comprised some 14% of daily trading on the New York Stock Exchange by volume in September 1989, but was widely criticized for lessening market stability. It has been blamed, among other factors, for the Stock Market crashes of 1987 and 1989.

progression sequence of numbers each occurring in a specific relationship to its predecessor. An arithmetic progression has numbers that increase or decrease by a common sum or difference (for example, 2, 4, 6, 8); a geometric progression has numbers each bearing a fixed ratio to its predecessor (for example, 3, 6, 12, 24); and a harmonic progression has numbers whose reciprocals are in arithmetic progression, for example $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$.

Project Gutenberg an electronic 'library' containing hundreds of 'etexts' – books made freely accessible via the World Wide Web and downloadable via FTP. The project started in 1971 at the University of Illinois. For copyright reasons, most of the books available are classics dating from before the 20th century, but there are also some current reference books – including the current CIA factbook.

projectile particle that travels with both horizontal and vertical motion in the Earth's gravitational field. If the frictional forces of air resistance are ignored, the two components of its motion can be analyzed separately: its vertical motion will be accelerated due to its

Programming Languages

| Language | Main uses | Description |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Ada | defence applications | high-level |
| assembler languages | jobs needing detailed control of the hardware, fast execution, and small program size | fast and efficient but require considerable effort and skill |
| ALGOL (algorithmic language) | mathematical work | high-level with an algebraic style, no longer in current use, but has influenced languages such as Ada and PASCAL |
| BASIC (beginners' all-purpose symbolic instruction code) | mainly in education, business, and the home, and among non-professional programmers, such as | easy to learn; early versions lacked the features of other languages |
| C | engineers' systems and general programming | fast and efficient; widely used as a general-purpose language; especially popular among professional programmers |
| C++ | systems and general programming, commercial software development | developed from C, adding the advantages of object-oriented programming |
| COBOL (common business-oriented language) | business programming | strongly oriented towards commercial work; easy to learn but very verbose; widely used on mainframes |
| FORTH | control applications | reverse Polish notation language |
| FORTRAN (formula translation) | scientific and computational work | based on mathematical formulae; popular among engineers, scientists, and mathematicians |
| Java | developed for consumer electronics; used for many interactive Web sites | multipurpose, cross-platform, object-oriented language with similar features to C and C++ but simpler |
| LISP (list processing) | artificial intelligence | symbolic language with a reputation for being hard to learn; popular in the academic and research communities |
| LOGO | teaching of mathematical concepts | high-level; popular with schools and home computer users |
| Modula-2 | systems and real-time programming; general programming highly-structured | intended to replace PASCAL for 'real-world' applications |
| OBBERON | general programming | small, compact language incorporating many of the features of PASCAL and Modula-2 |
| PASCAL (program appliqué à la sélection et la compilation automatique de la littérature) | general-purpose language | highly-structured; widely used for teaching programming in universities |
| Perl (pathological eclectic rubbish lister) | systems programming and Web development especially in UNIX environment | easy manipulation of text, files, and processes, |
| PROLOG (programming in logic) | artificial intelligence | symbolic-logic programming system, originally intended for theorem solving but now used more generally in artificial intelligence |

weight in the gravitational field; its horizontal motion may be assumed to be at constant velocity. In a uniform gravitational field and in the absence of frictional forces the path of a projectile is a parabola.

projection of the earth on paper, see map projection.

projector any apparatus that projects a picture on to a screen. In a slide projector, a lamp shines a light through the photographic slide or transparency, and a projection lens throws an enlarged image of the slide onto the screen. A film projector has similar optics, but incorporates a mechanism that holds the film still while light is transmitted through each frame (picture). A shutter covers the film when it moves between frames. A television projector, often used at sports events, produces an enlarged image of the television screen. It shines an intense light through a small LCD (liquid crystal display) throwing the television picture onto a large screen.

prokaryote in biology, an organism whose cells lack organelles (specialized segregated structures such as nuclei, mitochondria,

and chloroplasts). Prokaryote DNA is not arranged in chromosomes but forms a coiled structure called a nucleoid. The prokaryotes comprise only the bacteria and cyanobacteria (see blue-green algae); all other organisms are eukaryotes.

prolapse displacement of an organ due to the effects of strain in weakening the supporting tissues. The term is most often used with regard to the rectum (due to chronic bowel problems) or the uterus (following several pregnancies).

PROLOG (contraction of *programming in logic*) high-level computer-programming language based on logic. Invented in 1971 at the University of Marseille, France, it did not achieve widespread use until more than ten years later. It is used mainly for artificial intelligence programming.

PROM (acronym for *programmable read-only memory*) in computing, a memory device in the form of an integrated circuit (chip) that can be programmed after manufacture to hold information

permanently. PROM chips are empty of information when manufactured, unlike ROM (read-only memory) chips, which have information built into them. Other memory devices are EPROM (erasable programmable read-only memory) and DRAM (random-access memory).

promethium radioactive, metallic element of the lanthanide series, symbol Pm, atomic number 61, relative atomic mass 145.

It occurs in nature only in minute amounts, produced as a fission product/by-product of uranium in pitchblende and other uranium ores; for a long time it was considered not to occur in nature. The longest-lived isotope has a half-life of slightly more than 20 years.

Promethium is synthesized by neutron bombardment of neodymium, and is a product of the fission of uranium, thorium, or plutonium; it can be isolated in large amounts from the fission-product debris of uranium fuel in nuclear reactors. It is used in phosphorescent paints and as an X-ray source.

prominence bright cloud of gas projecting from the Sun into space 100,000 km/60,000 mi or more. Quiescent prominences last for months, and are held in place by magnetic fields in the Sun's corona. Surge prominences shoot gas into space at speeds of 1,000 kps/600 mps.

Loop prominences are gases falling back to the Sun's surface after a solar flare.

prompt symbol displayed on a screen indicating that the computer is ready for input. The symbol used will vary from system to system and application to application. The current cursor position is normally next to the prompt. Generally prompts only appear in command line interfaces.

pronghorn ruminant mammal *Antilocapra americana* constituting the family Antilocapridae, native to the W USA. It is not a true antelope. It is light brown and about 1 m/3 ft high. It sheds its horns annually and can reach speeds of 100 kph/60 mph. The loss of prairies to agriculture, combined with excessive hunting, has brought this unique animal close to extinction.

proof in mathematics, a set of arguments used to deduce a mathematical theorem from a set of axioms.

Some proofs command assent. Others woo and charm the intellect. They evoke delight and an overpowering desire to say 'Amen, Amen'.

JOHN WILLIAM STRUTT, 3RD BARON RAYLEIGH English physicist.

proof spirit numerical scale used to indicate the alcohol content of an alcoholic drink. Proof spirit (or 100% proof spirit) acquired its name from a solution of alcohol in water which, when used to moisten gunpowder, contained just enough alcohol to permit it to burn.

propane C_3H_8 gaseous hydrocarbon of the alkane series, found in petroleum and used as fuel.

propanol or **propyl alcohol** third member of the homologous series of alcohols. Propanol is usually a mixture of two isomeric compounds (see isomer): propan-1-ol ($\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$) and propan-2-ol ($\text{CH}_3\text{CHOHCH}_3$). Both are colourless liquids that can be mixed with water and are used in perfumery.

propanone CH_3COCH_3 (common name *acetone*) colourless flammable liquid used extensively as a solvent, as in nail-varnish remover. It boils at $56.5^\circ\text{C}/133.7^\circ\text{F}$, mixes with water in all proportions, and has a characteristic odour.

propellant substance burned in a rocket for propulsion. Two propellants are used: oxidizer and fuel are stored in separate tanks and pumped independently into the combustion chamber. Liquid oxygen (oxidizer) and liquid hydrogen (fuel) are common propellants, used, for example, in the space-shuttle main engines. The explosive charge that propels a projectile from a gun is also called a propellant.

propeller screwlike device used to propel some ships and aeroplanes. A propeller has a number of curved blades that describe a helical path as they rotate with the hub, and accelerate fluid (liquid or gas) backwards during rotation. Reaction to this backward movement of fluid sets up a propulsive thrust forwards. The marine screw propeller was developed by Francis Pettit Smith in the UK and Swedish-born John Ericson in the USA and was first used in 1839.

propene $\text{CH}_3\text{CH}=\text{CH}_2$ (common name *propylene*) second member of the alkene series of hydrocarbons. A colourless, flammable gas, it is widely used by industry to make organic chemicals, including polypropylene plastics.

propenoic acid $\text{H}_2\text{C}=\text{CHCOOH}$ (common name *acrylic acid*) acid obtained from the aldehyde propenal (acrolein) derived from glycerol or fats. Glasslike thermoplastic resins are made by polymerizing esters of propenoic acid or methyl propenoic acid and used for transparent components, lenses, and dentures. Other acrylic compounds are used for adhesives, artificial fibres, and artists' acrylic paint.

proper motion gradual change in the position of a star that results from its motion in orbit around our Galaxy, the Milky Way. Proper motions are slight and undetectable to the naked eye, but can be accurately measured on telescopic photographs taken many years apart.

