About the Author

Cliff Wootton lives in the south of England and works on multimedia systems and content management software for large data driven web sites. Currently he is developing interactive TV systems for BBC News Online in London (http://www.bbc.co.uk/news) and previously worked for other commercial broadcasters on their web sites. Before that he spent several years developing geophysical software and drawing maps with computers for oil companies.

Cliff is married with three daughters and a growing collection of bass guitars.

Acknowledgements

It's hard to believe I've actually reached the stage of writing the introductory pages to this book. It's been a long process and I don't think I would have reached this point without the help of Tim Briggs at Wrox, who very gently urged me onwards and gave me encouragement when I needed it. Tim's contribution to this project was vital to its success because he developed the process which converted my DOCBOOK output into something the Wrox editors could turn into a book. Tim also prepared the CD-ROM content from the same XML files; truly amazing!

Thanks also to all the other folks at Wrox who have helped, organised, checked and collated my material to present it in the form you now see it. Grateful thanks to my reviewers, who in a very short time provided me with some useful guidance and support; in particular Jon Stephens and Martin Honnen, who also provided some amazingly clever example code fragments for use as examples.

There are many other people who contributed without realising it. In particular Nick Cohen (formerly of the BBC and now at Turner Broadcasting) who provided some helpful insights into TV set-top-box workings. Also Matt Karas and Emyr Tomos (both ex-BBC, now at Talkcast) who threw down the gauntlet of several interesting challenges for me to implement on the BBC News Online web site. I also wouldn't be sitting here if it weren't for Bruce Morris at Carlton Online. It was through the happy chance of an article I wrote for Bruce's Web Developer's Journal (WDJ) web site that led to Wrox contacting me and the BBC inviting me to do some JavaScript work. What an amazing thing the web is.

Most importantly I dedicate this book to my family. To my wife, Julie and my daughters Hannah, Lydia and Ruth who kept me going with cups of coffee, hugs and the occasional giggle when they saw the photograph of me for the front cover.

Introduction

The JavaScript language is constantly developing, and continues to increase in popularity. Its evolution into a general purpose scripting language from what started life purely for scripting web browsers, is a great success story. You can now find JavaScript interpreters in many different environments and there are sure to be other new and interesting uses for the language in the future, especially now that embeddable interpreters are available.

In this book, we have attempted to snapshot the browsers that exist currently, which need to be supported by web sites, and collate that information together in a form that has broad scope and is deep enough to be useful on a day-to-day basis. As the language is growing all the time, this is likely to be an ongoing task.

Who is This Book For?

The book is aimed at people who already have some knowledge of JavaScript and need a companion volume to their daily work. It is primarily aimed at the experienced practitioner, and so does not attempt to be a tutorial for the beginner.

> *For a tutorial book, we suggest Paul Wilton's* Beginning JavaScript
> *(Wrox Press, ISBN 1-861004-06-0).*

Typical uses of the book include times when you:

- Need to check out the specific details of a particular language construct or object property
- Know what you want to do, but want to know how JavaScript helps you achieve that
- Want information on cross-browser compatibility issues for your script
- Have encountered a problem in your script and need help to debug it

One important motivation I had for writing this book was to reduce the amount of material I have to carry around when I'm working on projects in my clients' offices. My library now contains several shelves devoted purely to JavaScript, and in researching this book, I ended up with many megabytes of material. There have been many fine books written about JavaScript but I simply cannot carry them around on the train, even with a large rucksack! So, I set out to try and distil enough useful information into one book and organize it so that the information is easy to find. I've also put in material on issues that I've encountered in discussions with other programmers.

The Structure of the Book

To make it easy to navigate through the topics, titles describe the topic content and the topic type and are organized alphabetically. Where a topic might be referred to using several headings, a brief entry in the cross-reference at the end of the book shows the main topic for that subject.

I used a great deal of software automation to manage the book content and the whole thing was built in a database and exported as an XML file set using the DocBook DTD. There are now in excess of 3500 individual topics in this work. That is more than twice as many as we have room for in the printed book, so we've had to put a useful subset of the reference into the printed book, and the complete set of material onto the CD-ROM, which is available both in PDF and HTML formats. Some additional reference information that is not strictly part of the JavaScript language, but that you may find useful, is also included, such as country codes and MIME types.

Where we discuss an object all the important properties, methods, events, and any supporting material are broken out into their own topics, and these detailed entries are included on the CD. Where objects inherit properties and methods, they are listed in the object coverage, but to avoid duplication the information about the inherited properties is described as a member of the super-class. This slightly detracts from the lexical referencing but it saves space. In some cases these inherited properties/methods are deemed important enough to merit a cross-referencing entry of their own.

This allows us to indicate availability of features at a very fine level of detail. Within each topic we can also discuss bugs, gotchas, and areas of difficulty in a focused way.

Language syntax is illustrated by way of example code fragments that show how to access an object, method, or property. More extensive examples are given where necessary.

Because of the scoping rules, properties are available without the need for the `window` object to be specified as a prefix. Thus `navigator` as a topic is available under the `window.navigator` topic as well. Once you have found an entry topic, you can then use the cross-referencing listings to locate other related material.

The book content was developed inside a database system, which provided tools to relate topics. The benefit is a rich source of cross-referencing links between topics. The cross-reference in the printed book is complete; that is, it also includes entries found only on the CD. The italicized cross-references in the printed book can also be found in the printed book.

We will now look at some of the 'features' of JavaScript programming, as an introduction to what topics in the book will address.

Differences between Browsers

For some time, the most popular browsers have been Netscape Navigator 4.7 and Microsoft Internet Explorer 5.0 (MSIE). Other, newer browsers make a point of being standards compliant and so if your script conforms to the standards for core JavaScript as laid down by ECMA and the W3C DOM specifications, it should function correctly.

However, the dominant browsers have for a long time been competing with one another to add new features. Architecturally, this means their browsers have each gone in a completely different direction. The penalty has been that support for various language features has been implemented in each browser in ways that makes it difficult to use in a portable way. Indeed, to make use of some features requires twice the work, since the same code has to be written in two different ways and called after detecting which browser is being used.

Because of the proliferation of browser versions and platforms, features are generally referred to as being available in the revision in which they were first introduced. As the Netscape browser is available on so many different platforms, to test for compliance across all platforms would require a test suite of a dozen machines and 30 or more different installations of browser applications. Indeed, when building such a test suite just prior to starting on this book, I found more than a dozen distinctly different browser versions just for the Macintosh platform and many more than that for Windows. Similarly, MSIE comes in a bewildering variety of versions and platform variants. In addition, the JScript interpreter is a replaceable component that can be upgraded without changing the containing browser.

Browsers and Standards

There is still much that is ambiguous or not yet defined in the standards and the browser manufacturers continue to add new features in competition with one another. Even though they are standards compliant at a functional level, there are still significant differences if you 'look under the hood'.

We have included coverage of the following standards:

- ECMAScript core language up to edition 3 of the standard
- DOM coverage to level 1
- Some DOM coverage of level 2 where implemented in Netscape 6
- Discussion of the features being added at DOM level 3

JavaScript implementations we cover include:

- Netscape 3.0, 4.0, 4.05, 6.0 (the final release came out as we went to press)
- MSIE version 3.0, 4.0, 5.0, 5.5
- Opera 3, 4, 5
- Netscape Enterprise Server

By implication that means we cover JavaScript versions up to 1.5 and JScript up to 5.5. The coverage of Netscape 6.0 is based on it supporting the W3C DOM standards and several bugs in the currently released version prevented the verification of some functionality although that may be platform dependent. There are also some new and unexpected features.

We concentrate our discussions on the peculiarities of Netscape and MSIE because the other browsers that support JavaScript attempt to provide a fault-free standards-based implementation. Since this is a sub-set of the functionality of Netscape and MSIE, other platforms should be adequately covered.

Features and Versions

There are now a wide variety of sources of information about JavaScript and they don't all agree. In particular there is some uncertainty over which release of JavaScript introduces certain features.

The source material was assimilated by examining the standards documents and by inspecting objects with fragments of JavaScript. Then, the availability of features was checked against several alternative reference works. Occasionally, when a consistency error showed up, it was necessary to go back to the browser and test for the availability of a property or method.

Where there is some room for doubt, we have documented the release at which the feature became useful. This is because in earlier releases it may have had a serious flaw or been significantly revised later to make it work properly. Any implementation prior to that may be unreliable. So where we may appear to disagree with other commentators our coverage is based on whether it is practical to use a particular feature at a certain release.

Some browser features are available at an earlier release on some platforms than others are. We take the Windows 32-bit release as our baseline although significant testing was also done on the Macintosh versions, which disappointingly lagged somewhat in performance and feature availability. Both platforms exhibited instabilities and crash-prone behavior but in quite different areas of the language.

As there are so many variants of the browsers, the availability matrix for objects and their member properties/methods is huge and requires a large amount of work to test on all the available combinations. So far, no single reference source has proven to be error free and whilst the information here has been examined and cross-checked it is still likely that there are errors. If, in your work, you disagree with the information provided here, please send feedback (see the end of the *Introduction* for how to do this).

Core JavaScript

At first glance, the JavaScript environment appears to be built around a small core of objects and it is easy to fall into the trap of assuming the language is small and compact. That is certainly true if you are only considering core JavaScript functionality. The core language is defined by ECMA and both Netscape and MSIE both claim to be ECMA compliant. They may well be, but you cannot write much useful JavaScript for deployment in a web page by confining yourself only to the functionality of the ECMA standard. It is at that point that the two browsers begin to diverge.

DOM Support

Likewise, both browsers (MSIE 5 upwards and Netscape 6) claim to be DOM compliant. Browser support for the DOM is slowly converging but if you need to do any esoteric code development that involves DOM traversal and class names, they are still somewhat different.

MSIE implements a DOM model that is structurally right, but the class names of the objects that comprise that model are certainly not correct and do not conform to the DOM standard. Netscape 6 implements a DOM compliant model that does use the correct class names. Another slight difference is that MSIE implements distinctly different classes for some objects whereas Netscape Navigator instantiates the same class for several purposes.

These differences don't cause much grief to you when you are constructing simple scripts and web page enhancements but can be quite a problem if you need to manipulate the DOM structure and operate on objects by means of their class names. This difference did not become apparent until I used inspection scripts to examine internal document structures.

There are also areas where DOM specifies objects in a way that the browsers can implement ambiguously. For example, DOM describes documents as being a generic document class with an HTML document as a sub-class. Browsers simply provide a single document class with no access to the two separate class types.

Object Classes

You might also assume that there is a small and finite set of different object types. However if you inspect the constructor properties and examine the function names, you will find the opposite, there are a large number of object types. For example, the `applets` property that returns a list of applets in a document will give you an `AppletArray` object and not a `Collection` object in Netscape. Trying to work out class names on MSIE is a bit more problematic and it tends to provide generic `Collection` objects instead. By building fragments of JavaScript to inspect objects, you can determine these class names and learn a lot about how the browser maintains the internal model of the page.

The topics are constructed around a browser-centric model. The objects are defined based on their instantiation by an HTML tag in a web browser window. MSIE creates a distinct object class for each tag. Netscape does a similar trick, but not so convincingly in earlier versions. At version 6, the objects are DOM compliant and named differently to those in MSIE and earlier Netscape browsers. Netcsape 6 is so different as to be a new browser with little similarity to the earlier versions of Netscape.

There is an emerging standards-based model that frames the object hierarchy much more logically and, while it is still evolving, it may become a more robust way of describing the catalog of available classes. For now, though, the web and browser dominate use of JavaScript, so this seems like the more appropriate model.

Document Objects

Another area of debate is the `document` object. Typically, the previous documentation describes access to it as if there is only one `document` object. This is true within the context of a single script within a page. However, it is not necessarily true of a window in a web browser. A window may contain many frames or layers. Each one will have its own private `document` object. If you are writing scripts that operate across multiple frames or windows, you may refer to several `document` objects, so the syntax examples are designed to accommodate the different ways in which objects can be accessed.

The Future

JavaScript is becoming available in an ever-wider variety of applications. It is used in:

- PDF forms for validation
- For modifying the behavior of the GUI in developer tools
- Embedded interpreters in cell phones and television set-top boxes

There was not space enough or time to cover these extensively. They are also changing continually and will not be stable enough to document for a while yet.

What Do I Need to Use This Book?

All that is needed to use this book is a text editor and a JavaScript-enabled browser, such as Microsoft Internet Explorer or Netscape Navigator.

To use the CD you will need a browser to read the HTML files and a copy of Adobe Acrobat Reader/Adobe Acrobat eBook Reader to read the PDF files, which are freely available from www.adobe.com. To make navigation easier, the PDF files contain interactive bookmarks, thumbnails, and hyperlinks in the entries.

All of the code examples given in the book are available on the CD, and are also available to download from our web site, www.wrox.com.

Conventions Used in This Book

The convention used for syntax naming is that a variable created within the local scope would be prefixed with `my` while a global variable would be prefixed with `the`. Parameters passed into function and method calls are prefixed with `a`, `an`, or `some`.

The syntax description for an object shows how a reference to an object of that class can be retrieved via a property or method on another object. The syntax for properties and methods show them as members of an object that is referred to with a variable. This manifests itself as an object reference like this:

```
myDocument = document
myDocument = myElement.parentNode
myDocument = myFrame.document
myDocument = myLayer.document
```

Then a property reference looks like this,

```
myDocument.cookie
```

and not:

```
document.cookie
```

Of course you can omit the indirection through a referencing variable and any of these would be equally valid:

```
document.cookie
myElement.parentNode.cookie
myFrame.document.cookie
myLayer.document.cookie
```

But by using the indirection, the syntax descriptions for the member properties and methods are simplified.

In the tables, we have used the abbreviations N for Netscape, NES for Netscape Enterprise Server, and IE for Internet Explorer.

As for styles in the text:

- Filenames, and code in the text appear like so: `dummy.xml`
- Test on user interfaces, and URLs, are shown as: File/Save As…

Customer Support

Wrox has three ways to support books. You can:

- Post and check for errata at www.wrox.com
- Enroll at the peer-to-peer forums at p2p.wrox.com
- Email technical support a query or feedback on our books in general

Errata

You can check for errata for the book at our web site; www.wrox.com, simply navigate to the page for this book. There will be a link to the list of errata.

P2P Lists

You can enroll in our peer to peer discussion forums at p2p.wrox.com. The JavaScript list is available in the 'Web Design' section.

Email Support

If you wish to point out an errata to put up on the website or directly query a problem in the book with an expert who knows the book in detail, then e-mail `support@wrox.com`. A typical email should include the following things:

- The name of the book, the last four digits of the ISBN and the entry name for the problem in the Subject field
- Your name, contact info and the problem in the body of the message

You may want to tell us your opinion of this book, or you may have ideas about how it can be improved, in which case, e-mail `feedback@wrox.com`. We will do our utmost to act upon your comments.

A object (Object/HTML)

An object that represents an <A> element when instantiated in MSIE.

Availability:	JScript –1.0 Internet Explorer –3.02	
Inherits from:	Element object, Node object	
JavaScript syntax:	IE	*myA* = *myDocument*.all.*anElementID*
	IE	*myA* = *myDocument*.all.tags("A")[*anIndex*]
	IE	*myA* = *myDocument*.all[*aName*]
	IE	*myA* = *myDocument*.anchors.item(*aName*)[*anIndex*]
	-	*myA* = *myDocument*.anchors[*aName*]
	-	*myA* = *myDocument*.anchors[*anIndex*]
	-	*myA* = *myDocument*.getElementById(*anElementID*)
	-	*myA* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myA* = *myDocument*.getElementsByTagName("A")[*anIndex*]
	IE	*myA* = *myDocument*.links.item(*aName*)[*anIndex*]
	-	*myA* = *myDocument*.links[*aName*]
	-	*myA* = *myDocument*.links[*anIndex*]
HTML syntax:	<A> ... </A>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, dataFld, dataSrc, hash, host, hostname, href, Methods, mimeType, nameProp, pathname, port, protocol, protocolLong, rel, search, tabIndex, target	
Event handlers:	onBlur, onClick, onDblClick, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

See also:	Element object, Input.accessKey, Map object, Anchor object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
accessKey	-	3.0 +	-	4.0 +	-	1 +	-	-

ABBR object (Object/HTML)

An object representing the HTML content (an abbreviation) delimited by the <ABBR> HTML tags.

Availability:	HTML version – 4.0 JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object, `Node` object	
JavaScript syntax:	IE	*myABBR* = *myDocument*.all.*anElementID*
	IE	*myABBR* = *myDocument*.all.tags("ABBR")[*anIndex*]
	IE	*myABBR* = *myDocument*.all[*aName*]
	-	*myABBR* = *myDocument*.getElementById(*anElementID*)
	-	*myABBR* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myABBR* = *myDocument*.getElementsByTagName("ABBR")[*anIndex*]
HTML syntax:	<ABBR> ... </ABBR>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

See also:	`style.speak`, `Element` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

about: URL (Request method)

This is a special kind of URL that fetches content from a storage area inside the Netscape browser instead from using HTTP to get it from a web server.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0

This is a special request method provided by the Netscape browser to gain access to local client-side resources. The resources are loaded from inside the application itself.

In the Macintosh version of Navigator, this means they are stored in the resource fork of the browser application. If you need to deploy a custom version of Navigator within an intranet environment, with some care you can modify these resources with a resource-editing tool, such as ResEdit. Always work on a copy of the application and test the changes thoroughly.

On other platforms, the resources are likely to be stored in files located in folders adjacent to the application. You will need to study your own copy of Netscape to see what you can change.

These special URLs are mostly not present in early versions of MSIE, although there will be some internal resources, which may provide customization opportunities. MSIE also supports an `about:blank` URL that provides a blank page. There may be others hidden away inside the application.

You may also be able to obtain administration tools from Netscape and Microsoft to carry out legitimate customizations on the browsers before deploying them throughout your organization.

The following special URLs seem to work when typed into the location box:

URL	Description
`about:logo`	Netscape logo
`about:mozilla`	A fire & brimstone quote from the book of Mozilla (Yes it's really there – at least on some versions)
`about:authors`	Shows a cryptic message about the page having been removed, although the `authors.html` file is still present inside the application
`about:cache`	Displays a disk cache report
`about:document`	Displays the document info console
`about:fonts`	Displays the font info console
`about:global`	A global history report
`about:image-cache`	A report on the internal image cache
`about:license`	A hyperlink to the Netscape license document
`about:mailintro`	Displays the Netscape mail info page

URL	Description
about:memory-cache	A report on the memory cache
about:pics	Generates a security exception
about:plugins	A page of information about the plugins
about:security?advisor=XXX	Brings up a security console where XXX indicates the window to operate on.
about:security?banner-insecure	Serves an unlocked padlock image
about:security?banner-secure	Serves a locked padlock image
about:security?issuer-logo=XXX	Returns a graphic where XXX identifies which one
about:security?subject-logo=XXX	Returns a graphic where XXX identifies which one
about:coslogo2	Cosmo logo
about:fclogo	Full Circle software logo
about:hslogo	Beatnik logo
about:hype	An audio clip
about:insologo	Inso logo
about:javalogo	Java compatible logo
about:litronic	Litronic logo
about:mclogo	Marimba Castanet logo
about:mmlogo	Macromedia logo
about:ncclogo	Netcast logo
about:odilogo	Object Design logo
about:qtlogo	Apple QuickTime logo
about:rsalogo	RSA secure logo
about:symlogo	Symantec logo
about:tdlogo	TrueDoc logo
about:visilogo	VisiGenic logo
about:blank	Presents a blank page on Netscape Navigator 3 and MSIE version 5; used to create a blank page when a new window is opened

Some of these URLs can be used in frames, but others can't. A few can be used as HREF values. JavaScript complains that the `about: request` method is illegal. This means you cannot change the `location.href` within a page to any of the "`about:`" URLs. However, you might be able to write some `innerHTML` content into a `<DIV>` or `<SPAN>` to place a link to these assets.

Many of the built-in assets are used as image sources in the `about` page. It's possible you might want to display the Netscape logo. If you are aware that you are using software provided by the other third parties, you might (if they give you permission) place their logo on the screen when you are using features of their software. You should ask first, although Netscape probably won't mind their logo being served like this.

The interesting thing about this is that you are effectively serving assets out of a static cache in the client file system.

The URL that points at the license document may be useful as it is possible you might want to display the Netscape license if you are redistributing the browser.

The `about:plugins` URL yields a page containing some useful JavaScript that displays the plugins page. You may find some useful techniques in here for managing plugin facilities although they may be Netscape compatible only.

Mostly, these special URLs will be useful for debugging. Getting details of the disk cache, for example, may be useful. Pulling up the JavaScript debugger page if you detect an error in your script might also be a cool trick.

The MSIE and Netscape browsers can both use the `about:blank` URL value as a default page when the browser is started up.

Warnings:

- The `UniversalBrowserRead` privilege is required for access to internal browser values and state information such as the cache contents.

See also:	`javascript:` URL, `nethelp:` URL, `UniversalBrowserAccess`, `UniversalBrowserRead`, URL

abstract (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

AbstractView object (Object/DOM)

An object that belongs to the DOM level 2 views module.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myAbstractView* = *myMouseEvent*.view
	N	*myAbstractView* = *myUIEvent.view*

This is part of a new suite of functionality introduced at DOM level 2, which provides a way of looking at documents from alternative points of view. At present only the Abstract and Document views are standardized and, because the capabilities are quite new, implementations may be incomplete at this stage.

See also:	`MouseEvent` object, `MouseEvent.initMouseEvent()`, `UIEvent` object

Accessor method (Definition)

A method for accessing publicly available object properties.

Availability:	ECMAScript edition – 2

A method used to store or retrieve property values contained in objects.

In ECMAScript-compliant implementations, this is accomplished with internal functions named `Get()` and `Put()`.

If you add new properties to an object of your own, you may want to implement functions that operate by using the '`this`' variable to access properties. These functions are then associated with the object or its prototype, so that they can be shared. They are then referred to as methods rather than functions.

See also:	`function( ... )` ..., `Get()`, Method, `Put()`

ECMA 262 edition 3 – section – 8.6.2

ACRONYM object (Object/HTML)

An object representing the HTML content delimited by the `<ACRONYM>` HTML tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object, `Node` object	
JavaScript syntax:	IE	*myACRONYM* = *myDocument*.all.*anElementID*
	IE	*myACRONYM* = *myDocument*.all.tags("ACRONYM")[*anIndex*]
	IE	*myACRONYM* = *myDocument*.all[*aName*]
	-	*myACRONYM* = *myDocument*.getElementById(*anElementID*)
	-	*myACRONYM* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myACRONYM* = *myDocument*.getElementsByTagName("ACRONYM")[*anIndex*]

HTML syntax:	`<ACRONYM> ... </ACRONYM>`	
Argument list:	*anElementID*	The ID value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

See also:	`style.speak`, `Element` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Activation object (Object/internal)

The `activation` object is created when the flow of control first enters an execution context.

Availability:	ECMAScript edition – 2

The `activation` object is created when the flow of control first enters an execution context for declared function code, anonymous code or implementation-supplied code.

As the `activation` object is created, it is associated with the execution context. On initialization, it has a property called `arguments` that cannot be deleted and that refers to an `arguments` object.

This `activation` object is then used as the variable object for instantiating all the argument variables. The `activation` object is discarded when the function returns its result to the caller. The `activation` object is an internal mechanism and so cannot be passed to the outside world, although members of the `activation` object may well be accessible to a running script.

See also:	Execution context, `function(…)` …

ECMA 262 edition 3 – section – 10.1.6

Active Server Pages (Product)

A Microsoft web server product.

This is a server-side programming framework that supports JavaScript. More accurately, it supports JScript, which is Microsoft's flavor of JavaScript.

For more information, see *ASP 3.0 Programmer's Reference*, ISBN 1-861003-23-4 from Wrox Press.

See also:	`BODY.recordNumber`, `Event.bookmarks[]`, `Event.boundElements[]`, `Input.recordNumber`, `SCRIPT.recordNumber`, Server-side JavaScript, `TextStream` object

ActiveX (Product)

This is a Microsoft technology for embedding and sharing code.

In MSIE (on Windows), interactions between scripts and applets takes place by means of ActiveX. Microsoft prefers to treat applets as a special kind of `ActiveX` object. Netscape shows a similar preference towards treating applets as Java components.

If you are developing web-based applications for a captive audience who you know will be running MSIE on Windows, then this technology may be appropriate for your project.

However, ActiveX is not supported on Netscape and, in fact, is unlikely to be well supported on any other browsers aside from MSIE.

Coupling this with the fact that it is not supported outside the Windows platform, you will almost certainly find Java to be a more portable solution. The Java solution is also secured better than ActiveX, which can expose the internals of your system in ways you would rather avoid.

For a high degree of Windows integration and a very Microsoft-oriented solution, ActiveX is ideal. For portability across platforms and browsers, it's likely you'll do much better to select Java.

See also:	`Applet` object, `Dictionary` object, Glue code, LiveConnect

Web-references:

http://msdn.microsoft.com/scripting/

ActiveXObject object (Object/JScript)

A Windows and MSIE specific object that allows various document components to be embedded.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`myActiveX = ActiveXObject`
	IE	`myActiveX = new ActiveXObject (anApplication)`
Argument list:	*anApplication*	References an external application
Collections:	Depends on the object created by the constructor	

This is an object for embedding other applications into web pages on the Windows platform. The example shows the creation of an object that is managed by the Word application.

This is also used to create `Dictionary` objects by using the Scripting application to create a new `Dictionary` object.

Warnings:

- This is totally non-portable and non-standard, but if your scripts are likely to be deployed in a Windows-only environment, it may be useful.
- Using this construct in client-side scripting is subject to security restrictions. If a script in a web browser could just instantiate Word, then that implies that it has rights of access to the local file system. The normal IE security settings disallow that level of access.

Example code:

```
// An example that opens a Word document and writes
// text into it.
var myActiveX = new ActiveXObject("Word.Document");
myActiveX.Application.Visible=true;
myString="Some text to be written to the document";
// now write the text to the word document
myActiveX.application.selection.typeText(myString);
```

See also:	`Dictionary` object, `OBJECT` object

ActiveXObject() (Constructor)

Used for manufacturing new `ActiveX` objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`new ActiveXObject(`*`anObjectType`*`)`
	IE	`new ActiveXObject(`*`anObjectType`*`, `*`aLocation`*`)`
Argument list:	*`anObjectType`*	What sort of application and object class type to be created
	`aLocation`	A server name where the source object is located

You can use this constructor for creating new objects. You need to specify the kind of object to be created in the string argument value.For example, to create a Microsoft Word document, pass the string "Word.Document" to the constructor.

You can also specify a second optional argument to locate the application on a remote server.

Here are some example applications you can invoke:

- Word.Document – Create an empty Word document
- Excel.Sheet – Create an empty Excel spreadsheet
- Microsoft.XMLDOM – Create a new XML document

Other alternatives depend on the applications you have installed on your client system.

See also:	`GetObject()`

Add (+) (Operator/additive)

Add two numeric operands together. See concatenation for Strings.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 + anOperand2`*
Argument list:	*`anOperand1`*	An expression that evaluates to a number
	`anOperand2`	Another expression that evaluates to a numeric value

The addition operator adds two numeric values together or concatenates one string onto another.

When used with numeric operands, the plus sign adds the values together.

The addition is commutative, meaning that the order of the operands does not affect the outcome of the calculation. However, the calculation is not always associative (so `(a+b)+c` is not always the same as `a+(b+c)`) and so the precedence established with the grouping operator might affect the outcome.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

If either operand is `NaN`, the result will be `NaN`.

The sum of infinity and minus infinity will be `NaN`; they do not cancel one another out.

The sum of two infinity values of the same sign will be the infinity of that sign.

The sum of infinity and a finite value is equal to the infinite operand.

Internally the sum of two negative zero values is -0. However, the sum of two positive zero value or a positive and negative zero value added together will be +0. At the scripting level however, you cannot determine whether a zero is positive or negative, but its sense may affect subsequent computations.

The sum of zero and a non-zero value will be the non-zero value.

The sum of two non-zero finite values of the same magnitude but opposite signs will be zero.

Provided neither an infinity, a zero nor `NaN` is involved, adding two finite values results in the sum of the two values given that the result will be rounded to its nearest representable value. Where the result exceeds the largest presentable value, infinity will be substituted. A negative infinity may result from an underflow.

The addition/concatenation operator looks at the arguments and if either is a String already or preferentially converts to one, then a concatenation occurs. If neither operator prefers to be a String, then a Number conversion happens and the values are added.

See also:	Add then assign (+=), Additive expression, Additive operator, Associativity, Negation operator (-), Operator Precedence, String concatenate (+), Subtract (-), Type conversion, Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.6.1

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.6.1

Wrox *Instant JavaScript*, ISBN 1-861001-27-4 – page – 37

Add then assign (+=) (Operator/assignment)

Add two numeric operands and assign the result to the first. See concatenation for Strings.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 += anOperand2`*
Argument list:	*`anOperand1`*	An expression that evaluates to a number
	`anOperand2`	Another numeric value

Add the right operand to the left operand and assign the result to the left operand.

This is functionally equivalent to the expression:

`anOperand1` = *`anOperand1`* + *`anOperand2`*;

Although this is classified as an assignment operator, it is really a compound of an assignment and an additive operator.

It also works with string values and will concatenate the second onto the first.

The associativity is right to left.

Refer to the operator precedence topic for details of execution order.

The new value of *`anOperand1`* is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

Example code:

```
// Initialize with numeric valuesmyVar1 = 100;myVar2 = 1000;
// After this myVar1 contains 1100, myVar2 is unchanged
myVar1 += myVar2;
```

See also:	Add (+), Additive operator, Assign value (=), Assignment expression, Assignment operator, Associativity, Concatenate then assign (+=), Increment value (++), LValue, Operator Precedence, Subtract then assign (-=)

Adding JavaScript to HTML (Advice)

The most popular use of JavaScript is in web pages. Adding it is quite simple.

To add JavaScript to a web page, you can use the following techniques:

- The `<SCRIPT>` HTML tag containing the script source text
- From an external file using the `<SCRIPT SRC="filename.js">` HTML tag and attribute
- From an external file using the `<SCRIPT ARCHIVE="" SRC="">` HTML tag and attributes
- With an event handler attribute
- In a `javascript:` URL
- By means of a JavaScript style sheet
- As a JavaScript entity value for an HTML attribute
- Within a conditional comment

Refer to the individual topics for specific details covering each case.

See also:	`<SCRIPT ARCHIVE="...">`, `<SCRIPT SRC="...">`, `<SCRIPT>`, `<STYLE TYPE="...">`, Conditional comment, Event handler, JavaScript entity, `javascript:` URL

Additive expression (Definition)

This is an expression that adds or subtracts values.

Availability:	ECMAScript edition – 2

Additive expressions use the additive operators to yield a result by operating on two values, which may themselves be expressions.

See also:	Add (+), Decrement value (--), Expression, Increment value (++), Negation operator (-)

Cross-references:

ECMA 262 edition 2 – section – 11.6

ECMA 262 edition 3 – section – 11.6

Additive operator (Definition)

An operator that adds or subtracts values.

Availability:	ECMAScript edition – 2

Here is a table summarizing all operators that can be classified as additive, even those which are primarily classified in other categories:

Value	Meaning
`+`	Add
`-`	Subtract
`+=`	Add and assign
`-=`	Subtract and assign
`++`	Increment
`--`	Decrement

Additive operators perform numeric addition and subtraction or string concatenation depending on the native type of the operands.

It might seem perverse to call a subtraction symbol an additive operator, but the word additive is used in the same context as multiplicative when talking about division. That is, a negative value is added to perform subtraction. It's all about the kind of logic used in the interpreter kernel.

See also:	Add (+), Add then assign (+=), Arithmetic operator, Associativity, Decrement value (--), Increment value (++), Negation operator (-), Operator, Operator Precedence, Positive value (+), Postfix expression, Prefix decrement (--), Prefix expression, Prefix increment (++), String concatenate (+), String operator, Subtract (-), Subtract then assign (-=)

ECMA 262 edition 3 – section – 11.6

ADDRESS object (Object/HTML)

An object representing the HTML content delimited by the `<ADDRESS>` HTML tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Inherits from:	`Element` object, `Node` object

Table continued on following page

JavaScript syntax:	IE	*myADDRESS* = *myDocument*.all.*anElementID*
	IE	*myADDRESS* = *myDocument*.all.tags ("ADDRESS")[*anIndex*]
	IE	*myADDRESS* = *myDocument*.all[*aName*]
	-	*myADDRESS* = *myDocument*.getElementById(*anElementID*)
	-	*myADDRESS* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myADDRESS* = *myDocument*.getElementsByTagName ("ADDRESS")[*anIndex*]
HTML syntax:	<ADDRESS> ... </ADDRESS>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an *Element* object
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

See Also	Element object

ADO (Product)

ActiveX Data Objects is a Microsoft technology for accessing data.

This is a technology that enables an ASP server to access data from a data source. It provides an easy-to-use object interface to the OLE database access mechanisms.

The ADO object model is built around a set of objects of the following kinds:

- `Command`
- `Connection`
- `Record`
- `Recordset`
- `Stream`

The ADO object model includes the following collections containing objects of these types:

- `Errors`
- `Fields`
- `Parameters`
- `Properties`

This is all covered in greater depth in the Wrox book *ASP 3.0 Programmers Reference*, ISBN 1-861003-23-4.

See also: `BODY.recordNumber`, `Event.bookmarks[]`, `Input.recordNumber`, `SCRIPT.recordNumber`, Window furniture

Adornments (Definition)

The various control items that form the window border and can be selectively enabled as needed.

Aggregate type (Definition)

Data types built from several atomic components.

An aggregate data type is built by combining one or more atomic data types to build a more sophisticated data type. In compiled non-object-oriented languages one might create structures as aggregates of member variables. These are analogous to object classes.

Arrays are another example of an aggregate data type.

Other aggregate types include the various collection-based objects.

See also: `Array` object, `Cast` operator, `Function` object, `Object` object, Scalar type, Type

alert() (Method)

Present the alert dialog box to the user.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`alert(`*`aString`*`)`
	-	*`myWindow`*`.alert(`*`aString`*`)`
Argument list:	*`aString`*	Some text to display in the alert box

See Also	`Window.alert()`

Alias (Definition)

An indirect reference to an object.

By assigning an object to a variable, you are not copying that object but instead making a reference to it. A reference is sometimes called an alias. The same technique is used in Java, and in non-object-oriented languages you accomplish something similar with pointers.

See also:	Object

Alpha() (Filter/visual)

A visual filter for controlling transparency.

Availability:	JScript – 3.0 Internet Explorer – 4.0

AlphaImageLoader() (Filter/visual)

An image is displayed in the object, with some additional control over how it is displayed.

Availability:	JScript – 5.5 Internet Explorer – 5.5
See Also	Filter – `AlphaImageLoader()`

Anchor object (Object/HTML)

An object representing an HTML `<A>` tag.

Availability:	DOM level – 1 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Inherits from:	`Element` object, `Node` object	
JavaScript syntax:	-	*myAnchor* = *myAnchorArray*[*aName*]
	-	*myAnchor* = *myAnchorArray*[*anIndex*]
	-	*myAnchor* = *myDocument*.anchors[*aName*]
	-	*myAnchor* = *myDocument*.anchors[*anIndex*]
	-	*myAnchor* = *myDocument*.getElementById(*anElementID*)
	-	*myAnchor* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myAnchor* = *myDocument*.getElementsByTagName("A")[*anIndex*]
	-	*myAnchor* = *myDocument*.links[*aName*]
	-	*myAnchor* = *myDocument*.links[*anIndex*]
	IE	*myAnchor* = *myDocument*.all.*anElementID*
	IE	*myAnchor* = *myDocument*.all.tags("A")[*anIndex*]
	IE	*myAnchor* = *myDocument*.all[*aName*]
	IE	*myAnchor* = *myDocument*.anchors.item(*aName*)[*anIndex*]
	IE	*myAnchor* = *myDocument*.links.item(*aName*)[*anIndex*]
HTML syntax:	`<A> ... </A>`	
Argument list:	*aName*	An associative array reference to the `anchor` object.
	aName	The `name` property of the `anchor` object
	anIndex	An index into the `anchors` collection
	someText	The text (or `innerText`) property of the `anchor`
	anElementID	The ID value of an `Element` object

Table continued on following page

Object properties:	`accessKey`, `charset`, `coords`, `dataFld`, `dataSrc`, `hash`, `host`, `hostname`, `href`, `hreflang`, `Methods`, `mimeType`, `name`, `nameProp`, `pathname`, `port`, `protocol`, `protocolLong`, `recordNumber`, `rel`, `rev`, `search`, `shape`, `tabIndex`, `target`, `text`, `type`, `urn`, `x`, `y`
Object methods:	`blur()`, `focus()`
Event handlers:	`onClick`, `onMouseDown`, `onMouseOut`, `onMouseOver`, `onMouseUp`

See Also:	Filter – `Alpha()`

This object represents a named location in the HTML document. Only those `<A>` HTML tags that have a `NAME` attribute will have `anchor` objects created for them. All the anchors are listed in the `anchors[]` array object that belongs to the `document` object that represents the HTML.

Although the `<A>` tag is also used to create links using the `HREF` attribute, they are not anchors unless they are named. Any `<A>` tags that have `HREF` attributes (whether or not they have `NAME` attributes) will be listed in the `links[]` array.

In Netscape, you can construct new instances of the `Anchor` object, but there is no constructor property in MSIE to support this.

`<A>` tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

Warnings:

- If you put an `anchor` object into a `document.write()`, in Netscape you get a string containing the object class. In MSIE, you will get the `HREF` string if there is one and an empty string if there isn't.
- MSIE provides access to properties that would normally be considered part of the `link` object. Internally MSIE probably maintains a single object type for anchors and links, whereas Netscape implements two quite different classes.
- Netscape supports an associative reference to an `anchor` object within the `anchors[]` array according to the value of its `NAME` tag attribute. MSIE does not support this means of locating an `anchor` object in quite the same way.
- Note that although the syntax examples illustrate the use of an `innerText` property, Netscape does not support this mode of access and it will generate an error.

Example code:

```
<!-- Example showing how to dynamically replace -->
<!-- the anchor text -->
<HTML>
<HEAD></HEAD>
<BODY>
<A NAME="A1" HREF="www.apple.com">Click here</A>
<BR>
```

```
<A NAME="A2" HREF="www.wrox.com">Click here</A>
<BR>
<A NAME="A3" HREF="www.msdn.com">Click here</A>
<BR>
<BR>
<HR>
<SCRIPT>
myLength = document.anchors.length;
for (myEnumerator=0; myEnumerator<myLength; myEnumerator++ )
{
   document.anchors[myEnumerator].innerText =
document.anchors[myEnumerator].name;}
</SCRIPT>
</BODY>
</HTML>
```

onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Anchor() (Constructor)

You can construct new `Anchor` objects in Netscape.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Anchor` object	
JavaScript syntax:	N	`new Anchor`
	N	`new Anchor()`
	N	`new` *`myAnchor`*`.constructor`

Although you can construct new anchors in Netscape, inserting them into a document is somewhat problematic since the correct way to do that would be to rewrite a fragment of HTML. You may find that replacing an `anchor` object in the `document.anchors` array links your new object to the `<A>` HTML tag at the appropriate location in the document.

Warnings:

- This is only available on Netscape and is therefore not recommended for use in deployable applications. MSIE generates a run-time error if you attempt to make a new `Anchor` object.

See also:	`Anchor` object, `Anchor.host`

Anchor.accessKey (Property)

A key that needs to be pressed before the `anchor` object will respond to data entry.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myInputObject`*`.accessKey`

This is an extension that allows the anchor elements to be deadlocked unless a certain key is held down.

On some browsers and operating systems, you may need to hold down one of the modifier keys for this to work. The modifier key required depends on the environment you are using.

Warnings:

- This is not supported in some versions of the MSIE browser on Macintosh.

Anchor.blur() (Method)

Remove input focus from the `Anchor` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*`myInputObject`*`.blur()`

This will trigger the `onblur` event handler function attached to the `onblur` property of the object.

Anchor.charset (Property)

This property indicates the character encoding of the document at the location specified by the URL.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.charset`

This would contain the character set being used by the document. For example the value "`iso-8859-1`" is likely to be returned, but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry. In that registry are listed the names and aliases of a wide variety of character sets. Even though there are nearly 800 names and aliases, it seems on inspection that there are items missing.

See also:	`LINK.charset,Url.charset`

Web-references:

ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets

Anchor.coords (Property)

This defines an area map within an image that is inside the `<AREA>` HTML tags.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.coords`

When a shaped area is defined within an image map, the rectangle around the shape is defined with the `coords` property. The value is defined with the `COORDS` HTML tag attribute.

See also:	`Anchor.shape,Area.coords,Url.coords`

Anchor.dataFld (Property)

This binds the anchor object to a remote data source in MSIE.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myInputObject`*`.dataFld`

This is part of the MSIE data-binding mechanism that associates a column name in the data source with the `value` property of an `Anchor` object. You must also set the `dataSrc` property for the object. Normally, both the `dataFld` and `dataSrc` values would be defined with the `DATAFLD` and `DATASRC` HTML tag attributes in the document source.

Note that the value is case-sensitive and must refer to a column that exists within the data source.

Setting both the `dataFld` and `dataSrc` properties to an empty string will disconnect the element from the database.

Anchor.dataSrc (Property)

The name of a remote ODBC data source is stored in this property.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myInputObject`*`.dataSrc`

This is part of the MSIE data-binding support. It contains the name of an ODBC data source (which might be any kind of SQL database that supports such an adapter). The data source and element are bound together with each column of the data source providing a source value to different element objects through their `dataFld` property.

Normally, both the `dataFld` and `dataSrc` values would be defined with the `DATAFLD` and `DATASRC` HTML tag attributes in the document source.

Setting both the `dataFld` and `dataSrc` properties to an empty string will disconnect the element from the database.

Anchor.focus() (Method)

Brings input focus back to the `anchor` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myInputObject*`.focus()`

The receiving `Anchor` object will receive a Focus event trigger and execute its function referred to by the `onfocus` event handler property.

The element that previously had focus (if any element did) will receive a Blur event trigger.

Anchor.hash (Property)

On MSIE the `Url.hash` property is also available as the `Anchor.hash` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.hash`
	-	*myAnchor*`.hash = `*newValue*
HTML syntax:	`<A HREF="...">`	

This yields the hash suffix of the `HREF` value in an `<A>` tag.

You can assign a new value to this property, which will become a new anchor location within the document.

Warnings:

- This attribute may not work correctly when URLs are accessed from one frame to another in some versions of MSIE. You should check your target platforms for compliance.
- If you assign a value to this property in MSIE, you should omit the leading hash.
- Since the `hash` property of an `Anchor` object is not portable in all older browser versions, you should use the `pathname` property of the corresponding `Url` object to be able to work across MSIE and Netscape.
- As features become deprecated, it may become necessary to support both techniques in browser-specific code according to your needs regarding the support of legacy browsers.

See also:	`Anchor` object, `Anchor.host`, `Anchor.hostname`, `Anchor.href`, `Anchor.pathname`, `Anchor.port`, `Anchor.protocol`, `Anchor.search`, `Anchor.target`, URL, `Url.hash`, `Url.host`, `Url.hostname`, `Url.href`, `Url.pathname`, `Url.port`, `Url.protocol`, `Url.search`, `Url.target`

Anchor.host (Property)

On MSIE the `link.host` property is also available as the `anchor.host` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myAnchor*.host - *myAnchor*.host = *newHostPort*
HTML syntax:	`<A HREF="...">`

This yields the host and port value of the `HREF` value in an `<A>` tag.

You can redefine the host to request the URL by assigning a new value to this property.

Warnings:

- Since the `host` property of an `Anchor` object is not portable in all older browser versions, you should use the `pathname` property of the corresponding `Url` object to be able to work across MSIE and Netscape.
- As features become deprecated, it may become necessary to support both techniques in browser-specific code according to your needs regarding the support of legacy browsers.

See also:	`Anchor` object, `Anchor()`, `Anchor.hash`, `Anchor.href`, `Anchor.pathname`, `Anchor.port`, `Anchor.protocol`, `Anchor.search`, `Anchor.target`, URL, `Url.host`

Anchor.hostname (Property)

On MSIE the `link.hostname` property is also available as the `anchor.hostname` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.hostname`
	-	*myAnchor*`.hostname = `*newHostname*
HTML syntax:	`<A HREF="...">`	

This yields the host value of the `HREF` value in an `<A>` tag.

You can redefine the hostname to request the URL by assigning a new value to this property.

Warnings:

- Be careful not to assign a port number with the host name, otherwise your new URL may acquire two port numbers, which makes it invalid.
- Since the `hostname` property of an `Anchor` object is not portable in all older browser versions, you should use the `pathname` property of the corresponding `Url` object to be able to work across MSIE and Netscape.
- As features become deprecated, it may become necessary to support both techniques in browser-specific code according to your needs regarding the support of legacy browsers.

See also:	`Anchor` object, `Anchor.hash`, `Anchor.href`, `Anchor.pathname`, `Anchor.port`, `Anchor.protocol`, `Anchor.search`, `Anchor.target`, URL, `Url.hostname`

Anchor.href (Property)

On MSIE the `link.href` property is also available as the `anchor.href` property.

Availability:	DOM level – 1 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.href`
	-	*myAnchor*`.href = `*newHref*
HTML syntax:	`<A HREF="...">`	

This yields the entire value of the HREF attribute in an <A> tag.

You can redefine the entire HREF content by assigning a new value to this property.

Warnings:

- Since the href property of an Anchor object is not portable in all older browser versions, you should use the pathname property of the corresponding Url object to be able to work across MSIE and Netscape.
- As features become deprecated, it may become necessary to support both techniques in browser-specific code according to your needs regarding the support of legacy browsers.

See also:	Anchor object, Anchor.hash, Anchor.host, Anchor.hostname, Anchor.pathname, Anchor.port, Anchor.protocol, Anchor.search, Anchor.target, Location.href, URL, Url.href

Anchor.hreflang (Property)

The language code of the document at the location specified by the URL.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myAnchor*.hreflang

This property should contain values that use the international language two-letter abbreviation codes. These are not the same as the country codes, which are also two letter values.

Refer to the Language codes topic for a list of the available language codes.

See also:	Language codes, LINK.hreflang

Anchor.Methods (Property)

A property that can indicate some keywords regarding the action that the server provides when the link is clicked on. These reflect the request methods.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myAnchor*.Methods

The possible values of this property are those of the valid methods for the HTTP protocol. It could be one of the following:

- `GET`
- `HEAD`
- `POST`
- `PUT`
- `DELETE`
- `OPTIONS`
- `TRACE`

It is likely that only the `GET` and `POST` methods make any logical sense in this context. On rare occasions, the `PUT` method may be referred to, although it is unusual to find a web server that accepts documents with this request method. Likewise `DELETE` is normally only supported within very strict constraints.

The method name can be specified in upper or lower case.

See also:	`Url.Methods`

Anchor.mimeType (Property)

Contains a long form human readable version of the MIME type of the document at the location specified by the anchor's URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myAnchor`*`.mimeType`

The MSIE browser maps the file extension of the file belonging to the anchor to an extended description of the file format, which it makes available through the `mimeType` property. Here is a list of some `mimeType` values it pays special attention to.

File type:	MSIE expanded Mime type:
`.css`	Microsoft CSS1 Style Sheet (W3C would have been more appropriate)
`.gif`	GIF Image
`.htc`	Microsoft HTML Component file for behaviors
`.htm`	Microsoft HTML Document 4.0
`.html`	Microsoft HTML Document 4.0
`.jpg`	JPEG Image

File type:	MSIE expanded Mime type:
`.js`	Microsoft JScript File
`.txt`	Text Document
`.vbs`	Microsoft VBScript File
`.xxx`	All unrecognized file types are returned as `xxx File` with no further expansion

Microsoft asserts that `.htm` and `.html` files are "Microsoft HTML" and `.css` files are "Microsoft CSS1" style sheets. It also asserts that `.js` files are "Microsoft JScript" files. Microsoft doesn't really own those file extensions across all platforms, nor indeed does it even own them on the Windows platform.

Warnings:

- Do not confuse this value with other `mimeType` properties. For example the `Navigator` object has a `mimeTypes[]` collection property with references to `mimeType` objects. The `mimeType` property of an MSIE `Anchor` object is a simple string primitive value and not a `mimeType` object.

See also:	MIME types, `Url.mimeType`

Property attributes:

`ReadOnly`.

Anchor.name (Property)

This corresponds to the `NAME` attribute of the `<A>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.name`
	-	*myAnchor*`.name = `*aName*
HTML syntax:	`<A NAME="aName">`	
Argument list:	*aName*	A new name for the anchor.

The value of this property is defined by the `NAME` tag attribute in the HTML that describes the document. Without the `NAME` attribute, the `anchor` object does not get added to the `anchors[]` array.

This `name` property contains a case-sensitive value. It is case-sensitive because it can be used as a value in one of the document hierarchies to locate an object.

The example should present the word "EXAMPLE" on all compliant browsers.

Warnings:

- This value is read/write in MSIE, but read-only in Netscape. Logically there is not much purpose in changing the name of an `anchor` anyway.
- Beware that assigning a new name will affect the length of the `document.anchors[]`.
- Changing the name in MSIE actually adds a new item to the `document.anchors[]` array that can be reached associatively with the new name. There will now be two entries for the same anchor and you can continue to access it using the old name as well.
- If you are writing portable code and expect it to work in both MSIE and Netscape Navigator, this is the only property available in both browsers. Having located an anchor, being able to access only its name without any browser dependencies is rather limiting.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE" HREF="http://www.mydomain.com/folder/file.html#abcdef">Click
here</A>
<BR>
<SCRIPT>
document.write(document.anchors[0].name);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor` object, `AnchorArray.length`, `Document.anchors[]`, `NAME="..."`, `String.anchor()`, `Url.name`

Anchor.nameProp (Property)

The filename portion of the URL value.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myAnchor*`.nameProp`

This property extracts the filename portion of the `HREF` value for this `<A>` tag.

See also:	`Url.nameProp`

Property attributes:

`ReadOnly`.