Barnard's Star is the star with the largest proper motion, 10.3 arc seconds per year.

properties in chemistry, the characteristics a substance possesses by virtue of its composition.

Physical properties of a substance can be measured by physical means, for example boiling point, melting point, hardness, elasticity, colour, and physical state. Chemical properties are the way it reacts with other substances; whether it is acidic or basic, an oxidizing or a reducing agent, a salt, or stable to heat, for example.

prophylaxis any measure taken to prevent disease, including exercise and vaccination. Prophylactic (preventive) medicine is an aspect of public-health provision that is receiving increasing attention.

proportion the relation of a part to the whole (usually expressed as a fraction or percentage). In mathematics two variable quantities x and y are proportional if, for all values of x , $y = kx$, where k is a constant. This means that if x increases, y increases in a linear fashion.

A graph of x against y would be a straight line passing through the origin (the point $x = 0$, $y = 0$). y is inversely proportional to x if the graph of y against $1/x$ is a straight line through the origin. The corresponding equation is $y = k/x$. Many laws of science relate quantities that are proportional (for example, Boyle's law).

proportional font font in which individual letters of the alphabet take up different amounts of space according to their shape.

Computer fixed fonts are designed so that each letter has the same width and takes up the same amount of space on a line. A letter 'I', however, logically is thinner than a letter 'o'. Proportional fonts allow spacing according to these differences, and are therefore easier to read. Until the advent of personal computers and font software such as Adobe PostScript, proportional spacing was the province of professional typography, used in books, newspapers, magazines, and other commercial publishing.

proprioceptor in biology, one of the sensory nerve endings that are located in muscles, tendons, and joints. They relay information on the position of the body and the state of muscle contraction.

prop root or **stilt root** modified root that grows from the lower part of a stem or trunk down to the ground, providing a plant with extra support. Prop roots are common on some woody plants, such as mangroves, and also occur on a few herbaceous plants, such as maize. Buttress roots are a type of prop root found at the base of tree trunks, extended and flattened along the upper edge to form massive triangular buttresses; they are common on tropical trees.

propyl alcohol common name for propanol .

propylene common name for propene .

prosimian or **primitive primate** in zoology, any animal belonging to the suborder Strepsirrhini of primates. Prosimians are characterized by a wet nose with slitlike nostrils, the tip of the nose having a prominent vertical groove. Examples are lemurs, pottos, tarsiers, and the aye-aye.

prostaglandin any of a group of complex fatty acids present in the body that act as messenger substances between cells. Effects include stimulating the contraction of smooth muscle (for example, of the womb during birth), regulating the production of stomach acid, and modifying hormonal activity. In excess, prostaglandins may produce inflammatory disorders such as arthritis. Synthetic prostaglandins are used to induce labour in humans and domestic animals.

The analgesic actions of substances such as aspirin are due to inhibition of prostaglandin synthesis.

prostate cancer in medicine, cancer of the prostate gland. It is a slow progressing cancer and about 60% of cases are detected before metastasis (spreading) so it can be successfully treated by surgical removal of the gland and radiotherapy. It is, however, the second commonest cancer-induced death in males (after lung cancer).

Symptoms include a frequent need to urinate, with weak, painful, and interrupted urine flow.

prostatectomy surgical removal of the prostate gland. In many men over the age of 60 the prostate gland enlarges, causing obstruction to the urethra. This causes the bladder to swell with retained urine, leaving the sufferer more prone to infection of the urinary tract.

The treatment of choice is transurethral resection of the prostate, in which the gland is removed by passing an endoscope (slender optical instrument) up the urethra and using diathermy to burn away the prostatic tissue. This procedure has now largely replaced 'open' prostatectomy, in which the prostate is removed via an incision in the abdomen.

prostate gland gland surrounding and opening into the urethra at the base of the bladder in male mammals.

The prostate gland produces an alkaline fluid that is released during ejaculation; this fluid activates sperm, and prevents their clumping together. Older men may develop benign prostatic hyperplasia (BHP), a painful condition in which the prostate becomes enlarged and restricts urine flow. This can cause further problems of the bladder and kidneys. It is treated by prostatectomy.

PROSTHETIC HISTORY PAGE

<http://pele.repoc.nwu.edu/nupoc/prosHistory.html>

History of prosthetics from prehistory to modern times. The Web site describes artificial limbs in historical terms, citing many cases from classical texts. The Web site lacks the graphics which would make it much more interesting, but the text descriptions made are reasonably lengthy and complete.

prosthesis artificial device used to substitute for a body part which is defective or missing. Prostheses include artificial limbs, hearing aids, false teeth and eyes, heart pacemakers and plastic heart valves and blood vessels.

Prostheses in the form of artificial limbs, such as wooden legs and metal hooks for hands, have been used for centuries, although artificial limbs are now more natural-looking and comfortable to wear. The comparatively new field of bionics has developed myoelectric, or bionic, arms, which are electronically operated and worked by minute electrical impulses from body muscles.

protactinium Latin *protos* 'before' + *aktis* 'first ray' silver-grey, radioactive, metallic element of the actinide series, symbol Pa, atomic number 91, relative atomic mass 231.036. It occurs in nature in very small quantities, in pitchblende and other uranium ores. It has 14 known isotopes; the longest-lived, Pa-231, has a half-life of 32,480 years.

protandry in a flower, the state where the male reproductive organs reach maturity before those of the female. This is a common method of avoiding self-fertilization. See also protogyny .

protease general term for a digestive enzyme capable of splitting proteins. Examples include pepsin, found in the stomach, and trypsin, found in the small intestine.

protected mode operating mode of Intel microprocessors (80286 and above), which allows multitasking and provides other features such as extended memory and virtual memory (above 1 Gbyte). Protected mode operation also improves data security.

INTRODUCTION TO PROTEINS

http://biotech.chem.indiana.edu/pages/protein_intro.html

Lucid introduction to the world of proteins with discussions of their structures and sequences, as well as descriptions of some major kinds of proteins. The site also includes a useful glossary and offers a variety of photographic shots.

protein complex, biologically important substance composed of amino acids joined by peptide bonds. Proteins are essential to all living organisms. As enzymes they regulate all aspects of metabolism. Structural proteins such as keratin and collagen make up the skin, claws, bones, tendons, and ligaments; muscle proteins produce movement; haemoglobin transports oxygen; and membrane proteins regulate the movement of substances into and out of cells. For humans, protein is an essential part of the diet, and is found in

peptide — this is one made of just three amino acid units. Proteins consist of very large numbers of amino acid units in long chains, folded up in specific ways

protein A protein molecule is a long chain of amino acids linked by peptide bonds. The properties of a protein are determined by the order, or sequence, of amino acids in its molecule, and by the three-dimensional structure of the molecular chain. The chain folds and twists, often forming a spiral shape.

greatest quantity in soya beans and other grain legumes, meat, eggs, and cheese.

Other types of bond, such as sulphur-sulphur bonds, hydrogen bonds, and cation bridges between acid sites, are responsible for creating the protein's characteristic three-dimensional structure, which may be fibrous, globular, or pleated. Protein provides 4 kcal of energy per gram (60 g per day is required).

protein engineering the creation of synthetic proteins designed to carry out specific tasks. For example, an enzyme may be designed to remove grease from soiled clothes and remain stable at the high temperatures in a washing machine.

protein synthesis manufacture, within the cytoplasm of the cell, of the proteins an organism needs. The building blocks of proteins are amino acids, of which there are 20 types. The pattern in which the amino acids are linked decides what kind of protein is produced. In turn it is the genetic code, contained within ζ DNA, that determines the precise order in which the amino acids are linked up during protein manufacture.

Interestingly, DNA is found only in the nucleus, yet protein synthesis occurs only in the cytoplasm. The information necessary for making the proteins is carried from the nucleus to the cytoplasm by another nucleic acid, ζ RNA.

Proterozoic eon of geological time, 3.5 billion to 570 million years ago, the second division of the Precambrian. It is defined as the time of simple life, since many rocks dating from this eon show traces of biological activity, and some contain the fossils of bacteria and algae.

prothallus in botany, a short-lived gametophyte of many ferns and other pteridophytes (such as horsetails or clubmosses). It bears either the male or female sex organs, or both. Typically it is a small, green, flattened structure that is anchored in the soil by several rhizoids (slender, hairlike structures, acting as roots) and needs damp conditions to survive. The reproductive organs are borne on the lower surface close to the soil. See also ζ alternation of generations.

protist in biology, a single-celled organism which has a eukaryotic cell, but which is not a member of the plant, fungal, or animal kingdoms. The main protists are ζ protozoa.

Single-celled photosynthetic organisms, such as diatoms and dinoflagellates, are classified as protists or algae. Recently the term has also been used for members of the kingdom Protista, which features in certain five-kingdom classifications of the living world (see also ζ plant classification). This kingdom may include slime moulds, all algae (seaweeds as well as unicellular forms), and protozoa.

protocol in computing, an agreed set of standards for the transfer of data between different devices. They cover transmission speed, format of data, and the signals required to synchronize the transfer. See also ζ interface.

protogyny in a flower, the state where the female reproductive organs reach maturity before those of the male. Like protandry, in which the male organs reach maturity first, this is a method of avoiding self-fertilization, but it is much less common.

proton Greek '*first*' in physics, a positively charged subatomic particle, a constituent of the nucleus of all atoms. It belongs to the ζ baryon subclass of the ζ hadrons. A proton is extremely long-lived, with a lifespan of at least 10^{32} years. It carries a unit positive charge equal to the negative charge of an electron. Its mass is almost 1,836 times that of an electron, or 1.67×10^{-27} kg. Protons are composed of two up ζ quarks and one down quark held together by ζ gluons. The number of protons in the atom of an element is equal to the atomic number of that element.

protonema in botany, a young ζ gametophyte of a moss, which develops from a germinating spore (see ζ alternation of generations). Typically it is a green, branched, threadlike structure that grows over the soil surface bearing several buds that develop into the characteristic adult moss plants.

proton number alternative name for ζ atomic number.

Proton rocket Soviet space rocket introduced in 1965, used to launch heavy satellites, space probes, and the *Salut* and *Mir* space stations.

Proton consists of up to four stages as necessary. It has never been used to launch humans into space.

protoplasm contents of a living cell. Strictly speaking it includes all the discrete structures (organelles) in a cell, but it is often used simply to mean the jellylike material in which these float. The contents of a cell outside the nucleus are called ζ cytoplasm.

protostar in astronomy, early formation of a star that has recently condensed out of an interstellar cloud and which is not yet hot enough for hydrogen burning to start. Protostars derive their energy from gravitational contraction. See ζ Hayashi track.

prototheria subclass of mammals made up of the egg-laying monotremes. It contains only the echidna (spiny anteater) and the platypus.

prototype in technology, any of the first few machines of a new design. Prototypes are tested for performance, reliability, economy, and safety; then the main design can be modified before full-scale production begins.

protozoa group of single-celled organisms without rigid cell walls. Some, such as amoeba, ingest other cells, but most are ζ saprotrophs or parasites. The group is polyphyletic (containing organisms which have different evolutionary origins).

protractor instrument used to measure a flat ζ angle.

provitamin any precursor substance of a vitamin. Provitamins are ingested substances that become converted to active vitamins within the organism. One example is ergosterol (provitamin D_2), which through the action of sunlight is converted to calciferol (vitamin D_2); another example is beta-carotene, which is hydrolysed in the liver to vitamin A.

Proxima Centauri the closest star to the Sun, 4.2 light years away. It is a faint (red dwarf, visible only with a telescope, and is a member of the Alpha Centauri triple-star system).

It is called Proxima because it is about 0.1 light years closer to us than its two partners.

proxy server on the ζ World Wide Web, a server which 'stands in' for another server, storing and forwarding files on behalf of a computer which might be slower or too busy to deal with the request itself. Many ζ URLs (Web addresses) redirect the enquirer to a proxy server which then supplies the requested page.

In 1996, the authorities in Singapore imposed a legal requirement on local Internet providers to filter all traffic via a government-run proxy server that can block access to various sites - the first serious government attempt to censor the Internet.

prussic acid former name for ζ hydrocyanic acid.

pseudocarp in botany, a fruitlike structure that incorporates tissue that is not derived from the ovary wall. The additional tissues may be derived from floral parts such as the ζ receptacle and ζ calyx. For example, the coloured, fleshy part of a strawberry develops from the receptacle and the true fruits are small ζ achenes - the 'pips' embedded in its outer surface. Rose hips are a type of pseudocarp that consists of a hollow, fleshy receptacle containing a number of achenes within. Different types of pseudocarp include pineapples, figs, apples, and pears.

A ζ coenocarpium is a fleshy, multiple pseudocarp derived from an inflorescence rather than a single flower. The pineapple has a thickened central axis surrounded by fleshy tissues derived from the receptacles and floral parts of many flowers. A fig is a type of pseudocarp called a ζ syconium, formed from a hollow receptacle with small flowers attached to the inner wall. After fertilization the ovaries of the female flowers develop into one-seeded achenes.

Apples and pears are ζ opomes, another type of pseudocarp.

pseudocopulation The male bee, attracted to the orchid because of its resemblance to a female bee, attempts to mate with the flower. The bee's efforts cover its body with pollen, which is carried to the next flower it visits.

pseudocopulation attempted copulation by a male insect with a flower. It results in pollination of the flower and is common in the orchid family, where the flowers of many species resemble a particular species of female bee. When a male bee attempts to mate with a flower, the pollinia (groups of pollen grains) stick to its body. They are transferred to the stigma of another flower when the insect attempts copulation again.

pseudomorph mineral that has replaced another *in situ* and has retained the external crystal shape of the original mineral.

pseudonym in computing, name adopted by someone on the Internet, especially to participate in USENET or discussions using IRC (Internet Relay Chat). Pseudonyms are often jokey or witty, and are sometimes used to conceal the user's gender or identity.

psi in parapsychology, a hypothetical faculty common to humans and animals, said to be responsible for extrasensory perception, telekinesis, and other paranormal phenomena.

psoriasis chronic, recurring skin disease characterized by raised, red, scaly patches, on the scalp, elbows, knees, and elsewhere. Tar preparations, steroid creams, and ultraviolet light are used to treat it, and sometimes it disappears spontaneously. Psoriasis may be accompanied by a form of arthritis (inflammation of the joints).

PSORIASIS

<http://biomed.nus.sg/nsc/psoriasi.html>

Well-presented practical information about psoriasis from Singapore's National Skin Centre. The condition is explained in simple language supported by a picture. There are details of various treatment regimes.

PSSTN (abbreviation for **Public Switched Telephone Network**) telephone network used by the general public, and sometimes used as the medium to link LANs. PSSTNs are minor roads which lead to the information superhighway.

psychedelic drug any drug that produces hallucinations or altered states of consciousness. Such sensory experiences may be in the auditory, visual, tactile, olfactory, or gustatory fields or in any combination. Among drugs known to have psychedelic effects are LSD (lysergic acid diethylamide), mescaline, and, to a mild degree, marijuana, along with a number of other plant-derived or synthetically prepared substances.

psychiatry branch of medicine dealing with the diagnosis and treatment of mental disorder, normally divided into the areas of neurotic conditions, including anxiety, depression, and hysteria, and psychotic disorders, such as schizophrenia. Psychiatric treatment consists of drugs, analysis, or electroconvulsive therapy.