Anchor.pathname (Property)

In MSIE the `Url.pathname` property is also available as the `Anchor.pathname` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.pathname`
	-	*myAnchor*`.pathname = `*newPath*
HTML syntax:	`<A HREF="...">`	

This yields the pathname portion of the `HREF` attribute in an `<A>` tag.

MSIE and Netscape support the use of this property as an LValue. If you write to it, the pathname portion of the `HREF` value is modified. Be careful not to include a hash or search/query value.

Warnings:

- Since the `pathname` property of an `Anchor` object is not portable in all older browser versions, you should use the `pathname` property of the corresponding `Url` object to be able to work across MSIE and Netscape.
- As features become deprecated, it may become necessary to support both techniques in browser-specific code according to your needs regarding the support of legacy browsers.

See also:	`Anchor` object, `Anchor.hash`, `Anchor.host`, `Anchor.hostname`, `Anchor.href`, `Anchor.port`, `Anchor.protocol`, `Anchor.search`, `Anchor.target`, URL, `Url.pathname`

Anchor.port (Property)

In MSIE the `Url.port` property is also available as the `Anchor.port` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.port`
	-	*myAnchor*`.port = `*newPort*
HTML syntax:	`<A HREF="...">`	

This yields the port number value of the HREF attribute in an <A> tag.

You can assign a value to this property as if it were an LValue.

Warnings:

- Since the port property of an Anchor object is not portable, you should use the port property of the corresponding Url object to be able to work across MSIE and Netscape.
- Do not include the delimiting colon when you assign a value to this property.
- Make sure you assign a numeric value. Non-numeric values will be rejected to avoid the possibility of a completely invalid port number being used.

See also:	Anchor object, Anchor.hash, Anchor.host, Anchor.hostname, Anchor.href, Anchor.pathname, Anchor.protocol, Anchor.search, Anchor.target, URL, Url.port

Anchor.protocol (Property)

In MSIE the Url.protocol property is also available as the Anchor.protocol property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	String primitive
JavaScript syntax:	- *myAnchor*.protocol - *myAnchor*.protocol = *newProtocol*
HTML syntax:	<A HREF="...">

This yields the protocol value of the HREF attribute in an <A> tag.

Using this property as an LValue, you can redefine the protocol for the link if it has an HREF. You might want to do this if you want to change the way you access a particular document.

The URL topic enumerates a large number of available protocols that can be used in SRC and HREF HTML tag attributes.

Warnings:

- Since the protocol property of an Anchor object is not portable, you should use the protocol property of the corresponding Url object to be able to work across MSIE and Netscape.

See also:	Anchor object, Anchor.hash, Anchor.host, Anchor.hostname, Anchor.href, Anchor.pathname, Anchor.port, Anchor.search, Anchor.target, IMG.protocol, URL, Url.protocol

Anchor.protocolLong (Property)

A long form description of the protocol used by the URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myAnchor*`.protocolLong`

Only the MSIE browser supports this property. Its use would be limited even if it were available across multiple platforms.

See also:	`Url.protocolLong`

Property attributes:

`ReadOnly`.

Anchor.recordNumber (Property)

The record within the data set that defined the element content when the content came from a data source.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myBody*`.recordNumber`

This is a property that is part of the MSIE data-binding support. It contains an integer value that is the record number within the data set that created this object.

This is useful when you are building pages with Active Server Pages (ASP) and ActiveX Data Objects (ADO).

Property attributes:

`ReadOnly`.

Anchor.rel (Property)

A definition of the relationship between the current document and the document at the location specified by the URL.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*.rel

This is sometimes called a forward link. Although the `HREF` HTML tag attribute is normally the only means used to identify a target document, the browser is permitted to use the `REL` HTML tag attribute to decide whether to use the `HREF` value or how it should be used.

The following HTML version 4.0 standard link types are permitted in this property:

- `alternate`
- `appendix`
- `bookmark`
- `chapter`
- `contents`
- `copyright`
- `glossary`
- `help`
- `index`
- `next`
- `prev`
- `section`
- `start`
- `stylesheet`
- `subsection`

MSIE adds these as well:

- `same`
- `next`
- `parent`
- `previous`

When used or tested within a script, any comparisons should be case-insensitive.

See also:	`Anchor.rev`, `LINK.rel`

Anchor.rev (Property)

A complementary description of the link to the current document as viewed from the document at the location specified by the URL.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*.rev

This is sometimes called a reverse link. It defines the relationship between a document and another that calls it. The linkage is defined from the destination document's viewpoint.

This property supports the same HTML version 4.0 standard link types as the `rel` property. Refer to that topic for details.

When used or tested within a script, any comparisons should be case-insensitive.

Because `rel` and `rev` properties are complementary, the values in them are likely to be related. For example, if one contains the value "next" then the other is likely to contain "previous".

Refer to the Anchor.rel topic for a list of the available types you can use in this property.

See also:	`Anchor.rel`, `LINK.rev`

Anchor.search (Property)

The query portion of an `HREF` URL if there is one.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*.search
	-	*myAnchor*.search = *newSearch*
HTML syntax:	`<A HREF="...">`	

Warnings:

- Since the `search` property of an `Anchor` object is not portable, you should use the `search` property of the corresponding link object to be able to work across MSIE and Netscape.

See also:	`Anchor` object, `Anchor.hash`, `Anchor.host`, `Anchor.hostname`, `Anchor.href`, `Anchor.pathname`, `Anchor.port`, `Anchor.protocol`, `Anchor.target`, `request.<urlExtension>`, URL, `Url.search`

Anchor.shape (Property)

A map whose extent is defined by the `coords` property and which can be one of several different shapes.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*`.shape`

This property has a meaningful value when the `Anchor` object is instantiated via `<MAP>` and `<AREA>` tag. It defines the shape of the hotspot within the extent rectangle defined by the `coords` property. It might contain one of the following values:

- `default`
- `rect`
- `circle`
- `poly`

See also:	`Anchor.coords`, `Area.shape`, `Url.shape`

Anchor.tabIndex (Property)

A control of where the `Anchor` object appears in the tabbing order of the page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myInputObject*`.tabIndex`

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms or moving focus. Pressing the [*tab*] key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

Anchor.target (Property)

In MSIE the `Url.target` property is also available as the `Anchor.target` property.

Availability:	DOM level – 1 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myAnchor*`.target` - *myAnchor*`.target = `*newTarget*
HTML syntax:	`<A TARGET="...">`

This yields the value of the `TARGET` attribute in an `<A>`, `<AREA>`, or `<MAP>` tag.

You can assign a new value to this property so that the URL will be directed to a different window or frame.

Here are some example target values:

- `_parent`
- `_self`
- `_top`
- `_blank`
- Window name
- Frame name

Warnings:

- Since the `target` property of an `Anchor` object is not portable, you should use the `target` property of the corresponding `link` object to be able to work across MSIE and Netscape.

See also:	`<MAP TARGET="...">`, `Anchor` object, `Anchor.hash`, `Anchor.host`, `Anchor.hostname`, `Anchor.href`, `Anchor.pathname`, `Anchor.port`, `Anchor.protocol`, `Anchor.search`, `BASE.target`, `Form.target`, `Location.target`, `Map.target`, URL, `Url.target`

Anchor.text (Property)

The text between the <A> and </A> HTML tags in Netscape.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myAnchor*.text
	N	*myAnchor*.text = *aString*
HTML syntax:	<A>someText</A>	
Argument list:	*aString*	Some new text content for the anchor

This is equivalent to the `innerText` value that MSIE supports. It only works on Netscape and is somewhat less reliable than the `innerText` property in MSIE.

Assigning to this property in MSIE simply creates a text property, but does not affect the text of the anchor.

The value yielded by this property (when it does work) is the text between the <A> and </A> tags.

Warnings:

- You will need to detect the browser type before attempting to use this property.
- Does not work on Netscape Navigator version 4.7 on the Macintosh. Instead it displays some fragment of body text that comes from outside the anchor tags.
- Even if it does work, you may only extract a portion of the text from the anchor.

See also:	`Anchor` object, `Element.innerText`, `Url.text`

Property attributes:

`ReadOnly`.

Anchor.type (Property)

A MIME type value in its abbreviated machine recognizable form.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myAnchor*.type

The MIME type of the document associated with the `Anchor` object is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

See also:	`LINK.type`, MIME types

Anchor.urn (Property)

An alternative format of the contents of the URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myAnchor*`.urn`

See also:	URN

Anchor.x (Property)

The X location of the anchor within the document.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myAnchor*`.x`
	N	*myAnchor*`.x = `*aValue*
Argument list:	*aValue*	A new X coordinate value

The `Anchor.x` property yields the pixel distance of the anchor from the left edge of the document. The horizontal position of the object in the display is measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- This is not supported by MSIE. Instead you can use the `offsetLeft` property that is inherited from the `Element` object super-class. There may be some occasions when this is not an exact equivalent value though.

See also:	`Anchor` object, `Element.offsetLeft`, `Location.x`

Property attributes:

`ReadOnly`.

Anchor.y (Property)

The Y location of the anchor within the document.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myAnchor*`.y`
	N	*myAnchor*`.y = `*aValue*
Argument list:	*aValue*	A new Y coordinate value

The `Anchor.y` property yields the pixel distance of the anchor from the top edge of the document. The vertical position of the object in the display is measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- This is not supported by MSIE. Instead you can use the `offsetTop` property that is inherited from the `Element` object super-class. There may be some occasions when this is not an exact equivalent value though.

See also:	`Anchor` object, `Element.offsetTop`, `Location.y`

Property attributes:

`ReadOnly`.

AnchorArray object (Object/DOM)

An array of `Anchor` objects retrieved from the `document.anchors` property.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 3.0 Internet Explorer – 4.0 Netscape – 2.0	
JavaScript syntax:	-	*myAnchorArray* `= `*myDocument*`.anchors`
Object properties:	`length`	

The `AnchorArray` object is a sub-class of the `Array` object but has no additional properties. It responds to the `length` property request as you would expect.

Any `Anchor` objects in this array can be accessed by index value because the `Array` class supports that. In Netscape, the individual `Anchor` objects are accessible associatively by their `NAME` attribute. However, MSIE does not make this associative mechanism available.

In MSIE, the `AnchorArray` object is a kind of `Collection` object and so it can be searched with the `item()` and `tags()` methods.

Warnings:

- Netscape adds a `constructor` property to this object class from which you can request the name to determine the object class. Actually Netscape provides constructors for virtually everything, but MSIE only supports them when it's necessary and useful.
- Be aware that renaming an anchor in MSIE will add a new item to the `AnchorArray` collection without destroying the old one. However, the `length` property remains the same. It does mean that you could have problems enumerating the collection. But then, why would you ever want to rename an anchor after it has been instantiated and named within the HTML tag?

Example code:

```
<!-- Catalog of anchors in an array -->
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="A1" HREF="http://www.apple.com/">Apple</A><BR>
<A NAME="A2" HREF="http://www.wrox.com/">Wrox</A><BR>
<A NAME="A3" HREF="http://www.msdn.com/">Microsoft</A><BR>
<BR>
<HR>
<TABLE BORDER=1>
<TH>Index</TH>
<TH>Name</TH>
<TH>Text</TH>
<TH>URL</TH>
<TH>Tab index</TH>
<TH>Protocol (long)</TH>
<SCRIPT>
myLength = document.anchors.length;
for (myEnumerator=0; myEnumerator<myLength; myEnumerator++ )
{
document.write("<TR><TD>");
document.write(myEnumerator);
document.write("</TD><TD>");
document.write(document.anchors[myEnumerator].name);
document.write("</TD><TD>");
document.write(document.anchors[myEnumerator].innerText);
document.write("</TD><TD>");
document.write(document.anchors[myEnumerator].href);
document.write("</TD><TD>");
```

```
document.write(document.anchors[myEnumerator].tabIndex);
document.write("</TD><TD>");
document.write(document.anchors[myEnumerator].protocolLong);
document.write("</TD></TR>");
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

See also:	`Anchor` object, `Collection` object, `Document.anchors[]`

Property	**JavaScript**	**JScript**	**N**	**IE**	**Opera**	**DOM**	**Notes**
`length`	1.0 +	3.0 +	2.0 +	4.0 +	-	-	ReadOnly

AnchorArray.length (Property)

The number of named anchors in the current document.

Availability:	JavaScript – 1.0 JScript – 3.0 Internet Explorer – 4.0 Netscape – 2.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDocument*`.anchors.length`

The length of the `anchors` array, which indicates the number of named `<A>` HTML tags in the document.

See also:	`Anchor.name`, `Collection.length`, `Document.anchors[]`

Property attributes:

`ReadOnly`.

Anonymous code (Definition)

Script source executed by function objects.

Availability:	ECMAScript edition – 2

Anonymous code is script source text that is supplied to the constructor when an anonymous function is being instantiated.

As the constructor creates the function, one of the arguments to the constructor call will contain the script source text to be stored as the code block associated with that function. Only the code in the last argument on the constructor call is used in this way. All but the last argument are concatenated together separated by commas and are then passed as the formal parameter list to the anonymous function.

Anonymous code initializes the scope chain to include its `activation` object followed by the `global` object.

Variable instantiation is performed using the `activation` object as the variable object and any initial variables are flagged with a `DontDelete` attribute.

The caller provides this value, but in some situations the value null may be passed. In that case, the `global` object will be used in its place.

If you need more information, the ECMA standard is the authoritative source on what anonymous code is and how a compliant interpreter implementation should manage it.

Anonymous function (Definition)

A manually constructed function object with no identifying name.

Availability:	ECMAScript edition – 2

Anonymous functions are created dynamically by using the built-in `Function` object as a constructor in a function expression.

As they are called, the last argument is used to provide the script source, and all but the last argument are used as a formal parameter list for the function.

Anonymous functions are properly supported by the WebTV set-top box from the Summer 2000 release onwards. Earlier versions of this product only partially supported anonymous functions.

Applet object (Object/HTML)

An object representing an HTML `<APPLET>` tag.

Availability:	DOM level – 0 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0 Deprecated – HTML 4.0, DOM level 1
Inherits from:	`Element` object
JavaScript syntax:	- *myApplet* = *aName* - *myApplet* = *myAppletArray*[*aName*] - *myApplet* = *myAppletArray*[*anIndex*] IE *myApplet* = *myDocument*.all.*anElementID* IE *myApplet* = *myDocument*.all.tags("APPLET")[*anIndex*] IE *myApplet* = *myDocument*.all[*aName*] - *myApplet* = *myDocument*.*aName* - *myApplet* = *myDocument*.applets[*aName*] - *myApplet* = *myDocument*.applets[*anIndex*] - *myApplet* = *myDocument*.getElementById(*anElementID*) - *myApplet* = *myDocument*.getElementsByName (*aName*)[*anIndex*] - *myApplet* = *myDocument*.getElementsByTagName ("APPLET")[*anIndex*]
HTML syntax:	`<APPLET> ... </APPLET>`
Argument list:	*aName* – The name of an applet *anIndex* – An element in the `applets` collection *anElementID* – The ID value of an `Element` object
Object properties:	`accessKey`, `align`, `alt`, `altHTML`, `archive`, `code`, `codeBase`, `dataFld`, `dataSrc`, `form`, `height`, `hspace`, `name`, `object`, `src`, `tabIndex`, `vspace`, `width`
Object methods:	`start()`, `stop()`
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onBlur`, `onClick`, `onDataAvailable`, `onDataSetChanged`, `onDataSetComplete`, `onDblClick`, `onErrorUpdate`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onLoad`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onReadyStateChange`, `onResize`, `onRowEnter`, `onRowExit`

The properties and methods of an `Applet` object are inherited from the public properties and methods of the `Java` object it represents. However, in addition to these, MSIE also supports some additional properties.

The Java applet itself is the concrete object whose properties are accessed.

In Netscape, Applets are encapsulated as instances of the `JavaObject` class and communicate by means of the LiveConnect support. The mechanisms are quire different in MSIE, which uses ActiveX facilities to access applets.

When you access an `Applet` (`JavaObject`) object, you are really interacting with the Java applet itself.

The publicly accessible properties and methods depend on the applet, although all applets must support the `start()` and `stop()` methods.

It is generally safer to interact with methods that you have provided as custom additions to the applet, rather than hope that the applet supports any particular methods.

Because Java is so much more strongly data-typed than JavaScript, you must be careful with the kind of values you try and send to and receive from a Java applet. Java will also not forgive the omission of an argument. In JavaScript, all arguments are assumed to be optional as a general rule, although leaving them out will have strange side effects sometimes. Java will not allow you to do this and a run-time error will be generated if the arguments are not complete and all of the correct type.

In Netscape, you can build an enumerator loop to examine all the properties of an `Applet` object. Enumerating applet interfaces like this will yield a long list of function objects. Each function object represents an accessor for internal properties of the Java environment. Your applet may publish additional properties. With these functions, you can enquire about certain attributes of the applet and can change some of them from the script. Refer to the `JavaObject` topic for details about these generic capabilities, but bear in mind they only work in Netscape.

In MSIE, the `APPLET` object inherits its behavior from the `Element` object. Refer to the topic covering that for its generic properties and methods. MSIE supports many other properties and methods that are not generally available to `Element` objects and these are detailed here as properties and methods of the `Applet` object.

Warnings:

- MSIE implements this object as a member of the class `APPLET` rather than `Applet` as you would expect.
- Netscape implements it as a member of the class `JavaObject`, although this is masked by some shortcomings in the implementation that prevent it from displaying its class type.
- `<APPLET>` tags are deprecated in HTML 4.0 and DOM level 1, which suggests there may be some changes to the JavaScript support for them in subsequent implementations of JavaScript in browsers.

Inheritance chain:

`Element` object, `Node` object

Applet() (Constructor)

You normally would not use the constructor to create new applets, but it is possible to do this if you need to create an applet container.

Availability	`Deprecated`
Property/method value type:	`Applet` object

As is the case with many (but not all) objects in Netscape, you can call a constructor to create a new instance of an object. MSIE does not generally support this unless a constructor is really justified. Because this constructor is only supported in Netscape, you should avoid constructing new `Applet` objects. In any case, they are of limited use since you cannot easily place them into the page and make them visible, even if you could populate them with meaningful content. Because of this, the topic is marked as deprecated, although the functionality is likely to continue to be available.

Applet.align (Property)

Determines how the applet area aligns with its surrounding content.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.align`

The alignment of the applet with respect to its containing parent object is defined in this property. The following expected set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Applet.alt (Property)

The alternative text to be used instead of the applet block in case the applet fails to load or for use as a tool-tip text.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.alt`

If a browser loads a document containing an applet and discovers that it is unable to load the applet, this text value of this property will be displayed in the space where the applet was supposed to have been loaded.

The use of this property is somewhat problematical in some browsers and completely unsupported in others.

Setting this property from a script is unlikely to be very useful, as the script is probably going to be called after the applet has failed to load.

Applet.altHTML (Property)

Some alternative HTML to display if the applet fails to load.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myApplet`*`.altHTML`

If a browser loads a document containing an applet and discovers that it is unable to load the applet, this HTML will be displayed in the space where the applet was supposed to have been loaded.

However, this property cannot be set from an HTML tag attribute as the `alt` text can. It can only be set from a script.

Setting this property from a script is unlikely to be very useful, as the script is probably going to be called after the applet has failed to load.

Applet.archive (Property)

The name of a zip archive containing multiple class files.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 5.0 Internet Explorer – 5.0 Netscape – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myApplet*.archive

Netscape allows for multiple applet class files to be collected together into a single zipped archive file. Useful performance gains are possible if an applet depends on several classes for its implementation, because they can all be loaded at once.

For this to work, you must also specify the `CODE` HTML tag attribute so that the browser can determine which one of the classes is the main one.

There is some variance here from the HTML 4.0 definition of this value, which suggests that a list of space-separated URL values can be specified. That is intended for use with the `<OBJECT>` tag, which, according to the W3C organization, is the successor to the `<APPLET>` tag, which is likely to be come deprecated in due course. However, since the `<APPLET>` tag is used so widely, this is likely to take some considerable time to take effect.

See also:	`Applet.code`

Applet.code (Property)

The Java class code for the applet.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myApplet*.code

This specifies the main code class to be called when the applet is initially run. It is necessary to identify the main item in case there was a collection of class files loaded as an archive.

See also:	`Applet.archive`

Property attributes:

`ReadOnly`.

Applet.codeBase (Property)

The path to the directory containing the applet code.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.codeBase`

The codebase is the path to the directory where the classes used in the code or archive properties are located. The actual path to the required files is generated by a string concatenation of `codeBase+code` or `codeBase+archive` to generate a fully specified URL.

Due to security limitations, it is not permitted to access a codebase value that is outside the domain specified by the containing document.

Property attributes:

`ReadOnly`.

Applet.height (Property)

The height of the applet extent rectangle in pixels.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.height`

The extent rectangle around the applet reserves some space in the display before the applet is loaded. The height of that extent rectangle is specified in this property and is normally measured in pixels. Length values controlled by CSS styles allow for sizes to be specified in other measurement units.

See also:	`Applet.width`

Property attributes:

`ReadOnly`.

Applet.hspace (Property)

The width of the horizontal margin spacing around an `Applet` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.hspace`

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `hspace` property controls the margin to the left and right of the object.

Applet.name (Property)

This corresponds to the `NAME` attribute of the `<APPLET>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.name`
HTML syntax:	`<APPLET NAME="aName">`	
Argument list:	*`aName`*	A name to identify the `Applet` object

Objects are identified either by the `NAME` HTML tag attribute or by the `ID` HTML tag attribute.

Netscape shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

Property attributes:

`ReadOnly`.

Applet.object (Property)

An accessor that yields a reference to the containing JavaScript object when there is a possibility of naming conflicts between internally visible and externally visible property names.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Applet` object	
JavaScript syntax:	-	*myApplet*`.object`

There are occasional namespace conflicts when using applets. Public properties are created in a different environment, but are published into the JavaScript namespace and take precedence over the properties of the containing JavaScript object.

The problem is exhibited when the name of a public property collides with a property of the containing JavaScript object instantiated by the `<APPLET>` HTML tag. Access to the property belonging to the containing object is difficult because the scope search order will obtain the public property of the applet first. By using the `object` property, you can access the containing object explicitly and retrieve a property of that object even if there is an identically named property belonging to the enclosed `Applet` object.

This access mechanism applies to method invocations as well.

See also:	`OBJECT.object`

Applet.src (Property)

A supplementary property for passing in URL values to the applet.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myApplet*`.src`

Some applets may need to access a supplementary data file from the server. It is good practice to abstract such data values from the code itself, and so a means of passing this parameter value in from outside is necessary. The `SRC` HTML tag attribute is reflected into this property and is provided as a somewhat standardized means of passing one of the parameter values most likely to be defined.

Property attributes:

`ReadOnly`.

Applet.start() (Method)

A public method that starts an applet running.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
JavaScript syntax:	-	*myApplet*`.start()`

This method will start an applet running if it has previously been stopped. Note that, in general, applets will run automatically by default unless you do something to prevent it (possibly by setting HTML tag attributes).

See also:	`Applet` object, `Applet.stop()`

Applet.stop() (Method)

A public method that stops an applet running.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
JavaScript syntax:	-	*myApplet*`.stop()`

This method provides a way to stop the execution of an applet from outside. Applets may choose to stop themselves if that is what you have designed them to do. Other applets may be embedded into the page and instructed not to run automatically by setting the appropriate attributes in the `<APPLET>` HTML tag.

See also:	`Applet` object, `Applet.start()`

Applet.vspace (Property)

The height of the vertical margin spacing around an `Applet` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.vspace`

Margins placed around objects are modified either separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `vspace` property controls the margin at the top and bottom of the object.

Applet.width (Property)

The width of the applet extent rectangle in pixels.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myApplet`*`.width`

The extent rectangle around the applet reserves some space in the display before the applet is loaded. The width of that extent rectangle is specified in this property and is normally measured in pixels. Length values controlled by CSS styles allow for sizes to be specified in other measurement units.

See also:	`Applet.height`

Property attributes:

`ReadOnly`.

AppletArray object (Object/DOM)

A sub-class of the `Array` object that implements an applet collection.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
JavaScript syntax:	-	*myAppletArray* = *myDocument*.applets
Object properties:	length	

Warnings:

- Although Netscape supports a constructor for this object type, it appears to point at the wrong thing. In any case, it's unlikely you'd want to create a new `AppletArray`.

See also:	`Applet` object, `AppletArray.length`, `Collection` object, `Document.applets[]`

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
length	1.0 +	1.0 +	2.0 +	3.02 +	-	-	-	1 +	-	-	ReadOnly

AppletArray.length (Property)

The number of `Applet` objects in the collection.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myDocument*.applets.length

The length of the `applets` array, which indicates the number of `<APPLET>` HTML tags in the document.

See also:	`AppletArray` object, `Collection.length`

Property attributes:

`ReadOnly`.

Area object (Object/HTML)

An object representing an `<AREA>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myArea* = *myDocument*.all.*aMapID*.areas[*anIndex*]
	IE	*myArea* = *myDocument*.all.*anElementID*
	IE	*myArea* = *myDocument*.all.tags("AREA")[*anIndex*]
	IE	*myArea* = *myDocument*.all[*aName*]
	-	*myArea* = *myDocument*.getElementById (*anElementID*)
	-	*myArea* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myArea* = *myDocument*.getElementsByTagName ("AREA")[*anIndex*]
	-	*myArea* = *myDocument*.links[*anIndex*]
HTML syntax:	`<AREA>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, alt, coords, hash, host, hostname, href, name, noHref, pathname, port, protocol, search, shape, tabIndex, target, text, x, y	
Object methods:	add()	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDataAvailable, onDataSetChanged, onDataSetComplete, onDblClick, onErrorUpdate, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReadyStateChange, onResize, onRowEnter, onRowExit	

An `Area` object represents an area of an image map. They are generally referred to as `Link` objects, although Netscape and MSIE instantiate them as different classes.

Netscape supports these objects as objects of the `Url` class.

MSIE treats them as `Link` objects.

Event-handling support via properties containing function objects was added to `Area` objects at version 1.1 of JavaScript.

See also:	`Element` object, `HyperLink` object, `Input.accessKey`, `LINK` object, `LinkArray` object, `Location` object, `Map` object, `Url` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`accessKey`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`alt`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`coords`	1.5 +	3.0 +	6.0 +	3.02 +	-	1 +	-	-

onRowExit	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Area.accessKey (Property)

A key that needs to be pressed before the mapped link will respond to data entry.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*.accessKey

The key defined in this property needs to be held down for any input events to be triggered on this object or its children.

Area.add() (Method)

Add a new element to the `Area` object that describes the image map.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myArea*.add(*anObject*)
	IE	*myArea*.add(*anObject*, *anIndex*)
Argument list:	*anObject*	A new `link` object to add
	anIndex	A position in the collection to add the new item

Image maps can be modified from the scripting interface. You might find this useful if you present some new information and want to add a button to dismiss it. It is possible to avoid an unnecessary screen redraw and image load by adding an item to an image map collection.

Area.alt (Property)

The tool-tip text for the `Area` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.alt`

Objects can have an alternative text string associated with them. Browsers that cannot cope with the tag may display the text instead. If spoken styles are supported, the text may be read out to the user. Some browsers will also display the alt text as a tool-tip if the mouse is positioned over the object and remains static for a few seconds.

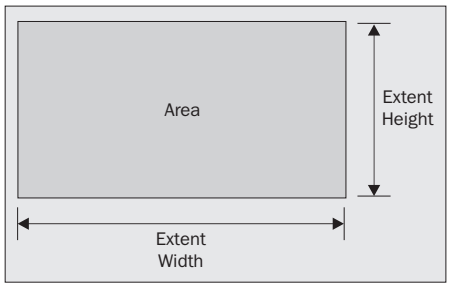
Area.coords (Property)

The extent rectangle for the `Area` object within a map.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 3.02 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.coords`

When a shaped area is defined within a an image map, the extent rectangle around the shape is defined with the `coords` property. The value is defined with the `COORDS` HTML tag attribute.

See also:	`Anchor.coords`, `Area.shape`



Area.hash (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.hash`

See also:	`Url.hash`

Area.host (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.host`

See also:	`Url.host`

Area.hostname (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.hostname`

See also:	`Url.hostname`

Area.href (Property)

MSIE represents URLs in `Link` objects.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myArea*.href
HTML syntax:	`<AREA HREF="...">`

See also:	`Location.href`, `Url.href`

Area.name (Property)

This corresponds to the `NAME` attribute of the `<AREA>` HTML tag.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myArea*.name

Objects are identified either by the `NAME` HTML tag attribute or by the `ID` HTML tag attribute.

Netscape shows a marginal preference for the `name` property, while MSIE seems slightly better disposed towards the `ID` property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`Url.name`

Area.noHref (Property)

A Boolean flag to indicate whether the area is a link or a dead spot within the map.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myArea*.noHref

When a shaped area is defined within a an image map, it can either define a live hotspot or a hole that has been cut out in the map. In this way, both concave and convex shapes can be created. You can also create shapes with holes in the middle.

Area.pathname (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*.pathname
See also:	`Url.pathname`	

Area.port (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myArea*.port
See also:	`Url.port`	

Area.protocol (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.protocol`

See also:	`IMG.protocol`, URL, `Url.protocol`

Area.search (Property)

MSIE represents URLs in `Link` objects.

Availability:	JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.search`

See also:	`request.<urlExtension>`, `Url.search`

Area.shape (Property)

The shape of the extent area within the map.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 1.0 Internet Explorer – 3.02 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArea*`.shape`

This property has a meaningful value when the `Area` object is instantiated via `<MAP>` and `<AREA>` tag. It defines the shape of the hotspot within the extent rectangle defined by the `coords` property. It might contain one of the following values:

- `default`
- `rect`
- `circle`
- `poly`

See also:	`Anchor.shape,Area.coords,Url.shape`

Area.tabIndex (Property)

A control of where the `Area` object appears in the tabbing order of the page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myArea*`.tabIndex`

This value indicates where this object and any of its children will be placed in the tabbing sequence. The tabbing order is used when filling in forms or moving focus. Pressing the [*tab*] key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

Area.target (Property)

MSIE represents URLs in `Link` objects.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myArea*`.target`
HTML syntax:	`<AREA TARGET="...">`
See also:	`<MAP TARGET="...">,Anchor.target,BASE.target, Form.target,Location.target,Map.target, Url.target`

Area.text (Property)

Netscape represents `<AREA>` tags as `Url` objects and therefore they inherit this property.

Availability:	JavaScript – 1.2 Netscape – 4.0
Property/method value type:	`String primitive`
JavaScript syntax:	N *myArea*`.text`
See also:	`Url.text`

Area.x (Property)

Netscape provides this as an enumerable property because it represents an `<AREA>` as a `Url` object.

Availability:	JavaScript – 1.2 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	N *myArea*`.x`

The horizontal position of the object in the display measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

See also:	`Location.x`

Area.y (Property)

Netscape provides this as an enumerable property because it represents an `<AREA>` as a `Url` object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myArea*`.y`

The vertical position of the object in the display measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

See also:	`Location.y`

areas[] (Collection)

A collection of all the `Area` objects that contribute to making an image map for the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myMap*`.areas`

See also:	`Map.areas[]`

Property attributes:

`ReadOnly`.

argc parameter (Definition)

A command-line argument count.

Since JavaScript can be used in many environments, it is possible that in a server-side application you will have access to the command-line arguments.

If that is the case, then it is likely that you will have an `argc` property, which indicates how many arguments have been passed.

In general, the first argument is the name of the script or program being executed. The `argc` value should never be zero and as a minimum should indicate that there is at least one argument.

The actual values of the arguments are collected in an array called `argv`. You should be able to access `argv` and `argc` in a similar manner.

See also:	`argv` parameter, Execution context, Execution environment, Host environment, `main()` function

Argument (Definition)

A value passed to a function.

Arguments are passed to functions when they are called. They are substituted for the formal parameters in the function declaration.

Because JavaScript is weakly typed, you will need to implement any type checking you need for yourself.

You can compare the `arity` property of the owning function with the `length` property of the `arguments` array. If they are unequal, then the function was called with the wrong number of arguments.

You can then check the type of the arguments one by one to compare them against the expected types.

This is a lot of work for little gain unless it is an important aspect of your design.

See also:	`Arguments` object, `Arguments.length`, Conversion, Definition, Function, `function(…) …`, `Function.arguments[]`, Parameter

Argument list (Definition)

A list of values that are passed to a function.

Availability:	ECMAScript edition – 2

Argument lists are used to pass information into functions.

An argument list can have any of the following structures:

- Empty – no arguments
- A single argument
- A series of arguments separated by commas

Each argument, if present, can be an expression that will be evaluated and whose resulting value will be used as the argument when it is passed to the function.

See also:	`Arguments` object, `Arguments.length`, `Function.arguments[]`, Left-Hand-Side expression, Parameter

ECMA 262 edition 2 – section – 11.2.4

ECMA 262 edition 3 – section – 11.2.4

Arguments object (Object/core)

An object represented as an array containing the argument values passed to the function when it is called.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 5.5 Internet Explorer – 5.5 Netscape – 3.0	
JavaScript syntax:	-	*myArguments* = arguments
Object properties:	callee, caller, length	

When you call a function, you can pass zero or more arguments to it from outside. These arguments are available as named variables whose names are defined in the function declaration.

However, they are also available as the elements in an array. The `arguments` array is referenced by the `arguments` property of the `call` object. Since the `call` object is added to the scope chain, you don't need to reference the `arguments` property with an object identifier prefix.

The array-based mechanism is useful for those times when you want to implement a function that has a variable number of arguments passed to it according to how and when it is called.

A new `arguments` object is created for each execution context. When the flow of control enters an execution context for a function block, a new `arguments` object is created. Declared functions, anonymous code, and implementation-specific code all use this technique.

When creating the `arguments` object, the initial conditions are set up like this:

- The internal `Prototype` property for the `arguments` object is that returned by calling `Object.Prototype`.
- A property is created with the name `callee`. The `callee` property cannot be enumerated. The initial value of the `callee` property is the `function` object being executed. Anonymous functions can then be executed recursively if you so desire.
- A property named `length` is created whose value is the number of arguments passed to the function. The `length` property cannot be enumerated.
- Each argument is associated with a property whose name is its integer position in an array of arguments. The arguments are accessed in presentation order. Although the names are strings, they represent purely numeric values and range from 0 to 1 less than the value in the `length` property. You can enumerate the arguments in a `for` loop.

Note that objects of this type can only exist within a function body in a web browser, because you cannot pass parameters to a script from outside. It is possible that an embedded JavaScript interpreter may provide a `host` object to the main entry point to perform the same function.

Warnings:

- In Netscape, the `arguments` array is implemented as an object of type `Arguments` but in MSIE its type is simply an `Object` object. In Netscape, the `arguments` object is extended with a `toString()` mechanism that returns the arguments as a comma separated list in a String. In MSIE, you get the object type.
- None of the properties of the `arguments` object are enumerable.
- Because the `arguments` object is meant to be used in a manner that is local to the function it was created in, you get unpredictable results if you pass it to another function as an argument itself.
- Note that at the time of writing the example given below did not seem to work on Netscape 6.0.

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Call a function and use its arguments array find out the
// name of the function that called it.  Demonstrates a one
// level call tracer.

level1();

function level1()
{
   testArgs(1, "ONE", true);
}

function testArgs(a1, a2,a3)
{
   document.write(callerName(arguments));
   document.write("<BR>");
}

function callerName(a1)
{
   myCallerObject = a1.caller.callee;
   myCallerSource = String(myCallerObject);
   mySplitArray1  = myCallerSource.split(" ");
   mySplitArray2  = mySplitArray1[1].split("(");
   myCaller       = mySplitArray2[0];
   return(myCaller);
}
</SCRIPT>

<BODY>
</HTML>
```

Arguments.callee (Property)

The `function` object being called.

Availability:	JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0	
Property/method value type:	`Function` object	
JavaScript syntax:	-	*`myArguments`*`.callee`

The value yielded by this property is the `function` object that owns the arguments.

You can work out the calling tree by tracing the callee and caller relationships back up the tree. The callee is a reference to the parent function that owns the `arguments` object.

This has no meaning outside of the context of a function.

See also:	`Arguments` object, `Arguments.caller`, Debugging – client side, `Function` object

Property attributes:

`DontEnum`.

Arguments.caller (Property)

The object that called the function that owns the arguments.

Availability:	JavaScript – 1.1 JScript – 5.5 Internet Explorer – 5.5 Netscape – 3.0 Deprecated	
Property/method value type:	`Arguments.object`	
JavaScript syntax:	-	*myArguments*`.caller`

This property refers to an `Arguments` object belonging to a parent function. Function call tracing can traverse a hierarchy based on `Arguments` objects to unwind a call stack. This might be useful when debugging complex script projects.

You can work out the calling tree by tracing the callee and caller relationships back up the execution context tree. The caller is a reference to the `arguments` object of the caller of the function.

To reference the function that called the current one, use this:

```
arguments.caller.callee
```

To get the name of the function that called the current one use this (so long as the interpreter supports the `name` property on functions):

```
arguments.caller.callee.name
```

With this, you could build a stack trace function that you can call and will unwind the calling context stack to show you how you got to the location you are in. Tools such as this are useful to have around and if they are in a separate `.js` file, you can include them when you need to debug a script problem.

When the `caller` value is Null, it refers to the global code context because there is no `arguments` array in that context – at least not in a web browser. Other host implementations may provide an additional level of arguments according to how the script is executed.

This has no meaning outside of the context of a function.

The example shows how to walk up the calling tree and should yield the following output when it is run:

```
level2

called by level1

called by global level
```

Warnings:

- This property is incorrectly implemented in Netscape 3, which returned a reference to the calling function and not its arguments. Since it works correctly in Netscape 4, you should consider that it is only available there.
- The example shown below did not work correctly on Netscape 6.0 at time of writing.
- This is not part of the ECMA standard and is at some risk of becoming deprecated and removed in later versions. In fact, it is deprecated as of JavaScript version 1.3 and should not be used in new projects.
- It is recommended that you do not build this into functional deployed applications, although the risks involved with using it for debugging are small.

Example code:

```
<HTML>
<BODY>

<SCRIPT>
// A function to extract the calling function name when
// passed the arguments object from a function.  Demonstrates
// how to recursively walk up a call tree.level1();

level1();

function level1()
{
   level2();
}

function level2()
{
   testArgs(1, "ONE", true);
}

function testArgs(a1, a2,a3)
{
   document.write(callerName(arguments));
   document.write("<BR>");
}

function callerName(a1)
{
   if(a1.caller == null)
   {
      return("global level");
   }
   myCallerObject = a1.caller.callee;
   myCallerSource = String(myCallerObject);
   mySplitArray1  = myCallerSource.split(" ");
   mySplitArray2  = mySplitArray1[1].split("(");
   myCaller       = mySplitArray2[0];
   return(myCaller+"<BR> called by "+callerName(a1.caller));
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Arguments` object, `Arguments.callee`, Debugging – client side, `Function` object, `Function.caller`, Hierarchy of objects

Property attributes:

`DontEnum`.

Arguments.length (Property)

The number of arguments passed to a function dictates the length of the array to hold them.

Availability:	JavaScript – 1.1 JScript – 5.5 Internet Explorer – 5.5 Netscape – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myArguments*`.length`

The number of arguments passed to a function when it is called.

The `length` property of the `Arguments` object can be inspected or used in an enumeration loop to access each argument in turn.

Even if no placeholder arguments are specified, you can still call a function and pass as many arguments to it as you like. They will be assembled into an array that you can manipulate in the way you would normally operate on any other array. You can build enumerators to process all the elements and do something with them.

You can compare this value with the `arity` property of the owner `function` object. This will allow you to determine whether the correct number of arguments was passed.

Example code:

```
<SCRIPT>
// Declare a function that processes a variable number of arguments
function summate()
{
   var total = 0;
   for(var ii=0; ii<arguments.length; ii++)
   {
      total += arguments[ii];
   }
   return total;
}

// Call the function
sum = summate(1, 2, 3, 4, 5);

document.write(sum);
</SCRIPT>
```

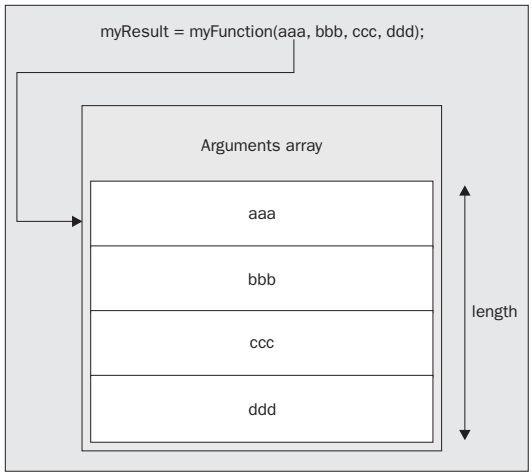
See also:	Argument, Argument list, `Arguments` object, `Collection.length`, `Function.arguments[]`, `Function.arity`, `Function.length`

Property attributes:

`ReadOnly`, `DontEnum`.

Cross-references:

Wrox *Instant JavaScript*, ISBN 1-861001-27-4 – page – 27



arguments[] (Collection)

A property that is available inside a function to access its `Arguments` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 5.5 Internet Explorer – 5.5 Netscape – 3.0

This property is only defined within a function body in a web browser. However, some implementations may provide external arguments via this property.

See also:	`Arguments` object, Function arguments, `Function.arguments[]`

Property attributes:

`ReadOnly`.

argv parameter (Definition)

A command-line argument collection.

Since JavaScript can be used in many environments, it is possible that in a server-side application you will have access to the command-line arguments.

If that is the case, then it is likely that you will have an `argv` property, which contains the argument values.

In general, the first argument is the name of the script or program being executed.

To establish the length of the `argv` array, you can inspect the `argc` value.

The values passed in the `argv` array are likely to be presented as strings, although they may be automatically cast to number, Boolean or other types without you needing to perform any type conversion yourself.

Warnings:

- If you call one script from another, the command-line arguments that were used to invoke the original script may not be propagated unless your calling script makes some arrangements to pass in the arguments it was given. Each script is likely to run in a separate execution context.

See also:	`argc` parameter, Execution context, Execution environment, Host environment, `Host` object, `main()` function

Arithmetic constant (Definition)

A constant derived from arithmetic (numeric) values.

An arithmetic constant is derived from one of the following:

- Unicode character code value of a character constant
- Enumeration constant
- Floating-point constant
- Integer constant
- Math object property
- Number object property
- Global object property

See also:	Constant expression, Floating-point constant, Infinity, Integer constant, `Math.E`, `Math.LN10`, `Math.LN2`, `Math.LOG10E`, `Math.LOG2E`, `Math.PI`, `Math.SQRT1_2`, `Math.SQRT2`, `NaN`, `Number.MAX_VALUE`, `Number.MIN_VALUE`, `Number.NaN`, `Number.NEGATIVE_INFINITY`, `Number.POSITIVE_INFINITY`

Arithmetic operator (Definition)

An operator that works with numeric operands.

The collection of arithmetic operators includes the operators in the following categories:

- Additive operator
- Multiplicative operator
- Postfix operator
- Prefix operator

Warnings:

- Applying some operators causes a strange degenerative effect in the accuracy. On the Macintosh in MSIE 5.0 and in Netscape 4, the following loop generates a very strange sequence of numbers that are quite erroneous:

```
for(myEnum = 1.5; myEnum > -2; myEnum -= 0.1)
{
 document.write(myEnum + "<BR>");
}
```

- There are some very odd and subtle mathematical errors in the arithmetic handling within the Macintosh platform, and it surely must be the platform since the same behavior is found on both MSIE and Netscape.

See also:	Additive operator, Expression, Mathematics, Multiplicative operator, Postfix operator, Prefix decrement (--), Prefix increment (++), Prefix operator, Remainder (%), Remainder then assign (%=), Subtract (-), Subtract then assign (-=), Type conversion

Cross-references:

Wrox Instant JavaScript – page – 18

Arithmetic type (Definition)

A subset of the native types concerned with numeric values.

In the C language, programmers need to be aware of the many and various types of numeric value. JavaScript hides a great deal of this complexity by presenting a Number data type.

However, internally it still uses 32 bit integer values, 16 bit integer values, signed and unsigned integers, and floating-point values.

Arithmetic type values are used with arithmetic operators to build arithmetic expressions.

Characters are maintained as single character strings, but can be represented numerically by converting them to their Unicode code point value using the method `String.charCodeAt()`. You can convert back again using the `String.fromCharCode()` method.

See also:	`String.charCodeAt()`,`String.fromCharCode()`

Array index delimiter ([ ]) (Delimiter)

Access elements of an array with this delimiter.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Depends on array content`	
JavaScript syntax:	-	*myArray*[*anIndex*]
Argument list:	*anIndex*	A legal index value into the array, not greater than the array length

Array elements are indexed by selecting them numerically within the set of elements contained in the array. The `length` property of an array indicates how many indexable locations there are. Array elements begin with the zeroth item.

Storing values into indexes that are higher than the current value of the `length` property will automatically extend the array and reset the `length` property. An array with only one entry in the 100th element (index value 99) is very sparsely populated but still should report a `length` value of 100.

In Netscape, referencing the array with no element delimiters will yield a comma-separated list of the contents of the array. So this:

```
myArray = new Array(6);myArray[0] = 0;myArray[1] = "XXX";myArray[2] = 0;myArray[3]
= "XXX";myArray[4] = 0;myArray[5] = "XXX";document.write(myArray);
```

Yields this when executed:

```
0,XXX,0,XXX,0,XXX
```

Accessing properties of an object by name simply requires the name to be added to the object reference with a dot separator between them. Numeric values cannot be used in this way. You must use a string to name the array element when it is assigned.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

Although JavaScript does not properly support multi-dimensional arrays, you can simulate them by storing references to one array in the elements of another. You need to create a separate array for each row and then one master array to arrange them into a column.

True multi-dimensional arrays would use a notation like this:

```
multiArray[1,2]
```

But in JavaScript we can at least manage this:

```
multiArray[1][2]
```

This is close enough that most programmers will be able to cope with it quite happily.

Another alternative way to do this is to use a single dimensional array, but calculate the indices. For example to make a 5 x 5 array, you would create a single dimensional array that is 25 elements long. Then to reach the rows you use the row number and multiply the value by 5 before adding the column number to access the desired cell. You need to be careful though because if you have an 'off-by-one' error, it all goes wrong.

Warnings:

- Be aware that your script is referring to array elements starting at zero. You can get subtle 'off-by-one' errors if you assume that the array begins at item 1.
- In Netscape 2.02, the `length` property of an array cannot be relied on to hold the right value.
- You should avoid putting spaces into associative names because it introduces a property whose name cannot be reached other than via an array index. Not all implementations will trap this error situation. A property name is an identifier and identifier names cannot contain spaces so it should throw an exception.

Example code:

```
<SCRIPT>
// Multidimensional array simulation
hExtent = 5;
vExtent = 6;
theExtent = hExtent * vExtent;
myArray = new Array(theExtent);
document.write("<TABLE BORDER=1>");
for(vEnum = 0; vEnum < vExtent; vEnum++)
{
   document.write("<TR>");
   for(hEnum = 0; hEnum < hExtent; hEnum++)
   {
      targetCell = (vEnum * hExtent) + hEnum;
      document.write("<TD>");
      document.write(vEnum);
      document.write(",");
      document.write(hEnum);
      document.write(" = ");
      document.write(targetCell);
      document.write("</TD>");
   }
   document.write("</TR>");
}
document.write("</TABLE>");
</SCRIPT>
```

Array literal (Declaration)

A means of creating and initializing an array at once.

Availability:	ECMAScript edition – 3 JavaScript – 1.3 JScript – 5.0 Internet Explorer – 5.0 Netscape – 4.7	
Property/method value type:	`Array` object	
JavaScript syntax:	-	`[ anElement, ... ]`
Argument list:	*`anElement`*	An element to be stored in the array

JavaScript version 1.2 introduces the capability of assigning values to an array as it is created and building the array without first using a constructor.

Now array construction can also be nested to create multi-dimensional arrays.

The result is an array containing the elements defined by the literal expression.

Warnings:

- Netscape 4 does not mind an extra trailing comma (as per the C language convention). To force an undefined element to be assigned to the end of the array, you must place two trailing commas.
- MSIE adds an undefined element for each trailing comma. This means that MSIE creates arrays that are one item longer than Netscape does if there is a trailing comma.
- Some revisions of Netscape exhibit a further problem in that a single numeric value in the square brackets is interpreted as an array length value. This is consistent with the `Array()` constructor but is not correct in this context. You can place a pair of trailing commas there to fix this at the expense of some wasted array items that contain undefined values. This is not a problem on all versions and may be encountered only rarely now.

Example code:

```
<SCRIPT>
// Create a simple array literal
var myArray = [ 100, 1.34, "String text", true, { prop:100 } ];
// Create a nested multi-dimensional array
var matarray = [ [1,0], [0,1]];
// JavaScript expression in arrays
var exprarray = [ Math.random()*10, Math.random()*100 ];
// Sparse array
var sparse = [100, , , , , 1000];
document.write(myArray[2] + "<BR>" + matarray[0,1] + "<BR>" +
   exprarray[1] + "<BR>" + sparse[5]);
</SCRIPT>
```

Array object (Object/core)

An object of the class "`Array`".

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0
JavaScript syntax:	- *myArray* = Array - *myArray* = *myVBArray*.toArray() - *myArray* = new Array() - *myArray* = new Array(*aLength*) - *myArray* = new Array(*anItem1*, *anItem2*, *anItem3*, ...)
Argument list:	*aLength* — An optional initial length to set the array to. *anItemN* — A variable number of initial elements to insert into the array.
Object properties:	constructor, index, input, length, prototype
Object methods:	concat(), join(), pop(), push(), reverse(), shift(), slice(), sort(), splice(), toLocaleString(), toSource(), toString(), unshift(), valueOf()

An array is basically an indexed collection of references to other objects or values.

In JavaScript version 1.0, arrays were simple objects and had limited functionality, scarcely enough really to be called arrays. Some commentators argue that the functionality was so limited that they should be flagged as available from version 1.1 of JavaScript only. They were usually simulated by creating an instance of the `Object` object and using its named properties as if the object was an array.

Much additional functionality was added for JavaScript version 1.1. JavaScript version 1.0 lacked the constructors and arrays had no special methods available. The ECMA standard enhances the functionality and Netscape 4 provides additional functionality.

An instance of the class "`Array`" is created by using the `new` operator on the `Array()` constructor. At JavaScript version 1.2, arrays can be created with an Array literal as well. The new object adopts the behavior of the built-in prototype object through the prototype-inheritance mechanisms.

All properties and methods of the prototype are available as if they were part of the instance.

Note that the `index` and `input` properties are available only for arrays that are produced as the result of a `RegExp` match. They are not generally available in Arrays or Collections.

An array is a collection of properties owned by an object and that can be accessed by name or by index position in the array. Because they are collected together and accessible as a set, they may be sorted into the order of the array.

`Array` objects give special treatment to property names, which are numeric values. These are used as an index value and will affect the value of the `length` property. The length supported depends on the platform, but is usually based on a 32 bit integer being used for addressing. That limits the range to 4 Billion array elements.

`Array` objects implement the `Put()` internal function slightly differently from non-array based objects.

The prototype for the `Array` prototype object is the `Object` prototype object.

In the C language, an array is referred to as an aggregate type since it is made from a collection or aggregate of individual members.

Warnings:

- Although arrays were partially supported prior to JavaScript version 1.1, the support was not reliably or completely implemented. There was no way for the script developer to create and modify the arrays. Netscape 2 lacks any realistic array support even though `Array` objects were returned by some object properties.
- The WebTV set top box limits the extent of the `Array` objects to contain only 32,768 elements instead of the 4 Billion or so that is defined as the normal maximum. This is because WebTV uses 16 bit integers for addressing arrays rather than 32 bit integers.

Example code:

```
<SCRIPT>
// Array object demonstration
var weekly_summary = new Array(7);
weekly_summary[1] = 10;
weekly_summary[2] = 25;
var day_names = new Array("Su","Mo","Tu","We","Th","Fr","Sa");
for(var i=0; i<7; i++)
{
   document.write("Summary for day (");
   document.write(day_names[i]);
   document.write(") = ");
   document.write(weekly_summary[i]);
   document.write("<BR>");
}
</SCRIPT>
```

Array() (Constructor)

An `Array` object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	- `new Array()`	
	- `new Array(`*`aLength`*`)`	
	- `new Array(`*`anItem1`*`, `*`anItem2`*`, `*`anItem3`*`, ...)`	
Argument list:	*`aLength`*	An optional initial length to set the array to
	`anItemN`	A variable number of initial elements to insert into the array

The `Array()` constructor is used in a `new` expression to manufacture a new instance of the `Array` object.

The arguments passed to the constructor affect the way that the array is initialized.

If no arguments are passed, then an empty array is created. Its length will be zero and it will only have the properties it inherits from its prototype parent.

If it has a single argument, and if that argument is a numeric value that can be realized as an unsigned 32-bit integer with no loss of precision, then it is taken as a length value to initialize the array with. However, according the ECMA standard, a numeric value that is not convertible to a Uint32 should cause a run-time error. This may not be the case with all host implementations and would be considered a minor deviation from the standard. You may find that a single numeric value results in a one-element array containing that value instead of a run-time error. A single argument of non-numeric type results in an array containing one element and having a length value of 1.

If there is more than one argument, then each argument is placed into the array in the order of presentation and the length value set according to the number of arguments provided.

Warnings:

- Netscape 2.02 does not understand the `new Array()` syntax. MSIE 3.02 with JScript 1.0 does not understand `new Array()` either. This can be simulated with objects however.

Array() (Function)

An `Array` object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	`Array()`
	-	`Array(`*`aLength`*`)`
	-	`Array(`*`anItem1, anItem2, anItem3, ...`*`)`
Argument list:	*`aLength`*	An optional initial length for the array
	`anItemN`	A variable number of initial elements to insert into the array

Calling the `Array()` constructor as a function behaves exactly the same as if it had been called with the `new` operator.

The function call `Array()` is equivalent to the object creation expression `new Array()` with the same arguments. With other primitive objects, calling the constructor as a function carries out a type conversion instead of an object instantiation.

The arguments passed to the constructor affect the way that the array is initialized in the same way as they do with a `new Array()` expression.

See also:	`Array` object, `Array()`, `Array.prototype`, `Cast` operator, `Constructor` function, `constructor` property, Implicit conversion

Array.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition – 2

This is an internal property that describes the class that an `Array` object instance is a member of. The reserved words suggest that in the future, this property may be externalized.

See also:	`Array` object, `Class`

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 – section – 8.6.2

ECMA 262 edition 2 – section – 15.4.2.1

ECMA 262 edition 3 – section – 8.6.2

Array.concat() (Method)

Concatenate arrays together.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Array object`	
JavaScript syntax:	-	*myArray*.concat(*someValues*, ...)
Argument list:	*someValues*	A sequence of values to concatenate onto the array

The result of this method is a new array consisting of the original array, plus the concatenation.

The values that are passed to the method are added to the end of the array.

If arrays are passed, they are flattened and their individual elements added.

The method returns an array consisting of the original Array plus the concatenated values.

If `Array1` contains "AAA", "BBB", "CCC" and `Array2` contains "000", "111", "222", then the method call `Array1.concat(Array2)` will return an array with all the elements in a single collection. The original arrays will be untouched.

Warnings:

- The `concat()` method will flatten arrays that are passed as arguments. However, it will not recursively flatten multi-dimensional arrays.

Example code:

```
<SCRIPT>
// Create two arrays and demonstrate concat() method
myArray1 = new Array("AAA", "BBB", "CCC");
myArray2 = new Array("000", "111", "222");

document.write("Array1<BR>");
displayArrayAsTable(myArray1);
document.write("Array2<BR>")
displayArrayAsTable(myArray2);
document.write("Result returned from Array1.concat(Array2)<BR>")
displayArrayAsTable(myArray1.concat(myArray2));
document.write("Result returned from Array1.concat('AAA')<BR>")
displayArrayAsTable(myArray1.concat("AAA"));
document.write("Result returned from Array1.concat('AAA').concat('DFG')<BR>")
displayArrayAsTable(myArray1.concat("AAA").concat("DFG"));

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
```

```
    for(myIndex = 0; myIndex < myLength; myIndex++)
    {
       document.write("<TR><TD>");
       document.write(myIndex);
       document.write("</TD><TD>");
       document.write(anArray[myIndex]);
       document.write("</TD></TR>");
    }
    document.write("</TABLE><BR><BR>")
}
</SCRIPT>
```

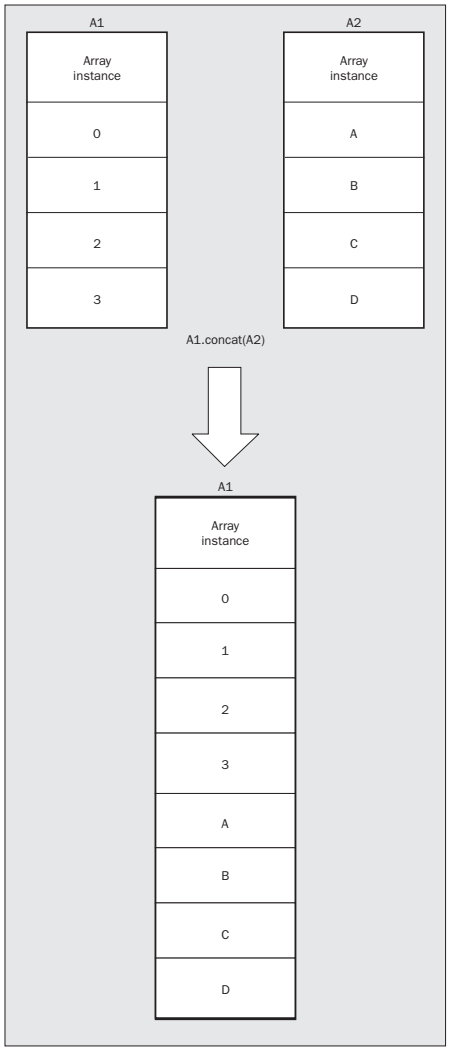
ECMA 262 edition 3 – section – 15.4.4.4



Array.constructor (Property)

A reference to a `constructor` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Array constructor`	
JavaScript syntax:	-	*myArray*`.constructor`

The constructor is that of the built-in `Array` prototype object.

You can use this as one way of creating arrays although it is more popular to use the `new Array()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`Array.length`,`Array.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.4.2

ECMA 262 edition 3 – section – 15.4.2

Array.index (Property)

A special property provided only when the array results from a string match.

Availability:	JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myArray*`.index`

When the `String.match()` method is used, it returns an array as a result. If the match used a pattern that made only a single match (that is, the `g` attribute was not used) then the array returned will have this additional `index` property.

The `index` property will contain the character location within the original string where the match occurred.

See also:	`Array.input`, `RegExp.exec()`, `String.match()`

Array.input (Property)

A special property provided only when the array results from a string match.

Availability:	JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArray*`.input`

When the `String.match()` method is used, it returns an array as a result. If the match used a pattern that made only a single match (i.e. the `g` attribute was not used) then the array returned will have this additional `input` property.

The `input` property will contain a copy of the original string that was searched.

See also:	`Array.index`, `RegExp.exec()`, `String.match()`

Array.join() (Method)

Concatenate array elements to make a string.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArray*`.join(`*aSeparator*`)`
Argument list:	*aSeparator*	A string to place between array elements as the array is concatenated to form a string

The result of this method will be a String primitive containing the array elements interposed with separators.

The elements in the array are converted to strings and are concatenated together to form a larger string. Each element has the separator value placed between it and the next element.

If the separator is not specified, then a single comma is used to join the array elements. This means that if you want no separation between the joined items you should pass an empty string as the separator value.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Demonstrate array joins
myString1 = "This is a sentence made of words.";
document.write("Original input string<BR>")
document.write(myString1)
myArray = myString1.split(" ");
document.write("<BR><BR>String split into an array<BR>")
displayArrayAsTable(myArray);
myString2 = myArray.join("+");
document.write("<BR><BR>Array joined up as a string<BR>")
document.write(myString2)

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE>")
}
</SCRIPT>
</BODY>
</HTML>
```

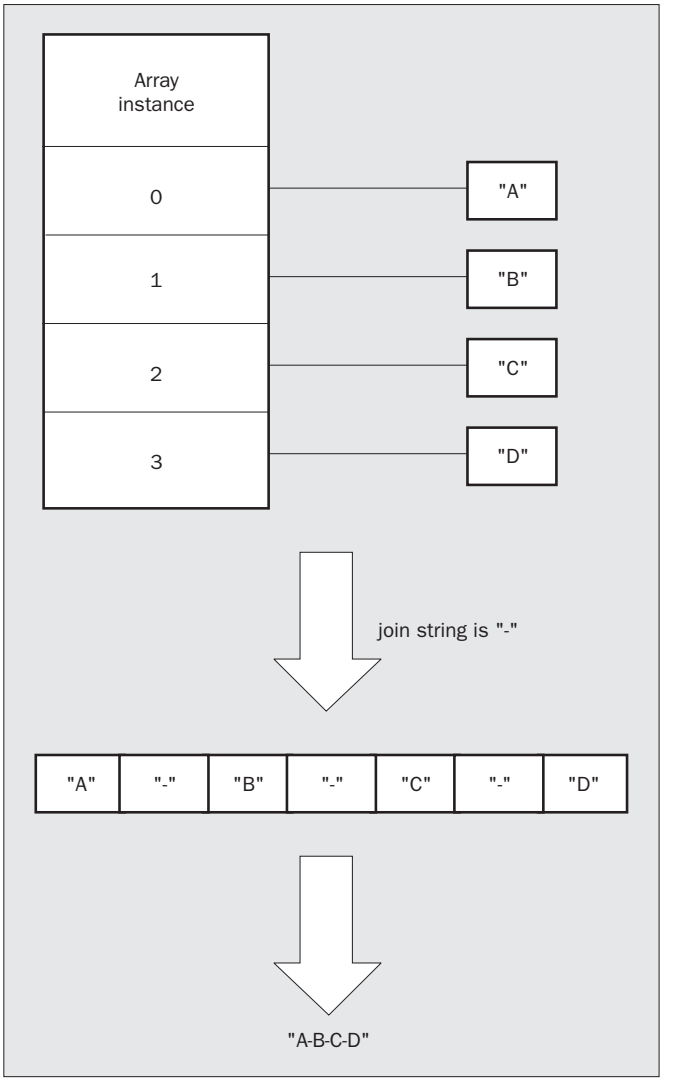
Cross-references:

ECMA 262 edition 2 – section – 15.4.4.3

ECMA 262 edition 3 – section – 15.4.4.5



Array.length (Property)

The number of elements in an array.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myArray*.length

The `length` property of an array indicates one more than the maximum numeric index value that has currently been used. This is because Array elements start indexing from zero rather than one.

Note that this is not necessarily a count of the exact number of elements in the array just an indication of its range of index values.

Whenever a property is added whose name is an array index, the `length` property is recomputed to allow the length of the array to contain the new element that was added.

Furthermore, when the length value is set explicitly, it may truncate the array and any properties whose names are numeric values that falls outside the bounds indicated by the length value will be deleted.

This does only affect properties that belong to an `Array` object itself though. Any properties that are inherited from a parent or prototype are unaffected.

The maximum value for an Array `length` is 4,294,967,295. This is because a 32 bit integer is used to index the array. Arrays of this length are unlikely to be encountered often! A web page containing an array of that size could take several weeks to download, that is assuming you had 4 GBytes of memory available and that your web browser could address that much storage.

Although this property is marked as `ReadOnly`, there are some sub-classes of the `Array` object that allow you to modify the `length` property directly.

Warnings:

- The `length` property is so unreliable as to be virtually unusable unless you strictly constrain the way you add elements to the array. If you add elements to an array using associative names, the `length` property is not changed at all and will return a zero value.
- If you then add an element to the array whose index is a numeric value, then the `length` property will be set to a value that is one more than the highest numbered numerically indexed item in the array. This following fragment of code yields an array *length* property value of 3:

```
var myArray = new Array();myArray[2] = "ABC";myArray["zero"] =
"ABC";myArray["one"] = "one";myArray["two"] = "two";myArray[0] = "ABC";
```

- This behavior is correct according to the ECMA specification but it is not a genuine measurement of the array length, merely an indication of the highest numerically indexed array element. It should be used for controlling enumeration loops but not for measuring array element item counts.
- WebTV platforms can only address array indices using a 16 bit value and can only access 32,768 items in an array.

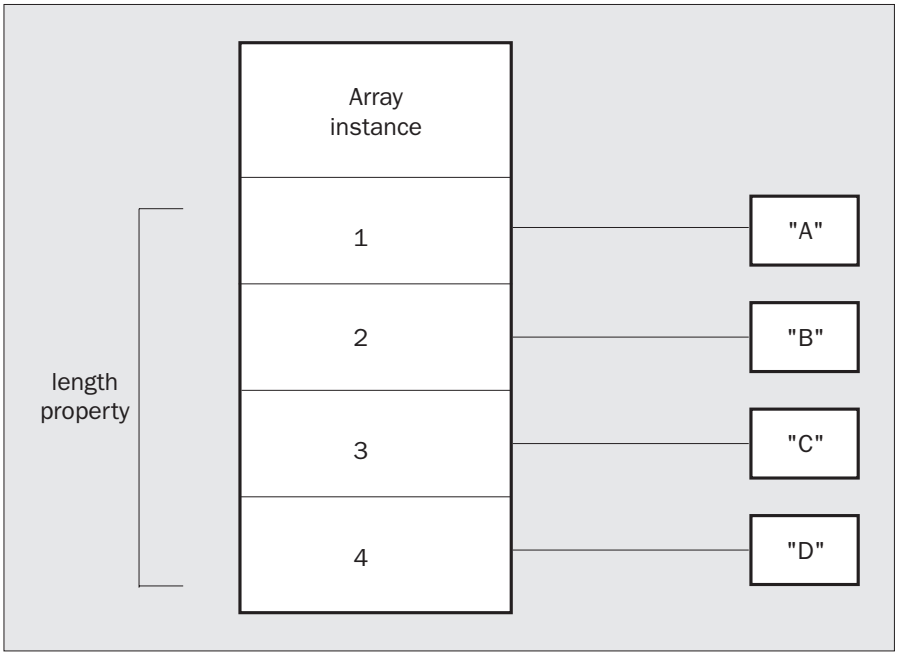
Wrox *Instant JavaScript* ISBN 1-861001-27-4 – page – 16



Array.pop() (Method)

Pops items off of the end of an array like a FILO stack.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Depends on the array content`	
JavaScript syntax:	-	*myArray*`.pop()`

The `pop()` method returns the element at the end of the array. In doing so, it deletes the item from the end of the array reducing the array length by one.

Elements are returned one at a time, even if several were pushed onto the stack together.

Arrays that were pushed onto the stack are returned as arrays.

Although this is very useful for programming stacks, it is not portable enough to deploy in a public facing site.

The result of this method is the item that was on the end of the stack.

Example code:

```
// Create an array and test the Array.pop() method
myArray = new Array("AAA", "BBB", "CCC");
document.write("Array<BR>")
displayArrayAsTable(myArray);
document.write("Array.pop()<BR>")
document.write(myArray.pop())
document.write("<BR><BR>")
document.write("Array after pop() call<BR>")
displayArrayAsTable(myArray);

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

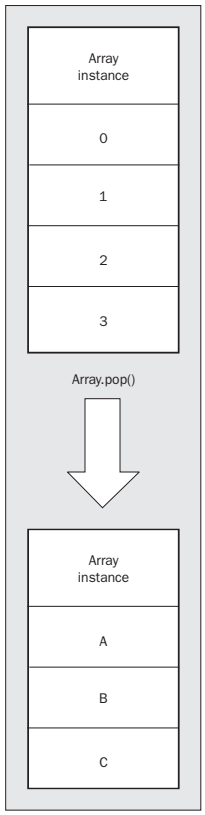
Cross-references:

ECMA 262 edition 3 – section – 15.4.4.6



Array.prototype (Property)

The prototype for the `Array` object, which can be used to extend the interface for all `Array` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	`Array.prototype`
	-	*`myArray`*`.constructor.prototype`

The prototype for an array is the original `Array` prototype object.

`Array` objects inherit many methods and properties from their prototype parent. Enquiring the prototype of a an object whose provenance is unknown will tell you what sort of object it is.

`Array` objects inherit these properties from the built-in `Array` prototype:

- `Array.constructor`
- `Array.prototype`

`Array` objects inherit these methods from the built in `Array` prototype:

- `Array.join()`
- `Array.reverse()`
- `Array.sort()`
- `Array.toString()`

Array instances provide these properties themselves even if the prototype has them:

- `Array.length`

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that duplicates the item at the end of
// the array
function dupe()
{
   if(this.length != 0)
   {
      myTail = this[this.length-1];
      this[this.length] = myTail;
      return myTail;
   }
}

// Register the new function
Array.prototype.dupe = dupe;

// Create an array and test the Array.dupe() method
myArray = new Array("AAA", "BBB", "CCC");
document.write("Array<BR>");
displayArrayAsTable(myArray);
document.write("Array.dupe()<BR>");
document.write(myArray.dupe());
document.write("<BR>");
document.write("<BR>");
document.write("Array after dupe() call<BR>");
displayArrayAsTable(myArray);
```

```
// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.4.3.1

Array.push() (Method)

Pushes items onto the end of an array like a FILO stack.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myArray`*`.push(`*`someValue`*`, ...)`
Argument list:	*`someValue`*	A series of values to be pushed onto the stack

The value is added to the end of the array.

If the value is an array itself, it is not flattened. When it is eventually popped, you get the array back.

If several values are passed to the `push()` method, they will all be added to the stack, but only the last one will be returned.

This modifies the receiving array, increasing the array length by the number of elements that were pushed onto the end.

The result of this method is the new length of the receiving array after the pushed item has been concatenated onto its tail.

Example code:

```
// Create an array and test the Array.push() method
myArray = new Array("AAA", "BBB", "CCC");
document.write("Array<BR>");
displayArrayAsTable(myArray);
document.write("Array.push()<BR>")
document.write(myArray.push("XXX"));
document.write("<BR><BR>");
document.write("Array after push('XXX') call<BR>");
displayArrayAsTable(myArray);

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

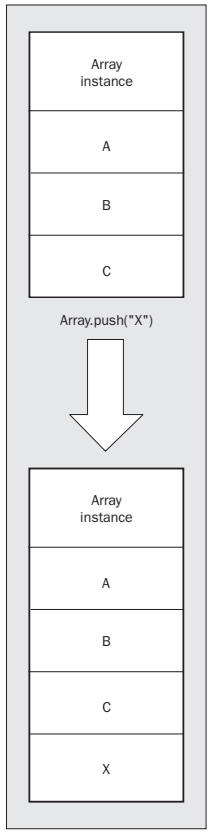
ECMA 262 edition 3 – section – 15.4.4.7



Array.reverse() (Method)

Reverse the order of array elements.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	*myArray*`.reverse()`

The elements in the array are rearranged into reverse order. The `Array` object is returned as the result.

Note that the `reverse()` method may possibly be applied to other object types. Host objects may support the `reverse()` method, but it will be in an implementation-dependant manner.

The result of this method is the array with its elements in reversed order.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Demonstrate array joins
myString1 = "This is a sentence made of words.";
document.write("Original input string<BR>")
document.write(myString1)
myArray = myString1.split(" ");
document.write("<BR><BR>String split into an array<BR>")
displayArrayAsTable(myArray);
myArray.reverse();
document.write("<BR><BR>Array reversed<BR>")
displayArrayAsTable(myArray);
myString2 = myArray.join(" ");
document.write("<BR><BR>Array joined up as a string<BR>")
document.write(myString2)

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE>")
}
</SCRIPT>
</BODY>
</HTML>
```

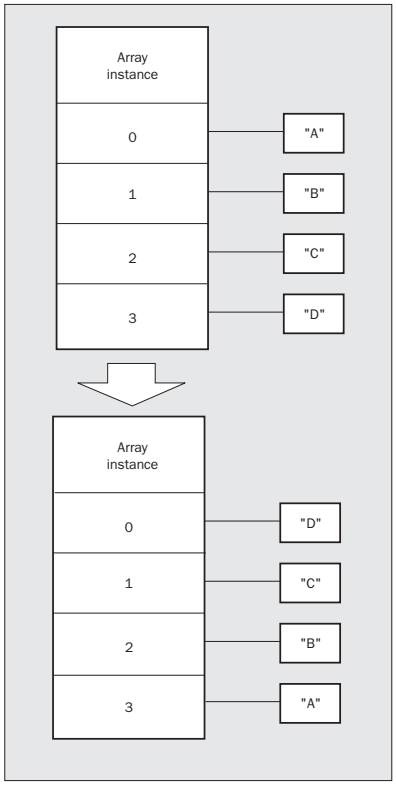
ECMA 262 edition 3 – section – 15.4.4.8



Array.shift() (Method)

Pull off of a stack whose access is FILO from the start rather than the end.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	Depends on array content	
JavaScript syntax:	-	*myArray*.shift()

This method pulls an item from the front of the array and removes that item.

The array elements are all moved down one index position.

This modifies the array in place.

The result of this method is the item that is deleted from the front of the stack.

Example code:

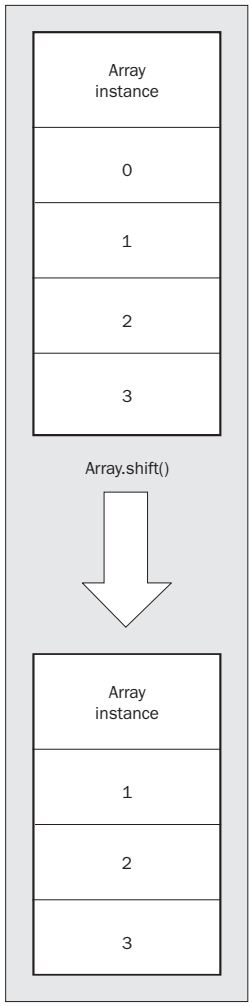
```
// Create an array and test the Array.shift() method
myArray = new Array("AAA", "BBB", "CCC");
document.write("Array<BR>")
displayArrayAsTable(myArray);
document.write("Array.shift()<BR>")
document.write(myArray.shift())
document.write("<BR>")
document.write("<BR>")
document.write("Array after shift() call<BR>")
displayArrayAsTable(myArray);

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

See also: `Array.prototype`, `Array.unshift()`, Queue manipulation, Stack manipulation

Cross-references:

ECMA 262 edition 3 – section – 15.4.4.9



Array.slice() (Method)

Slice out a sub-array from the receiving array.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	*myArray*`.slice(`*aRange*`)`
Argument list:	*aRange*	A range of array elements

This method returns the sliced-out sub-array presented as a new array.

The range values indicate which part of the receiving array is to be sliced out.

A positive value in the range specifier indicates a particular cell.The first cell index is 0.

A negative value in the range specifier indicates a cell counted back from the end of the array. The last cell is index -1.

If only one value is indicated in the range specifier, then the second is assumed to be the end of the array.

The first specifier should indicate an element earlier than the second although some implementations may check and swap as necessary.

Warnings:

- There are some bugs in the way this works in MSIE. These are mostly to do with specifying negative values for range specifiers. These bugs are still extant as of version 5 of MSIE so you should avoid using the negative indices, and instead measure the length of the array and compute a positive index to use instead. Be careful of 'off-by-one' errors when you do this.

Example code:

```
// Create an array and test the Array.slice() method
myArray = new Array("AAA", "BBB", "CCC", "DDD", "EEE");
document.write("Array<BR>")
displayArrayAsTable(myArray);
document.write("Array.slice(3)<BR>")
displayArrayAsTable(myArray.slice(3))
document.write("Array.slice(2,4)<BR>")
displayArrayAsTable(myArray.slice(2,4))
document.write("Array.slice(-1)<BR>")
displayArrayAsTable(myArray.slice(-1))
document.write("Array.slice(-3)<BR>")
displayArrayAsTable(myArray.slice(-3))

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

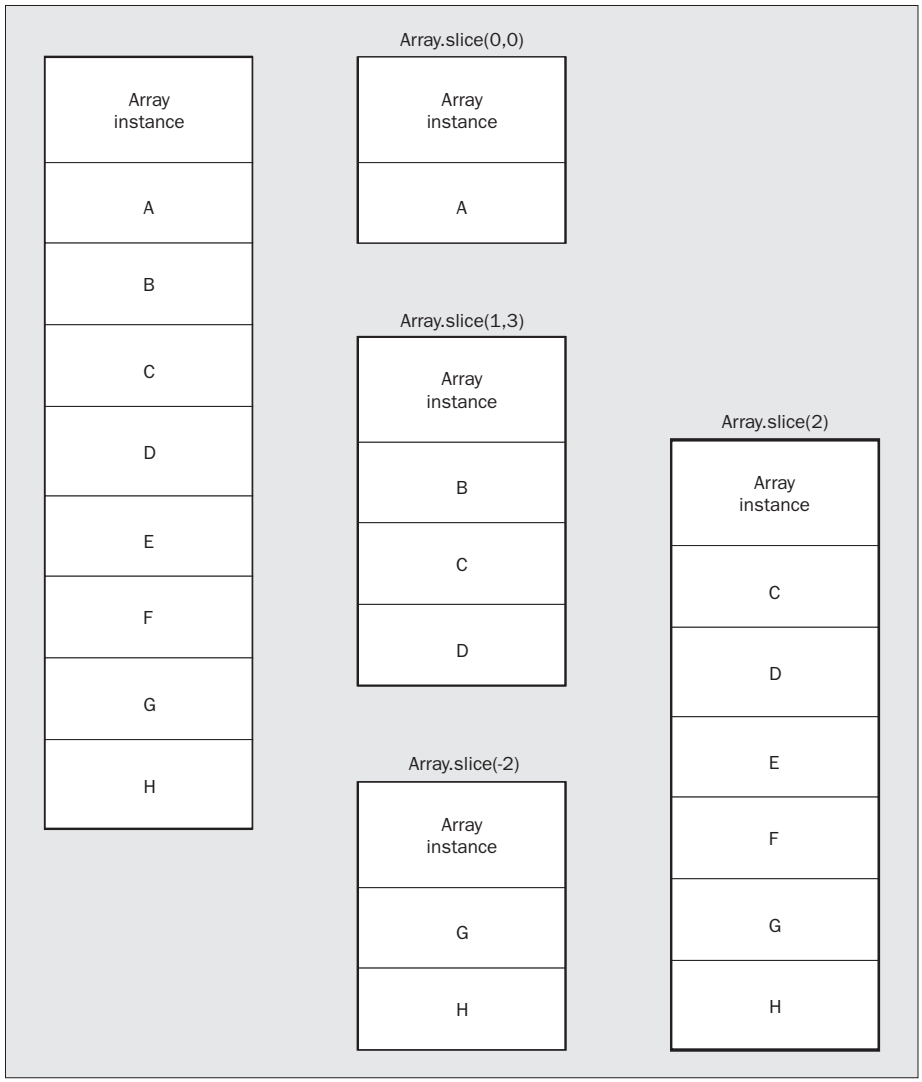
ECMA 262 edition 3 – section – 15.4.4.10



Array.sort() (Method)

Sort the elements in an array.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0

Property/method value type:	`Array` object	
JavaScript syntax:	-	*myArray*`.sort()`
	-	*myArray*`.sort(`*aComparator*`)`
Argument list:	*aComparator*	A function object that will compare two items and returns a flag indicating their order in the sort collating sequence

The elements in the array are sorted in place and the sorted array is returned as a result of this method. The argument provides a comparator function to determine the relationship between any two items.

The comparator function is necessary if you want to sort into any order other than alphabetically ascending. You can observe the operation of the comparator by placing `document.write()` methods into its source text. These will demonstrate how the comparison is called during the sort.

In the example, a comparator function shows how to custom-sort items. The example demonstrates sorting by length rather than charset collation sequence. You must make sure the comparator returns one of the following three values:

- Negative integer – signifies that the first argument is less than the second.
- Zero – Signifies that both arguments are the same.
- Positive integer – Signifies that the first argument is larger than the second.

You can reverse the sort direction by negating the result returned by this comparator function.

In the example, a more highly optimized comparator is shown as well. The more lengthy version is presented first to illustrate the algorithmic requirements of the comparator, but the second is functionally identical and can be accomplished in one line and therefore the sort is much faster.

The result of this method is the array with its elements sorted according to the comparator.

Warnings:

- According to the ECMA standard, this sort may not be stable.
- The `sort()` method is generic and may be applied to non-array objects. However, some objects may not be conducive to sorting like this and the exact behavior may be host implementation-dependant in some cases.
- The custom comparator is not supported by the WebTV platform as of the Summer 2000 release of the JellyScript interpreter.
- It is easy to make the mistake of returning `true` and `false` as a result of comparing the two values. For example the following is wrong:

```
function compare(aValue1, aValue2){
   if(aValue1.length <= aValue2.length)
   {
      return false;
   }
   return true;}
```

- This will not work properly and the resulting sort will be incorrect.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Demonstrate array joins
myString1 = "This is a sentence made of words.";
document.write("Original input string<BR>")
document.write(myString1)
myArray = myString1.split(" ");
document.write("<BR><BR>String split into an array<BR>")
displayArrayAsTable(myArray);
myArray.sort(compare);
document.write("<BR><BR>Array sorted<BR>")
displayArrayAsTable(myArray);
myString2 = myArray.join(" ");
document.write("<BR><BR>Array joined up as a string<BR>")
document.write(myString2)

// Comparator function
function compare(aValue1, aValue2)
{
   if(aValue1.length < aValue2.length)
   {
      return -1;
   }

   if(aValue1.length > aValue2.length)
   {
      return 1;
   }

   return 0;
}

// Optimised comparator function
function optimalCompare(aValue1, aValue2)
{
   return (aValue1.length - aValue2.length);
}

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD><TD>");
```

```
        document.write(anArray[myIndex].length);
        document.write("</TD></TR>");
    }
    document.write("</TABLE>")
}
</SCRIPT>
</BODY>
</HTML>
```

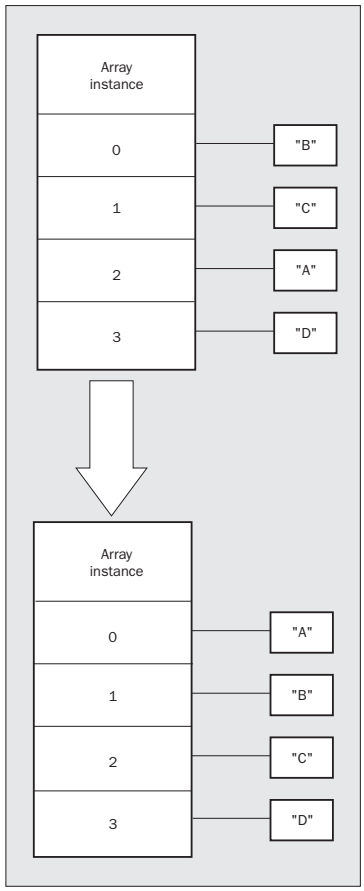
Cross-references:

ECMA 262 edition 2 – section – 15.4.4.5

ECMA 262 edition 3 – section – 15.4.4.11



Array.splice() (Method)

An array editing tool.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	*myArray*`.splice(`*startPos*`, `*aCount*`, `*newElements*`)`
Argument list:	*aCount*	An optional count of items to remove
	newElements	An optional list of items to add
	startPos	An entry at which to start splicing

The start position indicates where the splicing is to occur. If there are no other arguments, then the remainder of the array is truncated.

If there is a count argument present, only that number of items will be removed and the subsequent ones shuffled up to be adjacent to the front section of the array.

Any additional arguments are taken to be values to be inserted. They are not evaluated according to the techniques used by the `Array.concat()` method. If arrays are specified, they will not be flattened but will be inserted as they are.

This method operates on the array in place, therefore it modifies the original receiving array.

Specifying a count value of zero provides the functionality of an `insert()` method.

Specifying a count value larger than the array length does not cause an error, but instead truncates the array, behaving like a `replace()` method.

The method call returns an array containing the elements that were removed. This provides an alternative to the `slice()` method, but you should use `slice()` for portability since some MSIE browsers do not support the `splice()` method.

Warnings:

- In Netscape 4, there are some bugs with the values that get returned by this method. The receiving array does get spliced, but the deleted items are not always properly returned.

Example code:

```
// Create an array and test the Array.splice() method
myArray = new Array("AAA", "BBB", "CCC", "DDD", "EEE");
document.write("Array<BR>")
displayArrayAsTable(myArray);
document.write("Array.splice() result<BR>")
displayArrayAsTable(myArray.splice(3, 1, "XXX", "YYY", "ZZZ"));
document.write("Array after splice<BR>")
displayArrayAsTable(myArray);

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

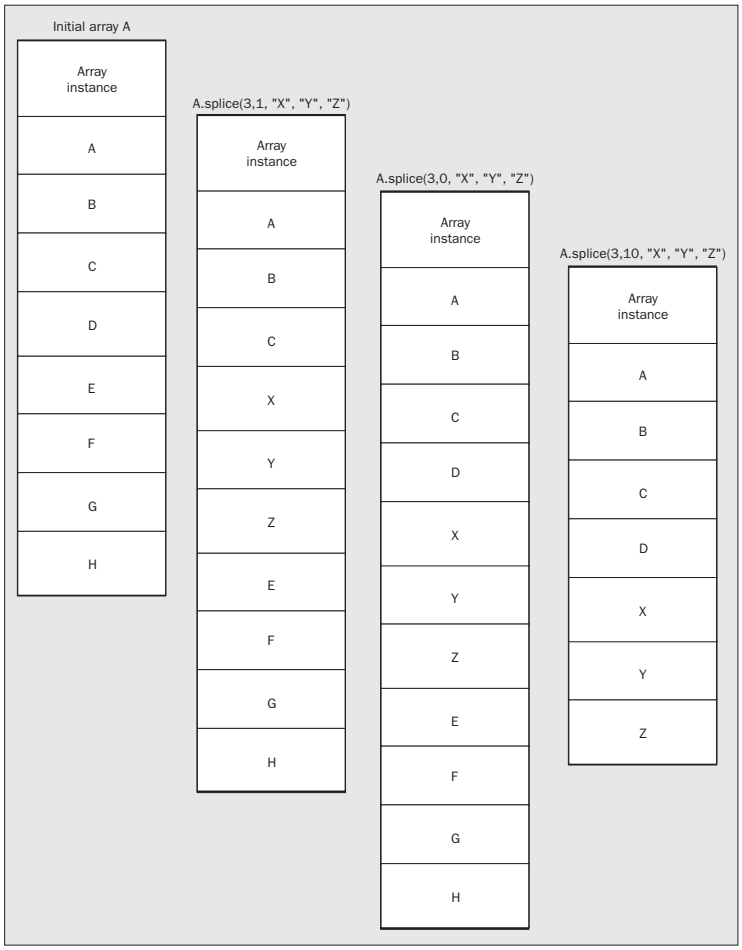
Cross-references:

ECMA 262 edition 3 – section – 15.4.4.12



Array.toLocaleString() (Method)

Returns a string primitive version of the array taking the present locale into account during the translation.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myArray`*`.toLocaleString()`

The locale context supplies some special conversion rules for strings. Depending on the locale, this might include special characters or a means of using double-byte characters. It may also affect the direction of the text, for certain Asian locales for example.

Warnings:

- The ECMA standard reserves the first argument of this method for future use. It does not specify what that is, but warns against implementations extending the syntax to include its use.

Cross-references:

ECMA 262 edition 3 – section – 15.4.4.3

Array.toSource() (Method)

Output an array formatted as an Array literal contained in a string.

Availability:	JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArray*`.toString()`

This is an alternative way to deliver a string version of an array. In this case, it is formatted as an Array literal and can then be used in an `eval()` function to assign another array. It means that Arrays can be deep copied more easily.

This functionality was previously available in Netscape 4 when the `toString()` method was executed in a `<SCRIPT>` block that was evaluated under explicit JavaScript version 1.2 language selection.

If you run the example, it should yield something like this:

```
["one", 2, "III"]
```

This is quite different from the result of a `toString()` method which would yield this for the same array contents:

```
one,2,III
```

The result of this method is a String primitive version of the array formatted as an Array literal.

Example code:

```
// Create an array and display its source
myObject = new Array("one", 2, "III");
document.write(myObject.toSource());
```

See also:	`Array.prototype,Array.toString()`

Array.toString() (Method)

Return a string primitive version of an object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myArray*`.toString()`

The elements in the array are converted to strings and are concatenated together to form a larger string.

This is functionally identical to using the `join()` method with no join string argument.

If you run the example, it will yield the following:

```
one,2,III
```

This is quite different from what you get if you use the `toSource()` method, which presents this result:

```
["one", 2, "III"]
```

The result of this method is a String primitive version of the array assembled by concatenation.

Warnings:

- Netscape supports a special conversion mechanism if this method is invoked within a `<SCRIPT>` HTML tag whose `LANGUAGE` attribute is set to the "JavaScript1.2" value.
- In that circumstance, the array is presented with enclosing square brackets. This means that it can be used as an array literal in an `eval()` function. This behavior was added in anticipation of the ECMA specification supporting some additional functionality. However, the standard mandates very specific behavior for `toString()`.
- In JavaScript 1.3, the `toString()` behavior will revert to what was expected. Because this source form output is so useful, it will continue to be supported by a new method called `toSource()`.

Example code:

```
// Create an array and display it as a string
myObject = new Array("one", 2, "III");
document.write(myObject.toString());
```

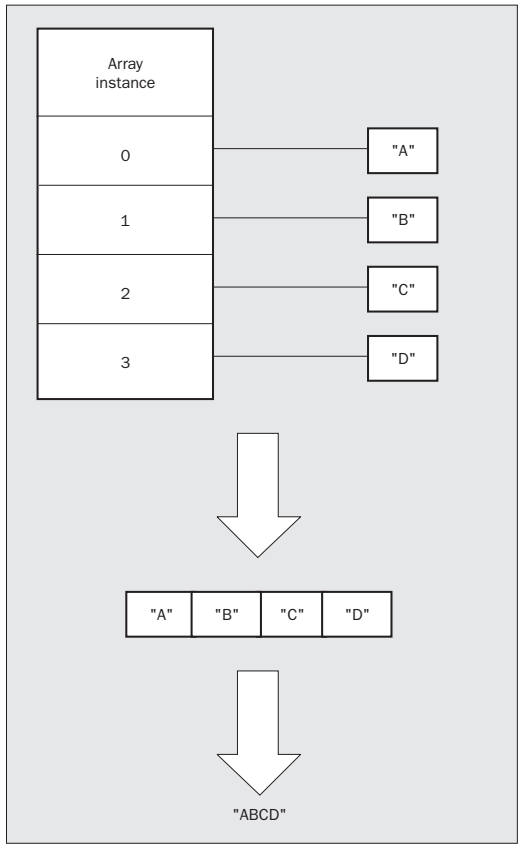
ECMA 262 edition 3 – section – 15.4.4.2



Array.unshift() (Method)

Push onto a stack whose access is FILO from the start rather than the end.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myArray`*`.unshift(`*`someValue, ...`*`)`
Argument list:	*`someValue`*	A series of values to be pushed onto the stack

This operates very like the `Array.push()` method except that items are added to the front of the stack rather than the end of the stack. The items are also pushed in reverse order if several are presented at once. That is to say, the order of presentation is preserved within the array.

When the push is completed, the item at the front of the array is returned.

The number of items that were added increases the array length.

If arrays are presented, they will be pushed on as they are and not flattened. When they are subsequently removed from the stack, they will still be arrays.

This method modifies the array in place.

The result of this method is the new length of the receiving array after the pushed item has been concatenated onto its front.

Example code:

```
// Create an array and test the Array.unshift() method
myArray = new Array("AAA", "BBB", "CCC");
document.write("Array<BR>")
displayArrayAsTable(myArray);
document.write("Array.unshift()<BR>")
document.write(myArray.unshift("XXX"))
document.write("<BR><BR>")
document.write("Array after unshift('XXX') call<BR>")
displayArrayAsTable(myArray);

// Display an array in a table
function displayArrayAsTable(anArray)
{
   myLength = anArray.length;
   document.write("<TABLE BORDER=1>");
   for(myIndex = 0; myIndex < myLength; myIndex++)
   {
      document.write("<TR><TD>");
      document.write(myIndex);
      document.write("</TD><TD>");
      document.write(anArray[myIndex]);
      document.write("</TD></TR>");
   }
   document.write("</TABLE><BR><BR>")
}
```

Array.valueOf() (Method)

Returns the contents of the array converted to a native primitive value.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myObject*`.valueOf()`

The primitive value of the receiving object is returned by this method. Because an array is an aggregation of many elements, a simple type conversion is not appropriate. The individual elements are converted to string values and are then concatenated together and returned as a single string primitive value. This applies even if an array comprises a collection of numeric values.

See also:	`valueOf()`

Array simulation (Definition)

A means of simulating arrays in JavaScript.

With a constructor, you can simulate arrays by making them from objects and property components. This may be useful if you want to run an array-based script in a very old JavaScript implementation although these days that likelihood is diminishing rapidly.

This was necessary in JavaScript version 1.0. Numbered index locations within an `Object` object could simulate `Array` objects. Named items simply allocate the next available numbered entry.

Thankfully we don't have to do this anymore.

Warnings:

- In Netscape 2.02 and MSIE 3.02 you can operate on existing arrays, but you cannot make a new one.
- In Netscape 2.02 the array length value does not work properly.

Example code:

```
// Simulate an array with an Object object
myArray = new Object();
myArray[0] = "One";
myArray[1] = "Two";

// Simulate an array with a constructor
function SimArray(aSize)
{
```

```
    this.length = aSize;
    for(var index = 0; index<aSize; index++)
    {
       this[index] = 0;
    }
    return this;
}

// Now make a simulated array
myArray = new SimArray(12);
```

ASCII (Standard)

A table of seven-bit binary numbers that encode the alphabet and other symbols.

ASCII stands for American Standard Code for Information Interchange. It describes an encoding for letters, numbers and punctuation symbols that can be realized in seven bits. It uses only seven of the 8 bits for historical reasons to allow the eighth bit to be used for parity control when the characters are transmitted through serial interfaces.

Many of the character codes are reserved to send control signals to terminals and to manage the communications. Modern networking provides this capability outside of the character encoding.

There is an extended ASCII encoding that provides all 8 bits for character code mapping. This defines the upper 128 characters in addition to the lower 128 characters in the 7-bit representation.

There are many alternative interpretations of the ASCII character set that allow for national extensions to the character set. In some cases, this may only result in the replacement of a few currency symbols.

JavaScript uses the Unicode character set. The lower 128 characters of Unicode are purposely mapped to the ASCII character. ASCII is described here to provide help when you are exchanging data files with ASCII-based systems or applications.

It may also be useful in some situations if you are using JavaScript to drive a serial interface to control some external system. Whether you could do that would depend on the hosting environment. A browser wouldn't give you those capabilities, but an embedded JavaScript interpreter in a process control system may well allow you to do that sort of thing.

This table summarizes the lower 128 characters in the ASCII character set:

Dec	Hex	Sym	Unicode	Description
000	00	NUL	\u0000	<ctrl-@> Null character
001	01	SOH	\u0001	<ctrl-A> Start of header

ASP (Object model)

The object model inside an ASP server module.

As of the time of writing the ASP object model is at version 3.0 and is now shipped with Windows 2000 as part of the core OS. It is a mechanism that enhances the Microsoft IIS product to provide server-side dynamically generated pages and uses JScript 5.0 as its programming language. It also supports VBScript.

Code that is executed in an ASP page is delimited with a special tag pair that does not conform to the HTML standards, but nevertheless should be ignored by browsers if the unprocessed pages ever escape out of the server.

Here is an ASP tag pair with an example fragment of code:

```
<%Response.Write('<HR>');%>
```

More detailed and in-depth information on ASP can be found in the Wrox *ASP 3.0 Programmer's Reference* ISBN 1-861003-23-4.

ASP (Product)

Active Server Pages. A Microsoft product.

See also:	ADO, Active Server Pages

Assign value (=) (Operator/assignment)

Assign one operand to a left value.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Depends on right value`	
JavaScript syntax:	-	*`anLValue = anExpression`*
Argument list:	*`anExpression`*	Some operation that yields a suitable value to assign
	`anLValue`	A target that can be assigned to

The expression value on the right is assigned to the target operand on the left.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

The source expression to the right is called an RValue, the target expression to the left is called an LValue. The LValue must be capable of having something assigned to it and the RVlaue must evaluate to a meaningful and compatible value or a run-time exception will be thrown.

Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.
- Be careful not to confuse the single equals with the double equals. Placing a double equals in place of an assignment will do a comparison without assigning the result. This is less dangerous than mistakenly assigning a value where you intended to compare for equality. The interpreter may be forgiving enough that a run-time error isn't generated, but the side effects could be subtle and make it hard to diagnose the cause.

See also:	= (Assign), Add then assign (+=), Associativity, Concatenate then assign (+=), Equal to (==), `Location.assign()`, LValue, Multiply then assign (*=), Operator Precedence, Reference, Remainder then assign (%=), Subtract (-), `var`

Assignment expression (Definition)

An expression that causes an assignment as a by-product.

Availability:	ECMAScript edition – 2

Assignment expressions can be broken down into a two-operand expression with the result being assigned to the value on the left.

Note that assignment expressions can be used in their entirety as an RValue. You may want to `void` the assignment expression in some cases to prevent the result of the assignment being used inadvertently as an `HREF`.

See also:	Add then assign (+=), Assignment operator, Concatenate then assign (+=), Expression, LValue, Multiply then assign (*=), Remainder then assign (%=), RValue, Subtract (-), `var`, Variable statement, `void`

Cross-references:

ECMA 262 edition 2 – section – 12.2

ECMA 262 edition 3 – section – 12.2

Assignment operator (Definition)

An operator that causes an assignment as a by-product.

Availability:	ECMAScript edition – 2

Here is a table summarizing the assignment operators, most of which can be secondarily classified as members of other operator categories:

Operator:	Equivalent:	Meaning:
=	a = b	Simple assignment to an LValue
+=	a = a + b	Add and assign to an LValue
-=	a = a – b	Subtract and assign to an LValue
*=	a = a * b	Multiply and assign to an LValue
/=	a = a / b	Divide and assign to an LValue
%=	a = a % b	Remainder and assign to an LValue
&=	a = a & b	Bitwise AND and assign to an LValue
|=	a = a | b	Bitwise inclusive OR and assign to an LValue
^=	a = a ^ b	Bitwise exclusive XOR and assign to an LValue
<<=	a = a << b	Bitwise shift left and assign to an LValue
>>=	a = a >> b	Bitwise shift right and assign to an LValue
>>>=	a = a >>> b	Bitwise shift right (unsigned) and assign to an LValue
++	a = a + 1	Increment LValue
--	a = 1 – 1	Decrement LValue

Assignment operators include the simple assignment as well as the compound OP= form where OP is one of the shift, bitwise, multiplicative, or additive operators.

Warnings:

- Note that these operators are destructive. That is one of the source operands is overwritten by the result. In most implementations, it is unlikely that this compound assignment executes more efficiently than the long form version, which reads more clearly and is less prone to accidental damage.
- Although the ECMA standard describes the algorithms to be used for evaluating operators, there is no guarantee that the operands themselves will be evaluated in any particular order. The right one might appear to be the sensible choice for being evaluated first, since the final value of the left one is dependant on it. However, this is implementation-dependant and certain interpreter designs are based around a recursive descent model, which may partially evaluate the left operand before pausing momentarily while the right is evaluated.
- The operand on the left of the operator must be a modifiable LValue. You cannot use these compound operators with a pair of constant literal values although the right-hand operand can be a constant. The left one must be capable of being assigned to.
- It is a general assumption that the left value will be a single variable. However it could be an array element or object property in which case the resolution of the identifier may cause some side effects that are undesirable and may interact with the right-hand operand value.
- The compound operators are considered to be a single token and the characters that compose them may not be separated by whitespace. The operator should be separated from the operands by whitespace however. Some implementations may forgive the lack of whitespace, but this could lead to ambiguities during interpretation. Such errors may be difficult to diagnose.

Wrox *Instant JavaScript* ISBN 1861001-27-4 – page – 20

Associative array indexing (Advice)

Accessing array elements with strings as symbolic names.

Arrays and collections can be accessed using numeric indexing where each pocket is referred to by a number.

The array may be sparse and not all entries need to be assigned, but the length value will be set to one greater than the highest numbered entry. The first numbered entry is item 0.

You can also use strings instead of numbers. These string values can be specified literally or be passed with a variable.

These are all valid array element references:

```
myIndex = "three";
myArray[0] = "A";
myArray[100] = "B";
myArray["one"] = "C";
myArray['two'] = "D";
myArray[three] = "E";
```

See also:	Array index delimiter ([ ])

Associativity (Definition)

A direction of evaluation of an operator-driven expression.

The associativity of an operator indicates the order of evaluation of its operands. An operator with an associativity of left to right evaluates the expression in the operand to its left and then the one to the right. The alternative is right to left associativity.

atob() (Method)

Decode some base-64 encoded data.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N `atob(`*`aBase64String`*`)` N `myWindow.atob(`*`aBase64String`*`)`	
Argument list:	*`aBase64String`*	A string containing base 64 encoded data
See also:	`Window.btoa()`	

attachEvent() (Method)

A means of attaching events to windows and documents.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE `attachEvent(`*`anEventName`*`, `*`anEventHandler`*`)` IE *`myWindow`*`.attachEvent(`*`anEventName`*`, `*`anEventHandler`*`)`	
Argument list:	*`anEventHandler`*	A reference to an event handler function
	`anEventName`	The name of an event to be handled
See also:	.htc, `<STYLE>`, `Document.attachEvent()`, `Document.detachEvent()`, HTML Component, `onContentReady`, `onDocumentReady`, `Window.detachEvent()`, `Window.attachEvent()`

Wrox *Professional JavaScript* – page – 115

Attr object (Object/DOM)

This is implemented in MSIE as an `Attribute` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Inherits from:	`Node` object	
JavaScript syntax:	-	*myAttr* = *myDocument*.createAttribute(*aName*)
Argument list:	*aName*	The name of the attribute to create

The DOM level 2 standard adds an `ownerElement` property to the `Attr` object specification. This is not yet supported in browsers.

See also:	`Attribute` object, `Document.createAttribute()`

Inheritance chain:

`Node` object

Attribute object (Object/DOM)

A DOM object that represents an HTML tag attribute.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Inherits from:	`Node` object	
JavaScript syntax:	-	*myAttribute* = *myAttributes*.*aPropertyName*
	-	*myAttribute* = *myAttributes*[*anIndex*]
	-	*myAttribute* = *myAttributes*[*aName*]
	-	*myAttribute* = *myDocument*.createAttribute(*aName*)
Argument list:	*aPropertyName*	The name of the tag attribute
	aName	An attribute name
	anIndex	A valid numeric reference to an element in the collection
Object properties:	`name`, `nodeName`, `nodeType`, `nodeValue`, `specified`, `value`	

This is used by the browser to maintain property values for HTML tag instantiated objects.

This object represents a single HTML tag attribute. The properties of this object indicate whether the tag attribute has been specified or not, and if it has, what the current value is.

The `Element` object should contain enough information for you to be able to determine the instantiating source tag name. The attributes can be inspected with a script and the complete source HTML reconstructed from a combination of the information supplied by the element and its associated `attributes` collection.

The `attributes` collection that belongs to an object also tells you what the expected complete set of attributes are for the tag, although this may not be completely reliable.

The example script demonstrates how you can make an `Attribute` object inspector with a fragment of JavaScript. These inspectors can be put into a library and called in for debugging when you are experiencing problems.

Note that the example overleaf does not work on Netscape 6.0 due to the use of the `all` property.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY alink=red>
<SCRIPT>
// An example attributes object inspector
myAttributeObject = document.all[3].attributes.aLink;
displayAttributes("BODY alink", myAttributeObject);
// Display attributes object
function displayAttributes(aTitle, anObject)
{
   document.write("<H3>");
   document.write(aTitle);
   document.write("</H3>");
   document.write("<TABLE BORDER=1 CELLPADDING=2><TR>");
   document.write("<TH>Description</TH>");
   document.write("<TH>Property</TH>");
   document.write("<TH>Value</TH></TR>");
   displayTableLine("Tag attribute name:", "name", anObject.name);
   displayTableLine("Tag attribute value:", "value", anObject.value);
   displayTableLine("DOM node name:", "nodeName", anObject.nodeName);
   displayTableLine("DOM node type:", "nodeType", anObject.nodeType);
   displayTableLine("DOM node value:", "nodeValue", anObject.nodeValue);
   displayTableLine("Specified flag:", "specified", anObject.specified);
   document.write("</TABLE>");
}
// Display a table line
function displayTableLine(aDescription, aProperty, aValue)
{
   document.write("<TR><TH ALIGN=LEFT>");
   document.write(aDescription);
   document.write("</TH><TD>");
   document.write(aProperty);
   document.write("</TD><TD>");
   document.write(aValue);
   document.write("</TD></TR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also: `Attr` object, `Attributes` object, `Document.createAttribute()`, `Element.getAttributeNode()`, `Element.removeAttribute()`, `Element.removeAttributeNode()`, `Element.setAttributeNode()`, `HasProperty()`, HTML tag attribute, `MutationEvent.attrChange`, `MutationEvent.attrName`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`name`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly
`nodeName`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nodeType`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nodeValue`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`specified`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly
`value`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Inheritance chain:

`Node` object

Attribute.name (Property)

The name of the HTML tag attribute this object represents.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myAttribute`*`.name`

The name of the HTML tag attribute that this object represents is reflected here. This is the same value as the property name within the `Attributes` array that refers to this object. You can use that value associatively or as if it were a property name.

This value is also the same as a property name belonging to the `Element` object that represents the HTML tag that this is an attribute of.

Property attributes:

`ReadOnly`.

Attribute.nodeName (Property)

Another alias for the `name` property of an `Attribute` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myAttribute*.nodeName

This is provided to support some previous usage that accessed the tag name under the `nodeName` property. The same value is available in the `name` property of the `Attribute` object. It may contain some values that the `name` property does not support.

The following values may be seen in this property:

- The tag name, also visible via the `tagName` property of the owning object
- The attribute name for those nodes that are `Attribute` objects
- The value `#text` for nodes that encapsulate a block of raw text and are `textNode` objects

See also:	`Element.tagName`, `textNode` object

Attribute.nodeType (Property)

Part of the internal document hierarchy management within MSIE.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myAttribute*.nodeType

The node hierarchy is built from objects that represent a variety of different kinds of Document Object Model content.

The two principle node types are HTML Element nodes (value 1) and Text content nodes (value 3).

Here is a list of the available node types:

Constant:	Type:	Description:
undefined	null	A member of the attributes collection
ELEMENT_NODE	1	HTML element object node
ATTRIBUTE_NODE	2	HTML tag attribute object
TEXT_NODE	3	Text object node
CDATA_SECTION_NODE	4	CDATA section
ENTITY_REFERENCE_NODE	5	Entity reference

Table continued on following page

Constant:	Type:	Description:
ENTITY_NODE	6	Entity node
PROCESSING_INSTRUCTION_NODE	7	Processing instruction node
COMMENT_NODE	8	Comment node
DOCUMENT_NODE	9	Document object
DOCUMENT_TYPE_NODE	10	Doctype object
DOCUMENT_FRAGMENT_NODE	11	Document fragment node
NOTATION_NODE	12	Notation node

See also:	Node object

Attribute.nodeValue (Property)

Another name for the value property of this object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myAttribute*.nodeValue

The value portion of the ATTRIBUTE="aValue" construct. Knowing the name and value of an attribute provides sufficient information to reconstruct the source HTML code from scratch. Some nodeValues may not be defined by ATTRIBUTE HTML tag attributes, but may be the content of the tag itself.

If the object that the attributes are associated with is a TxtNode object, then the nodeValue should return the textual content encapsulated by that object. In that case, the nodeValue cannot be modified although it may be writable for other object types.

If the nodeType is an attribute then the nodeValue reflects its HTML tag attribute value or null if it has not been defined.

If the nodeType is an HTML Element object, then the nodeName should be used to determine which tag it encapsulates. In that case the nodeValue should yield a null.

Attribute.specified (Property)

Whether the value has been specified or not.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`myAttribute`*`.specified`

This flag indicates whether the attribute is defined or not. This property is updated automatically when you change the value of a property belonging to an `Element` object.

The attribute contains a meaningful value only if this property is set to `true`. If it is set to `false`, the other properties belonging to the `Attributes` object don't hold any useful information.

The result is `true` if the value is specified by an HTML tag attribute and `false` if it is not currently specified.

Property attributes:

`ReadOnly`.

Attribute.value (Property)

The value of the HTML tag attribute if it has been specified.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myAttribute`*`.value`

This property reflects the value defined by the parent HTML tag attribute. It is part of the DOM support for HTML tag attributes.

If an HTML tag attribute is specified, the attribute flag for that property of the HTML tag's object will be set `true`. The actual value of the HTML tag attribute will be stored in this property. This `Attribute.value` property gets updated automatically if the owner `Element` object's property value is changed. Internally the two property accessors probably refer to the same storage location.

Attributes object (Object/DOM)

A sub-class of the `Array` object that contains a set of `Element` object attributes. This is a collection of all attribute objects that apply to an element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myAttributes* = *myElement*.attributes
Object properties:	`length`	

The `Attributes` array object is associated with an `Element` object as a container for a set of `Attribute` objects each of which relates to a property of the `Element` object. This is the correct implementation of the DOM specified `Attr` object class.

Not all `Element` object properties have an `Attribute` object, but those that do have related to HTML tag attributes. Thus the `Attributes` array corresponds to the HTML tag attributes for a tag.

The Attributes array has a length property so that you can enumerate all of the attributes of its instantiating HTML tag. It also has as many additional properties as are required to reflect each HTML tag attribute for that HTML tag. The properties reflected from the HTML tag attributes are named consistently with the HTML source text.

Properties are reserved to support event handlers and other tag attributes and so from the `Attributes` array for a particular `Element` object, you can establish what the supported features are for the HTML tag it represents. This means that the `length` property will vary from object to object.

The `Attributes` array seems to contain some properties that correspond to the imaginary HTML generic `Element` class. Although this is not really a genuine object class, it is a convenient way of documenting HTML object behaviors where they are common across a range of objects. The `Attributes` array does not support a complete set of properties that correspond to the `Element` class and therefore it is not true to say it inherits from that class.

The example script shows how you can inspect the attributes of an object. In this example, the attributes of a `<BODY>` tag are exposed. Because they are enumerable, you can determine what properties and what events the object instantiated by the `<BODY>` tag can respond to. Note that the example does not work on Netscape 6.0 due to the use of the `all` property.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY alink=red vlink="blue" leftmargin="100">
<TABLE BORDER=1 CELLPADDING=2>
<SCRIPT>
myAttributesObject = document.all[3].attributes;
displayTableLine("Object class:", myAttributesObject, "");
```

```
displayTableLine("Number of attributes:", myAttributesObject.length, "");
for(myEnumerator=0; myEnumerator<myAttributesObject.length; myEnumerator++)
{
   myAttrib = myAttributesObject[myEnumerator];
   displayTableLine("Attribute ("+ myAttrib.nodeName +"):", myAttrib.specified,
myAttrib.nodeValue);
}

// Output one line of a table
function displayTableLine(aHeading, aFlag, aValue)
{
   document.write("<TR>");
   document.write("<TH ALIGN=LEFT>");
   document.write(aHeading);
   document.write("</TH>");
   document.write("<TD>");
   document.write(aFlag);
   document.write("</TD>");
   document.write("<TD>");
   document.write(aValue);
   document.write("</TD>");
   document.write("</TR>");
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

See also:	`Attribute` object, `Attributes.length`, `Collection` object, `Element` object, `Element.attributes[]`, `Element.removeAttribute()`, `HasProperty()`, `HTML` object, HTML tag attribute

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`length`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly

Attributes.length (Property)

The number of tag attributes supported in this `Attributes` array.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myAttributes*`.length`

The number of attributes supported by the HTML tag that owns this `Attributes` object.

This is the principle property of an `Attributes` object. Most others depend on the object that is represented.

See also:	`Attributes` object, `Collection.length`

Property attributes:

`ReadOnly`.

ATVEF (Standard)

Advanced Television Enhancement Forum.

This extract from the ATVEF standard describes in outline the aims and scope of this web and TV convergence project. You should consult the specification for a complete description of how this is to be accomplished. There are several manufacturers already building and deploying these systems on a variety of broadcast mediums.

The Advanced Television Enhancement Forum (ATVEF) is a group of people from the broadcast TV and Internet industries who are working to specify a single public standard for delivering interactive television experiences. The intention is that these should be authored once using a variety of tools and deployed to a range of television, set-top, and PC-based receivers.

The Enhanced Content Specification defines the fundamental requirements that are necessary to enable creation of HTML-enhanced television content. This goes beyond normal Internet-based delivery to describe how it can be reliably broadcast across any network to any compliant receiver. Because the broadcast requires that there is no bidirectional link, some changes to the delivery protocols are outlined.

The ATVEF specification for enhanced television programming uses existing Internet technologies. It describes how to deliver enhanced TV programming over both analog and digital video systems using terrestrial, cable, satellite, and Internet networks. The specification can be used in both one-way broadcast and two-way video systems, and is designed to be compatible with all international standards for both analog and digital video systems.

Aural style sheets (Definition)

The CSS standard describes style properties for spoken text.

The aural style properties allow the control of spoken voice and other sound effects to be assigned to element objects so that as they are displayed, their content may be spoken or read out to the user. This then makes the World Wide Web more accessible to sight-impaired users.

So far, not much of this capability has found its way into the currently available web browsers.

There are many issues that have not yet been addressed with this aspect of style sheets. For example, controlling multi-lingual spoken text and dates may be somewhat problematic. Certainly the locale that the browser is operating in may be used to select a national language variant for the spoken word.

Warnings:

- This facility is not yet supported by any of the browsers.

AuthentiCode (Security related)

This is a security model that applies digital signatures to ActiveX objects in MSIE.

Warnings:

- This technique does not currently support signed scripts in MSIE and only applies to `ActiveX` objects.

See also:	Security policy, Signed scripts

Automatic semi-colon insertion (Definition)

The action of adding semi-colons where they have been omitted.

Availability:	ECMAScript edition – 2

A semi-colon explicitly placed in the source text must terminate certain statements. Your JavaScript interpreter may help by adding some automatically, but this may not work as you expect. As they say, "Your mileage may vary".

Semi-colons are used to explicitly terminate certain keywords so that the parser can determine exactly where the fragment of code begins and ends. The semi-colon removes the ambiguity about how a piece of code is intended to execute.

Line terminators greatly affect the automatic semi-colon insertion process.

The following statements must have trailing semi-colons:

- `empty` statement
- `variable` statement
- `expression` statement
- `continue` statement
- `break` statement
- `return` statement
- `throw` statement

There are cases where the the interpreter will automatically insert semi-colons as needed. You won't see them in the script source, but the interpreter knows they should be there. You should not rely on the interpreter doing your work for you. For example, semi-colons are never added inside `for` statement headers. Here are some instances of how the browser deals with automatic semi-colon insertion:

- Semi-colons are automatically placed before curly braces (}) that close code blocks if necessary.
- A semi-colon is added at the end of a script source text if necessary to parse the source as a complete program.
- Semi-colons are added to prevent accidental postfix increment or decrement operations. Postfix ++ or -- operators should be on the same line as the operand to which they apply. Actually it is good practice for there to be no whitespace between them.
- Semi-colons are added after the `return` statement when it is the last statement on a line. An expression to be evaluated as part of a `return` statement should be placed adjacent to it. It is good practice to form the return as if it were a function, enclosing the expression in parentheses:

```
return(expression);
```

- This is unaffected by automatic semi-colon insertion even though it is syntactically incorrect:

```
for (a; b)
```

- This is transformed:

```
returna + b
```

And becomes:

```
return;a + b;
```

However, `a + b` is not returned as a result because the line terminator separates them from the `return` statement.

- People take a great many liberties with the formatting of `if…else` constructions. This won't get fixed:

```
if(a > b)else c = d
```

- This won't get fixed either:

```
a = b + c(d + e).print()
```

It doesn't get fixed because the parentheses look like a function call.

Warnings:

- Careful programmers always put semi-colons in. If you come from a C or Java background, this may be instinctive, but otherwise you should develop the habit so that it becomes instinctive.

Automation object (Object/JScript)

An object created in the JScript environment for connecting to other applications within the host environment.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`myAutomation = GetObject(aLocation)`
	IE	`myAutomation = GetObject(aLocation, anObjectType)`
	IE	`myAutomation = GetObject(aLocation!aSubObject)`
	IE	`myAutomation = GetObject (aLocation!aSubObject, anObjectType)`
Argument list:	`anObjectType`	What sort of application and object class type to be created
	`aLocation`	A path to the file for the object to be instantiated
	`aSubObject`	A fragment identifier for a sub-object within the file

See also:	`ActiveXObject` object, `GetObject()`

B object (Object/HTML)

An object that represents the font style controlled by the <B> HTML tag.

Availability:	JScript –3.0 Internet Explorer –4.0		
Deprecated Usage:	Yes		
Inherits from:	`Element` object		
JavaScript syntax:	IE	*myB* = *myDocument*.all.*anElementID*	
	IE	*myB* = *myDocument*.all.tags("B")[*anIndex*]	
	IE	*myB* = *myDocument*.all[*aName*]	
	-	*myB* = *myDocument*.getElementById(*anElementID*)	
	-	*myB* = *myDocument*.getElementsByName(*aName*)[*anIndex*]	
	-	myB = *myDocument*.getElementsByTagName("B")[*anIndex*]	
HTML syntax:	<B> ... </B>		
Argument list:	*anIndex*		A valid reference to an item in the collection
	aName		The `name` attribute of an element
	anElementID		The `ID` attribute of an element
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart		

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

See also:	`Element` object

back() (Method)

Perform the same action as pressing the `[BACK]` button in the toolbar.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`back()`
	-	*myWindow*`.back()`

See also:	`History.back()`, `Window.forward()`, Window.back()

Background object (Object/browser)

A background image object associated with a Netscape Navigator layer.

Availability:	JavaScript – 1.2 Netscape Navigator version – 4.0	
JavaScript syntax:	N	*myBackground* = *myLayer*.background
Object properties:	src	

This object is used with a layer in Netscape Navigator and its properties correspond with properties of the `Image` object in Netscape Navigator.

See also:	`Background.src`,`BODY` object,`Image` object,`Layer.background`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
src	1.2 +	-	4.0 +	-	-	-	-

Background.src (Property)

The source location of an image to be associated with a layer and used as its background image.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myBackground*.src

This corresponds to the src property of a Netscape Navigator Image object. It defines the URL of an image to load into the background of a layer, as these are scriptable in Netscape Navigator whereas the background image of a document object is not.

See also:	`Background` object, `BODY.background`, `BODY.bgProperties`, `JSSTag.backgroundImage`,`style.background`

Back-quote (`) (External code call)

Call some external code during server-side execution.

The back-quote substitutions operate much like you may have seen them work in command-line shells and Perl interpreters. The text enclosed inside the back-quotes is parsed out from the HTML and is then executed as JavaScript.

ASP provides a means of substituting the output of JavaScript code into a block enclosed in `<% ... %>` markers which does a similar thing.

This allows us to include fragments of JavaScript into an HTML page and expect them to be parsed server-side.

This is somewhat analogous to JavaScript entities but they operate at the client-side.

The server-side example wraps its result inside quote symbols so that the HTML tag attribute syntax is preserved intact.

Example code:

```
<HTML>
<BODY>
<FORM>
<INPUT TYPE="text" VALUE=`server.hostname;`>
</FORM>
</BODY>
</HTML>
```

See also:	JavaScript entity, Netscape Enterprise Server

Bar object (Object/Navigator)

An object used to hold properties for toolbars, location bars etc.

Availability:	JavaScript – 1.2 Netscape Version – 4.0	
JavaScript syntax:	N	*myBar* = locationbar
	N	*myBar* = menubar
	N	*myBar* = *myWindow*.locationbar
	N	*myBar* = *myWindow*.menubar
	N	*myBar* = *myWindow*.personalbar
	N	*myBar* = *myWindow*.scrollbars
	N	*myBar* = *myWindow*.statusbar
	N	*myBar* = *myWindow*.toolbar
	N	*myBar* = personalbar
	N	*myBar* = scrollbars
	N	*myBar* = statusbar
	N	*myBar* = toolbar
Object properties:	visible	

This object is used to represent various items of window furniture (otherwise called chrome or adornments) in Netscape Navigator. It isn't supported by MSIE although the control facilities it offers are available when a new window is created with the `window.open()` method.

It only has one usable property. That is the `visible` property, which can be set to a Boolean value. Some early documentation referred to this as the `visibility` property but that is the wrong property name.

See also:	`Bar.visible`, `Window.locationbar`, `Window.menubar`, `Window.personalbar`, `Window.scrollbars`, `Window.statusbar`, `Window.toolbar`

Property	JavaScript	JScript	N	IE	Opera	Notes
`visible`	1.2 +	-	4.0 +	-	-	-

Bar.visibility (Pitfall)

An erroneous name for the `visible` property of a `Bar` object.

Warnings:

- Some reference works refer to the `visibility` property of the `Bar` object, possibly due to early prototype versions of the Netscape browser or in an attempt to document forthcoming features of the browser. In between publishing and release of the browser, the property changed its name to the `visible` property.
- You may even then have some difficulty in getting it to work on some platforms but you do need to make sure you are trying to set the correct property value when changing the visibility of `Bar` objects.

See also:	`Bar.visible`

Bar.visible (Property)

A flag indicating whether the bar that this object represents is visible.

Availability:	JavaScript – 1.2 Netscape Navigator version – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myBar*`.visible`
	N	*myBar*`.visible = `*aBoolean*
Argument list:	*aBoolean*	A switch value to control the visibility of a window control item

Setting this property to `true` makes the bar visible. Setting `false` hides the bar.

You must have been granted the `UniversalBrowserWrite` privilege to be able to set this property value.

See also:	`Bar` object, `Bar.visibility`

Barn() (Filter/transition)

A transition effect with the appearance of barn doors opening or closing.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `Barn()`

BASE object (Object/HTML)

Represents the `<BASE>` HTML tag that describes a base URL for the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myBASE* = *myDocument*.all.*anElementID*
	IE	*myBASE* = *myDocument*.all.tags("BASE")[*anIndex*]
	IE	*myBASE* = *myDocument*.all[*aName*]
	-	*myBASE* = *myDocument*.getElementById(*anElementID*)
	-	*myBASE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myBASE* = *myDocument*.getElementsByTagName ("BASE")[*anIndex*]
HTML syntax:	`<BASE>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The `ID` attribute of an element
Object properties:	`href,target`	
Event handlers:	`onClick,onDblClick,onHelp,onKeyDown,onKeyPress, onKeyUp,onMouseDown,onMouseMove,onMouseOut, onMouseOver,onMouseUp`	

The `<<BASE>>` tag must appear inside the `<<HEAD>>` block of a document and is used to define a base URL for the document, this can be useful if the document is not served from the same server that subsequent pages need to be served from.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`href`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`target`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOver`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

BASE.href (Property)

The URL defined by the `<<BASE>>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myBASE`*`.href`

The URL to be used as a base for any relative URLs in the remainder of the document.

BASE.target (Property)

The target window or frame defined by the `<<BASE>>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape Navigator version – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myBASE*.target

The target window or frame to be added to any relative (or non targeted) URL values in the remainder of the document.

You can assign a new value to this property so that any URLs that are built by the browser with a relative location will be directed to a different window or frame.

Here are some example target values:

- `_parent`
- `_self`
- `_top`
- `_blank`
- Window name
- Frame name

See also:	`Anchor.target`, `Form.target`, `Location.target`, `Map.target`, `Url.target`

BASEFONT object (Object/HTML)

A `<<BASEFONT>>` HTML tag is represented by this object and defines some generic font information to be used as a default in this page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape Navigator version – 6.0
Inherits from:	`Element` object

JavaScript syntax:	IE	*myBASEFONT* = *myDocument*.all.*anElementID*
	IE	*myBASEFONT* = *myDocument*.all.tags("BASEFONT")[*anIndex*]
	IE	*myBASEFONT* = *myDocument*.all[*aName*]
	-	*myBASEFONT* = *myDocument*.getElementById(*anElementID*)
	-	*myBASEFONT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myBASEFONT* = *myDocument*.getElementsByTagName("BASEFONT")[*anIndex*]
HTML syntax:	<BASEFONT>	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The ID attribute of an element
Object properties:	color, face, size	
Object methods:	getAttribute()	
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

Historically web developers will have used the <FONT> tag to set the attributes of blocks of text. Latterly, they will be using style sheets to control this.

The <BASEFONT> tag provides a way to set the font presentation style from the position of this tag to the end of the document unless overridden by further <BASEFONT> tags or <FONT> settings.

See also:	Element object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
color	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
face	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
size	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Method	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
getAttribute()	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

BASEFONT.color (Property)

The default color of text affected by the `<BASEFONT>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape Navigator version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBASEFONT.color`

The color of text affected by this `BASEFONT` object will be defined in this property.

The color can be specified in the normal way according to the HTML color specifiers.

See also:	Color value, `FONT. color`

BASEFONT.face (Property)

The default font face for text affected by the <BASEFONT> HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape Navigator version – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	myBASEFONT.face

The font face to be used for subsequent text is defined by this property. It is appropriate to define a list of font faces in priority order in the normal way. The browser will use the first one it encounters that it has available.

BASEFONT.size (Property)

The default size of text affected by the <<BASEFONT>> HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape Navigator version – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	myBASEFONT.size

The size of text rendered by the browser under control of the BASEFONT object is controlled by this property. Absolute and relative sizes are supported in the normal way.

Basic type (Definition)

Another name for the native types supported by the interpreter.

See also:	Native object, Primitive value

BasicImage() (Filter/visual)

Controls over the basic image display attributes of the containing HTML `Element` object.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `BasicImage()`

BDO object (Object/HTML)

An object representing the `<BDO>` HTML tag for supporting bidirectional text algorithms.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myBDO* = *myDocument*.all.*anElementID*
	IE	*myBDO* = *myDocument*.all.tags("BDO") [*anIndex*]
	IE	*myBDO* = *myDocument*.all[*aName*]
	-	*myBDO* = *myDocument*.getElementById (*anElementID*)
	-	*myBDO* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myBDO* = *myDocument*.getElementsByTagName("BDO")[*anIndex*]
HTML syntax:	`<BDO> ... </BDO>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `name` attribute of an element
	anElementID	The `ID` attribute of an element
Object properties:	`dir`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

This is the `Bi-Directional Override` object. The `LANG` and `DIR` attributes of HTML tags in the document will cover most eventualities but there may be times when you need to explicitly override the direction of text flow.

Usage of this is likely to be confined to scripts that operate in multiple-language environments and on pages containing text in more than one language.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`dir`	-	5.0 +	-	5.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onDblClick`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onHelp`	-	5.0 +	-	5.0 +	-	-	-	Warning
`onKeyDown`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onKeyPress`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onKeyUp`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onMouseDown`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onMouseMove`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onMouseOut`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onMouseOver`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
`onMouseUp`	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

BDO.dir (Property)

The direction attribute of the `<BDO>` HTML tag.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myBDO.dir`

The `dir` property may be set to indicate a left to right or right to left parsing direction.

This is part of the localization support and represents the contents of the `DIR=". . ."` tag attribute.

If you assign a value to this property it is case-sensitive and must be either "`ltr`" or "`rtl`".

This property works in conjunction with the `lang` property to control the direction of text flow.

See also:	`Element.dir`,`NOFRAMES.dir`,`NOSCRIPT.dir`

BeanConnect (Definition)

A Netscape Communications technology for interconnecting Java applets (Beans).

See also:	Java,Java exception events

Refer to:

LiveConnect

Behavior (Definition)

Implementations respond to different constructs according to their behavior.

The ECMAScript standard defines how an implementation should react to a language construct. Other non-ECMA-compliant implementations may behave in the same way most of the time and may deviate from the standard at others.

When the implementation conforms to the standard, its behavior is predictable according to the definitions of the standard. When an implementation is not conformant, it may behave according to one of the following abnormal behavior models:

- Unspecified behavior
- Undefined behavior
- Implementation-defined behavior
- Locale-specific behavior

Another meaning for the word behavior in the context of JavaScript is the way that MSIE supports the addition of JavaScript functionality to style definitions. This is covered under the descriptions of the `addBehavior`() and `removeBehavior`() methods that belong to the `Element` object.

See also:	Compliance, `Element.addBehavior()`,`Element.filters[]`, `Element.removeBehavior()`, Implementation-defined behavior,Locale-specific behavior, Undefined behavior, Unspecified behavior

BGSOUND object (Object/HTML)

An object representing a `<BGSOUND>` HTML tag that defines an audio track to play while the page is displayed.

Availability:	JScript – 3.0 Internet Explorer – 4.0 (as HTML in IE 3.0)
Inherits from:	`Element` object

JavaScript syntax:	IE	*myBGSOUND* = *myDocument*.all.*anElementID*
	IE	*myBGSOUND* = *myDocument*.all.tags("BGSOUND")[*anIndex*]
	IE	*myBGSOUND* = *myDocument*.all[*aName*]
	-	*myBGSOUND* = *myDocument*.getElementById (*anElementID*)
	-	*myBGSOUND* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myBGSOUND* = *myDocument*.getElementsByTagName ("BGSOUND")[*anIndex*]
HTML syntax:	<BGSOUND>	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The ID attribute of an element
Object properties:	balance,loop,src,volume	
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

This object is instantiated by the <BGSOUND> HTML tag and represents a sound effect that is to be played in the background. As the BGSOUND object is created during document loading and requires that a sound file be downloaded, there may some noticeable delay before the sound starts to play.

See also:	Element object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
balance	-	3.0 +	-	4.0 +	-	-	-	ReadOnly
loop	-	3.0 +	-	4.0 +	-	-	-	-
src	-	3.0 +	-	4.0 +	-	-	-	-
volume	-	3.0 +	-	4.0 +	-	-	-	ReadOnly

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

BGSOUND.balance (Property)

The stereo balance of the background sound.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myBGSOUND.balance`

The relative volume of the left and right channels will be adjusted according to the value of this property. This provides a limited amount of control over the apparent direction of the sound source.

Creative use of the balance property may be tied in to the horizontal scrolling of a page for creating virtual reality effects.

Much more sophisticated control is available through the aural style sheet properties, although these are not yet properly supported by browsers.

See also:	`style.azimuth`

Property attributes:

`ReadOnly`.

BGSOUND.loop (Property)

Whether the background sound should loop when it gets to the end.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myBGSOUND.loop`

This indicates the number of times that the sound should play before stopping.

BGSOUND.src (Property)

The URL that the background sound file can be fetched from.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myBGSOUND.src`

The sound will be loaded from this location while the page is being constructed. There may be some delay between requesting the sound and being able to play it.

You can define a new value here to load a different sound and play it in the background.

BGSOUND.volume (Property)

The volume setting at which the background sound should play.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myBGSOUND`*`.volume`

The volume setting of the background can be modified by this property.

The actual perceived volume may depend on other factors. If the sound has been digitized at an unusually low volume, you may need to raise the volume setting quite high. This may yield a very noisy sound as you will also be increasing the ambient noise in the sampled sound. Digitizing is a complex activity but you should always strive for the highest possible signal to noise ratio.

Other factors that may affect the apparent volume would be the user preference settings in the computer. There may also be system controls for blending and mixing sound sources and these may be set to unhelpful values.

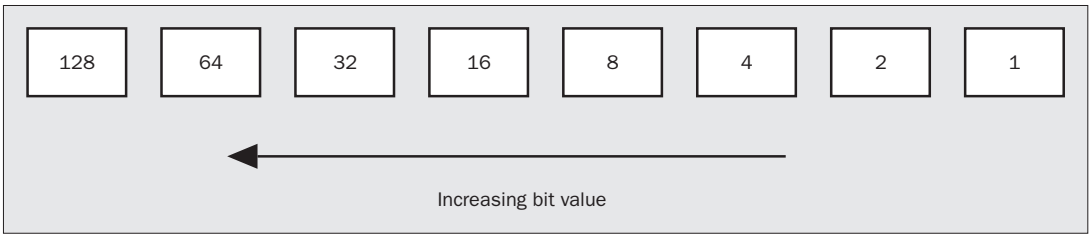
This property can obviously only control the source volume of the sound generated by the browser.

Property attributes:

`ReadOnly`.

Big endian (Definition)

A bit ordering standard for some CPU models.



Refer to:

byte

BIG object (Object/HTML)

An object that represents the font style controlled by the <<BIG>> HTML tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Deprecated Usage:	Yes	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myBIG* = *myDocument*.all.*anElementID*
	IE	*myBIG* = *myDocument*.all.tags("BIG") [*anIndex*]
	IE	*myBIG* = *myDocument*.all[*aName*]
	-	*myBIG* = myDocument.getElementById (anElementID)
	-	*myBIG* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myBIG* = *myDocument*.getElementsByTagName ("BIG")[*anIndex*]
HTML syntax:	`<BIG> ... </BIG>`	
Argument list:	`anIndex`	A valid reference to an item in the collection
	`aName`	The `name` attribute of an element
	`anElementID`	The `ID` attribute of an element
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onDblClick`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onKeyPress`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onKeyUp`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseDown`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseMove`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseOver`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseUp`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

Element object, `Node` object

Refer to:

`Element` object

Binary bitwise operator (Definition)

An operator that applies in a bitwise fashion.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

A binary bitwise operator converts its operands to 32 bit values and performs the operation on each corresponding bit in the two values.

Warnings:

- The result of a bitwise expression is a 32 bit binary value and should not be confused with the Boolean value returned by a logical operator.

See also:	Bitwise AND (&), Bitwise operator, Bitwise OR (|), Bitwise XOR (^)

Cross-references:

ECMA 262 edition 2 – section – 11.10

ECMA 262 edition 3 – section – 11.10

Binary logical operator (Definition)

An operator that works with Boolean `true` or `false` values.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

Binary logical operators test a pair of Boolean values according to logical rules. If necessary, JavaScript will convert the operands that are passed to the expression into Boolean values before testing them. You should consult the `toBoolean` rules for each type of object being passed to ensure that values are cast in a way that you expect.

The resulting value of a binary logical expression may be coerced to another data type on return.

There is no logical XOR operator. It can be simulated though by testing two Boolean values for inequality, since that is going to occur when either is one and the other is zero; the inequality will not test `true` if both are one or both are zero.

Warnings:

- This is not to be confused with the bitwise operators, which yield a 32-bit integer value instead of the Boolean value yielded by a logical expression.

See also:	Logical AND (&&), Logical operator, Logical OR (||)

Cross-references:

ECMA 262 edition 2 – section – 11.11

ECMA 262 edition 3 – section – 11.11

Binary operator (Definition)

An operator that works with two operands.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

Binary operators require two operands and with them form an expression. The operator determines the kind of expression.

Here is a list of the binary operators supported by JavaScript:

Operator	Description
`!=`	NOT equal to
`%`	Remainder
`%=`	Remainder and assign to an LValue
`&`	Bitwise AND
`&&`	Logical AND
`&=`	Bitwise AND and assign to an LValue
`*`	Multiply
`*=`	Multiply and assign to an LValue
`+`	Add
`+`	Concatenate string
`+=`	Add and assign to an LValue
`-`	Subtract
`-=`	Subtract and assign to an LValue
`/`	Divide
`/=`	Divide and assign to an LValue
`<`	Less than
`<<`	Bitwise left shift
`<<=`	Bitwise shift left and assign to an LValue
`<=`	Less than or equal to
`=`	Simple assignment to an LValue
`==`	Equal to
`>`	Greater than
`>=`	Greater than or equal to
`>>`	Bitwise shift right
`>>=`	Bitwise shift right and assign to an LValue
`>>>`	Bitwise shift right (unsigned)

Table continued on following page

Operator	Description
>>>=	Bitwise shift right (unsigned) and assign to an LValue
^	Bitwise XOR (exclusive OR)
^=	Bitwise exclusive XOR and assign to an LValue
|	Bitwise inclusive OR
|=	Bitwise inclusive OR and assign to an LValue
||	Logical OR

Binding (Definition)

Binding is used to resolve identifiers via the scope chain.

Availability:	ECMAScript edition – 2

Binding is the process of locating the appropriate object or property where a value is stored for a particular identifier.

The binding process uses the scope chain belonging to the current execution context to locate the earliest matching item according to the inheritance rules.

See also:	Identifier resolution

ECMA 262 edition 2 – section – 10.1.4

ECMA 262 edition 3 – section – 10.1.4

Bit (Definition)

A binary digit.

A Boolean value can be represented as a bit. Since a bit can maintain exactly two states (true or false), the two map very well to one another. Strictly speaking a Boolean value may yield an undefined state as well.

A continuous series of 8 bits forms a byte and 16 form a word. In JavaScript, 16 bit values tend to be the smallest that you operate with and correspond to a single character in a Unicode string. However, you can probably represent most characters that you want to use in the English language with only 8 bits. In fact only 7 bits are sufficient to describe your script source text in an ASCII representation.

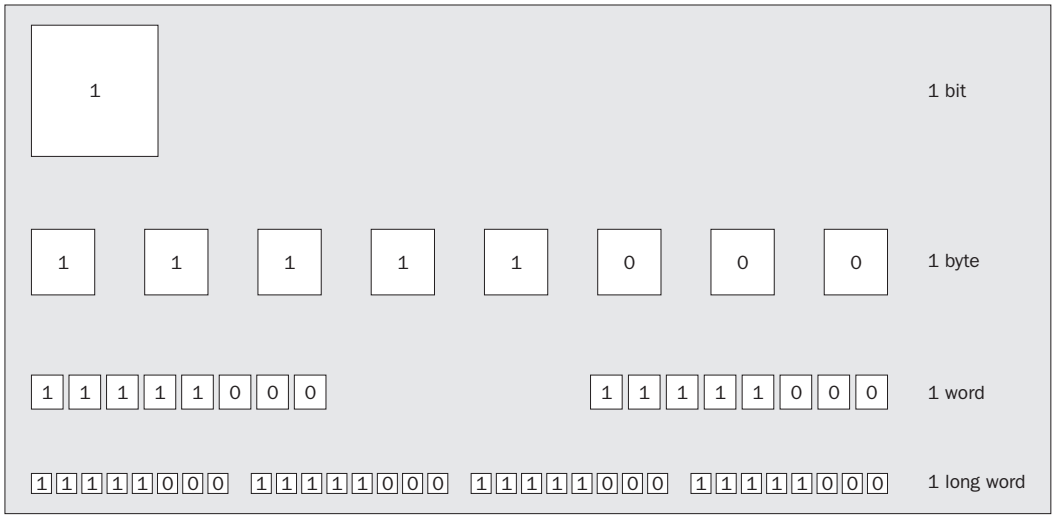
Bit manipulation of character values allows you to convert between upper and lower case. The `String.toUpperCase()` and `String.toLowerCase()` methods allow you to convert specifically to the case you want, but if the current case is unknown and you simply want to toggle the case of a character, the difference between 'A' and 'a' is a single bit.

In most cases, you won't be operating with binary digits in JavaScript-based projects. However, the language is quite capable of working with bit patterns provided you understand how they work.

Although you cannot store an individual bit on its own, you can keep collections of 32 of them in a Number value.

In C language you operate on these using Bit-Fields. JavaScript does not support bit-fields but the sort of things you do with them can be simulated.

This is likely to be of most use to people developing scripts for use in embedded interpreters and of less use to browser script developers.



Example code:

```
// Demonstrate bit inversion to change character case
myString = "AbCdEfGh";
myLength = myString.length;
document.write("Original source string : ");
document.write(myString);
document.write("<BR>");
document.write("<BR>");
document.write("<TABLE BORDER=1><TR><TH>");
document.write("Orig char</TH><TH>");
document.write("Char code</TH><TH>");
document.write("Bit inverted<BR>char code</TH><TH>");
document.write("New char</TH></TR>");
for(myEnum = 0; myEnum < myLength; myEnum++)
{
   myChar     = myString.charAt(myEnum);
   myCharCode = myString.charCodeAt(myEnum);
   myNewCharCode = myCharCode ^ 32;

   document.write("<TR><TD>");
   document.write(myChar);
   document.write("</TD><TD>");
   document.write(myCharCode);
   document.write("</TD><TD>");
   document.write(myNewCharCode);
   document.write("</TD><TD>");
   document.write(String.fromCharCode(myNewCharCode));
   document.write("</TD></TR>");
}
document.write("</TABLE>");
```

See also:	Bit-field, `String.toLocaleLowerCase()`, `String.toLocaleUpperCase()`,`String.toLowerCase()`, `String.toUpperCase()`

Bit-field (Definition)

A collection of binary digits.

Although JavaScript does not support bit-fields, you can perform many binary operations on patterns of bits by using the bitwise operators and various simple mathematical expressions to simulate other bit manipulation operators that are not provided as part of the standard.

Op	Description
~	Bitwise complement (NOT)
&	Bitwise AND
<<	Bitwise left shift
>>	Bitwise right shift
>>>	Bitwise right shift (unsigned)

Op	Description
|	Bitwise inclusive OR
^	Bitwise XOR (exclusive OR)
&=	Bitwise AND and assign to an LValue
|=	Bitwise inclusive OR and assign to an LValue
^=	Bitwise exclusive XOR and assign to an LValue
<<=	Bitwise shift left and assign to an LValue
>>=	Bitwise shift right and assign to an LValue
>>>=	Bitwise shift right (unsigned) and assign to an LValue

The bits are individually weighted according to their position relative to the least significant digit.

The single bit at the extreme right-hand end is defined by the integer value 1. The next significant bit is derived by using a zero-based indexing scheme to raise 2 to the power of its index position. Thus 2 raised to the power 0 is 1. The value 2 raised to the power 1 is 2 and thus the values proceed like this, moving from right to left:

1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096 etc.

To build bit masks containing a set bit for several positions, simply add the component bit values together. Thus a mask that includes all the four least significant bits in a value is equal to:

1 + 2 + 4 + 8

Here are some other useful mask values (note that we only show 8 bit values here to demonstrate the concept):

Mask	Value	Description
0000 0001	1	Least significant bit
0000 1111	15	Least significant nibble
0010 0000	32	ASCII upper/lowercase character bit
0101 0101	85	Simple encryption pattern for XOR
0111 1111	127	Valid ASCII character mask
1111 0000	240	Most significant nibble
1111 1111	255	Low 255 UNICODE character set mask

Bitwise AND (&) (Operator/bitwise)

Bitwise AND of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 & anOperand2`
Argument list:	*`anOperand1`* *`anOperand2`*	A binary bit pattern Another binary bit pattern

The result is the bitwise AND of both binary bit pattern values.

This operator performs a bit by bit AND of the 32-bit value derived from both operands. Effectively, each corresponding bit pair has a logical AND applied to it.

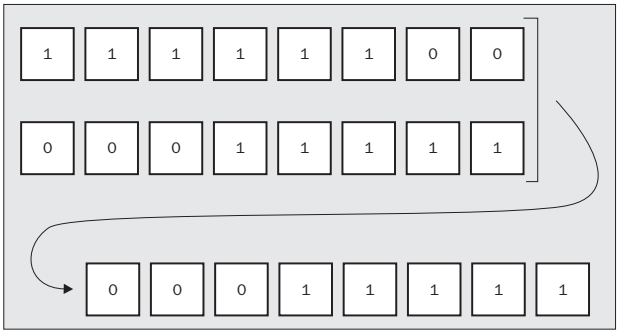
The truth table shows the result of this operator for two Boolean primitive values:

A	B	AND
false	false	false
false	true	false
true	false	false
true	true	true

Where a corresponding bit is 1 in both values, a 1 bit is inserted into the result otherwise the value is zero.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0xFFFF;
myValue2 = 0xFF00;
myValue3 = myValue1 & myValue2;

document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Val 2 : " + binary32(myValue2) + "<BR>");
document.write("AND : " + binary32(myValue3) + "<BR>");

// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
      myArray = new Array(32);

      for(myEnum=0; myEnum<32; myEnum++)
      {
            if(aValue & Math.pow(2, myEnum))
            {
                  myArray[31-myEnum] = "1";
            }
            else
            {
                  myArray[31-myEnum] = "0";
            }
      }

      return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 11.10

Bitwise AND then assign (&=) (Operator/assignment)

Bitwise AND two operands and assign the result to the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 &= anOperand2`
Argument list:	`anOperand1`	A binary value
	`anOperand2`	Another binary value

Bitwise AND the right operand with the left operand and assign the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 & anOperand2;
```

Although this is classified as an assignment operator it is really a compound of an assignment and a bitwise operator.

The associativity is right to left.

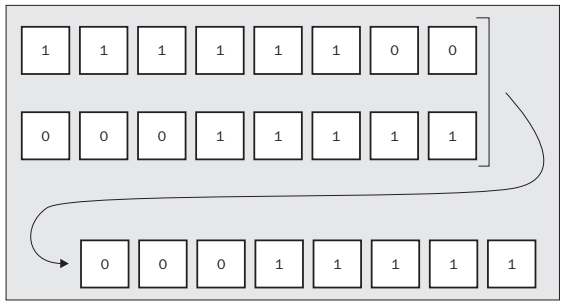
Refer to the Operator Precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.

The truth table shows the result of this operator for two Boolean primitive values:

A	B	AND
false	false	false
false	true	false
true	false	false
true	true	true

This is applied to each corresponding bit pair in the two values.



Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

See also:	Assignment operator, Associativity, Bit-field,Bitwise AND (&), Bitwise expression, Bitwise operator, Logical AND (&&), LValue, Operator Precedence

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

Bitwise expression (Definition)

An expression that applies in a bitwise manner.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Bitwise expressions perform a bit by bit operation across the entire integer width of the values.

See also:	Bit-field, Bitwise AND (&), Bitwise AND then assign (&=), Expression

Cross-references:

ECMA 262 edition 2 – section – 11.7

ECMA 262 edition 3 – section – 11.7

ECMA 262 edition 3 – section – 11.10

Bitwise NOT - complement (~) (Operator/bitwise)

Bitwise NOT of one operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

Property/method value type:	Number primitive	
JavaScript syntax:	-	~anOperand
Argument list:	anOperand	A numerical value

The operand is evaluated and then converted to a 32-bit integer value. Every bit is complemented and the result is a bitwise NOT.

The truth table shows the result of this operator for a Boolean primitive value:

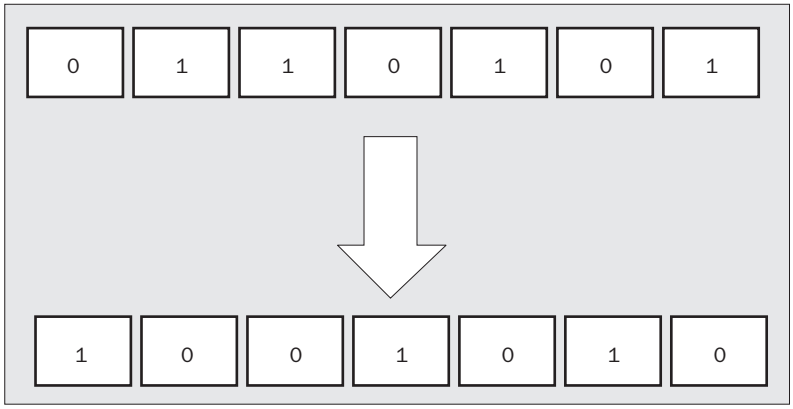
A	NOT
false	true
true	false

This operation is applied to each individual bit in the operand, inverting them one by one.

Note that this could be classified as a unary operator but here we have called it a bitwise operator on account of its functionality rather than its placement.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.



Warnings:

- There are some deficiencies in the handling of bitwise operators in the MSIE 5.0 browser on the Macintosh platform. It does not properly handle the sign bit and so you should observe some caution when using this operator.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0xFFFF;
myValue2 = ~myValue1
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("NOT : " + binary32(myValue2) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
  myArray = new Array(32);

  for(myEnum=0; myEnum<32; myEnum++)
  {
    if(aValue & Math.pow(2, myEnum))
    {
      myArray[31-myEnum] = "1";
    }
    else
    {
      myArray[31-myEnum] = "0";
  }
}
return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	Associativity, Bit-field,Logical NOT – complement (!), Operator Precedence, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.8

ECMA 262 edition 3 – section – 11.4.8

Bitwise operator (Definition)

An operator that is applied in a bitwise manner.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Bitwise operators convert both operands to 32 bit integers and apply the operator to them on a bit-by-bit basis.

Here is a table of all operators in the bitwise category and those are members of other categories but perform bitwise operations:

Op	Description
~	Bitwise complement (NOT)
&	Bitwise AND
<<	Bitwise left shift
>>	Bitwise right shift
>>>	Bitwise right shift (unsigned)
|	Bitwise inclusive OR
^	Bitwise XOR (exclusive OR)
&=	Bitwise AND and assign to an LValue
|=	Bitwise inclusive OR and assign to an LValue
^=	Bitwise exclusive XOR and assign to an LValue
<<=	Bitwise shift left and assign to an LValue
>>=	Bitwise shift right and assign to an LValue
>>>=	Bitwise shift right (unsigned) and assign to an LValue

Warnings:

- The result of a bitwise expression is a 32 bit binary value and should not be confused with the Boolean value returned by a logical operator.
- The bitwise operators may yield a value that in other languages is the same as the logical operator. However although in the C language, `true` and `false` are really integer values, in JavaScript the Boolean and Number values are distinctly different types.
- Be careful to use the correct number of ampersands and vertical bars to select the bitwise version of the operator. Refer to the Logical operator topic for a list of operators to avoid in bitwise expressions.