In practice there is considerable overlap between psychiatry and clinical psychology, the fundamental difference being that psychiatrists are trained medical doctors (holding an MD degree) and may therefore prescribe drugs, whereas psychologists may hold a PhD but do not need a medical qualification to practise. See also psychoanalysis.

psychoanalysis theory and treatment method for neuroses, developed by Sigmund Freud in the 1890s. Psychoanalysis asserts that the impact of early childhood sexuality and experiences, stored in the unconscious, can lead to the development of adult emotional problems. The main treatment method involves the free association of ideas, and their interpretation by patient and analyst, in order to discover these long-buried events and to grasp their significance to the patient, linking aspects of the patient's historical past with the present relationship to the analyst. Psychoanalytic treatment aims to free the patient from specific symptoms and from irrational inhibitions and anxieties.

concepts As a theoretical system, psychoanalysis rests on three basic concepts. The central concept is that of the unconscious, a reservoir within one's mental state which contains elements and experiences of which one is unaware, but which may to some extent be brought into preconscious and conscious awareness, or inferred from aspects of behaviour. The second and related basic concept is that of resistance, a process by which unconscious elements are forcibly kept out of the conscious awareness by an active repressive force. Freud came to experience the third basic concept in his work, known as transference, with his earliest patients, who transferred to him aspects of their past relationships with others, so that their relationship with him was coloured by their previous feelings. The analysis of the transference in all its manifestations has become a vital aspect of current psychoanalytic practice.

id, ego, and superego Freud proposed a model of human psychology based on the concept of the conflicting id, ego, and superego. The id is the mind's instinctual element which demands pleasure and satisfaction; the ego is the conscious mind which deals with the demands of the id and superego; the superego is the ethical element which acts as a conscience and may produce feelings of guilt. The conflicts between these three elements can be used to explain a range of neurotic symptoms.

other schools In the early 1900s a group of psychoanalysts gathered around Freud. Some of these later broke away and formed their own schools, notably Alfred Adler in 1911 and Carl Jung in 1913. The significance of early infantile experience has been further elaborated in the field of child analysis, particularly in the work of Melanie Klein and her students, who pay particular attention to the development of the infant in the first six to eight months of life.

psychology systematic study of human and animal behaviour. The first psychology laboratory was founded in 1879 by Wilhelm Wundt at Leipzig, Germany. The subject includes diverse areas of study and application, among them the roles of instinct, heredity, environment, and culture; the processes of sensation, perception, learning, and memory; the bases of motivation and emotion; and the functioning of thought, intelligence, and language. Significant psychologists have included Gustav Fechner, founder of psychophysics; Wolfgang Köhler, one of the Gestalt or 'whole' psychologists; Sigmund Freud and his associates Carl Jung and Alfred Adler; William James, Jean Piaget; Carl Rogers; Hans Eysenck; J B Watson; and B F Skinner.

Experimental psychology emphasizes the application of rigorous

Psychology: chronology

- 1846** E H Weber reported on his pioneering quantitative investigations of touch in *On Touch and Common Sensibility*.
- 1860** G T Fechner published *Elements of Psychophysics*, in which he presented the first statistical treatment of psychological data.
- 1879** Wilhelm Wundt founded the first psychological laboratory in Leipzig.
- 1885** H Ebbinghaus published his experimental research into memory.
- 1890** William James published the first comprehensive psychology text, *Principles of Psychology*.
- 1895** Joseph Breuer and Sigmund Freud published *Studies on Hysteria*, containing the first writings on psychoanalysis.
- 1896** The first psychology clinic was founded by Lightner Witmer at the University of Pennsylvania; the first use of the term 'clinical psychology'.
- 1900** Freud's *Interpretation of Dreams* published.
- 1905** Alfred Binet and Théodore Simon developed the first effective intelligence test.
- 1906** Ivan Pavlov first lectured in the West on conditioned reflexes in animals.
- 1908** The first textbook of social psychology was published by William McDougall and E A Ross.
- 1911** Max Wertheimer, Wolfgang Kohler, and Kurt Koffka founded the Gestalt School in Frankfurt.
- 1913** John B Watson's article 'Psychology as a behaviorist views it' was published and the behaviourist movement thus launched.
- 1923** Jean Piaget's *The Language and the Thought of the Child* published, the first of his many books on the development of thinking.
- 1927** C Spearman proposed in *The Abilities of Man* that intelligence comprises two kinds of factors, a general factor ('g') and specific factors.
- 1929** H Berger published his findings on the electroencephalogram (EEG).
- 1938** B F Skinner published *The Behavior of Organisms*, detailing his study of operant conditioning and his radical behaviourism.
- 1943** C L Hull published his influential book *Principles of Behavior*, the most rigorous account of conditioning and learning from the perspective of behaviourism.
- 1947** Hans Eysenck published *Dimensions of Personality*, a large-scale study of neuroticism and extraversion.
- 1948** Norbert Wiener coined the term 'cybernetics' and published *Cybernetics: Control and Communication in the Animal and Machine*.
- 1949** D O Hebb's *Organization of Behaviour* re-emphasized the role of central (brain) processes in the explanation of behaviour.
- 1950** Alan Turing proposed his test of whether a machine can be said to think, in the article 'Computing Machinery and Intelligence'. The *Authoritarian Personality* by Theodor Adorno and others published.
- 1953** E Aserinsky and N Kleitman published the first account of REM (rapid eye movement) sleep.
- 1957** Noam Chomsky published *Syntactic Structures*, a seminal work of psycholinguistics, which revolutionized the study of language. L Festinger published *A Theory of Cognitive Dissonance*.
- 1958** A Newell and H A Simon, with J C Shaw, published their article on human problem-solving, the first account of the information-processing approach to human psychology.
- 1958** Donald E Broadbent published *Perception and Communication*, a detailed account of information-processing psychology.
- 1960** G A Miller, E Galanter, and K Pribram applied the idea of a hierarchically structured computer program to the whole of psychology in their *Plans and the Structure of Behaviour*.
- 1961** A Newell and H A Simon published their pioneering computational model of human problem-solving, the General Problem Solver.
- 1962** M S Gazzaniga, J E Bogen, and R W Sperry first reported on the 'split brain' phenomenon in epileptic patients.
- 1963** Stanley Milgram published his first studies of obedience and the conditions under which individuals will inflict harm when so instructed.
- 1967** Konovsky published *Integrative Activity of the Brain*, a melding of conditioning principles with sensation and motivation. Ulrich Neisser's *Cognitive Psychology* marked renewed interest in the study of cognition after years in which behaviourism had dominated.
- 1968** R C Atkinson and R M Shiffrin developed their theory of interacting memory systems in cognitive processing.
- 1970** T Shallice and E K Warrington provided the first of much evidence from brain-damaged patients that short-term memory is parallel with long-term memory and is best viewed as a collection of separate processing modules.
- 1972** E Tulving distinguished episodic memory (for personal experience) and semantic memory (for general knowledge and facts about the world).
- 1983** J A Fodor published *The Modularity of Mind*, dividing the mind into independent cognitive processors and defining their activity.
- 1985** A new view of intelligence proposed by Robert J Sternberg in *Beyond IQ: A Triarchic Theory of Intelligence*.
- 1986** J L McClelland and D E Rumelhart developed complex computational networks using parallel processing to simulate human learning and categorization.
- 1989** The mathematician Roger Penrose, in *The Emperor's New Mind*, argued that the computational account of the mind is incomplete, particularly concerning consciousness.
- 1992** The philosopher John Searle, in *The Rediscovery of the Mind*, argued for the return of consciousness to its position as the central topic in psychology and cognitive science.

and objective scientific methods to the study of a wide range of mental processes and behaviour, whereas **social psychology** concerns the study of individuals within their social environment; for example, within groups and organizations. This has led to the development of related fields such as **occupational psychology**, which studies human behaviour at work, and **educational psychology**. **Clinical psychology** concerns the understanding and treatment of mental health disorders, such as anxiety, phobias, or depression; treatment may include behaviour therapy, cognitive therapy, counselling, psychoanalysis, or some combination of these.

Modern studies have been diverse; for example, the psychological causes of obesity; the nature of religious experience; and the underachievement of women seen as resulting from social pressures. Other related subjects are the nature of sleep and dreams, and the possible extensions of the senses, which leads to the more contentious ground of parapsychology.

psychometrics measurement of mental processes. This includes intelligence and aptitude testing to help in job selection and in the

clinical assessment of cognitive deficiencies resulting from brain damage.

psychopathy personality disorder characterized by chronic antisocial behaviour (violating the rights of others, often violently) and an absence of feelings of guilt about the behaviour.

Because the term 'psychopathy' has been misused to refer to any severe mental disorder, many psychologists now prefer the term 'antisocial personality disorder', though this also includes cases in which absence or a lesser degree of guilt is not a characteristic feature.

psychosis or **psychotic disorder** general term for a serious mental disorder where the individual commonly loses contact with reality and may experience hallucinations (seeing or hearing things that do not exist) or delusions (fixed false beliefs). For example, in a paranoid psychosis, an individual may believe that others are plotting against him or her. A major type of psychosis is schizophrenia.

psychosomatic of a physical symptom or disease thought to arise from emotional or mental factors.

The term 'psychosomatic' has been applied to many conditions, including asthma, migraine, hypertension, and peptic ulcers. Whereas it is unlikely that these and other conditions are wholly due to psychological factors, emotional states such as anxiety or depression do have a distinct influence on the frequency and severity of illness.

psychosurgery operation to relieve severe mental illness. See *leucotomy*.

psychotherapy any treatment for psychological problems that involves talking rather than surgery or drugs. Examples include cognitive therapy and psychoanalysis.

psychotic disorder another name for *psychosis*.

pt symbol for *point*.

ptarmigan hardy, northern ground-dwelling bird of genus *Lagopus*, family Phasianidae (which also includes *grouse*), with feathered legs and feet.

The willow ptarmigan *L. lagopus*, found in bushes and heather in northern parts of North America, Europe, and Asia, grows to 38 cm/15 in and turns white in the winter.

pteridophyte simple type of *vascular plant*. The pteridophytes comprise four classes: the Psilosida, including the most primitive vascular plants, found mainly in the tropics; the Lycoposida, including the club mosses; the Sphenopsida, including the horsetails; and the Pteropsida, including the ferns. They do not produce seeds.

They are mainly terrestrial, non-flowering plants characterized by the presence of a vascular system; the possession of true stems, roots, and leaves; and by a marked alternation of generations, with the sporophyte forming the dominant generation in the life cycle. The pteridophytes formed a large and dominant flora during the Carboniferous period, but many are now known only from fossils.

pterodactyl genus of *pterosaur*.

pterosaur extinct flying reptile of the order Pterosauria, existing in the Mesozoic age. They ranged from the size of a starling to the 12 m/39 ft wingspan of *Arambourgiania philadelphiae*; the largest of the pterosaurs discovered so far. Some had horns on their heads that, when in flight, made a whistling to roaring sound.

Ptolemy (c. AD 100–c. AD 170)

(*Claudius Ptolemaeus*) Egyptian astronomer and geographer. His *Almagest* developed the theory that Earth is the centre of the universe, with the Sun, Moon, and stars revolving around it. In 1543 the Polish astronomer Copernicus proposed an alternative to the Ptolemaic system. Ptolemy's *Geography* was a standard source of information until the 16th century.

The *Almagest* (he called it *Syntaxis*) contains all his works on astronomical themes, the only authoritative works until the time of Copernicus. Probably inspired by Plato, Ptolemy began with the premise that the Earth was a perfect sphere. All planetary orbits were circular, but those of Mercury and Venus, and possibly Mars (Ptolemy was not sure), were epicyclic (the planets orbited a point that itself was orbiting the Earth).

The sphere of the stars formed a dome with points of light attached or pricked through.

Pterosaurs were formerly assumed to be smooth-skinned dinosaurs, but recent discoveries show that at least some were furry, probably warm-blooded, and may have had muscle fibres and blood vessels on their wings, stiffened by moving the hind legs, thus allowing controlled and strong flapping flight.

PTFE abbreviation for *polytetrafluoroethene*.

ptomaine any of a group of toxic chemical substances (alkaloids) produced as a result of decomposition by bacterial action on proteins.

puberty stage in human development when the individual becomes sexually mature. It may occur from the age of ten upwards. The sexual organs take on their adult form and pubic hair grows. In girls, menstruation begins, and the breasts develop; in boys, the voice breaks and becomes deeper, and facial hair develops.

pubes lowest part of the front of the human trunk, the region where the external generative organs are situated. The underlying bony structure, the pubic arch, is formed by the union in the mid-line of the two pubic bones, which are the front portions of the hip bones. In women this is more prominent than in men, to allow more room for the passage of the child's head at birth, and it carries a pad of fat and connective tissue, the *mons veneris* (mount of Venus), for its protection.

public-domain software any computer program that is not under copyright and can therefore be used freely without charge. Much of this software has been written in US universities, under government contract. Public-domain software should not be confused with *shareware*, which is under copyright.

public key in *public-key cryptography*, a string of *bits* that is associated with a particular person and that may be used to decrypt messages from that person or to encrypt messages to him/her.

public-key cryptography system that allows remote users to exchange encrypted data without the need to transmit a secret key in advance. Under this system, first proposed by Whitfield Diffie and Martin Hellman in a widely read and influential paper 'New Directions in Cryptography' 1976, each party has a personal pair of keys, one private and one public. The private key is kept secret and not given out to anyone. The public key, however, is distributed widely, to friends, business partners, and even to public key servers – computers which store many users' public keys so that anyone can obtain a copy. Each user asks as many people as possible to sign his/her public key, to verify that it is actually his/hers.

The two keys are complementary. The sender of a message – usually known as Bob – encrypts his message with his private key and sends it to the recipient, usually called Alice. She decrypts it with her public key and by doing so verifies that the message came from him. If Bob wants the message to be unreadable by anyone but Alice, he encrypts it with her public key so it can only be decrypted with her private key, which she is keeping secret. Using both sets of keys authenticates the message and ensures its privacy.

Several algorithms in common use apply public-key cryptography, including the *RSA* algorithm, published in 1977 in *Scientific American* and named after its inventors, Ronald Rivest, Adi Shamir, and Leonard Adleman, and the *Skipjack* algorithm used in the *Clipper* chip. The disadvantage is that it is extremely slow, so it is common on the Net to see *Pretty Good Privacy* (PGP), which uses *RSA*, being used only to encrypt a digest of the message generated using a *hash* function. This is appended to the end of the message along with a listing of the user's public key.

public news server in computing, site, often provided by an institution, which provides free access to *USENET*. Public news servers offer an alternative to taking a news feed from an *Internet Service Provider* (ISP).

puddle clay clay, with sand or gravel, that has had water added and mixed thoroughly so that it becomes watertight. The term was coined in 1762 by the canal builder James Brindley, although the use of such clay in dams goes back to Roman times.

puff adder variety of *adder*, a poisonous snake.

puffball ball-shaped fruiting body of certain fungi (see *fungus*) that cracks open when it ripens, releasing the enclosed spores in the form of a brown powder; for example, the common puffball (*L. perlatum*). (Genera *Lycoperdon* and *Calvatia*.)

PUFFBALL

The giant puffball fungus can grow up to 1.8 m/6 ft in circumference.

puffer fish fish of the family Tetraodontidae. As a means of defence it inflates its body with water until it becomes spherical and the skin spines become erect. Puffer fish are mainly found in warm waters, where they feed on molluscs, crustaceans, and coral.

There are approximately 120 puffer fish species. They vary in size, up to 50 cm/20 in long. To allow inflation, they have elastic skin and no ribs. The skin of some puffer fish is poisonous (25 times more toxic than cyanide). In Japan, where they are called *fugu*, they are prized as a delicacy after the poison has been removed. Nevertheless, the death of about 100 diners is recorded each year.

puffin any of various sea birds of the genus *Fratercula* of the *auk* family, found in the N Atlantic and Pacific. The puffin is about 35 cm/14 in long, with a white face and front, red legs, and a large deep bill, very brightly coloured in summer. Having short wings and webbed feet, puffins are poor fliers but excellent swimmers. They nest in rock crevices, or make burrows, and lay a single egg.

pug breed of small dog with short wrinkled face, hanging ears, chunky body, and tail curled over the hip. It weighs 6–8 kg/13–18 lb. Its short coat may be black, beige or grey; the beige or grey dogs have black on the face and ears.

Pugwash group of scientists working towards nuclear disarmament. It came into being 1954 following a suggestion by Bertrand Russell to Polish physicist Joseph Rotblat. The name derives from the Nova Scotian town where the first meeting was held. Pugwash shared the 1995 Nobel Peace Prize with Rotblat.