See also:	Associativity, Binary bitwise operator, Bit-field,Bitwise AND (&), Bitwise AND then assign (&=), Bitwise OR then assign (|=), Bitwise shift left then assign (<<=), Bitwise shift right and assign (>>=), Bitwise unsigned shift right and assign (>>>=), Bitwise XOR and assign (^=),Logical operator, Operator, Operator Precedence,Type conversion

ECMA 262 edition 3 – section – 11.10

Wrox *Instant JavaScript* – page – 19

Bitwise OR (|) (Operator/bitwise)

Bitwise OR of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 | anOperand2`
Argument list:	`anOperand1`	A numeric value
-	`anOperand2`	Another numeric value

Performs a bit-by-bit OR of the 32-bit value derived from both operands.

Where a corresponding bit is 1 in either of the two operands, a 1 is inserted into the result. A zero is inserted only when neither operand has a 1 bit at that position.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

The truth table shows the result of this operator for two Boolean primitive values:

A	B	OR
false	false	false
false	true	true
true	false	true
true	true	true

This is applied to each corresponding bit pair in the operands.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0x00FF;
myValue2 = 0xFF00;
myValue3 = myValue1 | myValue2;
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Val 2 : " + binary32(myValue2) + "<BR>");
```

```
document.write("OR : " + binary32(myValue3) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
  myArray = new Array(32);

  for(myEnum=0; myEnum<32; myEnum++)
  {
    if(aValue & Math.pow(2, myEnum))
    {
      myArray[31-myEnum] = "1";
    }
    else
    {
    myArray[31-myEnum] = "0";
  }
}
return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 2 – section – 11.10

ECMA 262 edition 3 – section – 11.10

Bitwise OR then assign (|=) (Operator/assignment)

Bitwise OR two operands and assign the result to the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 |= anOperand2`
Argument list:	`anOperand1`	A numeric value that can be assigned to
-	`anOperand2`	Another numeric value

Bitwise OR the right operand with the left operand and assign the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 | anOperand2;
```

Performs a bit by bit OR of the 32-bit value derived from both operands.

Where a corresponding bit is 1 in either of the two operands, a 1 is inserted into the result. A zero is inserted only when neither operand has a 1 bit at that position.

Although this is classified as an assignment operator it is really a compound of an assignment and a bitwise operator.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.

The truth table shows the result of this operator for two Boolean primitive values:

A	B	OR
false	false	false
false	true	true
true	false	true
true	true	true

This is applied to each corresponding bit pair in the operands.

Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

See also:	Assignment operator, Associativity, Bit-field, Bitwise operator, Bitwise OR (|),LValue, Operator Precedence

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

Bitwise shift left (<<) (Operator/bitwise)

Bitwise shift leftwards one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 << anOperand2`
Argument list:	`anOperand1` `anOperand2`	A value to be shifted A distance to shift `anOperand1`

The bitwise shift left operator converts its left operand to a 32 bit integer and moves it leftwards by the number of bits indicated by the right operand.

As the value is shifted leftwards, bits that roll out of the left end of the register are discarded. The right-hand end of the register is filled with zero bits. Shifting leftwards by 32 bits will fill the register with all zero bits.

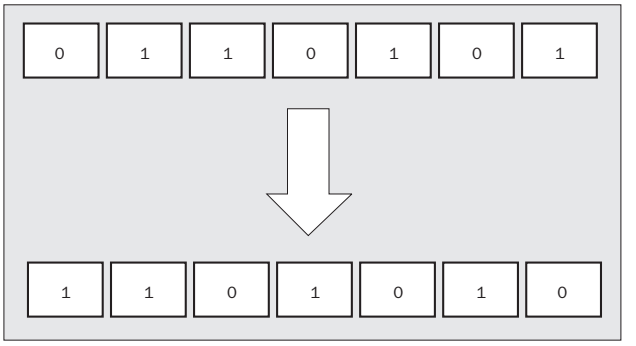
Because the value is converted to an integer, any fractional part is discarded as the shift begins.

The right-hand operand is converted to a 5 bit value with a bitwise mask to limit the distance of the shift to 32 bits. This can cause unexpected results if the right-hand side is derived from an expression that may yield a value larger than 32.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

You can accomplish bitwise shift lefts by multiplying values using powers of 2. Multiplying a value by 2 shifts leftwards by one bit position.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0x00FF;
myValue2 = myValue1 << 4;
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Result : " + binary32(myValue2) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
   myArray = new Array(32);

   for(myEnum=0; myEnum<32; myEnum++)
   {
      if(aValue & Math.pow(2, myEnum))
      {
         myArray[31-myEnum] = "1";
      }
      else
      {
         myArray[31-myEnum] = "0";
      }
   }
return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

Bitwise shift left then assign (<<=) (Operator/assignment)

Destructively bitwise leftwards shift the first of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera browser – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 <<= anOperand2`
Argument list:	`anOperand1`	A value to be shifted and assigned to
	`anOperand2`	A distance to shift `anOperand1`

Bitwise shift leftwards the left operand by the number of bits in the right operand and assign the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 << anOperand2;
```

The bitwise shift left operator converts it left operand to a 32 bit integer and moves it leftwards by the number of bits indicated by the right operand.

As the value is shifted leftwards, bits that roll out of the left end of the register are discarded. The right-hand end of the register is filled with zero bits. Shifting leftwards by 32 bits will fill the left operand with all zero bits.

Because the value is converted to an integer, any fractional part is discarded as the shift begins.

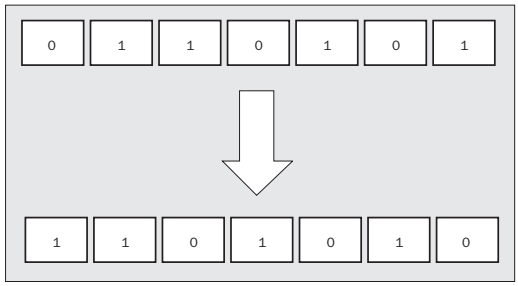
The right-hand operand is converted to a 5-bit value with a bitwise mask to limit the distance of the shift to 32 bits. This can cause unexpected results if the right-hand side is derived from an expression that may yield a value larger than 32.

Although this is classified as an assignment operator it is really a compound of an assignment and a bitwise operator.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.



Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

Bitwise shift operator (Definition)

A shift operator that moves the bits in an operand as if it were a shift register.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Bitwise shift operators convert their left operands to a 32-bit integer value and shift them according to their right operand. The operator determines the kind of shifting that is applied.

See also:	Bit-field, Bitwise shift left (<<), Bitwise shift left then assign (<<=), Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=),Shift expression, Shift operator

Cross-references:

ECMA 262 edition 2 – section – 11.7

ECMA 262 edition 3 – section – 11.7

Bitwise shift right (>>) (Operator/bitwise)

Bitwise shift right one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 >> anOperand2`
Argument list:	`anOperand1`	A value to be shifted
	`anOperand2`	A distance to shift the left operand

This is sometimes called shift right with sign extension.

The bitwise shift right operator converts its left operand to a 32 bit integer and moves it rightwards by the number of bits indicated by the right operand.

As the value is shifted rightwards, bits that roll out of the right end of the register are discarded. The left-hand end of the register containing the sign bit is duplicated to sign-fill the value as it shifts. Shifting rightwards by 32 bits will fill the register with all zero or all one bits according to the value of the sign bit at the outset.

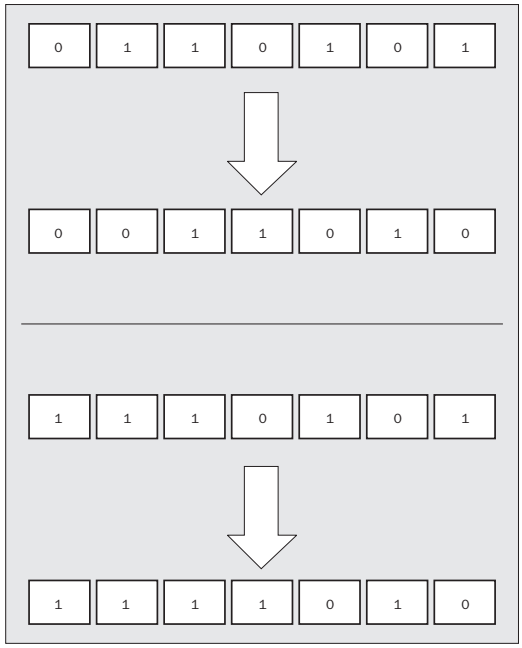
Because the value is converted to an integer, any fractional part is discarded as the shift begins.

The right-hand operand is converted to a 5-bit value with a bitwise mask to limit the distance of the shift to 32 bits. This can cause unexpected results if the right-hand side is derived from an expression that may yield a value larger than 32.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

You can accomplish bitwise shift rights by dividing values using powers of 2. Dividing a value by 2 shifts rightwards by one bit position.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0x00FF00;
myValue2 = myValue1 >> 4;
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Result : " + binary32(myValue2) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
   myArray = new Array(32);

   for(myEnum=0; myEnum<32; myEnum++)
   {
      if(aValue & Math.pow(2, myEnum))
      {
         myArray[31-myEnum] = "1";
      }
      else
      {
         myArray[31-myEnum] = "0";
      }
   }
   return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 11.13

Bitwise unsigned shift right (>>>) (Operator/bitwise)

Bitwise shift right one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 >>> anOperand2`
Argument list:	`anOperand1`	A value to be shifted
	`anOperand2`	A distance to shift the left operand

This is sometimes called shift right with zero extension.

The bitwise unsigned shift right operator converts its left operand to a 32 bit integer and moves it rightwards by the number of bits indicated by the right operand. The sign bit is not propagated.

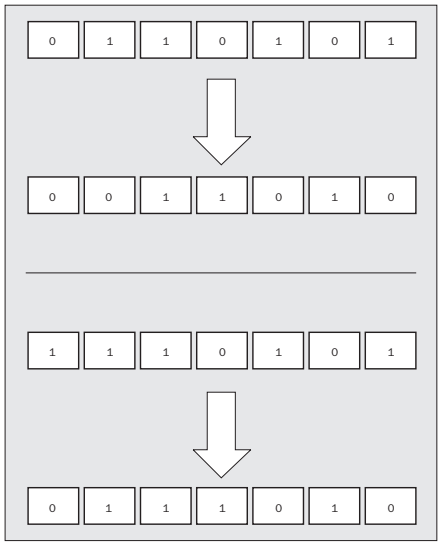
As the value is shifted rightwards, bits that roll out of the right end of the register are discarded. The left-hand end of the register containing the sign bit is zero-filled as the contents are shifted. Shifting rightwards by 32 bits will fill the register with all zero bits.

Because the value is converted to an integer, any fractional part is discarded as the shift begins.

The right-hand operand is converted to a 5-bit value with a bitwise mask to limit the distance of the shift to 32 bits. This can cause unexpected results if the right-hand side is derived from an expression that may yield a value larger than 32.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = -0x00FF00;
myValue2 = myValue1 >>> 4;
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Result : " + binary32(myValue2) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
   myArray = new Array(32);

   for(myEnum=0; myEnum<32; myEnum++)
   {
      if(aValue & Math.pow(2, myEnum))
      {
         myArray[31-myEnum] = "1";
      }
      else
      {
         myArray[31-myEnum] = "0";
      }
   }
   return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 >>>= anOperand2`
Argument list:	`anOperand1`	A value to be shifted and assigned to
	`anOperand2`	A distance to shift the left operand

Bitwise unsigned shift rightwards the left operand by the number of bits in the right operand and assign the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 >>> anOperand2;
```

The bitwise unsigned shift right operator converts its left operand to a 32 bit integer and moves it rightwards by the number of bits indicated by the right operand. The sign bit is not propagated.

As the value is shifted rightwards, bits that roll out of the right end of the register are discarded. The left-hand end of the register containing the sign bit is zero-filled as the contents are shifted. Shifting rightwards by 32 bits will fill the left operand with all zero bits.

Because the value is converted to an integer, any fractional part is discarded as the shift begins.

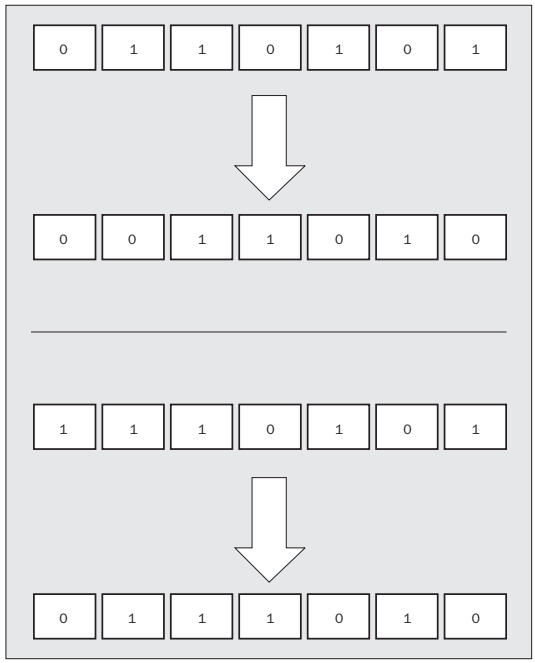
The right-hand operand is converted to a 5-bit value with a bitwise mask to limit the distance of the shift to 32 bits. This can cause unexpected results if the right-hand side is derived from an expression that may yield a value larger than 32.

Although this is classified as an assignment operator it is really a compound of an assignment and a bitwise operator.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.



Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

Bitwise XOR (^) (Operator/bitwise)

Bitwise XOR one operand with another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 ^ anOperand2`
Argument list:	`anOperand1`	A numeric value
	`anOperand2`	Another numeric value

Performs a bit-by-bit XOR of the 32-bit values derived from both operands.

Where a corresponding bit is different in both operands, a 1 bit will be inserted into the result. If the corresponding bit is identical in both operands, regardless of whether they both have a 1 bit or a zero bit, a zero will be inserted at that bit position in the result.

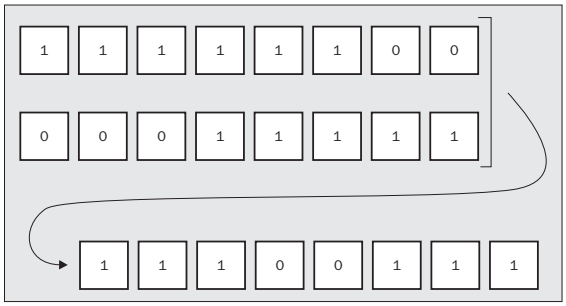
The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

This is the truth table for two Boolean primitive values being operated on with the XOR operator.

A	B	XOR
false	false	false
false	true	true
true	false	true
true	true	false

The bitwise operator performs this operation on each corresponding bit pair in the two operands.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myValue1 = 0xFFFF;
myValue2 = 0x0FF0;
myValue3 = myValue1 ^ myValue2;
document.write("Val 1 : " + binary32(myValue1) + "<BR>");
document.write("Val 2 : " + binary32(myValue2) + "<BR>");
document.write("XOR : " + binary32(myValue3) + "<BR>");
// Binary convertor (ignore sign bit on MSIE)
function binary32(aValue)
{
   myArray = new Array(32);

   for(myEnum=0; myEnum<32; myEnum++)
   {
      if(aValue & Math.pow(2, myEnum))
      {
         myArray[31-myEnum] = "1";
      }
      else
      {
         myArray[31-myEnum] = "0";
      }
   }
   return myArray.join("");
}
</SCRIPT>
</BODY>
</HTML>
```

blob object (Object/NES)

A special object that is designed to contain binary data extracted from a database or file.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`myBlob = blob()`
	NES	`myBlob = myCursor.colName.blobImage(...)`
Object methods:	`<methodname>blobImage()</methodname>`, `<methodname>blobLink()</methodname>`	

A `blob` object is so called because it encapsulates a Binary Large OBject or BLOB. This is a block of data, often quite large, that is stored in a binary form and which is likely to contain many non-printable characters and probably some nulls as well.

You cannot instantiate a `blob` object directly in JavaScript but you can obtain one by fetching the data from a database as shown in the example code.

Example code:

```
<SERVER>
// Example derived from Wrox Professional JavaScript
// This opens a database, selects some records
// Traverses the collection that was selected
// and for each one, outputs an image tag.
database.connect("ODBC", "TargetDB", "", "", "");
myCursor = database.cursor("SELECT * FROM TARGET_TABLE");
while(myCursor.next())
{
   myBlob = myCursor.blobData;
   write(myBlob.blobImage("bmp"));
}
myCursor.close();
</SERVER>
```

See also:	Netscape Enterprise Server, `unwatch()`, `watch()`

Method	JavaScript	JScript	NES	Notes
`blobImage()`	1.1 +	-	2.0 +	-
`blobLink()`	1.1 +	-	2.0 +	-

blob.blobImage() (Method)

This method creates an `<IMG>` element having the appropriate MIME type for the `blob` object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Image` object	
JavaScript syntax:	NES	`myBlob.blobImage(aFormat)`
	NES	`myBlob.blobImage(aFormat, aTxt)`
	NES	`myBlob.blobImage(aFormat, aTxt, anAlign)`
	NES	`myBlob.blobImage(aFormat, aTxt, anAlign, aPixWid)`
	NES	`myBlob.blobImage(aFormat, aTxt, anAlign, aPixWid, aPixHgt)`
	NES	`myBlob.blobImage(aFormat, aTxt, anAlign, aPixWid, aPixHgt, aPixBrdr)`
	NES	`myBlob.blobImage(aFormat, aTxt, anAlign, aPixWid, aPixHgt, aPixBrdr, isMap)`
Argument list:	`aFormat`	Image file format
	`anAlign`	The alignment of the image
	`aPixBrdr`	The border value
	`aPixHgt`	The height of the image
	`aPixWid`	The width of the image
	`aTxt`	The alt text for the image
	`isMap`	Whether the image is a map

The data is pulled out of the database according to the specified parameters. The BLOB can then be displayed as if it were an image in an <IMG> tag.

The format argument should contain an image specifier such as "GIF" or "JPEG" that can map conveniently to a file extension or MIME type.

The remaining parameters to this method mainly correspond to the HTML tag attributes that can be used with an <IMG> tag and are optional.

This method generates the necessary <IMG> tag to place into a document that refers to the BLOB data as if it were an image file on the server. When the document is parsed, the browser will request the image in the normal way; the contents of the BLOB are then returned in response to that request. The browser is not aware that the image data was retrieved from the database and by caching the image in memory when the link to it is placed in the document most of the latency associated with requesting objects out of the database is eliminated, albeit at the cost of increased memory usage in the server backend.

See also:	Cursor.blobImage(),blob object,MIME types

blob.blobLink() (Method)

This method creates an <A> element that links to the BLOB data.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Anchor` object	
JavaScript syntax:	NES	`myBlob.blobLink(aMimeType, aString)`
Argument list:	`aString`	The text inside the link
	`aMimeType`	The MIME type of the document being displayed

The data is pulled out of the database according to the specified parameters. The BLOB can then be displayed as if it were a document in an <A> tag.

This method generates the necessary URL to place into a document that links to it. If the user clicks on the link, the contents of the BLOB are then returned in response to that request.

Wrox *Instant JavaScript* – page – 17

Block-level tag (Definition)

A block-level tag cannot exist inside a line. It must be placed on a line by itself.

By default, block-level items will be placed on a line by themselves because they force a line break before and after they are displayed. However you can modify the alignment and text flow around a block-level object to make it appear to be inline.

BLOCKQUOTE object (Object/HTML)

An object that represents a `<BLOCKQUOTE>` text area.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myBLOCKQUOTE = myDocument.all.anElementID`
	IE	`myBLOCKQUOTE = myDocument.all.tags ("BLOCKQUOTE")[anIndex]`
	IE	`myBLOCKQUOTE = myDocument.all[aName]`
	-	`myBLOCKQUOTE = myDocument.getElementById (anElementID)`
	-	`myBLOCKQUOTE = myDocument.getElementsByName (aName)[anIndex]`
	-	`myBLOCKQUOTE = myDocument.getElementsByTagName("BLOCKQUOTE")[ anIndex]`

HTML syntax:	`<BLOCKQUOTE> ... </BLOCKQUOTE>`	
Argument list:	`anIndex`	A valid reference to an item in the collection
	`aName`	The `name` attribute of an element
	`anElementID`	The `ID` attribute of an element
Object properties:	`cite`	
Object methods:	`click()`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

This is used to set off a long quote inside a document and is intended to place an extract from a document into the displayed window with an active link to the document it quotes from. The style and appearance is that of a block quote text.

The `<BLOCKQUOTE>` tag is a block-level tag. That means that it forces a line break before and after unless the alignment and text flow around it are controlled very cleverly.

The DOM level 1 specification refers to this as a `QuoteElement` object.

See also:	`Element` object

Inheritance chain:

`Element` object, `Node` object

BLOCKQUOTE.cite (Property)

A URL pointing at the document that a quote is attributed to.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBLOCKQUOTE.cite`

The URL of the document being quoted from is noted in this property.

Blur() (Filter/visual)

A visual filter for blurring objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Filter – `Blur()`

blur() (Method)

Move the input focus away from the receiving element.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 3.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`blur()`
	-	`myWindow.blur()`
See also:	`Input.blur(),Window.focus(),Window.blur()`	

BODY object (Object/HTML)

An object that represents the body of a document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myBODY = myDocument.all.anElementID`
	IE	`myBODY = myDocument.all.tags("BODY") [anIndex]`
	IE	`myBODY = myDocument.all[aName]`
	-	`myBODY = myDocument.body`
	-	`myBODY = myDocument.getElementById (anElementID)`
	-	`myBODY = myDocument.getElementsByName (aName)[anIndex]`
	-	`myBODY = myDocument.getElementsByTagName ("BODY")[anIndex]`
HTML syntax:	`<BODY> ... </BODY>`	
Argument list:	`anIndex`	A valid reference to an item in the collection (should be 0)
	`aName`	The `name` attribute of an element
	`anElementID`	The `ID` attribute of an element
Object properties:	`accessKey, aLink,background,bgColor, bgProperties, bottomMargin, leftMargin, link,noWrap, recordNumber, rightMargin,scroll, tabIndex, text,topMargin, vLink`	
Object methods:	`createControlRange(), createTextRange()`	
Event handlers:	`onAfterUpdate, onBeforeUnload,onBeforeUpdate, onChange, onClick, onDataAvailable, onDataSetChanged, onDataSetComplete, onDblClick, onDragStart, onErrorUpdate, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit, onScroll, onSelectStart, onUnload`	
Collections:	`controlRange[]`	

Although this generally represents the `<BODY>` tag, there are also properties that relate to the body that belong to the `Document` and `Window` objects. In MSIE, there is also a `HEAD` object, which contains related information.

The `<BODY>` tag is a block-level tag. You can't place a `<BODY>` tag into the document but taken in the context of a framed environment it manifests itself as if it were a block-level tag.

See also:	`Background` object, `Document` object, `Document.bgColor`, `Document.body`, `Element` object, `Element.isTextEdit`, `Element.offsetParent`, `Frame` object,`HEAD` object, `Input.accessKey`, `Window` object

Inheritance chain:

`Element` object, `Node` object

BODY.aLink (Property)

The colour of an active link in the current page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.aLink`

This value controls the text of active links in the document body. You should use the normal color values to define the required color.

This property is equivalent to the `ALINK` attribute of the `<BODY>` HTML tag. This is the color that is used while the mouse is over the link and the button is held down by the user.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse.

Note also that its property name is not consistent with its counterpart, the `document.alinkColor` property whose value it reflects.

See also:	BODY.link, BODY.text, BODY.vLink, Color names, Color value, Document.alinkColor, Document.bgColor, Document.fgColor, Document.linkColor, Document.vlinkColor, HTML object

BODY.background (Property)

The URL of a background image for the current document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.background`

If a background image is available, then its URL is contained in this property. Changing the value in this property will replace the background with a new one; however, there may be a perceptible delay while the new image is fetched from the web server.

The background image for the document that is defined in the `<BODY>` tag is accessible via the `BODY.background` property in MSIE.

Warnings:

- You cannot access the background image directly in Netscape Navigator because the `BODY` object is not reflected into the JavaScript environment.

See also:	Background.src, BODY.bgProperties, Document.background, HTML object

BODY.bgColor (Property)

The background color of the current page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.bgColor`

This corresponds to the `BGCOLOR=". . ."` HTML tag attribute on the `<BODY>` tag.

You can modify this value at any time, the result of which will be to change the background color of the page.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape whereas style sheet controls do not. Later, a DOM-standardized approach to style handling will provide a cross-platform way to access style information from JavaScript. DOM level 2 introduces a first attempt at standardizing this area.

The background can be colored whether an image is loaded into the background of a document or not. In fact, it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

The background color for the document that is defined in the `<BODY>` tag is also reflected in the `bgColor` property of the `document` object, although that is now deprecated as of DOM level 1.

See also:	Color names, Color value, Document.bgColor, Document.linkColor ,`HTML` object

BODY.bgProperties (Property)

An attribute that controls the way the background image is managed when the page scrolls.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myBODY.bgProperties`

The value of this property can be set to either the value "`fixed`" or an empty string (""). When the "`fixed`" value is used, the background image (if it is specified) will be locked into position and if the page is scrolled, the background will stay fixed where it is as if it were on a separate layer.

See also:	Background.src, BODY.background

BODY.bottomMargin (Property)

A margin space at the bottom of the document in the current window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myBODY`*`.bottomMargin`

Normally, you would not need to specify this property. It allows the document to have some clear space at the bottom so, for example, the content could be made to scroll completely off the screen.

The distance is measured in pixels and can range from zero (which is the default) to any reasonably sensible value.

If a page is being created dynamically with `document.write()` methods, and a script error occurs, the margin is not appended. It appears to be added as a property of the body closure.

This corresponds to the `style.marginBottom` property and the `margin-bottom` attribute that is defined in a style sheet.

Warnings:

- Even when this value is set to zero, the Macintosh version of MSIE has a noticeable margin at the bottom.

See also:	`BODY.topMargin`

BODY.controlRange[] (Collection)

A collection of all the elements within the document body.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	`myBODY.controlRange`

This collection is returned by the `createControlRange()` method. The items in this collection would all represent component elements within the page but would not include simple text items.

See also:	`BODY.createControlRange()`

Property attributes:

`ReadOnly`.

BODY.createControlRange() (Method)

A constructor function to create a new `controlRange` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`ControlRange` object	
JavaScript syntax:	IE	`myElement.createControlRange()`

This method creates a collection of non-text elements. These are selectable items based on controls rather than text. If the `controlRange` (belonging to the `BODY` object) already exists, then it will be overwritten by the results of this method call.

See also:	`BODY.controlRange[]`

BODY.createTextRange() (Method)

Used in MSIE for creating a text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`TextRange` object	
JavaScript syntax:	IE	`myBODY.createTextRange()`

This method should only be used if the receiving object responds `true` to its `isTextEdit` property request.

See also:	`TextRange` object

BODY.leftMargin (Property)

A margin down the left edge of the document window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myBODY.leftMargin`

This property controls the amount of space down the left margin of a page. This indents all of the content away from the left edge of its containing window or frame.

This corresponds to the `style.marginLeft` property and `margin-left` stylesheet attribute.

Warnings:

- Note that the default values are platform-dependent and although it is only a couple of pixels difference it can throw off the layout of a page significantly if you make the wrong assumption.

See also:	`BODY.rightMargin`

BODY.link (Property)

The color of an as yet unvisited link in the page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.link`

This value controls the text of active links in the document body. You should use the normal color values to define the required color.

This property is equivalent to the `LINK` attribute of the `<BODY>` HTML tag. This is the color that is used for as yet unvisited links.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse.

Note also that its property name is not consistent with its counterpart, the `document.linkColor` property whose value it reflects.

See also:	`BODY.aLink`,`BODY. text`,`BODY.vLink`, Color names,Color value, `Document.alinkColor`, `Document.bgColor`, `Document.fgColor`, `Document.linkColor`, `Document.vlinkColor`, `HTML` object

BODY.noWrap (Property)

A switch to control whether text should wrap or not within the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`myBODY.noWrap`

This is a Boolean value that controls whether the textual content is wrapped at the right-hand window border or not.

If the value `false` is assigned to this property, then words will wrap as the page is drawn. This is the way you would expect a browser to behave. The text will flow according to the space available.

If the value `true` is assigned to this property, the line of text will continue to the right until a `<BR>` or other block level tag is encountered. This will force the horizontal width of the page to extremely large and the user will need to scroll furiously to be able to see the text and then scroll back again for the start of the next line.

Warnings:

- Only use this if you plan to place line breaks at frequent intervals yourself and really do need to control the line breaks manually.

BODY.recordNumber (Property)

The record within the dataset that defined the page content when the content came from a data source.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myBODY.recordNumber`

This is a property that is part of the MSIE data-binding support. It contains an integer value that is the record number within the data set that created this object.

This is useful when you are building pages with ASP and Active Data Objects (ADO).

See also:	Active Server Pages, ADO

Property attributes:

`ReadOnly`.

BODY.rightMargin (Property)

A margin space down the right hand side of the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myBODY.rightMargin`

This property controls the amount of space down the right-hand margin of a page. This indents all of the content away from the right edge of its containing window or frame.

This corresponds to the `style.marginRight` property and `margin-right` stylesheet attribute.

Warnings:

- Note that the default values are platform-dependent and, although it is only a couple of pixels difference, it can throw off the layout of a page significantly if you make the wrong assumption.

See also:	BODY.leftMargin

BODY.scroll (Property)

A switch for whether the scrollbars appear or not.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myBODY.scroll`

If this property contains "`yes`", then scrollbars will appear if the window content exceeds the size of the space available. If it is "`no`", then the scroll bars will not appear.

Although this is a switch, it is not strictly a Boolean value because it only takes the values "yes" and "no". A true Boolean value would accept only "true" or "false". This may be because the property might yield the value "auto" on some platform variants if it has been defined in the HTML tag attributes for a frame.

Warnings:

- Although the `BODY` object is not supported on Netscape Navigator, the HTML tag attribute properties that control scrollbar visibility are the same on both MSIE and Netscape Navigator.
- You should note, however, that the content of a page in Netscape Navigator cannot be scrolled unless the scrollbars are visible. Even if the content does not exceed the space available, the scroll bars will still be drawn but will be inactive. To scroll content in Netscape Navigator without scrollbars being visible, you will need to create a `<LAYER>` and scroll that.
- This leads to a further complication in that the vertical scroll value moves the content in the opposite direction in MSIE and Netscape Navigator as it is incremented.

BODY.tabIndex (Property)

An integer that represents the position of this document in the tabbing order.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`myBODY.tabIndex`

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms. Pressing the [*tab*] key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

BODY.text (Property)

The color of body text within the page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.text`

This value controls the foreground text in the document body. You should use the normal color values to define the required color.

This is the default text color for the document. It corresponds to the `TEXT` attribute in the `<BODY>` tag.

Default foreground text is colored according to this setting unless it is in an `<A>` tag when the `alinkColor`, `linkColor` and `vlinkColor` properties override it. The foreground text color can be changed inline with the `<FONT COLOR=". . .">` HTML tag attribute.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse.

Note also that its property name is not consistent with its counterpart, the `document.fgColor` property whose value it reflects.

See also:	`BODY.aLink`, `BODY.link`, `BODY.vLink`, Color names, Color value, `Document.alinkColor`, `Document.bgColor`, `Document.fgColor`, `Document.linkColor`, `Document.vlinkColor`, `HTML` object

BODY.topMargin (Property)

A margin value at the top of the document window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myBODY*`.topMargin`

Normally, you would not need to specify this property. It allows the document to have some clear space at the top so for example the content could be made to scroll completely off the screen when it is loaded.

The distance is measured in pixels and can range from zero (which is the default) to any reasonably sensible value. Making it any bigger than the screen size is pointless.

This corresponds to the `style.marginTop` property and the `margin-top` attribute that is defined in a style sheet.

Warnings:

- Note that the default values are platform-dependant and although it is only a couple of pixels difference it can throw off the layout of a page significantly if you make the wrong assumption.

See also:	`BODY.bottomMargin`

BODY.vLink (Property)

The color of visited links within the page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBODY.vLink`

This value controls the text of visited links in the document body. You should use the normal color values to define the required color.

This corresponds to the `VLINK` attribute in the `<BODY>` tag.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse.

Note also that its property name is not consistent with its counterpart, the `document.vlinkColor` property whose value it reflects.

See also:	BODY.aLink, BODY.link, BODY.text, Document.alinkColor, Document.bgColor, Document.fgColor, Document.linkColor, Document.vlinkColor, HTML object

Bookmarklets (Advice)

A means of storing fragments of JavaScript for execution as bookmarks.

Creating a `javascript:` URL with some attached JavaScript code and storing it in the bookmarks or favorites of your browser is a way of setting up some really useful debugging tools. It seems to work in most browsers, although some have a size limit on the URL that you can use.

See also:	JavaScript Bookmark URLs, JavaScript interactive URL, `javascript:` URL

Boolean (Primitive value)

A built-in primitive value.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

A Boolean value is a member of the Boolean type and may have one of two unique values, either `true` or `false`.

In some languages the values `true` and `false` also equate to numeric values. False is commonly 0 and `true` any non-zero value. In JavaScript this is not the case. The value `false` does not test equal against zero. However, a `false` Boolean value does become zero when converted to a number.

If you create a `Boolean` object and set it to the value `true`, you cannot convert it to a number with the `toNumber()` method, because this generates a run-time error. However, you can coerce the Boolean value into a numeric value by preceding it with a unary plus sign. So `+true` is a numeric primitive and yields the value 1, while `false` is converted to zero.

See also:	`false`, JavaScript to Java values, `true`

Wrox *Instant JavaScript* – page – 14

boolean (Reserved word)

Reserved for future language enhancements.

The `boolean` keyword represents both a Java data type and the native Boolean primitive data type in JavaScript. This suggests some potential extensions of JavaScript interfaces to access Java applet parameters and return values.

See also:	`java.lang.Boolean`, `LiveConnect`, Reserved word

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

Boolean (Type)

A native built-in type.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

Any object or expression that yields a result of type Boolean represents a logical entity.

Logical entities can only represent the `true` or `false` states.

These are useful as flags or conditional switches in your script.

See also:	Data Type, `false`, Fundamental data type, `true`, Type

O'Reilly *JavaScript Definitive Guide* – page – 41

Boolean literal (Primitive value)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

Boolean literals specify constant values for the `true` and `false` values used in relational expressions and are the only two values a Boolean primitive or object can resolve to.

See also:	`false`, Implicit conversion, Literal, Token, `true`

Cross-references:

ECMA 262 edition 2 – section – 7.7.2

ECMA 262 edition 3 – section – 7.8.2

Boolean object (Object/core)

An object of the class "`Boolean`".

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	`myBoolean = BooleanValue`
	-	`myBoolean = new Boolean()`
	-	`myBoolean = new Boolean(aValue)`
Argument List	`BooleanValue`	`A Boolean value (either true or false)`
	`aValue`	A value to be converted to a `Boolean` object.
Object properties:	`constructor,prototype`	
Object methods:	`toSource(),toString(),valueOf()`	

An instance of the class "`Boolean`" is created by using the `new` operator on the `Boolean()` constructor. The new object adopts the behavior of the built-in `Boolean` prototype object through the prototype-inheritance mechanisms.

All properties and methods of the prototype are available as if they were part of the new instance.

A `Boolean` object is a member of the type Object and is an instance of the built-in `Boolean` object.

Cloning the built-in `Boolean` object creates `Boolean` objects. This is done by calling the `Boolean()` constructor with the `new` operator. For example:

```
myBoolean = new Boolean(true);
```

A `Boolean` object can be coerced into a Boolean value and can be used anywhere that a Boolean value would be expected.

Programmers familiar with object-oriented techniques may be happy to use the `Boolean` object, while procedural language programmers may prefer to implement the same functionality with a Boolean value instead.

This is an example of the flexibility of JavaScript in its ability to accommodate a variety of users from different backgrounds.

The prototype for the `Boolean` prototype object is the `Object` prototype object.

See also:	`Boolean. prototype`, Native object, `Object` object, `unwatch()`, `watch()`

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	Notes
`constructor`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	2 +	-
`prototype`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	2.0 +	2 +	-

Method	JavaScript	JScript	N	IE	Opera	NES	ECMA	Notes
`toSource()`	1.3 +	-	4.06 +	-	3.0 +	-	-	-
`toString()`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	2.0 +	2 +	-

Boolean() (Constructor)

A Boolean object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Boolean` object	
JavaScript syntax:	-	`new Boolean()`
	-	`new Boolean(aValue)`
Argument list:	`aValue`	A value to be converted to a `Boolean` object.

The `Boolean()` constructor is used to manufacture new instances of the built-in `Boolean` object.

When the `Boolean()` constructor is called by the `new` operator, it initializes a brand new `Boolean` object instance.

The value of the new `Boolean` object instance is the same as the Boolean value yielded by the type conversion of the `Boolean()` constructor's parameter.

Value:	Result:
No value	Always `false`
undefined	Always `false`
null	Always `false`
Boolean	No conversion, the input value is returned unchanged
Number	The result is `false` if the argument is 0 or NaN, otherwise it is true
String	Zero length strings return `false` otherwise the result is `true`
Object	Always `true`

The result of calling the constructor is a `Boolean` object whose value is `true` or `false` depending on the input value. If the value-input parameter is omitted, then a `Boolean` object with value `false` is returned by default.

Warnings:

- Note that unlike the `Object()` constructor, which can be called without its parentheses, calling the `Boolean()` constructor without parentheses yields an uninitialized object.
- Note also that using `Boolean` objects in conditional code is prone to risks due to the fact that all objects yield a Boolean `true` value when tested in logical expressions. This includes `Boolean` objects whose present value is `false`.

Boolean() (Function)

A `Boolean` object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`Boolean()`
	-	`Boolean(aValue)`
Argument list:	`aValue`	A value to be converted to a Boolean result

When the `Boolean()` constructor is called as a function, it performs a type conversion on the value that is passed to it as a parameter.

The following results are yielded by the `Boolean()` constructor function:

Value:	Result:
No value	`false`
undefined	`false`
null	`false`
Boolean `false`	`false`
Boolean `true`	`true`
NAN	`false`
0	`false`
Non zero number	`true`
Zero length string ""	`false`
Non zero length string	`true`
Object	`true`

The result will be `true` or `false` depending on the parameter's value. If the parameter value is omitted, then `false` is returned by default.

Boolean.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition – 2

This is an internal property that describes the class that an instance of a `Boolean` object is a member of. The reserved words suggest that this property may be externalized in the future.

See also:	`Boolean.constructor`, Class

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 – section – 15.6.4

Boolean.constructor (Property)

A reference to the constructor for the boolean object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Boolean constructor`	
JavaScript syntax:	-	`myBoolean.constructor`

The constructor referenced by this property is that of the built-in `Boolean` prototype object.

You can use this referenced constructor as one way of creating `Boolean` objects, although it is more popular to use the `new Boolean()` technique. This property is especially useful if you have an object that you want to clone, but you don't know what sort of object it is. Simply use the property to access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective, so there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`Boolean.Class`, `Boolean.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.6.1

ECMA 262 edition 2 – section – 15.6.2

ECMA 262 edition 2 – section – 15.6.3

ECMA 262 edition 3 – section – 15.6.2

Boolean.prototype (Property)

The prototype for the `Boolean` object that can be used to extend the interface for all `Boolean` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Boolean` object	
JavaScript syntax:	-	`Boolean.prototype`
	-	`myBoolean.constructor.prototype`

The initial value of the prototype of a `Boolean` object is the built-in `Boolean` prototype object.

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the output capabilities of Boolean objects
function yesNo()
{
if(this == true)
{
return "The switch is ON";
}
else
{
return "The switch is OFF";
}
}
// Register the new function
Boolean.prototype.yesNo = yesNo;
```

```
// Create a Boolean object and test the Boolean.yesNo() method
myBoolean = new Boolean(true);
document.write(myBoolean.yesNo())
document.write("<BR>")
myBoolean = !myBoolean;
document.write(myBoolean.yesNo())
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Boolean` object,`Boolean.constructor`,`Boolean.toSource()`, `Boolean.toString()`,`Boolean.valueOf()`,`prototype` property, Boolean.prototype

Cross-references:

Boolean.toSource() (Method)

Returns a `Boolean` object formatted as a Boolean literal contained in a string.

Availability:	JavaScript – 1.3 Netscape – 4.06 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`myBoolean.toSource()`

This is an alternative way to retrieve a string version of a Boolean value. In this case, it is formatted as a Boolean literal and can then be used in an `eval()` function to assign another Boolean.

If you run the example below, it should yield this as a result:

```
(new Boolean(true))
```

However, you should note that this is not supported by MSIE browsers.

The result of calling this method is a string version of the Boolean formatted as a Boolean literal.

Example code:

```
// Create a boolean and then examine its source
myBoolean = new Boolean(true);
document.write(myBoolean.toSource());
```

See also:	`Boolean.prototype`,`Boolean.toString()`

Boolean.toString() (Method)

Returns a string primitive version of an object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBoolean.toString()`

The value of the object is converted to a string that represents its Boolean value.

See also:	`Boolean.prototype`, `Boolean.toSource()`, `Cast` operator, `toString()`

Cross-references:

ECMA 262 edition 2 – section – 15.6.4.2

ECMA 262 edition 3 – section – 15.6.4.2

Boolean.valueOf() (Method)

Returns the primitive value of the Boolean object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`myBoolean.valueOf()`

The `Boolean` object is converted to a Boolean primitive and returned to the caller.

See also:	`Boolean.prototype`, `Cast` operator, `valueOf()`

Cross-references:

ECMA 262 edition 2 – section – 15.6.4.3

ECMA 262 edition 3 – section – 15.6.4.3

BR object (Object/HTML)

An object that represents the `<BR>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	`myBR = myDocument.all.anElementID`
	IE	`myBR = myDocument.all.tags("BR") [anIndex]`
	IE	`myBR = myDocument.all[aName]`
	-	`myBR = myDocument.getElementById (anElementID)`
	-	`myBR = myDocument.getElementsByName (aName)[anIndex]`
	-	`myBR = myDocument.getElementsByTagName ("BR")[anIndex]`
HTML syntax:	` `	
Argument list:	`anIndex`	A valid index reference to an item in the collection
	`aName`	The `name` attribute of an element
	`anElementID`	The `ID` attribute of an element
Object properties:	`clear`	
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`	

This object represents a line break in the text. There are very few appearance-modifying properties you could apply to such an object.

The `<BR>` tag is a block-level tag. That means that it forces a line break before and after itself.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`clear`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

BR.clear (Property)

An property that controls how the browser treats the following paragraph alignment.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBR.clear`

The value of this property controls the way that text flows around inline images and other block-level objects. How this works will depend on how the object is fixed to either the left or right page border.

This property can contain any of the following values, or may simply contain an empty string:

- `all`
- `left`
- `right`

Additional accessor methods are defined in the DOM standard, but are yet to be implemented. Since this property is read/write accessible, they are largely unnecessary.

Braces { } (Delimiter)

A delimiting token for a block of executable script.

Availability:	ECMAScript edition – 2
See also:	`if( ... ) ...`,`if( ... ) ... else ...`, Code block delimiter {}

break (Statement)

Exit unconditionally from a loop or switch.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	`break aLabelName;`
	-	`break;`
Argument list:	`aLabelName`	The name of a label associated with some code

The `break` keyword is a 'jump' statement. It is used in an loop to abort the current cycle and exit from the smallest enclosing loop immediately. Execution continues at the line following the statement block associated with the loop.

A break statement can only legally exist inside a `while` or `for` loop in an ECMA-compliant implementation. Implementations that provide additional iterator types may also honor the same behavior for the `break` statement.

The `break` statement would normally be executed conditionally, otherwise it would cause the remaining lines in the loop to be redundant, since no execution flow would ever reach them. Compilers generally warn you about this, but JavaScript would simply ignore it.

At version 1.2 of JavaScript, the `break` statement was enhanced to support a label as a breaking destination. When the break is processed, it will jump to the end of the statement that has been labeled. If an iterator is labeled, then the break is associated with that iterator. This mechanism works like a 'goto'. It can work with an `if` block and with a labeled block of brace delimited code.

Wrox *Instant JavaScript* – page – 25

Broken-down time (Definition)

Time disassembled into component parts, for example hours or minutes.

Broken-down time is handled with a time structure in the C language. Breaking down a time value in that context can require several lines of code. However, JavaScript provides the `Date` object class, which supports methods for accessing the separate time and date components.

The following time components are available:

- Year number
- Month in year
- Date within month
- Day of week
- Hour within day
- Minute within hour
- Second within minute
- Millisecond within second
- Time of day in milliseconds

These values are available measured in either local time or UTC time.

There are also facilities to convert back and forth between local time and UTC time.

Document

Browser detection (Advice)

Browser detection techniques require some review in the light of recent browser upgrades.

Browser-detection techniques have been in use ever since the MSIE version 3 browser was launched. Since the features of this browser differed from others, it became necessary to determine what browser was being used to establish the features actually available.

The subject of browser detection is now extremely complex, with a wide variety of browsers. The technique of simply distinguishing between Netscape and MSIE is no longer sufficient. This is even more of an issue now that Netscape version 6.0 is shipping.

This Netscape version 6.0 browser was developed around a completely new source code base. Having started completely afresh, Netscape has not implemented any unnecessary legacy features and instead has pursued a strictly standards based approach. The most noticeable effect of this is the complete lack of support for layers.

The reason why this is such a big problem is that in the past we might typically have written a short script to determine whether we were running Netscape or MSIE, and coded accordingly. The first example shows how we would have done this using a classical detection technique.

However, now we have millions of web pages using this technique that also use layers. They will detect Netscape 6.0 and return a value saying "OK it's Netscape, so use the Netscape layers code alternative". This is going to break a lot of pages.

We now need something that tells us whether a particular feature is available rather than a particular browser. The second example is a skeleton of how we might do that. It adds a member object called `isAvailable` to the global object, that can have additional properties added as we need to extend it. In this example, it simply provides access to whether layers are available or not. It provides for three possible cases:

- `NO` – Layers are not available and no alternative simulation is possible
- `DIV` – Layers are not available, use `<DIV>` blocks and CSS positioning
- `YES` – Layers are available

So now we can build some code to exploit this using a `switch` statement thus:

```
isAvailable();
switch(isAvailable.Layers)
{
   case "YES" :
// Call the layer programmed version of our page
      break;
   case "DIV" :
// Call the <DIV> simulated layers version of the page
```

```
      break;
   case "NO" :
// Fall back to the legacy browser, no layers page
      break;
   default:
// Unexpected condition handled here
      break;
}
```

Because we need to know what browser and version the code is being run on to determine simulation capabilities, those get set as member properties of the `isAvailable` object.

Later you could add capabilities to access the DOM feature-detection mechanisms so that all these related feature-detection facilities are in a single reusable code block.

Note that the `appVersion` value picks up the Mozilla/X.YY value and uses that. This means that MSIE 5 reports an `appVersion` of 4 and Netscape version 6.0 reports an `appVersion` of 5, which is odd to say the least. You can do a bit more work to parse out the correct version numbers from the remainder of the user agent string or access special values that are platform dependant within a fragment of code that is selected on a per platform basis.

Example code:

```
<SCRIPT>
// Classic browser detection returning browser types
// and versions
function getBrowserType()
{
var myUserAgent;
var myMajor;
myUserAgent   = navigator.userAgent.toLowerCase();
myMajor       = parseInt(navigator.appVersion);
if( (myUserAgent.indexOf('mozilla')    != -1) &&
(myUserAgent.indexOf('spoofer')    == -1) &&
(myUserAgent.indexOf('compatible') == -1) &&
(myUserAgent.indexOf('opera')      == -1) &&
(myUserAgent.indexOf('webtv')      == -1)
)
{
if (myMajor > 4)
{
return "nav6";
}
if (myMajor > 3)
{
return "nav4";
}
return "nav";
}
if (myUserAgent.indexOf("msie") != -1)
{
if (myMajor > 4)
{
return "ie5";
}
if (myMajor > 3)
{
return "ie4";
}
return "ie";
}
return "other";
}
```

```
</SCRIPT>

<SCRIPT>
isAvailable();
document.write("Browser family : "  + isAvailable.Browser + "<BR>");
document.write("Browser version : " + isAvailable.Version + "<BR>");
document.write("Layer support : "   + isAvailable.Layers  + "<BR>");
// Modern extensible browser feature detection
// Becomes a member property of the global object
function isAvailable()
{
// Get user agent stuff
var myUserAgent   = navigator.userAgent.toLowerCase();

// Set initial conditions
isAvailable.Browser = "OTHER";
// Check for navigator
if( (myUserAgent.indexOf('mozilla')    != -1) &&
(myUserAgent.indexOf('spoofer')    == -1) &&
(myUserAgent.indexOf('compatible') == -1) &&
(myUserAgent.indexOf('opera')      == -1) &&
(myUserAgent.indexOf('webtv')      == -1)
)
{
isAvailable.Browser = "NAV";
}
// Check for MSIE
if (myUserAgent.indexOf("msie") != -1)
{
isAvailable.Browser = "MSIE";
}
// Store major version number from leading Moziilla/X.YY
// Portion of user agent string
isAvailable.Version = parseInt(navigator.appVersion);

// Work out if layers available
if(document.layers)
{
isAvailable.Layers = "YES";
}
else
{
if((isAvailable.Browser = "MSIE") && (isAvailable.Version > 3) ||
(isAvailable.Browser = "NAV")  && (isAvailable.Version > 4))
{
isAvailable.Layers = "DIV";
}
else
{
isAvailable.Layers = "NO";
}
}
}
// For further investigation look at the MSIE script engine version and build
number properties and map them to features.
</SCRIPT>
```

Browser version compatibility (Advice)

Browser upgrades are not always upwardly compatible.

It is fairly obvious that as browsers are improved, new features will be added. This suggests that you might upgrade and begin to exploit those new features. At the next browser upgrade, these features should still be available, while yet more are introduced. This is called upwards compatibility. This is generally no problem.

Downwards compatibility, where code using features in a later browser does not cause errors in an earlier browser, is a little more difficult to provide. HTML has good downwards compatibility due mainly to the fact that if a tag is unrecognized, it is simply ignored. That means web pages containing new features simply display any contained text inside the unrecognized block as if the unsupported tag did not exist.

This may be easy to manage with HTML, but is not feasible with a scripting language because you can't expect the browser simply not to execute a line of script. However, you can code defensively in such a way that your scripts may be downwards compatible.

To code defensively means to check for the existence of a feature before using it, and also to check that objects are defined before trying to modify their properties. You can check the version of the browser and switch various features of your scripts on and off accordingly.

With a little thought and planning, you can design your script so that it degrades graceful if it is run on less capable browser versions than that for which you originally designed it.

The differences between browsers are now so complex and so diverse that it is difficult to encompass them all in a single reference source. This book is structured to allow it to be revised on a component-by-component basis so that where browsers differ from one another, the granularity of the book is approximately the same and can track those differences as they become known.

The differences between the browsers may change in very subtle ways even with minor browser version changes. We concentrate on the differences between major versions and use annotations to cover important differences between minor browser versions.

Any feedback or observations you care to submit will be welcomed, tested, and added to the future editions of the book.

Good workaround techniques involve innovative use of scripts to create your own properties and methods to emulate missing functionality. For example, the `window.opener` property is not available on all versions of Netscape. You could create a property of your own that refers to the parent window when a new window object is created. If that property is always present and created under script control, then you can use that property rather than the one that may or may not be present in the built-in object model. This is generally more robust, but may not exploit the very latest features of the available browsers.

See also:	Compatibility, `Date` object, Defensive coding, Internet Explorer, `Window.opener`

Browser wars (Definition)

The contest between browser manufacturers to gain dominance in the market.

As this is being written, it is clear that Microsoft has won the war of the browsers – for now at least. The Netscape browser has lost market share, to the extent that it is fast becoming a minority browser.

This poses an interesting situation, in that Microsoft has sufficient market share that it can perhaps reduce the effort that it puts into browser support.

Actually, it is at such a time that it should put even more resources into it. That is because, now that it is so dominant, it should be obliged to make sure its browser is supported identically on every platform it is available on, and make it available on any remaining platforms.

Whether it will do this is open to question as it could detract from its dominance of the operating system marketplace.

This conflict of interests is potentially damaging for the end-user and the web developer.

Right at this moment, there is a significant proportion of the feature set in MSIE that is not supported on platforms other than Windows.

Granted, it is acceptable that COM and ActiveX cannot easily be provided on non-Windows platforms, but the CSS support should be identical, as should the integration with clipboards and other parts of the OS where it is possible.

Netscape 6.0 has just been released in its final form as this is being written. The new version is so radically different as to classify it as being a different browser. Its internal document model follows the DOM specification very closely. Netscape had adhered to the DOM specified class names where Microsoft has not, even though it has constructed a DOM representative object model in the browser.

Maybe Netscape can win back some proportion of the users it has lost to Microsoft in the last few years. However, there is still much to be done to correct some shortcomings in the released quality of the new Netscape browser.

btoa() (Method)

Used to encode some data into base-64 form.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`btoa(aBinaryString)`
	N	`myWindow.btoa(aBinaryString)`
Argument list:	`aBinaryString`	A string of binary data to be encoded

See also:	`Window.atob(),Window.btoa()`

Built-in function (Definition)

Functions that are part of the core JavaScript implementation.

Availability:	ECMAScript edition – 2

Built-in functions are implemented as `Function` objects.

Examples of built-in functions are `parseInt()` and `Math.exp()`. These are functions provided by the `Global` object and the `Math` object respectively. They may be referred to as built-in methods in some documentation.

None of the built-in functions implement the internal `Construct()` method and therefore they cannot be used with the new operator to create another instantiation.

Generally, none of the built-in functions will have a `prototype` property, but since they cannot be instantiated this should not cause any problems.

Built-in function objects have a `length` property whose value is an integer. This generally indicates the number of arguments the function expects to be supplied with. Sometimes functions may be supplied with optional arguments. The length value returns the maximum number of arguments that are expected. The `length` property of a built-in function has the `ReadOnly`, `DontDelete` and `DontEnum` attributes set for it.

Generally, all the other properties of a built-in function have the `DontEnum` attribute set.

See also:	`Function` object,Native object

ECMA 262 edition 3 – section – 15

Built-in method (Definition)

Object methods that are provided as part of the base JavaScript implementation.

Refer to:

Built-in function

Built-in object (Definition)

Objects that are part of the core JavaScript implementation.

Availability:	ECMAScript edition – 2

A built-in object is provided by the core interpreter independently of the host environment.

Built-in objects are available at the outset of script execution and do not need to be created. They are all native objects. Additional built-in objects may be added by the implementation over and above those specified by the core functionality in the language specification.

See also:	Native object

ECMA 262 edition 2 – section – 4.3.7

ECMA 262 edition 3 – section – 4.3.7

Button object (Object/DOM)

An object representing an `<INPUT TYPE="button">` HTML button in a form.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Inherits from:	`Input` object	
JavaScript syntax:	-	`myButton = myDocument.aFormName.anElementName`
	-	`myButton = myDocument.aFormName.elements [anItemIndex]`
	IE	`myButton = myDocument.all.anElementID`
	IE	`myButton = myDocument.all.tags("INPUT") [anIndex]`
	IE	`myButton = myDocument.all[aName]`
	-	`myButton = myDocument.forms[aFormIndex]. anElementName`
	-	`myButton = myDocument.forms[aFormIndex]. elements[anItemIndex]`
	-	`myButton = myDocument.getElementById (anElementID)`
	-	`myButton = myDocument.getElementsByName (aName)[anIndex]`
	-	`myButton = myDocument.getElementsByTagName ("INPUT")[anIndex]`
HTML syntax:	`<INPUT TYPE="button">`	
Argument list:	`anItemIndex`	A valid reference to an item in the collection
	`aName`	The `name` attribute of an element
	`anElementID`	The `ID` attribute of an element
	`aFormIndex`	A reference to a single form in the `forms` collection
	`anIndex`	A valid reference to an item in the collection
Object properties:	`type`, `value`	
Object methods:	`handleEvent()`	
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`,`onBlur`, `onClick`, `onDblClick`, `onErrorUpdate`, `onFilterChange`, `onFocus`,`onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onRowEnter`, `onRowExit`	

Many properties, methods and event handlers for this object are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

There isn't really a `Button` object class in Netscape, but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a button. In actual fact, the object is represented as an item of the `Input` object class.

In MSIE, there is a special `BUTTON` class that is used to represent a `<BUTTON>` tag. It is documented separately in its own topics. The `Button` object is the correct spelling for a DOM level 1 compliant implementation.

Event handling support via properties containing function objects was added to `Button` objects at version 1.1 of JavaScript.

Warnings:

- Note that on MSIE, `Input` objects are actually `INPUT` objects, because MSIE follows a general rule of naming object classes after the capitalized name of the HTML tag that instantiates them. However, in some special cases, MSIE creates other object types. For buttons, it uses the `BUTTON` class.
- Netscape does not support the `defaultValue` property for this sub-class of the `Input` object.

See also:	`Element` object, `Element.isTextEdit`, `Form.elements[]`, `FormElement` object, `Input` object, `Input.accessKey`, `onClick`, `TextRange` object

`onRowEnter`	-	3.0 +	-	4.0 +	-	-	-	-
`onRowExit`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Input` object, `Node` object

Button.handleEvent() (Method)

Passes an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`myResetButton.handleEvent (anEvent)`
Argument list:	`anEvent`	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent()`

Button.type (Property)

The type value for the object.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myButton.type`
HTML syntax:	`<INPUT TYPE="button">`	

The value of this property will be "`button`" when the `<INPUT>` HTML tag describes a form `Button` object.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

Button.value (Property)

The text string displayed in the button.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myButton.value`

The value of a button is also used to place a legend into the button image on screen.

Warnings:

- This property may be changed on some platforms, but not others.

See also:	`Input.value`

BUTTON object (Object/HTML)

An object that represents a special MSIE `<BUTTON>` element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myBUTTON = myDocument.all.anElementID`
	IE	`myBUTTON = myDocument.all.tags("BUTTON") [anIndex]`
	IE	`myBUTTON = myDocument.all[aName]`
	-	`myBUTTON = myDocument.getElementById (anElementID)`
	-	`myBUTTON = myDocument.getElementsByName (aName)[anIndex]`
	-	`myBUTTON = myDocument.getElementsByTagName ("BUTTON")[anIndex]`
HTML syntax:	`<BUTTON> ... </BUTTON>`	
Argument list:	`anIndex`	A valid reference to an item in the collection
	`aName`	The `NAME` attribute of an element
	`anElementID`	The `ID` attribute of an element
Object properties:	`accept`, `accessKey`, `alt`, `dataFld`, `dataFormatAs`, `dataSrc`, `form`,`name`, `status`, `tabIndex`, `type`, `value`	
Object methods:	`createTextRange()`	
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onBlur`, `onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onResize`,`onRowEnter`, `onRowExit`,`onSelectStart`	

This is an additional kind of button object, over and above that provided for the `<INPUT TYPE="Button">` tag.

Warnings:

- This object is not the same as a `Button` object, which is a convenience class that is really instantiated as an `Input` object. Netscape only supports `Button` (Input) objects and does not support `BUTTON` objects. MSIE supports both. The properties of each type of button object are different.

See also:	`Element` object, `Element.isTextEdit`, `Form.elements[]`, `FormElement` object,`Input` object, `Input.accessKey`, `onClick`,`TextRange` object

Inheritance chain:

Element object, Node object

BUTTON.accept (Property)

Defines an acceptable MIME type to be submitted to the server. Not supposed to be supported by the BUTTON class.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	myBUTTON.accept

Refer to the MIME types topic for a list of MIME types to use in this property.

Warnings:

- This property is inherited, but is not applicable to a BUTTON object.

See also:	MIME types

BUTTON.alt (Property)

The tool-tip text for the BUTTON object.

Availability:	JScript – 1.0 Internet Explorer – 3.02	
Property/method value type:	String primitive	
JavaScript syntax:	IE	myBUTTON.alt

Objects can have an alternative text string associated with them. This is especially useful on browsers that cannot cope with the tag, in which case they may display the alternative text. If spoken styles are supported, the text may be read out to the user. Some browsers will also display the text as a tool-tip if the mouse is positioned over the object and remains static for a few seconds.

BUTTON.name (Property)

This corresponds to the NAME attribute of the <BUTTON> HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	myBUTTON.name

Objects are identified either by the `NAME` tag attribute or by the `ID` tag attribute. MSIE seems slightly better disposed towards the `ID` attribute than earlier versions of Netscape. However, in many cases, both browsers support either technique and in some cases will locate items named with either attribute as if they existed in a single namespace. Version 6.0 of Netscape may restore parity with MSIE in this respect.

See also:	`Input.name`

BUTTON.type (Property)

The type of this `BUTTON` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBUTTON.type`

The property should contain one of the following values:

- `button`
- `reset`
- `submit`

See also:	`Input.type`

Property attributes:

`ReadOnly`.

BUTTON.value (Property)

The value of this `BUTTON` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myBUTTON.value`

The value of a button is also used to place a legend into the button image on screen.

See also:	`Input.value`

By reference (Definition)

A means of passing data to functions, methods, and property accessors.

Passing a value by reference means that you pass a pointer to the data value. This means that when you copy the reference to another variable, you then have two variables pointing at the same data.

The data for both is identical. Modifying the data value pointed at by one, changes the value for the other variable also.

Non-primitive values (Objects) are passed in this manner.

Note that although JavaScript has a good pass-by-reference technique built-in to the implementation, it does not support pointers as a specific data type as the C language does.

Passing a value by reference into a function allows the function to make changes that are visible outside the function.

In JavaScript, you cannot manipulate these parameter passing mechanisms. It will choose to pass by value or by reference according to the data type of the value being put into the argument. This is often the result of evaluating an expression. JavaScript takes care of all the type conversions for you.

By value (Definition)

A means of passing data to functions, methods, and property accessors.

Passing data by value means that the data itself is stored in the variable. Assigning one variable to another copies the value.

Changing the value in one variable leaves the other unaffected.

Non-object values (primitives) are generally passed in this manner.

Passing data by value to a function means that the function cannot affect the value outside the function since it only has a copy of the value to work on.

In JavaScript, you cannot manipulate these parameter passing mechanisms. It will choose to pass by value or by reference according to the data type of the value being put into the argument. This is often the result of evaluating an expression. JavaScript takes care of all the type conversions for you.

byte (Reserved word)

Reserved for future language enhancements.

A byte is a set of 8 adjacent binary digits (bits). It is big enough to hold an 8 bit character code, which will support the subset of 16 bit Unicode characters that most JavaScript users are likely to need, at least for developing scripts for use with the English language.

The least significant bit is called the low-order bit and the most significant bit is called the high-order bit. These do not necessarily map one to one to the bits stored in the memory of the computer, which may be big-endian or little-endian. This is thankfully hidden from the JavaScript programmer who will need to operate on a standardized IEEE-754 bit pattern when working with binary values stored in Numeric primitive values.

The fact that the ECMAScript standard (edition 2) reserves this word for future use, suggests that some byte level support is expected to be added to the language at some time in the future.

This keyword also represents a Java data type and the `byte` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

ECMA 262 edition 3 – section – 7.5.3

Calendar time (Definition)

Time values measured according to the Gregorian calendar.

Time values are one of the areas of least portability between languages and systems. Although many languages make a brave attempt to provide portable facilities, it is rarely indeed that you will find two systems that can sensibly exchange the binary or internal time values.

You can transfer time values between systems but you'll need to do it like this. First, you will need to convert from internal time values to some textual representation that can then be scanned and parsed back into an internal value on the other system. Then transmit the string to the other end and invoke some local processing there to convert the time value back in its internal form.

There are a variety of names for this internal time value, one of which is Calendar time.

See also:	Broken down time, Date and time, `Date` object, Daylight savings time adjustment, Local time, Time range, Time value, Universal coordinated time

Call (Function/internal)

An internal mechanism for executing function calls.

Availability:	ECMAScript edition –2

This is the internal mechanism by which functions are implemented.

Objects supporting this method are called functions.

When they are called, they add themselves to the scope chain and any variables subsequently declared are added to that scope. Hence local objects belong to the function being executed.

Another name for the function being executed is the `call` object.

Warnings:

- The `Global` object does not have a `Call` property and therefore you cannot use it as a function.

See also:	`Function` property, Internal Method, `JSObject.call()`

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 – section – 8.6.2

ECMA 262 edition 3 – section – 8.6.2

Call a function (Definition)

To invoke a function during script execution.

See also:	Call by reference, Call by value, `JSObject.call()`, Function call

Call by reference (Definition)

Calling functions and passing references to receiving LValues in the arguments.

If you want to modify a value that is passed to a function, you need to pass a reference to it. Normally you would depend on a function returning a single value.

You can do this by creating an object, passing the object but mutating the values of the object's properties. This bridges the scope chain because the locally scoped copy refers to the outer scoped LValue.

This is demonstrated in the example.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myObject = new Object();
myObject.myVar = 22;
callMe(myObject);
```

```
document.write("<BR>");
document.write(myObject.myVar);
function callMe(aValue)
{
   document.write(aValue.myVar);
   document.write("<BR>");
   aValue.myVar = 100;
   document.write(aValue.myVar);
}
</SCRIPT>
</BODY>
</HTML>
```

Call by value (Definition)

Calling functions and passing values in the arguments.

When you call by value, you are passing an immutable constant to a function. The function will create a copy locally and that copy will be accessible in a locally scoped variable having the name of the formal parameter.

However, on exit the local value is discarded leaving the original unchanged. It doesn't matter whether you pass a literal constant value or a variable containing a value. This is easier to understand if you already have a good grasp of the scope chain mechanism.

The example demonstrates this.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myVar = 22;
callMe(myVar);
document.write("<BR>");
document.write(myVar);
function callMe(aValue)
{
   document.write(aValue);
   document.write("<BR>");
   aValue = 100;
   document.write(aValue);
}
</SCRIPT>
</BODY>
</HTML>
```

See also: Scope chain

Call object (Object/internal)

The currently executing function is a `call` object.

Availability:	ECMAScript edition – 2
See also:	`Arguments` object, Function scope, `Function.arguments[]`, `JSObject.call()`,`Call`

Cross-references:

ECMA 262 edition 2 – section – 8.6.2

ECMA 262 edition 3 – section – 8.6.2

Call-back event (Definition)

A mechanism for creating frameworks that call user-supplied functions.

See also:	Event, `JSObject.call()`, Plugin events, Event handler

Calling event handlers (Definition)

Event handlers can be called in many different ways.

If you implement an event handler as a function, then you can call it from other functions as needed. For example, we can build a form validator and associate it with the `onSubmit` event for the form.

We might want to invoke that validator when something else changes on the page or as a result of the user clicking on various buttons. Because the submission is still handled by the browser, invoking the form validation event handler won't submit the form unless it is called as a result an `onSubmit` event being triggered.

The form only gets submitted to the server if the form validator returns the correct Boolean flag value when it is invoked in response to an `onSubmit` trigger event.

There is another way to submit the form's contents. That is by calling the `submit()` method belonging to a `Form` object. That doesn't trigger an `onSubmit` event if it is called within the context of an `onSubmit` event handler. You could use this technique if you wanted the form contents to be submitted by some action other than clicking on a submit button.

See also:	Event handler, Event handler properties, Function call

CanPut() (Function/internal)

Internal private function.

Availability:	ECMAScript edition – 2

This internal function returns a Boolean value to indicate whether the named property can be changed in the containing object.

If the property is found, the value of its `ReadOnly` attribute is checked. If it has a `ReadOnly` attribute, the result of `CanPut()` must be `false`. Otherwise, having found the property, the `true` result will be returned.

If the property does not exist in the receiving object, the prototype chain is walked until the property or a null prototype is encountered. At each inheritance level, the `CanPut()` function is used to determine the existence of the property.

If a null prototype is encountered, the result will be `true`, since the property can then be created in the original receiving object.

If the prototype is a `host` object that does not implement the `CanPut()` function, then `false` is returned as a result.

Because the prototype chain is walked extensively by the `CanPut()` function, if the prototype chain is not finite and terminated with a null at some stage, a recursive loop is built and the function never returns.

See also:	Internal Method

Property attributes:

`Internal`.

ECMA 262 edition 2 – section – 8.6.2.3

ECMA 262 edition 3 – section – 8.6.2.3

CAPTION object (Object/HTML)

An object that represents the `<CAPTION>` HTML tag, which is used inside a `<TABLE>`.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Inherits from:	`Element` object

JavaScript syntax:	IE	*myCAPTION* = *myDocument*.all.*anElementID*
	IE	*myCAPTION* = *myDocument*.all.tags("CAPTION")[*anIndex*]
	IE	*myCAPTION* = *myDocument*.all[*aName*]
	-	*myCAPTION* = *myDocument*.getElementById(*anElementID*)
	-	*myCAPTION* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCAPTION* = *myDocument*.getElementsByTagName("CAPTION") [*anIndex*]
HTML syntax:	<CAPTION> ... </CAPTION>	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The *name* attribute of an element
	anElementID	The *ID* attribute of an element
Object properties:	align, vAlign, align, vAlign	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDblClick, onDragStart, onErrorUpdate, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onScroll, onSelect, onSelectStart	

The caption forms an integral part of the table to which it belongs. It needs to be defined inside the <TABLE> tags.

The DOM level 1 standard describes these objects as TableCaptionElement objects.

See also:	Element object, style.captionSide, TABLE object, TABLE.caption, TABLE.createCaption(), TABLE.deleteCaption()

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

CAPTION.align (Property)

The horizontal alignment of the caption with respect to its parent table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCAPTION*.align

The alignment of the `CAPTION` object with respect to its containing parent table object is defined in this property. The expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`

- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

These may not all be supported by all browsers.

Note also that this property is deprecated in favor of using style properties such as `textAlign` and `verticalAlign`, which correspond to the style sheet attributes `text-align` and `vertical-align`.

Warnings:

- Browsers may not always render the caption identically. The left and right values in particular are rendered differently between MSIE and Netscape. MSIE draws the caption at the top and bottom but takes the left and right as a justification control. Netscape places the caption to the left or right of the table.
- Currently MSIE transgresses the rules laid down by the HTML 4.0 standard.

See also:	`style.captionSide`, `style.textAlign`, `style.verticalAlign`

CAPTION.vAlign (Property)

The vertical alignment of a caption with respect to its parent table.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myCAPTION*`.vAlign`

This is only supported by MSIE and is intended to provide for alignment correction, which the `align` property handles incorrectly with respect to the HTML 4.0 standard.

This property is basically supported for backwards compatibility.

The `vAlign` property may be set to these values:

- `bottom`
- `top`

Warnings:

- It is probably wise to use the `<CAPTION>` tag with discretion and care. You should probably do some cross-browser testing to ensure its placement is what you intended.

See also:	`style.captionSide`

captureEvents() (Function)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`captureEvents(`*`anEventMask`*`)`
	N	*`myObject`*`.captureEvents(`*`anEventMask`*`)`
	N	*`myWindow`*`.captureEvents(`*`anEventMask`*`)`
Argument list:	*`anEventMask`*	A mask constructed with the manifest event constants

Warnings:

- Since a bit mask is being used, this must be an int32 value. This suggests that there can only be 32 different event types supported by this event propagation model.
- This capability is deprecated and is not supported in Netscape 6.0 any more. It never was supported by MSIE, which implements a completely different event model. As it turns out, the DOM level 2 event model converges on the MSIE technique.

See also:	`Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event handler, Event management, Event propagation, Event type constants, `Frame` object, `handleEvent()`, Keyboard events, `Layer.captureEvents()`, `Layer.releaseEvents()`, `onLoseCapture`, `onMouseMove`, `Window` object, `Window.captureEvents()`, `Window.releaseEvents()`, `Window.routeEvent()`

Case Sensitivity (Definition)

Upper and lower case are not identical when used in identifiers.

Availability:	ECMAScript edition – 2

Identifiers in JavaScript are case-sensitive.

This means that, for example, variables will refer to distinctly different values if they differ in the case of any part of their names. Hence `aaa` is not the same variable as `Aaa`.

MSIE browsers prior to version 4 were less particular about case-sensitivity. Since the ECMA standard requires strict case-sensitive behavior, this is now the norm.

Some early versions of the WebTV set top box prior to the Summer 2000 release also lacked case-sensitive behavior regarding built-in method and property names.

Warnings:

- In MSIE version 3, all client-side object and property names were case-insensitive. Beware of any old scripts, which may have worked on MSIE version 3, but don't work on later browsers.

- JavaScript style sheets in Netscape 4 are also case-insensitive.

ECMA 262 edition 3 – section – 7.6

O'Reilly *JavaScript Definitive Guide* – page – 27

Cast operator (Definition)

A way of converting data types.

Primitive values can be converted from one type to another or rendered as objects by using object constructors to convert the values.

Type Name:	Description:
Aggregate	A collection of atomic types assembled collectively into an object.
Arithmetic	All types that yield a value that can be operated on numerically.
Array	Collections of objects and identifiers assembled into a sequence.
Basic	The fundamental simple, non-object types.
Boolean	This type can store and yield true or false values.
Completion	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
List	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Null	This has exactly one value, null, and is distinct from undefined.
Number	Integer and floating-point values are all stored in a generic number type.
Object	An object is an unordered collection of properties. Each property consists of a name, a value, and a set of attributes.
Reference	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Scalar	The non-object types.
String	Strings are arrays of characters that are accessible individually by indexing their position in the sequence.
Undefined	This value is returned by variables that have not yet been assigned a value.

In compiled languages, this is called casting. In JavaScript the values are actually converted using methods and function calls on the objects. This yields a new value rather than making the old one look like the new type that is required. It is really conversion rather than casting.

See also:	Aggregate type, Array simulation, Escape sequence (\), `escape()`, `MakeDate()`, `MakeDay()`, `MakeTime()`, Native object, null, Operator Precedence, Primitive value, `unescape()`

catch(...) (Function)

Part of the `try ... catch ...finally` error-handling mechanism.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	`catch(`*`anError`*`)`
Argument list:	*`anError`*	An instance of the error object

The ECMAScript standard (edition 2) defined the `catch` keyword and reserves it for future use. Edition 3 mandates that this should now be supported in a compliant interpreter.

In anticipation of that, it is available in JavaScript version 1.4. This is also now supported in JScript version 5.0 as well.

Refer to the `try ... catch ... finally` topic for more details.

See also:	`Error` object, `EvalError` object, Exception handling, `finally ...`, `RangeError` object, `ReferenceError` object, `SyntaxError` object, `throw`, `try ... catch ... finally`, `TypeError` object, `URIError` object

Cross-references:

ECMA 262 edition 3 – section – 12.14

Category of an object (Definition)

Why we categorize topics the way we do.

Objects, properties and methods fall into many categories. It helps to understand why an item is available and what it does if you can map it into a particular context. Here is a summary of the different categories we use:

Category:	Description:
Browser	Language elements that are really only useful on the browser side.
Core	Language elements that form part of the core of the language.
Desktop	Language facilities provided to aid desktop automation.

Table continued on following page

Category:	Description:
Embedded	Language facilities particularly intended for use in embedded interpreters.
Generic	Topics that discuss something that could be used server-side or client-side are categorized as generic. Properties and objects may be defined server-side and deployed client-side.
Microsoft	There are many proprietary additions by Microsoft. These are the particularly noteworthy items and are generally non-portable.
Server	Language elements that are really only useful on the server side.
Shell	Language facilities that are added for use in shell scripts.

CDATASection object (Object/DOM)

Part of the extended interface that DOM describes for supporting non-HTML content.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Inherits from:	`textNode` object
JavaScript syntax:	- *myCDATASection* = *myDocument*.createCDATASection(*someData*)
Argument list:	*someData* — The data content for the new object

The extended interface supports various document forms other than HTML. This object is used to encapsulate marked up XML without needing to escape all of the markup characters.

You can test for the availability of this feature by means of the `Implementation.hasFeature()` method. In this case, test for a feature name of "`XML`" and a version value of "`1.0`"

See also:	`Document.createCDATASection()`

Inheritance chain:

`CharacterData` object, `Node` object, `textNode` object

CENTER object (Object/HTML)

An object that represents the `<CENTER>` HTML tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Inherits from:	`Element` object

JavaScript syntax:	IE	*myCENTER* = *myDocument*.all.*anElementID*
	IE	*myCENTER* = *myDocument*.all.tags("CENTER")[*anIndex*]
	IE	*myCENTER* = *myDocument*.all[*aName*]
	-	*myCENTER* = *myDocument*.getElementById(*anElementID*)
	-	*myCENTER* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCENTER* = *myDocument*.getElementsByTagName ("CENTER")[*anIndex*]
HTML syntax:	<CENTER> ... </CENTER>	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The *name* attribute of an element
	anElementID	The *ID* attribute of an element
Object methods:	removeAttribute()	
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

Method	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
removeAttribute(0	-	3.0 +	-	4.0 +	-	-	-	-

File extensions

CGI-Driven JavaScript (Definition)

Using JavaScript in the request - response loop of a web server.

You can use JavaScript to generate the response to a web browser's incoming requests at the web server.

This is a useful and powerful way to extend the CGI capabilities of your web server. Forms handling with products such as ScriptEase WSE (Web Server Edition) are streamlined due to the interpreter having additional features that usefully package the request data before your script is called.

char (Reserved word)

Reserved for future language enhancements.

The ECMAScript (edition 2) reserves the `char` keyword for future use. This suggests some additional C-like functionality may be added in the future. A `char` may be represented by a byte.

However in JavaScript, characters are really double-byte values since they encode a Unicode code point in each character.

This keyword also represents a Java data type and the `char` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	byte, `java.lang.Character`, LiveConnect, Reserved word

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.2

Character constant (Definition)

A literal description of a single character.

Property/method value type:	`String primitive`

A character constant in JavaScript is represented by a single character length String primitive. Technically it is a string, not a character. In JavaScript the single quote delimiter encloses strings as well as the double quote delimiter.

Beware of this if you are familiar with C language character constants. In C, the single quote (apostrophe) is used to enclose a single character that can be represented by a byte.

Some character constant escape codes are listed in the following table:

Escape Sequence:	Name:	Symbol:
`\"`	Double Quote	"
`\'`	Single Quote (Apostrophe)	'
`\\`	Backslash	\
`\a`	Audible alert (MSIE displays the letter a)	<BEL>
`\b`	Backspace (ignored silently in MSIE)	<BS>
`\f`	Form Feed (ignored silently in MSIE)	<FF>
`\n`	Line Feed (Newline - MSIE inserts a space)	<LF>
`\r`	Carriage Return (MSIE inserts a space)	<CR>
`\t`	Horizontal Tab (MSIE inserts a space)	<HT>
`\v`	Vertical tab (MSIE displays the letter v)	<VT>
`\0nn`	Octal escape	-
`\042`	Double Quote	"
`\047`	Single Quote (Apostrophe)	'
`\134`	Backslash	\
`\xnn`	Hexadecimal escape	-

Table continued on following page

Escape Sequence:	Name:	Symbol:
\x22	Double Quote	"
\x27	Single Quote (Apostrophe)	'
\x5C	Backslash	\
\unnnn	Unicode escape	-
\u0022	Double Quote	"
\u0027	Single Quote (Apostrophe)	'
\u005C	Backslash	\
\uFFFE	A special Unicode sentinel character for flagging byte reversed text	-
\uFFFF	A special Unicode sentinel character	-

See also:	Character handling, Constant, Constant expression, Escape sequence (\), Literal, Primitive value

Character display semantics (Definition)

How characters are displayed on the implementation's console.

Although the standard defines many escape sequences (see table), how these are displayed depends very much on the way that the implementation uses the output of JavaScript:

Escape Sequence:	Name:	Symbol:
\"	Double Quote	"
\'	Single Quote (Apostrophe)	'
\\	Backslash	\
\a	Audible alert (MSIE displays the letter a)	<BEL>
\b	Backspace (ignored silently in MSIE)	<BS>
\f	Form Feed (ignored silently in MSIE)	<FF>
\n	Line Feed (Newline - MSIE inserts a space)	<LF>
\r	Carriage Return (MSIE inserts a space)	<CR>
\t	Horizontal Tab (MSIE inserts a space)	<HT>
\v	Vertical tab (MSIE displays the letter v)	<VT>
\0nn	Octal escape	-
\042	Double Quote	"
\047	Single Quote (Apostrophe)	'
\134	Backslash	\
\xnn	Hexadecimal escape	-
\x22	Double Quote	"
\x27	Single Quote (Apostrophe)	'

Table continued on following page

Escape Sequence:	Name:	Symbol:
\x5C	Backslash	\
\unnnn	Unicode escape	-
\u0022	Double Quote	"
\u0027	Single Quote (Apostrophe)	'
\u005C	Backslash	\
\uFFFE	A special Unicode sentinel character for flagging byte-reversed text	-
\uFFFF	A special Unicode sentinel character	-

Encoding line feeds, form feeds, and tabs into data that ultimately gets output as part of a `document.write()` method suggests that the target is an HTML page. When HTML is rendered, any embedded tabs and line terminators have no effect at all on the displayed output apart from some undesirable side effects in older browsers, which used to display line terminators inside anchor tags in a very odd way.

On the other hand, JavaScript that is generating a text data stream that is going to be returned via a TCP socket may well want to encode all kinds of escaped control characters.

Warnings:

- Generally a browser will ignore any escape sequences it cannot cope with. Some it will ignore silently such as a `\b` which results in no output in the MSIE browser. For others, such as `\a`, MSIE ignores the backslash but writes the letter 'a' into the document output. A few escape characters result in a space character being inserted into the output text.
- You should, as a matter of course, clean your HTML text of any unwanted escape characters if you can.

See also:	Character set, Environment, Escape sequence (\)

Character entity (Definition)

A means of escaping difficult-to-type characters for use in HTML.

Refer to:

HTML Character entity

Character handling (Advice)

Functions for testing character attributes.

Developers who use the C language and who are converting to JavaScript may be used to having support for testing various properties of character codes.

These functions are not formally part of the JavaScript language, although some of them are provided as part of the host environment through additional objects that provide C-like functionality. These are modeled on the `Math` object and cannot usually be instantiated by belonging to the `Global` object in the same way as the `Math` object does.

ScriptEase by Nombas is one interpreter that provides support for C language functionality through its `Clib` object.

If you are using other interpreters, you can simulate these character handling functions with fragments of script and some bitwise operators.

The following functions that are normally available to C programmers are simulated with the script examples in the following sections:

- `isalnum()`
- `isalpha()`
- `iscntrl()`
- `isdigit()`
- `isgraph()`
- `islower()`
- `isprint()`
- `ispunct()`
- `isspace()`
- `isupper()`
- `isxdigit()`

See also:	`isAlnum()`,`isAlpha()`,`isCtrl()`,`isDigit()`,`isGraph()`, `isLower()`,`isODigit()`,`isPrint()`,`isPunct()`,`isSpace()`, `isUpper()`,`isXDigit()`

Character set (Definition)

The collection of characters that the script can operate on.

Since JavaScript 1.3 and JScript 3.0, the language has been built around the Unicode standard. This means its identifiers and hence its script source code is intended to be represented by a sequence of Unicode characters. The benefit of this is that identifiers can be named using international characters. The reality is that some implementations don't support this very well, even if they can parse and process Unicode correctly as data.

As is the case with many languages, there may be a character set that can be used for data and a smaller sub-set that is valid for use when editing script source text.

Strictly speaking, a JavaScript script source can be encoded with 7 bit ASCII characters since there are mechanisms to escape generated character codes that are multi-byte Unicode code points.

The Unicode standard describes a large number of international character sets in terms of the character glyphs supported by them. There are also a large number of ISO standardized character sets.

See also:	ASCII, Character display semantics, Character handling, Character-case mapping, Environment, Escape sequence (\), `isLower()`,`isUpper()`, Locale-specific behavior, Localization, Multi-byte character, Unicode

Character testing (Definition)

Testing characters for attributes.

The following functions that are normally available to C programmers are simulated with script examples in the following sections:

- `isalnum()`
- `isalpha()`
- `iscntrl()`
- `isdigit()`
- `isgraph()`
- `islower()`
- `isprint()`
- `ispunct()`
- `isspace()`
- `isupper()`
- `isxdigit()`

Strictly speaking, these functions should be coded to be aware of locale-specific issues. You may want to take example simulations provided here and modify them to your own needs to support that. These are just basic working examples.

See also:	Character handling, Character-case mapping, `isAlnum()`, `isAlpha()`, `isCtrl()`, `isDigit()`, `isGraph()`, `isLower()`, `isODigit()`, `isPrint()`, `isPunct()`, `isSpace()`, `isUpper()`, `isXDigit()`, `String.charAt()`, `String.charCodeAt()`, `String.fromCharCode()`

Character value (Definition)

A numeric value based on the Unicode and ASCII character code points.

See also:	ASCII, Integer constant, Unicode

Character-case mapping (Overview)

Character case conversion.

The conversion of characters from upper to lower case and vice versa is accomplished in JavaScript by means of the `String` object. This provides two methods that can be applied to a `String` object to change its case. However, this would not work on String primitives so you may need to do an object conversion first.

The ECMAScript standard mandates that only the base characters need be mapped between the upper and lower case. Sorting and case conversion may support other international characters in some implementations, but this is not covered by the standard.

Localization issues may affect this sort of operation.

The interpreter should automatically convert any String primitives to `String` objects so that the method can be applied. This means that this should work:

```
"aaaa".toUpperCase()
```

And you should not need to do this:

```
String("aaaa").toUpperCase()
```

See also:	ASCII, Character handling, Character set, Character testing, `isLower()`, `isUpper()`, Locale-specific behavior, `String.charCodeAt()`, `String.fromCharCode()`, `String.toLocaleLowerCase()`, `String.toLocaleUpperCase()`, `String.toLowerCase()`, `String.toUpperCase()`, Unicode

CharacterData object (Object/DOM)

A sub-class of the `node` object with extensions to support access to character data within the object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Inherits from:	`Node` object	
JavaScript syntax:	-	*myCharacterData* = new CharacterData()
Object properties:	`data`, `length`	
Object methods:	`appendData()`, `deleteData()`, `insertData()`, `replaceData()`, `substringData()`	

See also:	`COMMENT` object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`data`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`length`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`appendData()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`deleteData()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`insertData()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`replaceData()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`substringData()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Inheritance chain:

`Node` object

CharacterData.appendData() (Method)

Append some text to the end of the character data.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myCharacterData*.appendData(*aString*)
Argument list:	*aString*	Some data to append

CharacterData.data (Property)

The current contents of the character data node.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCharacterData*.data

CharacterData.deleteData() (Method)

Remove a section of text from the data contained in the character data node.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myCharacterData*.deleteData(*anOffset*, *aCount*)
Argument list:	*anOffset*	The start of the deleted section
	aCount	The length of the deleted section

CharacterData.insertData() (Method)

Insert some additional text into the character data node.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myCharacterData*.insertData(*anOffset*, *aString*)
Argument list:	*anOffset*	A location to insert the data at
	aString	The data to insert

CharacterData.length (Property)

Return the length (in characters) of the character data node.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	Number primitive
JavaScript syntax:	- *myCharacterData*.length

CharacterData.replaceData() (Method)

Replace a section of text in the character data node with some new text.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myCharacterData*.replaceData(*anOffset*, *aCount*, *aString*)
Argument list:	*anOffset*	The location where the replacement starts
	aCount	The length of data to be replaced
	aString	The new data to insert

CharacterData.substringData() (Method)

Non destructively extract a section of the text from the character data node.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCharacterData*.substringData(*anOffset*, *aCount*)
Argument list:	*anOffset*	A location where the substring starts
	aCount	The length of the substring

Checkbox object (Object/DOM)

A checkbox to be used in a form. It toggles as it is clicked, but is not related to other checkboxes in the way that radio buttons are related to one another in families.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Inherits from:	`Input` object	
JavaScript syntax:	-	*myCheckbox* = *myDocument*.*aFormName*.*anElementName*
	-	*myCheckbox* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*myCheckbox* = *myDocument*.all.*anElementID*
	IE	*myCheckbox* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myCheckbox* = *myDocument*.all[*aName*]
	-	*myCheckbox* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myCheckbox* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*myCheckbox* = *myDocument*.getElementById(*anElementID*)
	-	*myCheckbox* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCheckbox* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]

HTML syntax:	`<INPUT TYPE="checkbox">`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `name` attribute of an element
	anElementID	The `ID` attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the `forms` collection
Object properties:	`checked`, `defaultChecked`, `indeterminate`, `status`, `type`, `value`	
Object methods:	`handleEvent()`	
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onBlur`, `onClick`, `onDblClick`, `onErrorUpdate`, `onFilterChange`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onRowEnter`, `onRowExit`	

Many properties, methods, and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

There isn't really a `Checkbox` object class but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a checkbox. In actual fact, the object is represented as an item of the `Input` object class.

Checkboxes may be used in groups where each one has the same name. However, this breaks the mechanism by which a form element can be accessed associatively since there is now more than one object with the same name. The fix for this is to support an `InputArray` so that you can access the items with the same name from a collection.

Although Checkbox items should not deactivate other items in the same family in the way that Radio buttons do, you can relate their states to one another by means of the `onclick` event handler.

Unlike MSIE, Netscape does not support the `defaultValue` property or the `select()` method for this sub-class of the `Input` object.

Warnings:

- If you enumerate a `form` object that has several elements having the same name, in Netscape these will be represented by a single property of that name that refers to an `InputArray`. In MSIE, you will get multiple properties with the same name, but each will refer to a collection object. This is probably a bug in MSIE, which exhibits this behavior in version 5 for Macintosh and probably on other platforms too.
- Note that on MSIE, `Input` objects are actually `INPUT` objects because MSIE follows a general rule of naming object classes after the capitalised name of the HTML tag that instantiates them.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT">?</DIV>
<FORM onClick="handleClick()">
<INPUT TYPE="checkbox" VALUE="A" NAME="BOX_A">Selection A<BR>
<INPUT TYPE="checkbox" VALUE="B" NAME="BOX_B">Selection B<BR>
<INPUT TYPE="checkbox" VALUE="C" NAME="BOX_C">Selection C<BR>
<INPUT TYPE="checkbox" VALUE="D" NAME="BOX_D">Selection D<BR>
</FORM>
<SCRIPT>
function handleClick()
{
   myString  = "Selection [";
   myString += event.srcElement.value;
   myString += "], State [";
   myString += event.srcElement.checked;
   myString += "]";
   document.all.RESULT.innerText = myString;
}
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Input` object, `Node` object

Checkbox.checked (Property)

The state of the checkbox is maintained in this property.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myCheckbox*.checked
HTML syntax:	`<INPUT CHECKED>`	

If the checkbox has a mark in it (depending on the UI display appearance guidelines, this may be a tick or a cross), then this value will return `true`. Otherwise it will return `false`.

Checkbox.defaultChecked (Property)

The original initial default state of a checkbox.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myCheckbox*.defaultChecked
HTML syntax:	`<INPUT CHECKED>`	

The `defaultChecked` state of an Input item is the value that was defined in the HTML document source when the page was loaded. You can use this value if you need to reset the status of a page or determine whether the user has changed the settings on an input item since the page was loaded.

Checkbox.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myResetButton*.handleEvent(*anEvent*)
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event-handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent()`

Checkbox.indeterminate (Property)

A checkbox is in this state if it was selected, but then disabled. The state cannot be accurately and unambiguously determined.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myCheckbox`*`.indeterminate`

Checkboxes may be enabled and disabled. If you have a checkbox that was enabled and then checked, and then if it is subsequently disabled, this flag property is set to `true` which indicates that the current state of the checkbox is indeterminate.

Checkbox.status (Property)

The current highlighted or checked status of the input element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myCheckbox`*`.status`

This is the current status of the checkbox item. It is either checked or not. If the checkbox has not been changed since the page was loaded from the server, then this value will be the same as the `defaultChecked` property of the checkbox.

Warnings:

- Because this is not supported on all browsers, you should use the `Checkbox.checked` property instead if portable code is important to your project.

Checkbox.type (Property)

The type value for the `<INPUT>` tag that describes the form checkbox.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myCheckbox*.type
HTML syntax:	<INPUT TYPE="CHECKBOX">	

The type value for a checkbox is always "checkbox". This value is necessary to determine the type of form element because this object is really an instance of the Input class and not the Checkbox class. There is actually no Checkbox class.

See also:	Input.type

Property attributes:

ReadOnly.

Checkbox.value (Property)

The text string for this particular checkbox object.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myCheckbox*.value
HTML syntax:	<INPUT VALUE="...">	

This value is returned to the server during a submit only if the checked state for this radio button is on.

Warnings:

- If the checkbox is used in a group or even if it isn't, the state of the checkbox is in the checked property not the value property.

See also:	Input.value

CheckerBoard() (Filter/transition)

A transition effect with the appearance of chequer board blinds opening or closing.

Availability:	JScript - 5.5 Internet Explorer - 5.5

Refer to:

filter - CheckerBoard()

ChildNodes object (Object/DOM)

A collection of all the children belonging to a DOM `Node` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myChildNodes* = *myElement*.childNodes

This is part of the internal DOM hierarchy model in the browser. There are several tree hierarchies supported and this one maintains a tree of parent-child node relationships across the document.

See also:	`Element` object, `Element.childNodes[]`, Hierarchy of objects

Chroma() (Filter/visual)

A visual filter for chroma key effects.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Filter - `Chroma()`

CITE object (Object/HTML)

An object representing the HTML content delimited by the `<CITE>` HTML tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myCITE* = *myDocument*.all.*anElementID*
	IE	*myCITE* = *myDocument*.all.tags("CITE")[*anIndex*]
	IE	*myCITE* = *myDocument*.all[*aName*]
	-	*myCITE* = *myDocument*.getElementById(*anElementID*)
	-	*myCITE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCITE* = *myDocument*.getElementsByTagName("CITE")[*anIndex*]
HTML syntax:	`<CITE> ... </CITE>`	

Argument list:	*anElementID*	The *ID* value of the element required
	anIndex	A valid reference to an item in the collection
	aName	The *name* attribute of an element

Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	3.0 +	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	3.0 +	-	4.0 +	Warning

onMouseUp	-	3.0 +	-	4.0 +	3.0 +	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition – 2

This internal property returns a string value containing the class name of the containing object.

Every object type must implement this property.

It is supported by all built-in native objects in an ECMA-compliant JavaScript interpreter.

Host objects may supply any value as a `Class` identifying string. They may even masquerade as one of the built-in classes, but good sense suggests that if they do, then they must obey the protocol of that built-in class in precisely the same way as if they were a real built-in object. It's probably sensible for host implementers to avoid overloading the built-in class names like that.

At edition 2 of the ECMA standard, there is no publicly accessible method to retrieve this property in a script. However, the reserved keyword values suggest that this may be offered at a later revision of the standard.

See also:	`Array.Class`, `Boolean.Class`, `class`, `Date.Class`, `Function.Class`, Internal Property, `Number.Class`, `Object.Class`, Reserved word, `String.Class`

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 – section – 8.6.2

ECMA 262 edition 3 – section – 8.6.2

class (Reserved word)

Reserved for future language enhancements.

Although you cannot request the class of a particular object, you can probably establish what class it belongs to with the `typeof` operator.

This keyword also represents a Java object type and the `class` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	`Class`, Internal Property, `java.lang.Class`, LiveConnect, Reserved word, `typeof`

Class method (Definition)

Methods owned by a constructor function object.

Refer to:

Static method

Class variable (Definition)

Static variables owned by a constructor function object.

See also:	Property

Refer to:

Static variable

CLASS="..." (HTML Tag Attribute)

A means of associating a tag with a stylesheet class. Represented by the `className` property of an `Element` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

In MSIE, virtually any object can be associated with a `style` object by means of the `CLASS` attribute. This is reflected into the `className` property of the object. It is especially applicable to DOM-related objects, which are considered to be sub-classed from the `Element` object. Netscape 6.0 brings that browser into line with these capabilities.

See also:	DOM, `Element` object, `Element.className`, `Element.style`, `STYLE` object (1), `style` object (2)

classes (Property)

An alternative reference to the `document.classes` property in JSS.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated – Netscape 6.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	N	`classes`
	N	*`myDocument`*`.classes`

Warnings:

- This functionality is removed from Netscape 6.0.

See also:	JavaScript Style Sheets, `Document.classes[]`

CLASSPATH (Environment variable)

This is an important environment variable that helps Java code locate resources on your system. It needs to be set correctly.

See also:	Java, LiveConnect

clearInterval() (Method)

Cancel a previous `setInterval()` timer.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	- `clearInterval(`*`anIntervalID`*`)`	
	- *`myWindow`*`.clearInterval(`*`anIntervalID`*`)`	
Argument list:	*`anIntervalID`*	The ID of an interval returned by the `setInterval()` method

See also:	`Window.clearTimeout(),Window.clearInterval()`

clearTimeout() (Method)

A function that removes a pending timeout event.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	- `clearTimeout(`*`aTimeoutID`*`)`	
	- *`myWindow`*`.clearTimeout(`*`aTimeoutID`*`)`	
Argument list:	*`aTimeoutID`*	The ID of a timeout returned by the `setTimeout()` method

Warnings:

- This can cause problems if the timeout event you have identified has already been executed. Pending timeouts quite reasonably can be removed. Already executed timeout actions cannot be removed and may crash the browser if you try to remove them. Be sure that you are really removing a pending timeout.
- A better technique is to set flags in global variables and use them to inhibit the creation of a new timeout event if you are using this for a kind of interval timer.

See also:	`Window.clearTimeout()`,`Window.setTimeout()`

client object (Object/NES)

A server-side object available in NES.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`client`
HTML syntax:	`client`	
Object methods:	`destroy()`,`expiration()`	

One `client` object is created for each browser user. It is created when the user first accesses the NES application and persists until some time after they have last visited. A timeout allows the server to garbage-collect these `session` objects and purge them out. If a client comes back again later, a new object will need to be created.

Because there is no `session` object in Netscape Enterprise Server, this object serves the purpose of maintaining session state as well as holding details of the client.

To maintain state across all session in an application, you should use the `project` object discussed in a separate topic.

`Client` objects have a limited lifetime. It is configurable but typically they will expire and be discarded after 10 minutes of inactivity.

See also:	Netscape Enterprise Server, `project` object, `response.client`, `unwatch()`,`watch()`

Method	JavaScript	JScript	NES	Notes
`destroy()`	1.1 +	-	2.0 +	-
`expiration()`	1.1 +	-	2.0 +	-

client.destroy() (Method)

This destroys the `client` object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`client.destroy()`

Calling this method on a `client` object will remove it and if the user makes another request, a new `client` object will have to be created.

This is slightly inconsistent with the normal way that objects are destroyed. Normally the `delete` operator would be used.

client.expiration() (Method)

This method will define the timeout after which the `client` object will expire. Used to set the life-span of a `client` object in an NES server.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`client.expiration(`*`aTime`*`)`
Argument list:	*`aTime`*	A time value measured in seconds

This method allows the number of seconds before a session times out to be defined. After this time, the `client` object will be purged automatically and if the user connects again after that, a new `client` object will need to be created.

The expiration time can be set for individual `client` objects. You may have one that needs to persist longer based on the kind of session the user is experiencing.

For example, it might be useful to expire an e-commerce session quickly to prevent misuse. A content administrator may need a session to be active for a much longer time than usual.

Typical expiry time for this sort of thing would be about 30 minutes. This is in line with current practice of log analysis techniques and log auditing. Breaks of more than 30 minutes are considered to be multiple sessions.

Client pull techniques (Definition)

This is a technique whereby the client end pulls content from the server at regular intervals.

Refer to:

Timer events

Client-side JavaScript (Definition)

The JavaScript that gets executed in the web browser or other client application.

See also:	`.jar`, `.java`, `.js`, Desktop JavaScript, HTML file, Server-side JavaScript, Web browser

Cross-references:

Wrox *Instant JavaScript* – page – 3

Wrox *Instant JavaScript* – page – 5

clientInformation (Property)

Details of the browser, A.K.A. the `navigator` object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Navigator` object	
JavaScript syntax:	IE	`clientInformation`
	IE	*`myWindow`*`.clientInformation`

See also:	Cross platform compatibility, `Navigator` object, `Window.clientInformation`, `Window.navigator`

Property attributes:

`ReadOnly`, `DontEnum`.