The Pugwash conference in 1961 included both the US presidential science adviser and the vice president of the Soviet Academy of Sciences and led to a follow-on discussion with President Kennedy on a nuclear test ban (a test-ban treaty was signed in 1963).

puli breed of herding dog originating in Hungary. It has a long black or dark grey coat with a rough 'corded' texture. The puli stands about 44 cm/17 in tall. Its head is rounded, with a short muzzle, drooping ears, and its tail is curved back.

pull-down menu in computing, a list of options provided as part of a graphical user interface. The presence of pull-down menus is normally indicated by a row of single words at the top of the screen. When the user points at a word with a mouse, a full menu appears (is pulled down) and the user can then select the required option. Compare with *pop-up menu*.

In some graphical user interfaces the menus appear from the bottom of the screen and in others they may appear at any point on the screen when a special menu button is pressed on the mouse.

pulley simple machine consisting of a fixed, grooved wheel, sometimes in a block, around which a rope or chain can be run. A simple pulley serves only to change the direction of the applied effort (as in a simple hoist for raising loads). The use of more than one pulley results in a mechanical advantage, so that a given effort can raise a heavier load.

The mechanical advantage depends on the arrangement of the pulleys. For instance, a block and tackle arrangement with three pulleys supporting the load will lift it with one-third of the effort needed to lift it directly (if friction is ignored), giving a mechanical advantage of three.

pulley The mechanical advantage of a pulley increases with the number of rope strands. If a pulley system has four ropes supporting the load, the mechanical advantage is four, and a 5 Newton force will lift a 20 Newton load.

pulmonary pertaining to the lungs.

pulsar celestial source that emits pulses of energy at regular intervals, ranging from a few seconds to a few thousandths of a second. Pulsars are thought to be rapidly rotating neutron stars, which flash at radio and other wavelengths as they spin. They were discovered in 1967 by Jocelyn Bell Burnell and Antony Hewish at the Mullard Radio Astronomy Observatory, Cambridge, England. Over 500 radio pulsars are now known in our Galaxy, although a million or so may exist.

LITTLE GREEN MEN, WHITE DWARFS, OR PULSARS?

<http://www.bigear.org/vollnol/burnell.htm>

Entertaining first-hand history of the discovery of pulsars. This is the text of an after-dinner speech given by Bell Burnell. It gives an intimate account of the excitement and challenges of gamma and X-ray astronomy. There is also a brief biography of the pioneering astronomer.

Pulsar: Discovery

by Peter Lafferty

Little green men?

Making a major scientific discovery is not as many people imagine; often, there is no 'eureka moment' or single instant of discovery. Discovery is more often a process of checking and rechecking, of gradually eliminating spurious effects, until the truth is apparent. The discovery of the first pulsar shows this process in action.

Luck played a part in the discovery. In 1967 Antony Hewish at the Mullard Radio Astronomy Laboratory, Cambridge, England, constructed a new type of radio telescope – a large array of 2,048 aerials covering an area of 1.8 hectares/4.4 acres – to study the 'twinkling' or scintillation of radio galaxies. This is caused by clouds of ionized gas ejected from the Sun. It is most noticeable at metre wavelengths, so the new telescope had to be sensitive to radiation of this wavelength. Most radio telescopes achieve high sensitivity by averaging incoming signals for several seconds, and so are unsuitable for studying rapidly varying signals. They collect radiation with wavelengths of around a centimetre. The new telescope's ability to detect rapidly varying signals of metre wavelength was just what was needed to detect a pulsar.

Twinkle, twinkle, little galaxy

The telescope began work in July 1967. Its first task was to locate all radio galaxies twinkling in the area of sky accessible to it. Each day, as the Earth rotated, the telescope swept its radio eye across a band of sky. A complete scan took four days. Initially a graduate student, Jocelyn Bell, ran the survey and analysed the results, output on about 30 m/100 ft of chart paper each day.

After a few weeks, Bell noticed an unusual signal: not a single blip, but an untidy bunch of squiggles on the chart. It was nothing like the signals she was looking for, so she marked a query on the chart and did not investigate further. Later, when she saw the same signal on another chart, she realized it merited closer attention. The signal came from a part of the sky where scintillations were normally weak. It occurred at night, and scintillations are strongest during the day. A faster chart recorder was installed for a more detailed look at the signal. It would stretch out the signal over a longer chart, like a photographic enlargement.

What was going on?

For a while, Bell and Hewish's efforts were frustrated – the signal weakened and vanished. For a month, there was no sign of it. The

researchers feared that they had seen a one-off event; possibly a star flaring brightly for a short time. If so, they had missed the chance to study it in detail. However, on 28 November, it returned. This time, the new recorder revealed the true nature of the signal. It was a series of short pulses about 1.3 seconds apart. Timing the pulses more accurately showed that they were in step to within one-millionth of a second. Their short duration indicated that they were coming from a very small object. Something peculiar was going on, but what?

The task now was to rule out spurious effects. Did the signal result from a machine malfunction? Was it caused by a satellite signal? Or a radar echo from the Moon? The fact that the signal appeared at regular intervals hinted that it was not a machine malfunction. Having calculated when the signal would next appear, at the appointed time the research team stood around the recorder. Nothing! Hewish and the others began to wander away. But before they reached the door, they were called back. 'Here it is!' said a student. They had miscalculated when the signal would be picked up. They knew now that it came from outside the laboratory.

Is there anybody there?

Further study established that the signal rotated with the stars, and came from beyond the Solar System, but from within our galaxy. At one stage, Hewish thought that the signal might be a message from an extraterrestrial civilization. It was given the name 'LGM', for 'little green men'. However, this possibility was ruled out. Other beings must live on a planet circling round a star. The planetary motion would show up as a slight variation in the pulse rate. After carefully timing the pulses for several weeks, the idea of a planetary origin was given up.

On 21 December 1967 Bell discovered a second signal elsewhere in the sky. This clinched the reality of the phenomenon, and the name 'pulsar' was quickly coined to describe the object radiating the pulsation. The results were published in February 1968; within a year it was generally accepted that the signals came from rapidly spinning neutron stars. Since then more than 500 pulsars have been discovered. Antony Hewish shared the 1974 Nobel Prize for physics with British radio astronomer Martin Ryle for their work in radio astronomy and, in particular, the discovery of pulsars.

Pulsars slow down as they get older, and eventually the flashes fade. Of the 500 known radio pulsars, 20 are millisecond pulsars (flashing 1,000 times a second). Such pulsars are thought to be more than a billion years old. Two pulsars, one (estimated to be 1,000 years old) in the Crab nebula and one (estimated to be 11,000 years old) in the constellation Vela, give out flashes of visible light.

pulse impulse transmitted by the heartbeat throughout the arterial systems of vertebrates. When the heart muscle contracts, it forces blood into the aorta (the chief artery). Because the arteries are elastic, the sudden rise of pressure causes a throb or sudden swelling through them. The actual flow of the blood is about 60 cm² ft a second in humans. The average adult pulse rate is generally about 70 per minute. The pulse can be felt where an artery is near the surface, for example in the wrist or the neck.

pulse crop such as peas and beans. Pulses are grown primarily for their seeds, which provide a concentrated source of vegetable protein, and make a vital contribution to human diets in poor countries where meat is scarce, and among vegetarians. Soybean is the major temperate protein crop in the West; most are used for oil production or for animal feed. In Asia, most are processed into soya milk and bean curd. Peanuts dominate pulse production in the

tropical world and are generally consumed as human food.