Clip object (Object/Navigator)

An object that represents a clip region within a layer.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
JavaScript syntax:	N	*`myClip`* `=` *`myLayer`*`.clip`
	N	*`myClip`* `=` *`myStyle`*`.clip`
	N	*`myClip`* `=` *`myTextRectangle`*
	N	*`myClip`* `=` *`myRect`*
Object properties:	`bottom`, `height`, `left`, `right`, `top`, `width`	

This object represents a clipping rectangle that the visible part of a display object is viewed through. This is most likely used with a `layer` object. The layer contents would be drawn off-screen and then that part that falls within the clipping rectangle would be displayed in the window.

This can be useful for performing wipes and making parts of a layer progressively visible within some kind of transition loop.

In the MSIE browser, these rectangular objects are manufactured as needed with the `rect()` constructor function.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.clip`, `Rect` object, `style.clip`, `textRectangle` object

Property	JavaScript	JScript	N	IE	Opera	Notes
`bottom`	1.2 +	-	4.0 +	-	-	Warning, Deprecated
`height`	1.2 +	-	4.0 +	-	-	Warning, Deprecated
`left`	1.2 +	-	4.0 +	-	-	Warning, Deprecated
`right`	1.2 +	-	4.0 +	-	-	Warning, Deprecated
`top`	1.2 +	-	4.0 +	-	-	Warning, Deprecated
`width`	1.2 +	-	4.0 +	-	-	Warning, Deprecated

Clip.bottom (Property)

The bottom of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myClip*`.bottom`

This defines the bottom edge of the clip region. You could modify this in a loop to create a vertical downwards wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.clip.bottom`, `Rect.bottom`

Clip.height (Property)

The height of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myClip`*`.height`

The clip region is defined by an extent rectangle that surrounds the space occupied by the clip region. An extent rectangle is the smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.clip.height,Rect.height`

Clip.left (Property)

The left of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myClip`*`.left`

This defines the left edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.clip.left,Rect.left`

Clip.right (Property)

The right of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0

Property/method value type:	Number primitive	
JavaScript syntax:	N	*myClip*.right

This defines the right edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	Layer.clip.right, Rect.right

Clip.top (Property)

The top of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myClip*.top

This defines the top edge of the clip region. You could modify this in a loop to create a vertical downwards wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	Layer.clip.top, Rect.top

Clip.width (Property)

The width of a layer clip region.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated Netscape 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myClip*.width

The clip region is defined by an extent rectangle that surrounds the space occupied by the clip region. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.clip.width`, `Rect.width`

clipboardData (Property)

A global browser variable that refers to the `clipboardData` object for the window.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`clipboardData` object	
JavaScript syntax:	IE	`clipboardData`
	IE	*`myWindow`*`.clipboardData`

See also:	`clipboardData` object, `Window.clipboardData`

clipboardData object (Object/JScript)

An object that can be used with editing operations to provide script-driven access to the clipboard contents.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*`myClipboardData`* `= clipboardData`
	IE	*`myClipboardData`* `= myWindow.clipboardData`
Object methods:	`clearData()`, `getData()`, `setData()`	

If you want to move data in and out of the clipboard on a Windows platform from within the MSIE browser, this object encapsulates the clipboard contents.

Refer to the `dataTransfer` object for a description of the `clearData()`, `getData()`, and `setData()` methods that may also be used with the `clipboardData` object.

See also:	`dataTransfer.clearData()`, `dataTransfer.getData()`, `Window.clipboardData`

Method	JavaScript	JScript	N	IE	Opera	Notes
`clearData()`	-	5.0 +	-	5.0 +	-	-
`etData()`	-	5.0 +	-	5.0 +	-	-
`setData()`	-	5.0 +	-	5.0 +	-	-

close() (Method)

A function that closes the receiving window.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`close()`
	-	*`myWindow`*`.close()`

See also:	`UniversalBrowserAccess`,`UniversalBrowserWrite`, `Window.close()`

closed (Property)

A flag indicating the window disposition.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer version – 4.0 Netscape Navigator version – 3.0 Opera browser – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`closed`
	-	`myWindow.closed`
Argument list:	`false`	The window is still open
	`true`	The window has been closed

Property attributes:

`ReadOnly`.

Refer to:

`Window.closed`

Closure object (Object/internal)

A special kind of function object that preserves prototype inheritance and scope.

Availability:	JavaScript – 1.2 Netscape – 4.0	
JavaScript syntax:	N	`myClosure = new Closure()`
Object properties:	`__parent__`, `__proto__`	

This is a special kind of object, which maintains some contextual state information when it is created.

It can behave like a function, but is a kind of function wrapper that references a function and a scope. Since it inherits everything from the `Function` object, it can behave like a function and can be called as such.

Because it also stores the scope chain at the time it is manufactured, it can restore that scope chain when it is executed.

See also:	Lexical scoping

Property	JavaScript	JScript	N	IE	Opera	Notes
`__parent__`	1.2 +	-	4.0 +	-	-	-
`__proto__`	1.2 +	-	4.0 +	-	-	-

Closure() (Object/Navigator)

A `Closure` object constructor.

Availability:	JavaScript – 1.2 Netscape – 4.0	
JavaScript syntax:	N	`new Closure(aFunction, aTarget)`
Argument list:	*aFunction*	The declaration of a function
	aTarget	An object to associate the function with

This constructor is used internally to create a `Closure` object containing the function associated with a target object.

The `Closure()` constructor is used in Netscape 4 to create an event-handler function that can be forced to run in a scope containing a target object.

Example code:

```
document.form1.myButton.onclick =
new Closure(
   function()
   {
      document.validated = false;
   },
   document.form1.myButton
   );
```

See also:	Constructor function, `constructor` property, `Global` object, Object constant

Closure.__parent__ (Property)

A reference to a scope-chain object that is preserved with the function by the `Closure` object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`ScopeChain` object	
JavaScript syntax:	N	*`myClosure`*`.__parent__`

See also:	`__parent__`, `__proto__`, Lexical scoping, `Closure` object

Closure.__proto__ (Property)

A reference to a function that is encapsulated by the `Closure` object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Function object`	
JavaScript syntax:	N	*`myClosure`*`.__proto__`

See also:	`__parent__`, `__proto__`, Lexical scoping, `Closure` object

clsid: URL (Request method)

Used by MSIE to locate ActiveX controls for the `<OBJECT>` tag.

A special request method for loading `ActiveX` objects from the locally stored object repository. This provides a portable, cross-platform, installation,independent way to refer to the folder where you have installed shared `ActiveX` objects on your system. It is more or less equivalent to the `file:` request method but without the need to specify a path to the folder.

See also:	`OBJECT.classid`, URL

Code block delimiter {} (Delimiter)

A delimiting token for a block of executable script source text.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	*aLabel*`: { `*someScript*` }`
Argument list:	*aLabel*	An optional identifier to name the code block
	someScript	Some legal JavaScript source text

A block is a list of statements that form one syntactic unit enclosed in curly brace characters (`{ }`).

This is particularly useful in conditional execution and iterative execution. Both of those are expected to operate on a single syntactic unit. A block allows that single syntactic unit to be composed of multiple lines of source script text.

Because the curly brace characters are used to delimit a block of code that comprises a list of semi-colon terminated statements, you do not need to place any semi-colons after the closing curly brace.

A block of code is most often used like this with a iterator or conditional test to either call the same section of code repetitively or to execute it as the result of a conditional expression returning a `true` value.

In compiled languages, variables declared inside a block are sometimes local to that block and are garbage-collected when the block exits. The ECMA standard indicates that variables created inside a code block will be global unless that code block is the body of a function. In ECMA-compliant interpreters, a block does not instantiate a new execution context, whereas in C language it does create a new scope within which the variables exist.

This means that variables created inside an 'if keyword' controlled compound statement will be function-local or globally accessible according to whether the 'if keyword' is in a function or global code section.

Braces must be used in pairs. Although the JavaScript interpreters may forgive you when you miss out some language elements, very subtle and difficult-to-diagnose errors can occur if you misplace a brace character.

Modern text editors give you a lot of help when balancing pairs of braces.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

At version 1.2 of JavaScript, you can name the code block and use the labeled form of the `break` keyword to exit the block prematurely.

See also:	Associativity, `else if( ... ) ...`, `if( ... ) ... else ...`, Label, Operator Precedence, Punctuator

CODE object (Object/HTML)

An object representing the HTML content delimited by the `<CODE>` HTML tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myCODE* = *myDocument*.all.*anElementID*
	IE	*myCODE* = *myDocument*.all.tags("CODE")[*anIndex*]
	IE	*myCODE* = *myDocument*.all[*aName*]
	-	*myCODE* = *myDocument*.getElementById(*anElementID*)
	-	*myCODE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCODE* = *myDocument*.getElementsByTagName("CODE")[*anIndex*]
HTML syntax:	`<CODE> ... </CODE>`	
Argument list:	*anElementID*	The `ID` value of the element required
	anIndex	A valid reference to an item in the collection
	aName	The `name` attribute of an element
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

See also:	KBD object, LISTING object

Inheritance chain:

Element object, Node object

Refer to:

Element object

Code signing (Definition)

A security mechanism to allow scripts to inter-communicate.

Signed scripts are allowed higher privileges to communicate with one another because the browser assumes they are more secure.

See also:	Security policy, Signed scripts

COL object (Object/HTML)

An object that represents a <COL> HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Inherits from:	`Element` object	
JavaScript syntax:	IE	*myCOL* = *myDocument*.all.*anElementID*
	IE	*myCOL* = *myDocument*.all.tags("COL")[*anIndex*]
	IE	*myCOL* = *myDocument*.all[*aName*]
	-	*myCOL* = *myDocument*.getElementById(*anElementID*)
	-	*myCOL* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCOL* = *myDocument*.getElementsByTagName("COL")[*anIndex*]
HTML syntax:	`<COL> ... </COL>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `name` attribute of an element
	anElementID	The `ID` attribute of an element
Object properties:	`align`, `ch`, `chOff`, `span`, `vAlign`, `width`	
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`	

This object represents the `<COL>` tag, which is used within `<TABLE>` constructs to provide a way of controlling an entire table column from a single definition. It is used in conjunction with a `<COLGROUP>` construct.

The HTML 4 specification describes functionality that currently none of the widely available browsers supports properly.

The DOM specification describes a `HTMLTableColElement` object, which is the standardized interface to this class.

See also:	`COLGROUP` object, `Element` object, `style.columnSpan`, `TABLE` object, `TABLE.rules`, `TableColElement` object, `TableColElement.align`, `TableColElement.ch`, `TableColElement.chOff`, `TableColElement.span`, `TableColElement.vAlign`, `TableColElement.width`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`align`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`ch`	1.5 +	-	6.0 +	-	-	1 +	-	-
`chOff`	1.5 +	-	6.0 +	-	-	1 +	-	-

onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

COL.align (Property)

An attribute controlling the alignment of a column contained in a `<COL>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCOL*.align

The alignment of the `COL` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `char`
- `justify`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Note that not all of these are available in every browser. In particular the `justify` and `char` values are recent additions.

See also:	`COLGROUP.align`

COL.ch (Property)

The alignment character for cells in a column arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`myTHEAD.ch`

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR` HTML tag attribute is reflected in this property and is active when the `CHAROFF` HTML tag attribute is present.

See also:	`COLGROUP.ch`, `TD.ch`, `TH.ch`, `THEAD.ch`, `TR.ch`

COL.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myTHEAD`*`.chOff`

The `CHAR` alignment style requires that an alignment character be specified with the `ch` property and that an offset measured in pixels be defined as its value. The offset value can be defined with the `CHAROFF` HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	`COLGROUP.chOff`, `TD.chOff`, `TH.chOff`, `THEAD.chOff`, `TR.chOff`

COL.span (Property)

The number of columns that the style for this object spans.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myCOL*`.span`

This corresponds to the `COLSPAN` attribute within a `<TD>` or `<TH>` table cell description. It defines how many table columns this column is to span.

See also:	`COLGROUP.span`, `TD.colSpan`, `TH.colSpan`

COL.vAlign (Property)

The vertical alignment of items within this column.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCOL*`.vAlign`

This property controls text alignment in the vertical axis. This applies to text cells in the column group.

The `vAlign` property may be set to these values:

- `baseline`
- `bottom`
- `middle`
- `top`

See also:	`COLGROUP.vAlign`

COL.width (Property)

The width of each column in the column group.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myCOL*.width

The columns within the column group are set to a width defined by this property. Changing the value will cause the page content to be re-flowed to reflect the new value.

See also:	`COLGROUP.width`

COLGROUP object (Object/HTML)

An object that represents the `<COLGROUP>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myCOLGROUP* = *myDocument*.all.*anElementID*
	IE	*myCOLGROUP* = *myDocument*.all.tags("COLGROUP")[*anIndex*]
	IE	*myCOLGROUP* = *myDocument*.all[*aName*]
	-	*myCOLGROUP* = *myDocument*.getElementById(*anElementID*)
	-	*myCOLGROUP* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myCOLGROUP* = *myDocument*.getElementsByTagName("COLGROUP")[*anIndex*]
HTML syntax:	`<COLGROUP> ... </COLGROUP>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `name` attribute of an element
	anElementID	The `ID` attribute of an element
Object properties:	`align`, `ch`, `chOff`, `span`, `vAlign`, `width`	
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`	

The <COL> and <COLGROUP> tags correspond to objects that represent the column or group of columns within a <TABLE> construct. Individual columns map to the COL object and groups of columns to the COLGROUP object. Attributes can be applied to a group of columns and overridden on an individual column basis if necessary.

The DOM specification mentions an HTMLTableColElement object, which provides the functionality of this class.

See also:	COL object, style.columnSpan, TABLE object, TABLE.rules, TableColElement object, TableColElement.align, TableColElement.ch, TableColElement.chOff, TableColElement.span, TableColElement.vAlign, TableColElement.width

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

Element object, Node object

COLGROUP.align (Property)

The alignment settings for a column group.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCOLGROUP*.align

The alignment of the `COLGROUP` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

See also:	`COL.align`

COLGROUP.ch (Property)

The alignment character for cells in a column group arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTHEAD*.ch

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR` HTML tag attribute is reflected in this property and is active when the `CHAROFF` HTML tag attribute is present.

See also:	COL.ch, TD.ch, TH.ch, THEAD.ch, TR.ch

COLGROUP.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myTHEAD*.chOff

The CHAR alignment style requires that an alignment character be specified with the ch property and that an offset measured in pixels be defined as its value. The offset value can be defined with the CHAROFF HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	COL.chOff, TD.chOff, TH.chOff, THEAD.chOff, TR.chOff

COLGROUP.span (Property)

The span settings for a column group.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myCOLGROUP*.span

This property contains a definition of the number of adjacent columns that are affected by the <COLGROUP> tag's attributes. It corresponds to the COLSPAN attributes of the <TD> and <TH> tags and the objects that encapsulate them.

See also:	COL.span, TD.colSpan, TH.colSpan

COLGROUP.vAlign (Property)

The vertical alignment of items in a column group.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myCOLGROUP*.vAlign

This property controls text alignment in the vertical axis. This applies to text cells in the column group.

The `vAlign` property may be set to these values:

- `baseline`
- `bottom`
- `middle`
- `top`

See also:	`COL.vAlign`

COLGROUP.width (Property)

The width of items in a column group.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myCOLGROUP*.width

The columns within the column group are set to a width defined by this property. Changing the value will cause the page content to be re-flowed to reflect the new value.

See also:	`COL.width`

Collation sequence (Definition)

The order in which objects are sorted lexically according to the locale.

Collation sequences determine the way that information is sorted into the correct sequence. This is likely to be very locale-dependant and therefore if you are going to sort data, you may need to provide a means of plugging in a sort comparator function that is aware of the national language variants if your scripts belong to sites that will be deployed in foreign languages.

This is covered in some depth in the Unicode standard manual.

See also:	Localization

Collection object (Object/DOM)

An array of `Element` objects.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera browser – 3.0	
JavaScript syntax:	IE	*myCollection* = *myDocument*.all
	IE	*myCollection* = *myDocument*.children
	IE	*myCollection* = *myDocument*.filters
	-	*myCollection* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	IE	*myCollection* = *myElement*.all
	IE	*myCollection* = *myElement*.children
	IE	*myCollection* = *myElement*.filters
	-	*myCollection* = *myDocument*.getElementsByTagName(*aTag*)[*anIndex*]
Argument list:	*aName*	The `name` attribute of an element
	anIndex	A valid reference to an item in the collection
	aTag	The name of a tag
Object properties:	`length`	
Object methods:	`Item(),namedItem(),tags()`	

A `collection` object is an enhancement to the basic `array` object to provide some additional searching capabilities for managing the contents of the document object model in a web browser.

Do not confuse DOM `NodeList` arrays with `Enumerator` or `Collection` objects. The `NodeListitem()` method is subtly different from the `Enumerator.Item()` method.

See also:	TABLE.cells[]

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
length	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	1 +	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
Item()	1.5 +	3.0 +	6.0 +	4.0 +	5.0 +	1 +	Warning
namedItem()	1.5 +	5.0 +	6.0 +	5.0 +	5.0 +	1 +	-
tags()	-	3.0 +	-	4.0 +	-	-	-

Collection.Item() (Method)

Select an Element object by index number.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0
Property/method value type:	Node object
JavaScript syntax:	- *myCollection*.item(*anIndex*) - *myCollection*.item(*aSelector*) - *myCollection*.item(*aSelector*, *anIndex*) - *myCollection*[*anIndex*]
Argument list:	*anIndex* A zero based index into the collection *aSelector* A textual value that selects all matching objects

This is a search method that traverses a collection looking for an item or collection of items by the index in the collection.

If the first argument is a numeric value, the object at the indexed position is returned. You may not place a second argument in the call. This is the DOM standard specified behavior.

If the first argument is a string, then any object in the collection that has an ID or name property that matches the selector will be assembled into another collection. If there is no second argument, that new collection will be returned as a sub-set of the original receiving collection. This is an extension to the DOM specified behavior.

If the first argument is a string and the second argument is a numeric value, the sub-set collection is manufactured but the element in that collection indexed by the second argument is returned as a single object. This is also an extension to the DOM specified behavior.

This extension is useful because you can apply a filter and selection in one call without needing to extract and then store a sub-set collection. On the downside, this will repeat the sub-setting search each time it is called which can lead to performance problems.

When using the *myCollection*.item(*anIndex*) syntax variation, it is functionally equivalent to myCollection[*anIndex*].

Note that the DOM specification does not allow for the alternative array-like addressing mode, which is implemented in browsers as a convenience.

Warnings:

- You may get back a single object if there is only one item that matches. However, if the selection criteria match more than one item, you will get back an array of objects. This is slightly problematic; it would be better if you consistently got back an array even if it contained zero or only one item. You could then operate on it consistently.
- The Item() method of an MSIE Collection object is not the same as the item() method for the DOM NodeList object. The DOM specifies the method name in lower case, though it is upper case in MSIE (although JScript is somewhat forgiving of upper-lower case errors in scripts).
- In addition, the Item() method of an MSIE Collection supports several different addressing modes, whereas the item() method of a Nodelist supports only one.

See also:	Collection object, NamedNodeMap.item(), OptionsArray.item(), style.item()

Collection.length (Property)

Returns the length of a collection array.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 3.0
Property/method value type:	Number primitive
JavaScript syntax:	- *myCollection*.length

The collection behaves exactly like an array object and returns a number representing a count of all the elements in the collection.

See also:	AnchorArray.length, AppletArray.length, Arguments.length, Array.length, Attributes.length, Form.elements.length, Form.length, FormArray.length, LayerArray.length, LinkArray.length, NodeList.length, Plugin.length, PluginArray.length, ScriptArray.length, StyleSheetList.length, Window.length

Property attributes:

`ReadOnly`.

Collection.namedItem() (Method)

Select an `Element` object by `name` or `ID` value.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`Node` object	
JavaScript syntax:	- *myCollection*.namedItem(*aString*)	
	- myCollection[*aString*]	
Argument list:	*aString*	A textual value that selects all matching objects

This is a search method that traverses a collection looking for a named item or collection of items.

The argument is a string containing the `name` or `ID` value of the `Element` to be located.

Collection.tags() (Method)

Extract a sub-list of `Element` objects of a particular tag type.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	IE	*myCollection*.tags(*aTagName*)
Argument list:	*aTagName*	The name of a tag to be filtered

The collection is traversed and all objects are examined to see if they were created by an HTML tag that is the same as that specified in the argument.

The argument must always be specified in upper case and the resulting collection will contain all objects of that type selected from the receiving `collection` object.

You can then manipulate the sub-set collection in the normal way, accessing items within it by index or by other means.

See also:	`Collection` object, `Select.tags()`

Colon (:) (Delimiter)

A delimiter used with labels and conditional operators.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0

This delimiter is used with the `case` keyword and the `default` keyword in `switch` statement blocks.

Refer to the `switch` topic for details of how this is used.

See also:	`switch( ... ) ... case: ... default: ...`

Color names (Definition)

There are standard definitions of color names for use in web pages.

Property/method value type:	`String primitive`

Although the color names are used in HTML tags, you can use Hexadecimal values as well.

Here is a list of the standard color definitions:

Name:	Value:
`AliceBlue`	`#F0F8FF`
`AntiqueWhite`	`#FAEBD7`
`Aqua`	`#00FFFF`
`Aquamarine`	`#7FFFD4`
`Azure`	`#F0FFFF`
`Beige`	`#F5F5DC`
`Bisque`	`#FFE4C4`
`Black`	`#000000`
`BlanchedAlmond`	`#FFEBCD`
`Blue`	`#0000FF`
`BlueViolet`	`#8A2BE2`
`Brown`	`#A52A2A`
`BurleyWood`	`#DEB887`
`CadetBlue`	`#5F9EA0`
`Chartreuse`	`#7FFF00`
`Chocolate`	`#D2691E`
`Coral`	`#FF7F50`
`CornFlowerBlue`	`#6495ED`
`CornSilk`	`#FFF8DC`
`Crimson`	`#DC143C`

If you prefer to compute the color names, there is a very neat color picker tool on the Netscape developer's web site.

See also:	Color value

Web-references:

http://home.netscape.com/computing/webbuilding/studio/feature19981111-5.html

Color value (Advice)

Color values can be specified numerically or mnemonically.

Property/method value type:	`String primitive`

A numeric color specification is a 6 digit (3 pairs) hexadecimal value with a leading hash symbol.

Each pair of digits defines the intensity of a single color (RGB) in the display.

The web-safe palette of 216 colors is defined by every possible combination of the following values:

00, 33, 66, 99, CC and FF

There are other values supported through the mnemonic named color palette, which includes 100 shades of gray.

You can use non-web-safe values if you have a greater than 8 bit deep display. These days most platforms can resolve at least 16 bits, but some legacy systems may have problems resolving non-web-safe colors.

When using color values for defined styled colors, the `rgb()` function can be used.

In the MSIE browser, the values can also be specified as 32 bit integer values, although in practice this is extremely difficult to manage.

In certain circumstances, where an alpha value is available, the color value can be specified using hexadecimal notation to define a 32 bit integer. In this case, the value is comprised of four pairs of hex digits as follows:

0xAARRGGBB

The value AA controls the alpha channel transparency, while the RR, GG, and BB values are the intensity of Red, Green and Blue respectively.

When passed as a string value, the same hexadecimal value can be used but must be preceded by a hash rather than the `0x` prefix. Thus `0xAARRGGBB` becomes `#AARRGGBB`

Warnings:

- Be wary of spellings when specifying color values. The UK English spelling of "colour" will not set the property values you intend. Property values to do with color values will be spelled "color". In addition some of the color names may be spelled in the American English tradition.

See also:	Colour names, `rgb()`

Comma expression (Definition)

Used to separate individual operands or arguments.

Availability:	ECMAScript edition – 2

Comma expressions occur rarely and are used to evaluate several expressions at once.

See also:	Comma operator (,), Expression

Cross-references:

ECMA 262 edition 2 – section – 11.14

ECMA 262 edition 3 – section – 11.14

Comma operator (,) (Delimiter)

An argument separator token.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

The comma operator provides a way to evaluate several assignment expressions at once.

It is provided as a way to express the arguments to a function in a manner consistent with the ECMA standard.

It is also used in variable declaration lists to declare more than one variable with a single `var` statement.

Its most subtle use is to exploit the side effects of an expression without assigning the result of that expression to anything. This is actually so subtle as to confuse what it's actually doing. There is probably a simpler way to express the same functionality that doesn't execute any slower and is a lot easier to maintain.

The associativity is left to right. This means that the expressions should be executed in left to right order of appearance in the script source text. The result of the entire expression will be the evaluation of the last comma-separated item. It is not good style to use a comma separated list as an RValue in an assignment to an LValue.

Example code:

```
// Declaring several variables
var e, c, d, x, y;

// Arguments in a for iterator header
for(a=0, b=0; a<10 ; a++, b++)
{
;
}

// assign variables
c = 1;
d = 2;
x = 3;
y = 4;
z = 5;

// Add c to d and assign the result to e with incrementing
// side effects
e = (x++, y++, c) + (z--, d);
```

Wrox *Instant JavaScript* – page – 21

Comment (Definition)

Sections of inactive code.

Availability:	ECMAScript edition – 2

A comment is some text that is embedded within the script source text but is ignored by the interpreter. It is intended to provide guidance and documentation to the reader of the source code.

Comments can be contained completely on a single line or can span multiple lines.

A single-line comment can contain any character except for a line terminator. The line terminator at the end of the single line comment is not part of the comment and must obey the rules of placement of line terminators in general. Multiple-line comments are replaced by a single line terminator regardless of how many line terminators they actually contain. This means that a multiple-line comment behaves syntactically as if it were a line terminator.

Warnings:

- You cannot nest multi-line comments within one another.

Comment (// and /* ... */) (Delimiter)

Mark a multi-line comment block.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
JavaScript syntax:	- /* First line of comment text - // Comment text - Second line of comment text - Third line of comment text */

There are two kinds of comment blocks supported by JavaScript. They each have a different kind of delimiter.

Single-line comments commence with a pair of slash characters (//) and stop at the end of the current line.

Multi-line comments start with a slash-asterisk (/*) and finish at the first following asterisk-slash (*/). This means you cannot nest multiple line comment blocks inside one another. The disadvantage with that is that it is common practice in some languages to comment out sections of code by marking the start and end of the inactive sections as a multi-line comment block. This won't work if there are any multi-line comment blocks anywhere in this inactive block. A better technique, although slightly more cumbersome is to use single line comments (//) to 'switch-off' the lines of code you want to deactivate. Thus:

```
//a = 1000;
//b = 2000;
//c = 3000;
```

ECMA 262 edition 3 – section – 7.4

COMMENT object (Object/DOM)

An object that represents a section of HTML enclosed in comment delimiter tags.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`CharacterData` object	
JavaScript syntax:	IE	*myCOMMENT* = *myDocument*.all.*anElementID*
	IE	*myCOMMENT* = *myDocument*.all.tags("COMMENT")[*anIndex*]
	IE	*myCOMMENT* = *myDocument*.all[*aName*]
	-	*myCOMMENT* = *myDocument*.getElementById(*anElementID*)
	-	*myCOMMENT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	N	*myCOMMENT* = *myDocument*.createComment(*aString*)
	-	*myCOMMENT* = *myDocument*.getElementsByTagName("COMMENT")[*anIndex*]
HTML syntax:	`<!-- ... -->`	
Argument list:	*anIndex*	An item within the collection
	aString	A comment string
	aName	The `name` of an element
	anElementID	The `ID` attribute of an element
Object properties:	`text`	
Object methods:	`click(),getAttribute(),removeAttribute(),setAttribute()`	
Collections:	`all[],children[]`	

It is somewhat unlikely you would ever want to modify the contents of a comment tag. However, access to the text contained within it may be a way of passing hidden data values to your scripts without them being visible in the displayed page. Of course they would still be visible in the document source, but you might be able to avoid the creation of a `<FORM>` and hidden `<INPUT>` object.

Warnings:

- The DOM level 1 specification describes this as a `Comment` object, but MSIE implements it as a `COMMENT` object instead. You may need to be aware of this in case other platforms implement the DOM specified class exactly as it is intended.

See also:	`CharacterData` object, `Document.createComment()`, `Element` object, Hiding scripts from old browsers

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`text`	-	3.0 +	-	4.0 +	-	-	-

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`click()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	Warning
`getAttribute()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	Warning
`removeAttribute()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	Warning
`setAttribute()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	Warning

Inheritance chain:

`CharacterData` object, `Node` object

COMMENT.text (Property)

The text within a comment block.

Availability:	JScript – 3.0 Internet Explorer version – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myCOMMENT`*`.text`

This is the internal text within the comment block. The DOM standard treats comment blocks as character data to standardize the access to their content, but you should not expect to be able to access the internal text of a comment for any functional purpose.

Compatibility (Definition)

Creating web content is an exercise in portable programming that would severely test the most experienced programmer.

There are so many issues to do with portability and compatibility that unless you are doing something very simple, its is an amazing achievement to get your web page to display even remotely similarly on several browsers or platforms.

Leaving aside the creative issues to do with color matching, gamma correction, and display resolution, there are problems with fonts, style sheets and table layout. Layers and dynamic HTML behave differently even within the same browser family as the browsers are revised. Even scrolling a page means you have to increment the scroll value in opposite directions in Netscape and MSIE, and Netscape won't scroll at all without the scroll bars being visible.

To cope with this, it helps to break the compatibility issues down into sub-sets and to understand the underlying reason for incompatibility. You do need to know about and be able to identify issues based on platforms, browsers, or versions of client software.

Wrox *Instant JavaScript* – page – 60

Compatibility strategies (Advice)

Choose how compatible you want to be from the outset.

You need to establish a strategy for how compatible you need to be. Here are some questions you need to think about and consider their relative importance.

- Is it important that your pages work perfectly in browsers that do not support JavaScript? If so, don't deploy any at all.
- If you really need JavaScript, can you design your forms and page content to degrade gracefully? If not, you may need to browser-detect and present warnings. If you cannot browser-detect with JavaScript at the client end, you may need to browser-detect at the server end and return a different page.
- Are you in control of browser deployment to the target desktop systems? This is likely in an intranet situation. If it is true, then you can use all of the features of the browser your deploy, including platform-specific and version-specific capabilities. You may need to co-ordinate content upgrades with browser upgrades though.
- Are you only using JavaScript to define proxy settings? If so, you only need to be cross-platform and browser-version aware.
- Are you only using JavaScript to set preference values in Netscape? If so, you only need to be cross-platform and browser-version aware.
- Can you sacrifice old-browser users? If you can get some meaningful statistics of your readership, you may find that only a few percent have an old browser. Are you prepared to support all users or can you disregard some? You need to set a threshold, say 5%, and work out a sub-set of browsers that you will support and from that derive a functionality profile that your must enforce in your design department.
- Must you guarantee to work on all browsers of every vintage? In which case, you could consider the lowest common denominator approach and only use those capabilities that are supported by your choice of target browsers.

- Do you think you need to only support the latest version of a browser? Users are generally keen to upgrade if it is well worth their while. They likely may not consider your site a compelling reason to upgrade though.
- Are you hardwired to a very specific platform/browser combination? Some sites only work on MSIE running on Windows. This is very frustrating for Netscape users or people using any web browser on other non-Windows platforms. Things change and you cannot rely on Microsoft Windows always being the dominant platform. This could change within the hardware replacement cycle that large corporations like to implement. That might be between 2 and 4 years. If your site only works on a single platform, your traffic may go down as that platform loses market share.
- Do you just not care about it? If your page breaks on someone's browser, so what? Maybe it's not important at all. However, don't expect that user to come back – ever. If the script fails to draw some cute animation or change a color the effect is likely to be cosmetic anyway and may not even be noticed. Maybe it fails fairly gracefully if you are lucky.

See also:	Compatibility, `Date` object

Completion type (Definition)

An internal type used by the interpreter.

Availability:	ECMAScript edition – 2

This is an internal type used by the interpreter for processing expression evaluation results. It cannot be stored as an object property.

A completion happens when a statement is evaluated and completes normally. A completion can involve a value and may still be a normal completion.

Abrupt completions are triggered by `break`, `continue`, and `return` statements, which are all classified as program steps that may redirect the flow of control. This may cause sections of code to be skipped or repeated. In the case of a `return`, it may prematurely exit a function.

In the set of ECMA-defined reserved words, there is evidence that new flow control changes may be introduced and therefore other completion type values may be added later.

The set of completion type values are summarized in this table:

Type:	Reason:
Normal completion	-
Normal completion after evaluation	-
Abrupt completion	`break`
Abrupt completion after evaluation	`break`
Abrupt completion	`continue`
Abrupt completion after evaluation	`continue`
Abrupt completion	`return`
Abrupt completion after evaluation	`return`

See also:	`break`, `continue`, Identifier resolution, `return`, Scope chain, Type

ECMA 262 edition 3 – section – 8.9

Compliance (Overview)

The degree to which an implementation adheres to the standard.

The formal definition of the core JavaScript language is embodied in the ECMA standard 262.

Until recently, where implementations conformed it was to the second edition of the standard, which was published in August 1998.

In December 1999, the third edition was made available and new implementations or revisions to existing products released in the early part of the year 2000 onwards complied with that new version of the standard.

To comply with the standard, an implementation must provide and support all the types, values, objects, properties, methods, and program syntax described in the standard.

See also:	Behavior, Conformance, Definition, ECMA, ECMAScript, ECMAScript – edition 2, ECMAScript – edition 3, Limits

Compositor() (Filter/visual)

As content is added to an object, it can be colored to indicate it is changed content.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter - `Compositor()`

Compound statement (Definition)

A block of code handled as if it were one statement.

A compound statement is a block of one or more statements gathered together and executed as if they were a single statement. This is a somewhat wordy description of what a function declaration provides. Other similar uses are the code that is iterated in a `while` or `for` loop and the code that is conditionally executed in an `if ... else` construct.

Any variables created within a compound statement will be local to the enclosing function if the compound statement exists inside a function's execution context, otherwise they will be globally scoped. In JavaScript you cannot localize the scope of a variable to within an `if()`, `while()`, or `for()` construct in the way that you can in C language.

See also:	Definition, `for( ... in ... ) ...`, Function code, `if( ... ) ...`, `if( ... ) ... else ...`, Scope chain, Statement, `var`, `while( ... ) ...`

Concatenate (+) (Operator/string)

Join two strings end to end. See Addition for numeric values.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0
Property/method value type:	`String primitive`

See also:	Add (+), Additive operator, `Array.join()`, `Array.toString()`, Concatenate then assign (+=), String, String, String literal, `String` object, String operator, `String.concat()`, `String.split()`, Type conversion, String concatenate (+)

Cross-references:

ECMA 262 edition 2 – section – 11.6.1

Wrox *Instant JavaScript* – page – 21

Concatenate then assign (+=) (Operator/assignment)

Concatenate two string operands and assign the result to the first. See Addition for numeric values.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0
Property/method value type:	`Number primitive`

JavaScript syntax:	-	*anOperand1* += *anOperand2*
Argument list:	*anOperand1*	A numeric value that can be assigned to
	anOperand2	Another numeric value

Concatenate the right operand to the left operand and assign the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 + anOperand2;
```

Although this is classified as an assignment operator, it is really a compound of an assignment and a concatenation operator.

It also works with numeric values and will add the second to the first.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

The new value of *anOperand1* is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

See also:	Add then assign (+=), Assign value (=), Assignment expression, Assignment operator, Associativity, LValue, Operator Precedence

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

Conditional code block (Pre-processor)

A pseudo pre-processor mechanism for conditionally executing code in MSIE.

There is an implementation of a C language inspired pre-processor in the MSIE JScript interpreter.

The usual pre-processor directives for conditional code use are reproduced here except that in the C language they are prefixed with a hash symbol (`#`) and in JScript the commercial at sign (`@`) is used instead.

There are several directives and a set of pre-defined constants

- `@cc_on` Statement
- `@if` Statement

- `@set` Statement
- `@elif( ... ) ...` Statement
- `@else ...` Statement
- `@end` Statement
- `@<variable_name>` Reference
- `@_alpha` Pre-defined constant
- `@_jscript` Pre-defined constant
- `@_jscript_build` Pre-defined constant
- `@_jscript_version` Pre-defined constant
- `@_mac` Pre-defined constant
- `@_mc680x0` Pre-defined constant
- `@_PowerPC` Pre-defined constant
- `@_win16` Pre-defined constant
- `@_win32` Pre-defined constant
- `@_x86` Pre-defined constant

Warnings:

- This is not supported prior to MSIE version 4.

See also:	Pre-processing - `@cc_on`, Pre-processing - `@elif( ... ) ...`, Pre-processing - `@else ...`, Pre-processing - `@end`, Pre-processing - `@if( ... ) ...`

Conditional comment (HTML Tag)

A portability trick that only works in Netscape.

Availability:	JavaScript – 1.2 Netscape – 4.0

Conditional comments use JavaScript entities to enclose a block of JavaScript and only execute it conditionally on some value being `true`.

It is accomplished by embedding a JavaScript entity with a logical expression evaluation in it. If the expression proves `true` then the `<SCRIPT>` HTML tag enclosed in the comment block is parsed, otherwise it is ignored.

This is how it's done. A conditional comment is formed by adding an ampersand character to the leading tag of a comment. Rather than use "`<!--`" the comment is introduced with "`<!--&`" instead. The comment is closed in the normal way with a trailing "`-->`" string. Inside the comment a `<SCRIPT></SCRIPT>` block is placed with some global code to be executed if called for.

Warnings:

- This only works in Netscape 4 or later, which limits its usefulness somewhat. MSIE supports an alternative, but completely incompatible technique that only works inside the `<SCRIPT>` tag.

Example code:

```
<!--&{navigator.userAgent == "Mozilla/4.7 (Macintosh; I; PPC) "};
<SCRIPT>
document.write("Power Macintosh running Navigator 4.7");
</SCRIPT>
-->
```

See also:	Adding JavaScript to HTML

Conditional expression (Definition)

Conditionally execute one code branch or another.

Availability:	ECMAScript edition – 2

Conditional expressions test a logical expression and perform one of two possible alternative code blocks.

The grammar for a conditional expression in ECMA-compliant JavaScript implementation is slightly different from that you may have seen before in Java and C language. Java and C set restrictions on the kind of expression you can put into the second code block, whereas JavaScript does not. This is a subtle distinction and is intended to simplify the use of this expression and avoid the use of a comma operator.

See also:	Conditionally execute (`?:`), Expression

Cross-references:

ECMA 262 edition 2 – section – 11.12

ECMA 262 edition 3 – section – 11.12

Wrox *Instant JavaScript* – page – 18

Conditional operator (Definition)

Conditionally execute one code branch or another.

Availability:	ECMAScript edition – 2

Refer to:

Conditionally execute (`?:`)

Cross-references:

ECMA 262 edition 2 – section – 11.12

ECMA 262 edition 3 – section – 11.12

Conditionally execute (?:) (Operator/conditional)

Conditionally execute one code branch or another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	Depends on arguments	
JavaScript syntax:	- *aCondition* ? *someCode* : *moreCode*	
Argument list:	*aCondition*	A relational or logical expression that yields `true` or `false`
	moreCode	Code that is executed if *aCondition* is `false`
	someCode	Code that is executed if *aCondition* is `true`

The two associated code blocks are executed according to the value yielded by a Boolean test on the first operand. If it is `true`, then the first code block is executed, otherwise the second is used.

The associativity is right to left.

Refer to the Operator Precedence topic for details of execution order.

This is sometimes called a Ternary operator, because it takes three operands.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
mySwitch = false;
myResult = (mySwitch) ? "TRUE VALUE" : "FALSE VALUE" ;
document.write(myResult);
</SCRIPT>
</BODY>
</HTML>
```

See also:	Associativity, Conditional expression, Flow control, `if( ... ) ...`,`if( ... ) ... else ...`, Operator Precedence, Selection statement, Ternary operator

Cross-references:

ECMA 262 edition 2 – section – 11.12

config.jsc (Special file)

A JavaScript configuration file for Netscape.

Refer to:

Preferences

Cross-references:

Wrox *Instant JavaScript* – page – 59

confirm() (Method)

A dialog box to get confirmation from the user.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myResult* = confirm(*aString*) - *myResult* = *myWindow*.confirm(*aString*)
Argument list:	*aString* — Some text to explain what is to be confirmed

See also:	`Window.alert(),Window.confirm()`

Conformance (Definition)

An interpreter may or may not conform to the ECMAScript specification.

Availability:	ECMAScript edition – 2

Conforming implementations of ECMA 262 edition 2 must properly support Unicode version 2.0 and ISO/IEC 10646-1 with UCS-2 as the encoding form. There are various sub-clauses to that encoding requirement and implementers should build their systems around the specifications laid down therein. Edition 3 requires slightly different character coding support.

Conforming implementations may provide additional capabilities. In particular, functionality flagged under the 'Future Reserved Word' category is encouraged by ECMA.

A strictly conforming implementation is one that only provides the features outlined in the standard. Since ECMAScript only defines core functionality and absolutely none of the host environment, a strictly conforming implementation of ECMAScript would be of limited use.

A conforming implementation provides the behavior outlined in the standard with some allowable additional behavior to support the hosting environment.

See also:	Compliance, ECMA, ECMAScript, ECMAScript – edition 2, ECMAScript – edition 3

Cross-references:

ECMA 262 edition 2 – section – 2

ECMA 262 edition 3 – section – 2

Connection object (Object/NES)

An object that represents a connection from the server to the back-end database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	`myConnection = myDbPool.connection(aName, aTimeout)`
Argument list:	`aName`	A connection name
	`aTimeout`	Timeout in seconds
Object properties:	`prototype`	
Object methods:	`beginTransaction(),commitTransaction(),connected(), cursor(),execute(),majorErrorCode(),majorErrorMessage(), minorErrorCode(),minorErrorMessage(),release(), rollbackTransaction(),SQLTable(),storedProc(),toString()`	

This object is used to maintain the connection state details between the Netscape Enterprise Server and the backend database it is retrieving data from.

A `connection` object is created by calling the `connection()` method of the `DbPool` object.

Example code:

```
<SERVER>
// An example of how to create a connection object
// Based on the one in Wrox Professional JavaScript
myDbPool     = new DbPool("ODBC", "myDatabase", "", "", "");
myConnection = myDbPool.connection("ExampleConnection", 30);
myConnection.SQLTable("SELECT * FROM MY_TABLE");
</SERVER>
```

See also:	`DbPool.connection()`, Netscape Enterprise Server, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
`prototype`	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
`beginTransaction()`	1.2 +	-	3.0 +	-
`commitTransaction()`	1.2 +	-	3.0 +	-
`connected()`	1.2 +	-	3.0 +	-
`cursor()`	1.2 +	-	3.0 +	-
`execute()`	1.2 +	-	3.0 +	-
`majorErrorCode()`	1.2 +	-	3.0 +	-
`majorErrorMessage()`	1.2 +	-	3.0 +	-
`minorErrorCode()`	1.2 +	-	3.0 +	-
`minorErrorMessage()`	1.2 +	-	3.0 +	-
`release()`	1.2 +	-	3.0 +	-
`rollbackTransaction()`	1.2 +	-	3.0 +	-
`SQLTable()`	1.2 +	-	3.0 +	-
`storedProc()`	1.2 +	-	3.0 +	Warning
`toString()`	1.2 +	-	3.0 +	-

Connection.beginTransaction() (Method)

Commence a new transaction with the database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	*myConnection*`.beginTransaction()`

Call this method to signify the start of a new transaction with the database. This is a reference point to which you can rollback the changes if necessary. Note that you cannot rollback after the commit has occurred.

Connection.commitTransaction() (Method)

Commit the changes made to the database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	*myConnection*.commitTransaction()

Relational databases support the facility of a two phase commit. That is, any changes made to the database require that a commit is requested before the session is disconnected. If the session is disconnected without a commit, then the changes are unwound and discarded leaving the database in the state it was in after the previous commit.

Sometimes people place a commit after every transaction. This is somewhat wasteful and can lead to low performance. Placing a commit every 25 or so transactions is better.

You do need to be sure that you have made the changes you need to and that any referential integrity is maintained and any constraints on the data are satisfied, otherwise the commit may fail.

Connection.connected() (Method)

A method that returns a flag indicating the state of the connection.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	NES	*myConnection*.connected()

If the session is currently connected to the database, this method will return a `true` value. If the session is no longer connected it yields `false`.

Connection.cursor() (Method)

Create a cursor object on the connection with the SQL database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	Cursor object	
JavaScript syntax:	NES	*myConnection*.cursor(*aQuery*)
	NES	*myConnection*.cursor(*aQuery*, *aFlag*)
Argument list:	*aQuery*	A valid SQL query for the database
	aFlag	Indicates whether the cursor can be updated

These `Cursor` objects are used to run SQL queries against the database we are currently connected to. It is probably a good idea to consult the reference documentation for your database to fully understand how it handles cursors.

See also:	`Cursor` object

Connection.execute() (Method)

Execute some SQL on the database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myConnection*`.execute(`*someSQL*`)`
Argument list:	*someSQL*	A string containing valid SQL for the database

The SQL to be executed on the database is passed as an argument to this method.

Connection.majorErrorCode() (Method)

Provide the code for an error raised by the database server or the ODBC interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myConnection*`.majorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields a return code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server message number.

For a status code value of 7 when using the Informix database, this yields the Informix error code.

For a status code value of 7 when using the Sybase database, this yields the DB-Library error number.

See also:	`database.majorErrorCode()`, `DbPool.majorErrorCode()`, Error handling, Status code

Connection.majorErrorMessage() (Method)

Provide the descriptive text message for an error raised by the database server or by the ODBC interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myConnection`*`.majorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields a text string describing the server error.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields a text string from SQL server.

For a status code value of 7 when using the Informix database, this yields the text string from the vendor error library.

For a status code value of 7 when using the Sybase database, this yields a text string from the DB-Library.

See also:	`database.majorErrorMessage()`, `DbPool.majorErrorMessage()`, Error handling, Status code

Connection.minorErrorCode() (Method)

Returns a supplementary error code for an error raised by the database server or the ODBC interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myConnection`*`.minorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields an operating system error code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the severity level from SQL server.

For a status code value of 7 when using the Informix database, this yields the ISAM error code.

For a status code value of 7 when using the Sybase database, this yields the severity level of the error from the DB-Library.

See also:	`database.minorErrorCode()`, `DbPool.minorErrorCode()`, Error handling, Status code

Connection.minorErrorMessage() (Method)

Returns a supplementary error message text for an error raised by the database server or the ODBC interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myConnection*`.minorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields the Oracle server name.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server name.

For a status code value of 7 when using the Informix database, this yields a text string describing the ISAM error.

For a status code value of 7 when using the Sybase database, this yields the text of the operating system error from the DB-Library.

See also:	`database.minorErrorMessage()`, `DbPool.minorErrorMessage()`, Error handling, Status code

Connection.prototype (Property)

The prototype for the `connection` object that can be used to extend the interface for all `connection` objects.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`Connection` object	
JavaScript syntax:	NES	`Connection.prototype`
	NES	*myConnection*`.constructor.prototype`

Refer to:

`prototype` property

Connection.release() (Method)

Releases this connection back into the pool for reuse.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	*myConnection*`.release()`

There are a limited number of connections available for accessing the database. This is intentional. It prevents the database from being swamped by connections.

The limit may be large or small depending on the scale of the database server and the software it is using.

Requesting a connection from the `DbPool` object consumes one of the available connections. You must ensure that you release them back to the pool when you are finished, otherwise your server will soon use them all up and will be unable to form new connections to the database.

Connection.rollbackTransaction() (Method)

A means of undoing transactions that have not yet been committed.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	*myConnection*.rollbackTransaction()

Until you commit a transaction on the database, you can rollback to the previous commit state. Once you have committed a transaction, this opportunity to undo is lost. To undo after that, you must make changes under your own script's control. That means that if you anticipate that possibility, you will need to remember the previous values. On the whole, it's easier to let the database do this and to commit only when you are sure the transaction is complete and correct.

Connection.SQLTable() (Method)

Create an HTML table as a result of a SQL query on the database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	String primitive	
JavaScript syntax:	NES	*myConnection*.SQLTable(*someSQL*)
Argument list:	*someSQL*	A string containing valid SQL for the database

The argument to this method is a database query that is expected to yield some rows and columns. These are then reformatted with the requisite HTML tags to form a table.

The table is likely to be fairly generic in appearance so you may need to modify the HTML that is returned or perhaps you could use style sheets to control its appearance.

Connection.storedProc() (Method)

This method creates a `Stproc` object and then runs the stored procedure on the database server.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0

JavaScript syntax:	NES	*myConnection*.storedProc(*aProcName*)
	NES	*myConnection*.storedProc(*aProcName*, *aProcParm*)
Argument list:	*aProcName*	The name of a stored procedure to call
	aProcParm	A parameter or parameters to pass to the stored procedure

Stored procedures are pre-programmed code that lives inside the database. They generally encompass searches that are more complex than the simple `select … from … where …` SQL statements.

Stored procedures in some database products cannot yield a record structure the same as a select query would. This is because they are not associated with any particular table and so they return the results as a resultset rather than a table record. You may need to do additional work to turn the resultset into the objects you need.

Warnings:

- Every middle-ware application server supports a completely different way of running stored procedures. At least it seems like that sometimes when you are using several different products. Fundamentally they all do the same thing but databases provide different mechanical implementations and so there are many different ways in which to develop code to exploit them.

See also:	`Stproc` object

Connection.toString() (Method)

Returns a string containing a representation of the `Connection` object.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myConnection*.toString()

The value of the object is converted to a string value that represents its value.

const (Reserved word)

Reserved for future language enhancements.

This keyword suggests that future standardization may support immutable constant values. This may allow stronger type casting of formal parameters in function prototypes.

See also:	Function prototype, Reserved word, Type, volatile

Constant (Definition)

A literal description of a fixed value.

A constant is a lexical element that represents a set numerical or string value.

Numeric values can be integer or floating-point. String values may define only a single character but are nevertheless still considered to be a string.

The `Number` and `Math` objects provide constant values as properties of the object class. These are static constants. Other static constants are provided by the implementation. For example the `Event` object supplies a set of masks in some implementations. These masks can be used to determine keyboard states. The DOM standard defines others as part of the event model.