Pulses play a useful role in crop rotation as they help to raise soil nitrogen levels as well as acting as break crops. In the mid-1980s, world production was about 50 million tonnes a year.

pulse-code modulation (PCM) in physics, a form of digital modulation in which microwaves or light waves (the carrier waves) are switched on and off in pulses of varying length according to a binary code. It is a relatively simple matter to transmit data that are already in binary code, such as those used by computer, by these means. However, if an analogue audio signal is to be transmitted, it must first be converted to a pulse-amplitude modulated signal (PAM) by regular sampling of its amplitude. The value of the amplitude is then converted into a binary code for transmission on the carrier wave.

puma also called *cougar* or *mountain lion* large wild cat *Felis concolor* found in North and South America. Tawny-coated, it is 1.5 m/4.5 ft long with a 1-m/3-ft tail. Cougars live alone, with each male occupying a distinct territory; they eat deer, rodents, and cattle. Although in some areas they have been hunted nearly to extinction, in California puma populations have grown, with numbers reaching an estimated 5,000-6,000 by 1996.

pulse-code modulation The amplitude, duration, position and presence of a series of pulses are controlled in pulse-code modulation, which is relatively simple for digital data already in binary code. Analogue signals need to be converted into a recognizable binary code (a pulse-amplitude modulated signal) by regular sampling of its amplitude. Morse code is a very simple example of pulse-code modulation.

pumice light volcanic rock produced by the frothing action of expanding gases during the solidification of lava. It has the texture of a hard sponge and is used as an abrasive.

pump any device for moving liquids and gases, or compressing gases.

Some pumps, such as the traditional **lift pump** used to raise water from wells, work by a reciprocating (up-and-down) action. Movement of a piston in a cylinder with a one-way valve creates a partial vacuum in the cylinder, thereby sucking water into it.

Gear pumps, used to pump oil in a car's lubrication system, have two meshing gears that rotate inside a housing, and the teeth move the oil. **Rotary pumps** contain a rotor with vanes projecting from it inside a casing, sweeping the liquid round as they move.

pumped storage hydroelectric plant that uses surplus electricity to pump water back into a high-level reservoir. In normal working conditions the water flows from this reservoir through the turbines to generate power for feeding into the grid. At times of low power demand, electricity is taken from the grid to turn the turbines into pumps that then pump the water back again. This ensures that there is always a maximum 'head' of water in the reservoir to give the maximum output when required.

pumpkin creeping plant whose large round fruit has a thick orange rind, pulpy flesh, and many seeds. Pumpkins are used in cookery (especially pies and soups) and are hollowed out to form candle lanterns at Hallowe'en. (*Cucurbita pepo*, family Cucurbitaceae.)

punched card in computing, an early form of data storage and input, now almost obsolete. The 80-column card widely used in the

1960s and 1970s was a thin card, measuring 190 mm x 84 mm/7.5 in x 3.33 in, holding up to 80 characters of data encoded as small rectangular holes.

The punched card was invented by French textile manufacturer Joseph-Marie Jacquard (1752-1834) about 1801 to control weaving looms. The first data-processing machine using punched cards was developed by US inventor Herman Hollerith in the 1880s for the US census.

punctuated equilibrium model evolutionary theory developed by Niles Eldredge and US palaeontologist Stephen Jay Gould in 1972 to explain discontinuities in the fossil record. It claims that periods of rapid change alternate with periods of relative stability (stasis), and that the appearance of new lineages is a separate process from the gradual evolution of adaptive changes within a species.

The pattern of stasis and more rapid change is now widely accepted, but the second part of the theory remains unsubstantiated.

The **turnover pulse hypothesis** of US biologist Elisabeth Vrba postulates that the periods of rapid evolutionary change are triggered by environmental changes, particularly changes in climate.

punnett square graphic technique used in genetics for determining the likely outcome, in statistical terms, of a genetic cross. It resembles a game of noughts and crosses, in which the genotypes of the parental generation gametes are entered first, so that the subsequent combinations can then be calculated.

pupa nonfeeding, largely immobile stage of some insect life cycles, in which larval tissues are broken down, and adult tissues and structures are formed.

In many insects, the pupa is exarate, with the appendages (legs, antennae, wings) visible outside the pupal case; in butterflies and moths, it is called a chrysalis, and is obtect, with the appendages developing inside the case.

pupa The pupae or chrysalises produced by many butterflies inhabiting tropical rainforests often bear a striking resemblance to a large drop of water. In an environment where water drips almost constantly from leaves, this makes them less conspicuous to predators. Premaphotos Wildlife

Purkinje, Jan Evangelista (1787–1869)

Czech physiologist who made pioneering studies of vision, the functioning of the brain and heart, pharmacology, embryology, and cells and tissue. In 1819 Purkinje described the visual phenomenon in which different-coloured objects of equal brightness in certain circumstances appear to the eye to be unequally bright; this is now called the Purkinje effect.

purple emperor handsome high-flying butterfly, with rusty black wings, lustrous in the male, and with seven white spots and a transverse white band.

classification The purple emperor *Apatura iris* is in order Lepidoptera, class Insecta, phylum Arthropoda.

purpura condition marked by purplish patches on the skin or mucous membranes due to localized spontaneous bleeding. It may be harmless, as sometimes with the elderly, or linked with disease, allergy, or drug reactions.

pus yellowish fluid that forms in the body as a result of bacterial infection; it includes white blood cells (leucocytes), living and dead bacteria, dead tissue, and serum. An enclosed collection of pus is called an abscess.

push-button in computing, in a dialog box or toolbar, a square, oval, or oblong button which presents the user with an option. By clicking on the button, the user opts to initiate an action such as centering text or saving a file. Most programs offer keyboard shortcuts as an alternative to using a push-button, for example one can often hit the return key instead of clicking the 'OK' button in a dialogue box. Compare radio button.

putrefaction decomposition of organic matter by microorganisms.

PVC abbreviation for polyvinyl chloride.

P-wave (abbreviation of *primary wave*) in seismology, a class of seismic wave that passes through the Earth in the form of longitudinal pressure waves at speeds of 6–7 kps/3.7–4.4 mps in the crust and up to 13 kps/8 mps in deeper layers. P-waves from an earthquake travel faster than S-waves and are the first to arrive at monitoring stations (hence primary waves). They can travel both through solid rock and the liquid outer core of the Earth.

PWR abbreviation for pressurized water reactor, a type of nuclear reactor.

pyelitis inflammation of the renal pelvis, the central part of the kidney where urine accumulates before discharge. It is caused by bacterial infection and is more common in women than in men.

pyramid in geometry, a three-dimensional figure with triangular side-faces meeting at a common vertex (point) and with a polygon as its base. The volume V of a pyramid is given by $V = \frac{1}{3}Bh$, where B is the area of the base and h is the perpendicular height.

Pyramids are generally classified by their bases. For example, the Egyptian pyramids have square bases, and are therefore called square pyramids. Triangular pyramids are also known as tetrahedra ('four sides').

pyramid of numbers in ecology, a diagram that shows how many plants and animals there are at different levels of a food chain.

There are always far fewer individuals at the top of the chain than at the bottom because only about 10% of the food an animal eats is turned into flesh, so the amount of food flowing through the chain drops at each step. In a pyramid of numbers, the primary producers (usually plants) are represented at the bottom by a

pyrethrum popular name for several cultivated chrysanthemums. The ornamental species *C. coccineum*, and hybrids derived from it, are commonly grown in gardens. Pyrethrum powder, made from the dried flower heads of some species, is a powerful pesticide for aphids and mosquitoes. (Genus *Chrysanthemum*, family Compositae.)

pyridine C_5H_5N a heterocyclic compound (see cyclic compounds). It is a liquid with a sickly smell and occurs in coal tar. It is soluble in water, acts as a strong base, and is used as a solvent, mainly in the manufacture of plastics.

pyridoxine or **vitamin B₆** $C_8H_{11}NO_3$ water-soluble vitamin of the B complex. There is no clearly identifiable disease associated with deficiency but its absence from the diet can give rise to malfunction of the central nervous system and general skin disorders. Good sources are liver, meat, milk, and cereal grains. Related compounds may also show vitamin B₆ activity.

pyrite iron sulphide FeS_2 ; also called **fool's gold** because of its yellow metallic lustre. Pyrite has a hardness of 6–6.5 on the Mohs' scale. It is used in the production of sulphuric acid.

pyrogallol $C_6H_3O_3$ (technical name **trihydroxybenzene**) derivative of benzene, prepared from gallic acid. It is used in gas analysis for the measurement of oxygen because its alkaline solution turns black as it rapidly absorbs oxygen. It is also used as a developer in photography.

pyrolysis decomposition of a substance by heating it to a high temperature in the absence of air. The process is used to burn and dispose of old tyres, for example, without contaminating the atmosphere.

pyrometer in physics, any instrument used for measuring high temperatures by means of the thermal radiation emitted by a hot object. In a **radiation pyrometer** the emitted radiation is detected by a sensor such as a thermocouple. In an **optical pyrometer** the colour of an electrically heated filament is matched visually to that of the emitted radiation. Pyrometers are especially useful for measuring the temperature of distant, moving or inaccessible objects.

pyroxene any one of a group of minerals, silicates of calcium, iron, and magnesium with a general formula $X_2Si_2O_6$, found in igneous and metamorphic rocks. The internal structure is based on single chains of silicon and oxygen. Diopside ($X = Ca$, $Y = Mg$) and

Pythagoras' theorem Pythagoras' theorem for right-angled triangles is likely to have been known long before the time of Pythagoras. It was probably used by the ancient Egyptians to lay out the pyramids.

augite ($X = \text{Ca}$, $Y = \text{Mg, Fe, Al}$) are common pyroxenes.

Jadeite ($\text{NaAlSi}_2\text{O}_6$), which is considered the more valuable form of jade, is also a pyroxene.

Pythagoras' theorem in geometry, a theorem stating that in a right-angled triangle, the area of the square on the hypotenuse (the longest side) is equal to the sum of the areas of the squares drawn on the other two sides. If the hypotenuse is h units long and the lengths of the other sides are a and b , then $h^2 = a^2 + b^2$.

The theorem provides a way of calculating the length of any side of a right-angled triangle if the lengths of the other two sides are

Pythagoras (c. 580–500 BC)

Greek mathematician and philosopher who formulated Pythagoras' theorem.

Much of Pythagoras' work concerned numbers, to which he assigned mystical properties. For example, he classified numbers into triangular ones (1, 3, 6, 10, ...), which can be represented as a triangular array, and square ones (1, 4, 9, 16, ...), which form squares. He also observed that any two adjacent triangular numbers add to a square number (for example, $1 + 3 = 4$; $3 + 6 = 9$; $6 + 10 = 16$).

known. It is also used to determine certain trigonometrical relationships such as $\sin^2 \theta + \cos^2 \theta = 1$.

python any constricting snake of the Old World subfamily Pythoninae of the family Boidae, which also includes boas and the anaconda. Pythons are found in the tropics of Africa, Asia, and Australia. Unlike boas, they lay eggs rather than produce living young. Some species are small, but the reticulated python *Python reticulatus* of SE Asia can grow to 10 m/33 ft.

A healthy adult can survive from six to twelve months without food. When food is scarce females do not ovulate so energy is not used up in reproducing.

qat or **kat** or **khat** evergreen shrub with white flowers belonging to the staff-tree family, native to Africa and Asia. The leaves are chewed as a mild narcotic drug in some Arab countries. Its use was banned in Somalia 1983. (*Catha edulis*, family Celastraceae.)

quadrat in environmental studies, a square structure used to study the distribution of plants in a particular place, for instance a field, rocky shore, or mountainside. The size varies, but is usually 0.5 or 1 metre square, small enough to be carried easily. The quadrat is placed on the ground and the abundance of species estimated. By making such measurements a reliable understanding of species distribution is obtained.

QUADRATIC, CUBIC, AND QUARTIC EQUATIONS

http://ww-history.mcs.st-and.ac.uk/~history/HistTopics/Quadratic_etc_equations.html

History and usage of quadratic equations in mathematics. The site chronicles the discovery and development of this area of mathematics, and also provides biographical background information on those mathematicians responsible.

quadratic equation in mathematics, a polynomial equation of second degree (that is, an equation containing as its highest power

the square of a variable, such as x^2). The general formula of such equations is $ax^2 + bx + c = 0$, in which a , b , and c are real numbers, and only the coefficient a cannot equal 0.

In ϕ coordinate geometry, a quadratic function represents a ϕ parabola.

Some quadratic equations can be solved by factorization, or the values of x can be found by using the formula for the general solution $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$. Depending on the value of the discriminant $b^2 - 4ac$, a quadratic equation has two real, two equal, or two complex roots (solutions). When $b^2 - 4ac > 0$, there are two distinct real roots. When $b^2 - 4ac = 0$, there are two equal real roots. When $b^2 - 4ac < 0$, there are two distinct complex roots.

quadrature position of the Moon or an outer planet where a line between it and Earth makes a right angle with a line joining Earth to the Sun.

quadrilateral plane (two-dimensional) figure with four straight sides. The following are all quadrilaterals, each with distinguishing properties: **square** with four equal angles and sides, four axes of symmetry; **rectangle** with four equal angles, opposite sides equal, two axes of symmetry; **rhombus** with four equal sides, two axes of symmetry; **parallelogram** with two pairs of parallel sides, rotational symmetry; and **trapezium** one pair of parallel sides.

quad speed in computing, a ϕ CD-ROM drive that transfers data at 600 ϕ kilobytes per second – four times as fast as the first CD-ROM drives on the market. Because ϕ access time remains a key factor in the movement of data, the extra speed does not necessarily translate into a fourfold improvement in performance.

quagga South African zebra that became extinct in the 1880s. It was brown, with a white tail and legs, and unlike surviving zebra species, had stripes only on its head, neck, and forequarters. An intriguing attempt to recreate the quagga by breeding from a zebra with poorly developed stripes began in 1991.

quail any of several genera of small ground-dwelling birds of the family Phasianidae, which also includes grouse, pheasants, bobwhites, and prairie chickens. Species are found in Africa, India, Australia, North America, and Europe.

patch at the bottom, and a yellowish belly. It is found in Europe, Asia, and Africa, and has been introduced to North America. The nest is a small hollow in the ground, and in it are laid about ten yellowish-white eggs blotched with brown. The bird feeds upon grain seeds and insects.

Quake computer game released 1996 as a successor to *ζDoom* and produced by id Software. It is a strategy game using 3-D graphics.

Players navigate their way around 32 levels of mazes, uncovering secrets and combatting alien enemies. A command line console system allows players to enter *ζ*source code to enhance play.

qualitative analysis in chemistry, a procedure for determining the identity of the component(s) of a single substance or mixture. A series of simple reactions and tests can be carried out on a compound to determine the elements present.

quantitative analysis in chemistry, a procedure for determining the precise amount of a known component present in a single substance or mixture. A known amount of the substance is subjected to particular procedures.

Gravimetric analysis determines the mass of each constituent present; **colorimetric analysis** determines the concentration of a solution by titration against a solution of known concentration.

quantum chromodynamics (QCD) in physics, a theory describing the interactions of *q*uarks, the elementary particles that make up all *q*uadrans (subatomic particles such as protons and neutrons). In quantum chromodynamics, quarks are considered to interact by exchanging particles called gluons, which carry the *q*uark nuclear force, and whose role is to 'glue' quarks together.

The mathematics involved in the theory is complex, and, although a number of successful predictions have been made, the theory does not compare in accuracy with *q*uantum electrodynamics, upon which it is modelled. See *q*forces, fundamental.

quantum electrodynamics (QED) in physics, a theory describing the interaction of charged subatomic particles within electric and magnetic fields. It combines *q*uantum theory and *q*relativity, and considers charged particles to interact by the exchange of photons. QED is remarkable for the accuracy of its predictions; for example, it has been used to calculate the value of some physical quantities to an accuracy of ten decimal places, a feat equivalent to calculating the distance between New York and Los Angeles to within the thickness of a hair. The theory was developed by US physicists Richard Feynman and Julian Schwinger, and by Japanese physicist Sin-tiro Tomonaga in 1948.

quantum mechanics branch of physics dealing with the interaction of *q*uamatter and *q*uadradiation, the structure of the atom, the motion of atomic particles, and with related phenomena (see elementary particle and *q*uantum theory).

This problem of getting the interpretation proved to be rather more difficult than just working out the equations.

quantum number in physics, one of a set of four numbers that uniquely characterize an electron and its state in an *q*uatom. The principal quantum number *n* defines the electron's main energy level. The orbital quantum number *l* relates to its angular momentum. The magnetic quantum number *m* describes the energies of electrons in a magnetic field. The spin quantum number *m_s* gives the spin direction of the electron.

The principal quantum number, defining the electron's energy level, corresponds to shells (energy levels) also known by their spectroscopic designations K, L, M, and so on. The orbital quantum number gives rise to a series of subshells designated s, p, d, f, and so on, of slightly different energy levels. The magnetic quantum number allows further subdivision of the subshells (making three