See also:	Character constant, Constant expression, Escape sequence (`\`), Floating constant, Integer constant, Lexical element, Literal, `Math` object, `Number` object, Primary expression, Variable

Cross-references:

Wrox *Instant JavaScript* – page – 13

Constant expression (Definition)

A constant expression is a combination of constants and an operator.

A constant expression can always be degenerated to a simpler constant form.

For example `100 + 101` is a constant expression, but could be replaced by the value `202`.

A constant expression involving strings is `"abcdef" + "ABCDEF"`. This yields the result `"abcdefABCDEF"`.

Warnings:

- In JavaScript you should always try to avoid the use of string concatenation unless you really have to use it. It is very useful. However, in Netscape and MSIE, over-using a string concatenation in a loop can lead to significant memory leaks. It is quite easy to leak several megabytes of memory in a few minutes simply by concatenating strings and passing them to a `document.write()`. The garbage does eventually get collected, but not until the page is refreshed. This means that a page that implements a ticker for instance can leak horribly until the page is refreshed. There are techniques you can employ to minimize this effect and you could trigger a garbage collection by reloading the page periodically under script control.

See also:	Arithmetic constant, Character constant, Constant, Date constant, Escape sequence (`\`), Expression, Expression statement, Floating constant, Floating-point constant, Initialization, Integer constant, JavaScript language, Logical constant, Object constant

Constraint (Definition)

A restriction placed on a script to be executed.

A constraint determines a restriction that the syntax and semantics of the language must set upon the interpretation of the elements of the language. Violating these constraints should generate an interpretation error in a compliant implementation.

See also:	Definition, Diagnostic message, Error handling

Construct (Property/internal)

An object constructor call.

Availability:	ECMAScript edition – 2

The internal constructor is invoked via the `new` operator.

This is not implemented by all objects. Those that do support it are called constructor objects. In other languages these might be called factory objects.

Warnings:

- The `global` object does not have a `Construct` property and you cannot make copies of it with the `new` operator.

See also:	Constructor function, `constructor` property, Internal Method

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 2 – section – 15

ECMA 262 edition 3 – section – 15.1.4

Constructor function (Definition)

A function that can create new objects.

Availability:	ECMAScript edition – 2

A constructor is analogous to a factory class in a truly object-oriented system. It instantiates new objects of its class by copying a built-in prototype object.

A constructor function is a method that creates and initializes new objects or values. It is a way of calling the `constructor` object as a function rather than with the `new` operator.

These constructor functions are available from the `global` object; the host implementation may add others for you to use:

- `Object()`
- `Function()`
- `Array()`
- `String()`
- `Boolean()`
- `Number()`
- `Date()`

Calling the constructor as a function is a way of carrying out type conversion.

You can also create your own constructor functions. You name them with the name of the class you want to create. Depending on how you implement them, they may or may not work as type converting functions.

When we use the `new` operator, it understands that the function is a constructor and as it constructs the new object, it associates the constructor function with it so you can locate it again, via the `prototype` and `constructor` properties. Because this function makes use of the '`this`' keyword, it could be a method belonging to another object. However, it doesn't have to belong to an object to be used as a constructor in the first place. The object creation process will properly associate it in due course when it needs to.

You don't need to pass parameters to add properties to objects as they are created.

Constructors are generally a better way of making self documenting objects than simply instantiating more copies of the `Object` object. In addition, there is more opportunity to reuse and share code between multiple instances. It's probably not a good thing to add properties and methods to the base `Object` class as it means they would get inherited just about everywhere, because ultimately all prototype inheritance chains descend from the topmost `Object`.

With a constructor, you can simulate arrays by making them from objects and property components. This may be useful if you want to run an array-based script in a very old JavaScript implementation although these days that likelihood of that is diminishing rapidly.

The Netscape browser creates a constructor for virtually every object it instantiates. This can be an aid to debugging and making more flexible scripts. You can inspect an object by requesting its `constructor` property. This will normally convert to a string that contains the function definition and to determine the class it may be more useful to request the `constructor.name` property instead.

This technique is not so useful in MSIE where constructors are only made available for objects that can genuinely be instantiated usefully by a script.

Example code:

```
// This constructor function defines a class called Tree:
function Tree(aName, aNode1, aNode2)
{
   this.name        = aName;
   this.leftbranch  = aNode1;
   this.rightbranch = aNode2;
}

// We can now implement tree walking algorithms and
// associate them with the prototype for the tree object:
function tree_walk()
{
   if((this.leftbranch  == null) &&
      (this.rightbranch == null))
   {
      document.write(this.name);
      document.write("<BR>");
   }
   if(this.leftbranch != null)
   {
      document.write(this.name);
      document.write(" -L- ");
      this.leftbranch.walk();
   }
   if(this.rightbranch != null)
   {
      document.write(this.name);
      document.write(" -R- ");
      this.rightbranch.walk();
   }
}

// Now associate the tree walk with the prototype.
Tree.prototype.walk = tree_walk;
// Here we create a new tree object:
// In this case, we have defined null values to signify we have reached
// the end of the branching structure so we must be at a leaf node.
myTree1 = new Tree("AAA", null, null);
// Let's create another and join both to a third:
myTree2 = new Tree("BBB", null, null);
myTree3 = new Tree("CCC", myTree1, myTree2);
// Now we walk the tree
myTree3.walk();
// We could have created an array in the tree class and
// stored more than two branches.  B-Trees, Quad trees,
// and Oct trees are all useful modelling tools for
// building simulations.
```

ECMA 262 edition 3 – section – 4.3.4

Wrox *Instant JavaScript* – page – 31

constructor property (Definition)

A reference to a constructor function.

Availability:	ECMAScript edition – 2

A `constructor` property is a function object that creates and initializes new objects. Each constructor has an associated prototype object that provides inheritance and shared properties.

There are `constructor` properties belonging to the `Global` object for all the Built-in (Native) object prototypes. These constructors are available as part of the core language from the `global` object. They are defined in the ECMA standard at editions 2 and 3. The host implementation may add others for you to use:

- `Object()`
- `Function()`
- `Array()`
- `String()`
- `Boolean()`
- `Number()`
- `Date()`

To create new objects, a new expression is formed with the constructor as its operand. The result is to create a new object by means of the constructor.

For any object the constructor is a property of the prototype. The prototype is a property of the object and the constructor points back at the object. In that sense the `prototype` and `constructor` properties each point at the other's parent object.

This needs to hold true for a constructor to be correctly set up:

```
myObject.prototype.constructor
```

is the same as:

```
myObject
```

They should test `true` with the `===` operator since they are supposed to be identical objects.

Warnings:

- Both Netscape and MSIE support a `constructor` property for the `Math` object. You won't find very many circumstances where you will need to create a new instance of the `Math` object. Note that the `constructor` is not a `Math` object but an `Object` object, therefore a `new Math()` statement will produce a new `Object` object and not a new `Math` object.

- In both cases, attempting to execute a `new Math()` statement will cause a run-time error. Arguably, this is a bug because objects that should not be instantiated or cloned ought not to support a constructor so that you can sensibly write general-purpose routines that can test for the existence of a `constructor` property and can then exit gracefully if it is not supported.
- The `constructor` property is supported so inconsistently across the browsers that this kind of test before use approach is almost impossible to deploy.

ECMA 262 edition 2 – section – 4.3.4

ECMA 262 edition 2 – section – 15.1.3

ECMA 262 edition 3 – section – 4.3.4

constructor.name (Definition)

The name of the constructor that created an object.

You can determine the class of an object by requesting the `name` property from its constructor. Since the constructor is a function, you are actually asking a `function` object for its name. Functions know all about their names. If you get the name of a function that's been used as a constructor, you have effectively gotten its class. Its type is still an object, but its class lets you tell one kind of object from another.

See also:	Determining the object type

Content Model (Definition)

A new model in the DOM level 3 specification describes how documents can be exchanged between implementations.

The DOM level 3 content model is embodied in the following object classes:

- `CMObject`
- `CMExternalObject`
- `CMNode`
- `CMNodeList`
- `NamedCMNodeMap`
- `CMDataType`
- `CMType`
- `ElementDeclaration`
- `ElementCMModel`
- `AttributeDeclaration`
- `EntityDeclaration`

- DocumentCM
- DomImplementationCM
- ErrorHandler
- NodeCM
- TextCM

contextual() (Method)

A JSS style control method.

Availability:	JavaScript – 3.0 Netscape – 4.0 Deprecated	
JavaScript syntax:	N	`contextual(tags.`*`anItem`*`, ...).`*`aProperty`*` = `*`aValue`*
Argument list:	*anItem*	A tag name such as `P` or `B` or `H1`
	aProperty	A style property of the returned tags object
	aValue	A value to be stored in the property of the nominated tags

This function can take a variable number of arguments, each one indicating a tag property within the tag's object. It is followed by a dot-delimited property value and basically provides a way to modify the same property across a large number of objects in a single call.

This could be a quite useful function for a variety of other non-style-related cases. You may want to experiment and see whether, in your browser, the `contextual()` method is useful. However, it may only be present in Netscape browsers, thus limiting its usefulness for deployment.

When used in a JSS context, this is more or less equivalent to `H1 P { color: red }`.

Warnings:

- This functionality is removed from Netscape 6.0.

Example code:

```
// Set the color property for several objects at once.
contextual(tags.P, tags.H1)color = "red";
```

Wrox *Instant JavaScript* – page – 50

continue (Statement)

Force the next iteration of a loop.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.0 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
JavaScript syntax:	- `continue aLabelName;` - `continue;`
Argument list:	*`aLabelName`* The name of a label associated with some code

The `continue` keyword is a jump statement. It is used in an iterator loop to proceed to the next cycle without executing the remaining lines in the statement block.

A `continue` statement can only legally exist inside a `while` or `for` loop in an ECMA-compliant implementation. Implementations that provide additional iterator types may also honor the same behavior for the `continue` statement.

The `continue` statement would normally be executed conditionally, otherwise it would cause the remaining lines to be redundant since no execution flow would ever reach them. Compilers generally warn you about this, but JavaScript would likely simply ignore it.

The `continue` statement is obeyed by the smallest enclosing iterator loop.

At version 1.2 of JavaScript, the `continue` statement was enhanced to support a label as a continuing destination. When the `continue` is processed, it will jump to the start of the statement that has been labeled. If an iterator is labeled, then the `continue` is associated with that iterator. This mechanism can only be used in a `while`, `for` or `for ... in` loop.

A labeled `continue` behaves differently according to the iterator it has been used in.

Warnings:

- In Netscape 4, there is a bug with labeled `continue` statements and `do ... while` loops that causes the `continue` to vector to the top of the loop without testing the condition. This can set up an endless loop. You could work round this by creating a `while` loop and modifying the test condition.
- When the `continue` statement is used, its behavior inside a while loop suggests that a `while` loop is not exactly similar to a `for` loop. In a `while` loop, it simply runs the test condition again before deciding to loop or not. In a `for` loop, the incrementor gets executed again and then the test condition. You cannot perfectly simulate a `for` loop with a `while` loop if a `continue` statement is involved.

Control character (Definition)

A non-printing character entity.

A control character is any character code point in the locale-specific character set that does not print a visible glyph when it is output.

See also:	ASCII, Character handling, `isCtrl()`,`isGraph()`,`isPrint()`, Printing character, Unicode

Conversion (Definition)

Changing the type of a value, object, function or constant.

Values are continuously being changed from one type of value to another inside a JavaScript interpreter. The very nature of its weak data typing and the automatic promotion and demotion of values in expressions causes implicit changes in the type of values at almost every step of a script's execution.

The conversion behavior of each type is discussed in the coverage of each of the Native primitive types that are built into the interpreter.

Refer to the `Cast` operator description as well for further information.

There are also some internal conversion operators that provide the basic underlying conversion facilities. These are described in the following topics:

- `ToBoolean`
- `ToInt32`
- `ToInteger`
- `ToNumber`
- `ToObject`
- `ToPrimitive`
- `ToString`
- `toString()`
- `ToUint16`
- `ToUint32`

These are given individual topics on account of their description in the ECMA standard. There are however four basic and fundamental conversions. These are:

- Boolean
- Number
- String
- Object

The internal function topics cover what happens inside an interpreter. In this topic and the several following, we are concerned with the script visible effects of conversion.

There are some circumstances where the conversion of an object to a number or a string can be ambiguous. The cases of concatenate or add and the relative expression operators are such an example. The `Date` objects will prefer to be converted to a string rather than a number if at all possible and consistent with the context.

Many objects have `toString()` methods. Not as many will support the `valueOf()` method. The `valueOf()` method is so named because it is not implicitly a `toNumber()` method. It may return a string because that is the most reasonable primitive. It is really a `toPrimitive()` method.

See also:	Argument, `Cast` operator, Integer constant, Integer promotion, LValue, `ToBoolean`, `ToInt32`, `ToInteger`, `ToNumber`, `ToObject`, `ToPrimitive`, `ToString`, `toString()`, `ToUint16`, `ToUint32`

Conversion to a Boolean (Definition)

Converting values to a Boolean representation.

There are three conversions to study. Obviously Boolean values will remain as they are.

This table summarizes the effects of converting values to Boolean:

Value:	Boolean equivalent:
`null`	`false`
Undefined value	`false`
Non empty string	`true`
Empty string	`false`
0	`false`
`NaN`	`false`
Infinity	`true`
Negative infinity	`true`
Any other non zero number	`true`
Object	`true`
Array	No direct boolean equivalent
Function	`true`

There is no proper Boolean equivalent for an array. The ECMA standard does not address this either. The standard does suggest that any non-null object reference convert to `true` and since an array is an object, it should rightly become a `true` value.

Warnings:

- Some non-portable behavior has been implemented in the MSIE and Netscape browsers. In some cases, the array becomes `true` in all cases. In others, a non-empty array is `true`, while an empty array is `false`. This seems to be based on the `length` value.
- You should test your target browsers to see what behavior persists if you intend to use this capability and not rely on any implicit array conversion facilities. It is probably safest to implement your own conversion method.
- The array to Boolean conversion is so inconsistently supported as to render it unusable in any cross-browser implementation.
- A more insidious side effect is exhibited by the fact that all objects convert to the Boolean `true` value, even a `Boolean` object whose value is `false`. This is demonstrated in the example. You really need to be careful if you are storing Boolean values in objects rather than simple variables, especially if they are driving some conditional code execution.

Example code:

```
<!-- Is this a bug or a feature??? -->
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myTrueObject = new Boolean(false);
if(myTrueObject)
{
   alert("True");
}
else
{
   alert("False");
}
</SCRIPT>
</BODY>
</HTML>
```

Conversion to a number (Definition)

Converting values to a numeric representation.

There are three conversions to study. Obviously numeric values will remain as they are. This table summarizes the effects of converting values to numbers:

Value:	Numeric equivalent:
`null`	`0`
Undefined value	`NaN`

Table continued on following page

Value:	Numeric equivalent:
Empty string	`0`
Numeric string	Numeric value of string
Non-numeric string	`NaN`
Boolean `true`	`1`
Boolean `false`	`0`
Object	Result of `Object.valueOf()`.
Object lacking a `valueOf()` method.	Result of conversion of result from `Object.toString()` method.
Object without `toString()` or `valueOf()` methods.	An error
Array	No direct numeric equivalent
Function	`NaN`

Converting objects to numbers will first attempt to use the `valueOf()` method and then the `toString()` method, converting the resulting string to a number after that.

There is no proper numeric equivalent for an array. The ECMA standard does not address this either.

Warnings:

- Some non-portable behavior has been implemented in the MSIE and Netscape browsers. In some cases, the array becomes `NaN`. In others, the first element is converted to a number. For some browsers this may only happen if the array is a single element long and the array is otherwise converted to `NaN`. Some browsers will take the length of the array and use that value.
- You should test your target browsers to see what behavior persists if you intend to use this capability and not rely on any implicit array conversion facilities. It is probably safest to implement your own conversion method.
- The array to number conversion is so inconsistently supported as to render it unusable in any cross browser implementation.

Conversion to a string (Definition)

Converting values to a string representation.

There are three conversions to study. Obviously string values will remain as they are.

This table summarizes the effects of converting values to strings:

Value:	Resulting string:
Zero	`"0"`
`null`	`"null"`
Undefined value	`"undefined"`
`NaN`	`"NaN"`
Infinity	`"Infinity"`
Negative infinity	`"-Infinity"`

Table continued on following page

Value:	Resulting string:
Numeric value	That numeric value as a sequence of characters.
Boolean `true`	`"true"`
Boolean `false`	`"false"`
Object	Result of `Object.toString()`.
Object lacking a `toString()` method.	Result of conversion of result from `Object.valueOf()` method.
Object without `toString()` or `valueOf()` methods.	An error
Array	Comma elements joined by a comma.
Function	Depends on implementation.

Converting objects to strings will first attempt to use the `toString()` method and then the `valueOf()` method, converting the resulting number to a string after that.

Conversion to an object (Definition)

Converting values to a object-structured representation.

There are three conversions to study. Obviously Object values will remain as they are.

This table summarizes the effects of converting values to objects:

Value:	Object representation:
`null`	An error
Undefined value	An error
Empty string	`String` object
Non-empty string	`String` object
`0`	`Number` object
`NaN`	`Number` object
Infinity	`Number` object
Negative infinity	`Number` object
Any other non-zero number	`Number` object
Boolean `true`	`Boolean` object
Boolean `false`	`Boolean` object

Cookie (Advice)

A means of maintaining state in the client machine by storing information in a cookie that is associated with the document.

A cookie is a small fragment of textual data that is associated with the current page. It is not modeled particularly well for access by JavaScript and you will need to use some scripting to disassemble and reassemble the name-value pairs that are concatenated together to make the cookie.

The `cookie` property for a `document` returns a string containing ALL the cookies that apply to the document. You will need to split them into individual cookies by separating them at semicolon boundaries. From there you will need to obtain for each cookie a `name=value` construct that you can further dismantle and process.

Note that you will not get any of the special attributes of the cookie since they are write only. The only thing you can get back is its `value` property.

When you read the `cookie` property from a document, you get a list of cookie values, one for each cookie. When you assign to the `cookie` property of a document, you define only a single cookie whose name is the first name-value pair in the string. Other attributes are appended by concatenation and delimited from one another by a semicolon. The other attributes are optional and all that is required is the new cookie name and value pair.

You must make sure the cookie value you assign is properly URL escaped so that it can be sent back to the server when necessary.

Cookie values should be defined as a series of `name=value` pairs. As well as the fundamental cookie value, you can define the following `name=value` pairs:

- `expires`
- `path`
- `domain`
- `secure`

Cookies can be redefined whenever you want. To delete a cookie, set it to some value with an expiry date defined to be prior to the current date and time.

Cookies are useful but you should not rely on them 100%. It is possible that the user may have disabled cookie support in their browser. You should also avoid storing sensitive information in a cookie and it is intended that the value you store there is small. Storing huge amounts of data in a cookie is somewhat bad etiquette.

The example code demonstrates how two functions (`setCookie` and `getCookie`) can be created to simplify the creation and parsing of cookies. The comments in the example explain how they work.

Warnings:

- There are limitations to the size and quantity of cookies that can be used. Typically these days browsers will exceed these limitations, but you should always code for the minimum specification.
- The specification for cookies says that browsers need support no more than 300 different cookies. Of those, no more than 20 should be associated with any particular server. For each cookie, the data stored is not expected to exceed 4 kilobytes.
- You should therefore try to store as much data in a single cookie as you can for a given web site and not create different cookies for each page. Indeed for a properly designed data-driven site, it is hard to see how you would need more than one single cooking containing a short but unique user identifier. As long as you can look up that user's record quickly when a new session commences, all session and user state information can then be maintained on the server unless you want to traverse through some static pages. Even then state can be carried by means of cookies and special web-server code to intercept the request-response loop.

Example code:

```
// Example provided by Martin Honnen
// A function that sets cookie values properly
// The cookieName and cookieValue arguments are mandatory
// but all other arguments are optional.
// The expires argument is a Date object.
// The path defines the part of the document tree on the server
// that the cookie is valid for.
// The domain argument allows multiple server hosts to be used.
// The secure value is boolean and only applicable for use
// with HTTPS: connections.
function setCookie(cookieName, cookieValue, expires, path, domain, secure)
{
   document.cookie = escape(cookieName) + '=' + escape(cookieValue)
      + (expires ? '; EXPIRES=' + expires.toGMTString() : '')
      + (path ? '; PATH=' + path : '')
      + (domain ? '; DOMAIN=' + domain : '')
      + (secure ? '; SECURE' : '');
}

// A complementary function to unwrap a cookie.
function getCookie(cookieName)
{
   var cookieValue = null;
   var posName = document.cookie.indexOf(escape(cookieName) + '=');

   if (posName != -1)
   {
      var posValue = posName + (escape(cookieName) + '=').length;
      var endPos = document.cookie.indexOf(';', posValue);
      if (endPos != -1)
      {
         cookieValue = unescape(document.cookie.substring(posValue, endPos));
      }
      else
      {
         cookieValue = unescape(document.cookie.substring(posValue));
      }
   }
   return cookieValue;
}

// Tryout 1: Set a session cookie which expires after
//           the browser is closed
setCookie ('TRYOUT', '1');

// Tryout 2: Set a cookie which expires after 24 hours
var now = new Date();
var tomorrow = new Date(now.getTime() + 1000 * 60 * 60 * 24);
setCookie ('TRYOUT', '2', tomorrow);

// Tryout 3: Set a cookie with a path
setCookie ('TRYOUT', '3', null, '/');

// Tryout 4: Delete a cookie by setting its expiry date to
//           be sometime in the past
var now = new Date();
var yesterday = new Date(now.getTime() - 1000 * 60 * 60 * 24);
setCookie('TRYOUT', '4', yesterday);
```

http://www.netscape.com/newsref/std/cookie_spec.html

Cookie domain (Attribute)

An attribute that defines the domain scope of a cookie.

For security reasons, cookies can only be sent back to the web-server the creating document originated from. However, in large web-server farms, the web pages may be distributed for load balancing reasons. Because of this, the domain attribute provides a way to widen the scope to any machine within a domain.

Cookie expires (Attribute)

An attribute that defines the expiry date and time of a cookie.

The lifetime of a cookie is defined with this attribute. From JavaScript, you can set this attribute but you cannot read it since there is no real object model for the cookies.

To define this attribute, you add a name-value pair to the cookie definition string whose name is "expires" and whose value is defined according to the `Date.toGMTString()` method.

A cookie only survives for the duration of the page in the browser unless you define an expiry date for it. If the expiry date is in the future when the browser exits, they will be remembered in a persistent cache inside the browser. If not, the cookie is discarded and unavailable next time you run the browser.

See also:	`Date.toGMTString()`

Cookie path (Attribute)

An attribute that defines the path scope of a cookie.

The scope of a cookie can be limited to a certain part of the document tree within the web server. By defining a node within the document hierarchy, the cookie will only be sent to the web server when requesting a page that exists at that path or lower down in any sub-directories within it.

Unless you specify this value, the cookie will by default be available to any pages in the same directory as the page that created it or in pages lower down in sub-directories. These might be referred to as sibling or child pages. The path value is usually modified to be more inclusive than the default settings.

Cookie secure (Attribute)

A Boolean attribute that defines whether a cookie is secure or not.

The secure attribute is a Boolean value that defines whether the secure protocol is required. If it is activated, then the cookie is only sent to a server when the secure `https:` protocol is used. To activate this facility simply add the secure attribute to the cookie.

Cookie value (Attribute)

An attribute containing the value of a cookie.

Refer to:

Cookie

Copying objects (Advice)

Object references are normally duplicated in preference to the objects themselves.

When you assign the result of a new operation to a variable, you are actually storing a reference to the object. Copying the contents of one variable to another by assignment copies the reference and not the object.

Creating a new object and copying all the top-level properties across from the original is a shallow copy, so called because it only goes one layer into the hierarchy.

If you are able to create a new instance of the object and then recursively copy all the properties across from one to the other, you will have made a deep copy of the object. To do this, you need to traverse all of the branches of the object references, instantiating new copies of any objects you find. This may or may not be possible since some properties may be hidden from view, may be read-only or may not be enumerable and therefore impossible to copy without knowing what they are.

In practice though, any properties you put into the original object from a script are likely to be copyable and you are likely to know enough about your objects to be able to accomplish this at least to the extent that you need.

Comparing two objects may yield a different result depending on whether you are comparing shallow copies or deep copies. Comparing two shallow copies is actually the act of comparing references. If they both refer to the same object, then they must be identical and equal. Comparing deep copies requires a comparison on a property-by-property basis. This may prove that the objects are equal but not identical. A simple compare of the references would prove `false`.

To compare deep copies, you should implement an object method called `isEqualTo()` and pass the object that you want to compare. The receiving object can then enumerate its properties and test the passed object for the existence and content of those properties.

You may need to make your deep copy algorithm recursive if you are copying objects that contain references to objects. For example, `Arrays` of `Arrays`.

Writing a generalized algorithm is quite difficult if you want it to work across browsers. This is because you need to be able to determine the class of any objects you encounter so that you can perform the right kind of copying on them. This might be easier if you limit the kind of objects you use.

Example code:

```
// Copying only an object reference
myObject1 = new Array("AAA", "BBB", "CCC");
myObject2 = myObject1;

// Shallow copying (one layer deep)
myObject1 = new Array("AAA", "BBB", "CCC");
```

```
myObject2 = new Array(myObject1.length);
for(ii=0; ii < myObject1.length; ii++)
{
   myObject2[ii] = myObject1[ii];
}

// Deep copying (knowledge of the internal structure required)
myItem1   = new Array("A", "B", "C");
myItem2   = new Array("1", "2", "3", myItem1);
myObject1 = new Array("X", "Y", "Z", myItem2);
myObject2 = new Array();
myObject2[0] = myObject1[0];
myObject2[1] = myObject1[1];
myObject2[2] = myObject1[2];
myObject2[3] = new Array();
myObject2[3][0] = myObject1[3][0];
myObject2[3][1] = myObject1[3][1];
myObject2[3][2] = myObject1[3][2];
myObject2[3][3] = new Array();
myObject2[3][3][0] = myObject1[3][3][0];
myObject2[3][3][1] = myObject1[3][3][1];
myObject2[3][3][2] = myObject1[3][3][2];
```

Core JavaScript (Definition)

That part of the language that is deemed to be fundamental.

The core part of the language includes the operators and basic language elements. This covers constructs such as `for` loops, `while` loops, `if/else` conditions and `switch/case` trees.

The `Global` object is included in the core language, but gets extended with additional functionality when the interpreter is hosted.

The prototype-inheritance mechanisms, scope chain, and function call support is part of the core language too, as are the constructor frameworks.

These are built around the generic set of objects that represent the primitive data types such as Number, Boolean, String, and Array.

The core language also includes the `Math` and `Date` object support.

Core Object (Definition)

Objects that are built into the base language.

Core objects describe the fundamental primitive data types such as `Number`, `Boolean`, `String`, and `Array`. The `Object` object, which is considered to be the super-class of all objects, is a fundamental core object.

`Math` and `Date` are core objects too and provide support for mathematical capabilities and date handling respectively.

Cross-browser compatibility (Definition)

Different browsers have different features and capabilities.

The differences between browsers are most acute when considering Netscape vs. MSIE. The Opera and iCab browsers are keen to become ECMAScript-compliant. Recent versions of MSIE also make this claim and it is likely that imminent versions of Netscape will be at least as ECMAScript-compliant as the other browsers. This bodes well for the future in that we can code for a base level of functionality and be able to deploy a useful sub-set of the JavaScript capabilities of each browser.

Inevitably, they will continue to present features that are browser-specific. Some of those will be accommodated in the next revision of the ECMA standard. But some won't.

You may find that your script needs to do something more esoteric than a simple form validation or mouse rollover. In particular doing any dynamic HTML and changing `<DIV>`, `<SPAN>`, or `<LAYER>` content. For these kinds of things, you may need to use browser-detection scripts and then provide alternative versions of some of your functions so that you select one that is appropriate for the browser the script happens to find itself running in.

See also:	Compatibility, Defensive coding

Cross-platform compatibility (Definition)

Portability is a major issue for web developers.

When you write JavaScript that exploits capabilities of either Netscape or MSIE, you may already be taking account of the differences between the two browsers.

However, those browsers, even at the same versions, may not always behave identically on different platforms.

Netscape is available on more platforms than MSIE. Opera and iCab are likely to be available as widely as Netscape, but both are stressing their adherence to the standards and both make bold claims to be compliant. That suggests that their behavior across computing platforms will be identical.

In actual fact, there are minor differences even on the best crafted browser projects. MSIE and Netscape fall some way behind the lesser known browsers in this respect.

If you are deploying a major web site that contains JavaScript, you really must consider setting up a test suite to check the cross-platform capabilities.

It is possible to install a variety of browsers onto a single Macintosh system. It is a little more difficult with Windows installations, which generally do not cope well with more than one version of any particular product being installed. You experience difficulties installing older versions of MSIE onto recent versions of Windows that already have an embedded web browser.

You could, if you are serious about cross platform testing, easily end up with a test suite of 10 or more machines. That way you would likely be able to cover Linux as well.

Although you may install many browser applications on a single Macintosh, you may want to add more hard disks and install multiple operating system versions so you can multiple-boot the machine.

This is because some cross-platform differences are due to underlying operating system level code, which may be revised with a new release of the OS and which may manifest itself as an artifact on the web page when it is displayed.

The `navigator` property tells you a lot about the browser and platform. However, MSIE supports other platform and browser detection methods that are not available on other browsers.

See also:	Compatibility, `Navigator` object

crypto (Property)

A reference to a `Crypto` object for security encoding.

Availability:	JavaScript – 1.2 Netscape – 4.04	
Property/method value type:	`Crypto` object	
JavaScript syntax:	N	`crypto`
	N	`myWindow.crypto`

Property attributes:

`ReadOnly`.

Refer to:

`Window.crypto`

Crypto object (Object/Navigator)

An object to manage cryptographic resources.

Availability:	JavaScript – 1.2 Netscape – 4.04	
JavaScript syntax:	N	`crypto`
Object properties:	`constructor`	
Object methods:	`random(),signText()`	

This object appears to be quite opaque. That seems to make sense as you wouldn't want security-related information to be visible simply by enumerating the properties.

There appear to be no enumerable properties belonging to this object.

See also:	`Window.crypto`

Property	JavaScript	JScript	N	IE	Opera	Notes
constructor	1.2 +	-	4.04 +	-	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
random()	1.2 +	-	4.04 +	-	-	-
signText()	1.2 +	-	4.04 +	-	-	-

Crypto.constructor (Property)

A constructor function for the `Crypto` object in Netscape.

Availability:	JavaScript – 1.2 Netscape – 4.04	
Property/method value type:	`Crypto` object	
JavaScript syntax:	N	`crypto.constructor`

You can use this as a way of creating `Crypto` objects.

This property is useful if you have an object that you want to clone, but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

Crypto.random() (Function)

Return a string of randomly generated characters.

Availability:	JavaScript – 1.2 Netscape – 4.04	
JavaScript syntax:	N	`crypto.random()`

Refer to:

Security policy

Crypto.signText() (Function)

Request a digital signature from a user.

Availability:	JavaScript – 1.2 Netscape – 4.04	
JavaScript syntax:	N	`crypto.signText()`

Refer to:

Security policy

Cryptoki (Security related)

Part of the Netscape security facilities.

Cryptoki is pronounced crypto-key and is short for cryptographic token interface. It is provided by RSA Data Security, Inc and can be accessed from the C language and Java.

See also:	`Pkcs11` object

CSS (Standard)

Cascading Style Sheets.

In the early days of the web, page designers were intent on creating ever more complex HTML in an effort to be able to organize how the content would appear on every browser. It became important to be able to render the page with pixel perfect accuracy. This was not the original intent of HTML.

With the introduction of CSS, designers were given a much larger range of tools with which to control the appearance of web pages. For some time CSS level 1 was thought to be sufficient. Eventually this was superseded by CSS level 2.

The Netscape 4 browser supports a third alternative, that of JavaScript Style Sheets or JSS for short. With the release of Netscape 6.0 providing standards-based support, JSS has no future and should not be used in any new projects. Our JSS coverage has accordingly been marked as deprecated.

CSS is constructed from packages of rules, which are assembled into style-sheets.

There is no object model defined for style sheets as of DOM level 1. Until this is ratified in a later DOM specification, Netscape and MSIE continue to support mutually incompatible style sheet API specifications.

The DOM level 2 implementation of CSS style objects (the CSS Object model) provides a complex hierarchy of objects. These are only partly implemented in current browsers. The most complete implementation is in the MSIE browser, and even then the objects are factored differently and the classes named in an MSIE-specific manner.

The DOM CSS suite is embodied in the following classes:

- `CSSStyleSheet`
- `CSSRuleList`
- `CSSRule`
- `CSSStyleRule`
- `CSSMediaRule`
- `CSSFontFaceRule`
- `CSSPageRule`
- `CSSImportRule`

- `CSSCharsetRule`
- `CSSUnknownRule`
- `CSSStyleDeclaration`
- `CSSValue`
- `CSSPrimitiveValue`
- `CSSValueList`
- `RGBColor`
- `Rect`
- `Counter`
- `ViewCSS`
- `DocumentCSS`
- `DOMImplementationCSS`
- `ElementCSSInlineStyle`
- `CSS2Properties`

See also:	`<STYLE>`, CSS level 1, CSS level 2, CSS-P, Dynamic HTML

CSS level 1 (Standard)

A standard for describing style sheets.

The CSS level 1 standard was issued in December 1996 and describes a simple formatting model intended mainly for screen, based presentations. It makes available approximately 50 properties for controlling the appearance of a web page.

See also:	`<STYLE>`, CSS, CSS level 2, JavaScript Style Sheets

Web-references:

http://www.w3.org/TR/REC-CSS1

CSS level 2 (Standard)

A standard for describing style sheets.

The CSS level 2 standard was presented around May 1998 and was based on the earlier CSS1 standard. It adds another 70 properties to the 50 already available with CSS level 1.

See also:	`<STYLE>`, CSS, CSS level 1, CSS-P, Dynamic positioning

Web-references:

http://www.w3.org/TR/REC-CSS2

CSS-P (Standard)

Specifically and only the positional controls for HTML entities, nowadays folded into the CSS level 2 standard.

Warnings:

- The CSS-P specification allows that any tag can be positioned. However Netscape 4 only supports the positioning of elements that have an opening and closing tag. This means you cannot control the position of an `IMG` object on its own unless you encapsulate it correctly within the document. You can control the posistion of an `IMG` object if it is enclosed within a set of balanced `<SPAN>`, `<DIV>`, or `<A>` HTML tags.
- Netscape 4 also converts any absolutely positioned `<DIV>` tags into layers. This means you can manipulate them as layers but this requires special script code that is only usable on version 4 of Netscape. This has completely changed on Netscape 6.0.

See also:	CSS, CSS level 2, Dynamic positioning

Currency symbol (Definition)

A symbol that denotes a locale-specific currency.

Many (but not all) currency symbols are defined as Unicode character code points. The currently extant standard does not adequately support the Euro symbol in common use, although it is generally available in the fonts that ship with MacOS and Windows.

Here is a list of the Unicode defined currency symbols at this time:

Code:	HTML:	Description:
0023	&#035;	Hash sign
0024	&#036;	USA (Dollar)
00A2	&#162;	USA (Cent)
00A3	&#163;	United Kingdom (Pound)
00A4	&#164;	General currency symbol
00A5	&#165;	Japan (Yen)
0192	&#131;	Florin
0E3F	-	Thailand (Baht)
20A0	-	Euro currency sign
20A1	-	Costa Rica & El Salvador (Colon)
20A2	-	Brazil (Cruzeiro)
20A3	-	France (Franc)
20A4	£	Italy (Lira - similar to 00A3)
20A5	-	USA (Mill - 1/10 cent)

Table continued on following page

Code:	HTML:	Description:
20A6	-	Nigeria (Naira)
20A7	-	Spain (Peseta)
20A8	-	India (Rupee - can be drawn as Rs)
20A9	-	Korea (Won)
20AA	-	Israel (New Sheqel)
20AB	-	Vietnam (Dong)

See also:	Localization

currentStyle object (Object/JScript)

An object that represents the cascaded format and style of its parent object.

Availability:	JScript – 5.0 Internet Explorer – 5.0
Inherits from:	style object
JavaScript syntax:	IE *myCurrentStyle* = *myElement*.currentStyle
Object methods:	getAttribute(),getExpression(),removeExpression(), setAttribute(),setExpression()

Because the style values are cascaded from style sheet to style sheet and may include some inline styles as well as some explicit styles, objects need to maintain a current style value that is the result of all the inheritances applied on top of one another.

In addition they maintain a runtime style that reflects dynamic changes as well. The runtime style is based on the current style in the first place.

This represents the cascaded format and style of its parent object.

The properties belonging to this object correspond closely to those of the style object and so there is little point in discussing them again here. Refer to the style object property descriptions for details of the various properties.

See also:	Element.currentStyle, Element.runtimeStyle, runtimeStyle object, style object (2)

Method	JavaScript	JScript	N	IE	Opera	Notes
getAttribute()	-	5.0 +	-	5.0 +	-	-
getExpression()	-	5.0 +	-	5.0 +	-	-
removeExpression()	-	5.0 +	-	5.0 +	-	-
setAttribute()	-	5.0 +	-	5.0 +	-	-
setExpression()	-	5.0 +	-	5.0 +	-	-

Cursor object (Object/NES)

This object encapsulates a cursor that was returned from the database as a result of an SQL query.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	*myCursor* = Connection.cursor(*aQuery*)
	NES	*myCursor* = Database.cursor(*aQuery*)
Argument list:	*aQuery*	A valid SQL query for the database
Object properties:	<column_name>	
Object methods:	blobImage(),blobLink(),close(),columnName(),columns(), deleteRow(),insertRow(),next(),updateRow()	

You can construct a `cursor` object by requesting it via the `Connection` object or `database` object, both of which have `cursor` methods.

Example code:

```
<SERVER>
// An example cursor retrieved from a database
// Based on the example from Wrox Professional JavaScript
database.connect("ODBC", "myDatabase", "", "", "");
myCursor = database.cursor("SELECT * FROM MY_TABLE");
</SERVER>
```

See also:	Connection.cursor(),database object, database.cursor(), Netscape Enterprise Server, unwatch(),watch()

Property	JavaScript	JScript	NES	Notes
<column_name>	1.1 +	-	2.0 +	-

Method	JavaScript	JScript	NES	Notes
blobImage()	1.1 +	-	2.0 +	-
blobLink()	1.1 +	-	2.0 +	-
close()	1.1 +	-	2.0 +	-
columnName()	1.1 +	-	2.0 +	-
columns()	1.1 +	-	2.0 +	-
deleteRow()	1.1 +	-	2.0 +	-
insertRow()	1.1 +	-	2.0 +	-
next()	1.1 +	-	2.0 +	-
updateRow()	1.1 +	-	2.0 +	-

Cursor.<column_name> (Property)

The columns within the answer set are reflected into properties with the same names.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myCursor.aColumnName*
Argument list:	*aColumnName*	The name of a column within the answer set

The column names are inherited from the tables in the database that the cursor is traversing.

Cursor.blobImage() (Method)

This method creates an `<IMG>` element having the appropriate mimeType for the `blob` object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Image` object	
JavaScript syntax:	NES	*myCursor*.blobImage(*aFormat*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*, *anAlign*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*, *anAlign*, *aPixWid*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*, *anAlign*, *aPixWid*, *aPixHgt*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*, *anAlign*, *aPixWid*, *aPixHgt*, *aPixBrdr*)
	NES	*myCursor*.blobImage(*aFormat*, *aTxt*, *anAlign*, *aPixWid*, *aPixHgt*, *aPixBrdr*, *isMap*)
Argument list:	*aFormat*	Image file format
	anAlign	The alignment of the image
	aPixBrdr	The border value
	aPixHgt	The height of the image
	aPixWid	The width of the image
	aTxt	The alt text for the image
	isMap	Whether the image is a map

The data is pulled out of the database according to the specified parameters. The BLOB can then be displayed as if it were an image in an `<IMG>` tag.

The format argument should contain an image specifier such as "GIF" or "JPEG" that can map conveniently to a file extension or MIME type.

In general, the remaining parameters to this method correspond to the HTML tag attributes that can be used with an <IMG> tag and are optional.

See also:	blob.blobImage()

Cursor.blobLink() (Method)

This method creates an <A> element that links to the BLOB data.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	Anchor object	
JavaScript syntax:	NES	*myCursor*.blobLink(*aMimeType*, *aString*)
Argument list:	*aString*	The text inside the link
	aMimeType	The MIME type of the document being displayed

The data is pulled out of the database according to the specified parameters. The BLOB can then be displayed as if it were an document in an <A> tag.

See also:	blob.blobLink()

Cursor.close() (Method)

To close the cursor.

Availability:	JavaScript - 1.1 Netscape Enterprise Server - 2.0	
JavaScript syntax:	NES	*myCursor*.close()

After a cursor has been closed, there can be no further access to it until it is reopened by creating a new instance from the cursor property belonging to the Connection or database objects.

All open cursors are automatically closed by NES at the end of the client request.

Cursor.columnName() (Method)

Returns the name of the indexed column within the cursor.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	String primitive	
JavaScript syntax:	NES	*myCursor*.columnName(*anIndex*)
Argument list:	*anIndex*	A valid column number within the cursor

The columns are arranged in order as they appear in the answer set. This method indexes the name list in the answer set and returns the names for each column using a zero-based index.

Cursor.columns() (Method)

Returns the number of columns in the cursor.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myCursor*`.columns()`

The answer set contains a list of columns that were retrieved from the database. This method returns a count of the columns in the answer set.

Cursor.deleteRow() (Method)

Deletes the current row in the cursor.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myCursor*`.deleteRow(`*aTableName*`)`
Argument list:	*aTableName*	The name of a table to have a record deleted from it

If the cursor is updateable, then you can remove a row from the table. The row removed corresponds to the one the cursor is currently referencing.

The row following the current row becomes the current row unless the cursor is on the last row of the cursor in which case it is indexed backwards to the previous row.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	Status Code

Cursor.insertRow() (Method)

A new row is inserted into the table that the cursor is pointing at.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myCursor*`.insertRow(`*aTableName*`)`
Argument list:	*aTableName*	The name of a table to have the new data inserted into it

New rows can be inserted into the table if the cursor is updateable.

Note that there is no guarantee as to the position of the new inserted record. There may be automatic sorting triggers activated in the database that cause it to be sorted into the correct position or the new record may simply be appended to the end. It is implementation-dependent.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	Status Code

Cursor.next() (Method)

Index the cursor onwards to the next row.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	*myCursor*.next()

The cursor is moved onwards to point at the next sequential record.

When the cursor reaches the end of the selection, it cannot be indexed any further onwards. What happens in this case is implementation-dependent, but there should probably be an error generated.

Cursor.prototype (Property)

The prototype for the `Cursor` object that can be used to extend the interface for all `Cursor` objects.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Cursor` object	
JavaScript syntax:	NES	`Cursor.prototype`
	NES	*myCursor*`.constructor.prototype`

Refer to:

`prototype` property

Cursor.updateRow() (Method)

Any pending changes to the current row are saved back to the database.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0
Property/method value type:	`Number primitive`

JavaScript syntax:	NES	*myCursor*.updateRow(*aTableName*)
Argument list:	*aTableName*	The name of a table to be updated with the new data

If the cursor is updateable, then the row currently referred to by the cursor can be updated.

You may need to perform a commit action on the database to confirm the changes and avoid them being rolled back when the session is closed. Whether this is necessary depends on whether there are auto-confirm triggers or whether the target database even supports a two phase commit.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	Status Code

Custom object (Definition)

A user-defined object inheriting the properties of an `Element` object within the MSIE browser model.

Refer to:

`Element` object

Data Type (Definition)

The type of data contained in a variable or described by a literal.

Fundamentally, JavaScript works with the following value types:

- Numbers
- Strings
- Boolean values
- Objects

All other data types are aggregates of those.

Objects are really collections of primitive values and are accessed by reference.

See also:	Boolean, Number, Object, String

Cross-references:

O'Reilly *JavaScript Definitive Guide* –page –34

Data-tainting (Security related)

A mechanism for marking data in the client and controlling its use. An obsolete security work-around.

The data-tainting model was implemented in Netscape 3 but deprecated by version 4. It was never implemented in MSIE.

Rather than prevent access to data in other parts of the browser space, it allows full access even to private data. However, that access marked the data as tainted and any values that were derived from it were also tainted. Tainted data values could not be sent back to the server and in fact were not permitted to leave the client.

These capabilities were not used very much in production systems and have now been superseded by the signed scripts and privilege model.

Warnings:

- This is deprecated and should not be used in new projects.

See also:	Restricted access, Security policy, Signed scripts

database object (Object/NES)

An object that encapsulates the access to a back end database from Netscape Enterprise Server.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0
JavaScript syntax:	NES `database`
Object properties:	`prototype`
Object methods:	`beginTransaction()`, `commitTransaction()`, `connect()`, `connected()`, `cursor()`, `disconnect()`, `execute()`, `majorErrorCode()`, `majorErrorMessage()`, `minorErrorCode()`, `minorErrorMessage()`, `rollbackTransaction()`, `SQLTable()`, `storedProc()`, `storedProcArgs()`, `toString()`

The `database` object is always available through the `database` property of the `Global` object within the Netscape Enterprise Server session. Before using any other methods belonging to this object, you must first successfully connect to a database.

Until the `database` object has made a connection to the database, the only methods that have any meaning are `database.connect()` and `database.connected()`.

See also:	`Cursor` object, Netscape Enterprise Server, `response.database`, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
`prototype`	1.1 +	-	2.0 +	-

Method	JavaScript	JScript	NES	Notes
`beginTransaction()`	1.1 +	-	2.0 +	-
`commitTransaction()`	1.1 +	-	2.0 +	-
`connect()`	1.1 +	-	2.0 +	-
`connected()`	1.1 +	-	2.0 +	-

`storedProcArgs()`	1.1 +	-	3.0 +	-
`toString()`	1.1 +	-	2.0 +	-

database.beginTransaction() (Method)

Marks the beginning of a transaction with the database.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`database.beginTransaction()`

This commences a transaction on the database. The transaction methods are useful if you want to maintain control over the two phase commit process in the database. The alternative `database.execute()` method can accomplish the same but it will automatically commit any changes as the SQL is executed. This transaction based technique provides a finer degree of control and allows for rollbacks.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	`database.commitTransaction()`, `database.rollbackTransaction()`, Status code

database.commitTransaction() (Method)

Commit the changes made during this transaction.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`database.commitTransaction()`

In the transaction based mechanism, you can control the commit and rollback of the transaction if necessary. You will need to explicitly call this method to commit the changes to the database.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	`database.beginTransaction()`, `database.rollbackTransaction()`, Status code

database.connect() (Method)

Forms a connection to the database using the database type to select the correct one.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`database.connect(aType, aServer, aUser, aPassword, aDb);`
	NES	`database.connect(aType, aServer, aUser, aPassword, aDb, maxCon);`
	NES	`database.connect(aType, aServer, aUser, aPassword, aDb, maxCon, aFlag);`
Argument list:	*aDb*	The name of a database
	aFlag	Commit or roll back on close
	aPassword	A valid password for the user
	aServer	The name of a database server
	aType	A valid connection type
	aUser	A user registered for database access on the server
	maxCon	The maximum number of simultaneous connections

When connecting to a database, you need to indicate the type of database you are connecting to. The following are examples of commonly available database types:

- ORACLE
- SYBASE
- INFORMIX
- DB2
- ODBC

Use one of these values in the first argument to this method.

You will also need to know the name of your target server, a valid username and password and if multiple databases are supported by your database server, then you will need to know the name of the target database you want to connect to.

The last two arguments indicate the maximum number of connections available at once and a flag to indicate the commit policy on closure. You can elect to automatically commit any changes (dangerous) or roll back any uncommitted changes.

See also:	`DbPool` object, `DbPool()`, `DbPool.connect()`

database.connected() (Method)

A flag, indicating the connection status for this `database` object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	`database.connected()`

This method returns a Boolean value that tells you whether the database object is connected to a database or not.

See also:	`DbPool.connected()`

database.cursor() (Method)

Creates a new cursor object with the SQL supplied in the argument.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Cursor object`	
JavaScript syntax:	NES	`database.cursor(`*`aQuery`*`)`
	NES	`database.cursor(`*`aQuery, aFlag`*`)`
Argument list:	*`aFlag`*	Defines whether the cursor is updateable or not
	`aQuery`	A valid SQL query for the database

This method returns an answer set as a `cursor` object.

The updateable flag controls whether the cursor can be updated or not. Setting it `true` means the cursor can be used to send an update change to the database. `False` renders it read only.

See also:	`Cursor` object

database.disconnect() (Method)

Severs the current connection to the database.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
JavaScript syntax:	NES	`database.disconnect()`

It is a good idea to disconnect from the database when you know you won't need it anymore. This is good practice and allows other processes to connect when resources are scarce.

Until the database is connected again, only the `connect()` and `connected()` methods have any meaning.

See also:	`DbPool.disconnect()`

database.execute() (Method)

Executes the SQL passed in the argument.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`database.execute(`*`someSQL`*`)`
Argument list:	*`someSQL`*	A fragment of valid SQL for the database

This method cannot return an answer set. It does return a status code indicating how successfully it managed the query.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

Warnings:

- This method will automatically perform a commit on any SQL that you send. You can avoid this by using transaction methods.

See also:	Status code

database.majorErrorCode() (Method)

Returns the error code for an error that may have happened in the database or the interface to it.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`database.majorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields a return code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server message number.

For a status code value of 7 when using the Informix database, this yields the Informix error code.

For a status code value of 7 when using the Sybase database, this yields the DB-Library error number.

See also:	`Connection.majorErrorCode()`, `DbPool.majorErrorCode()`, Error handling, Status code

database.majorErrorMessage() (Method)

Returns the error message text for an error that may have happened in the database or the interface to it.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`database.majorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields a text string describing the server error.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields a text string from SQL server.

For a status code value of 7 when using the Informix database, this yields the text string from the vendor error library.

For a status code value of 7 when using the Sybase database, this yields a text string from the DB-Library.

See also:	`Connection.majorErrorMessage()`, `DbPool.majorErrorMessage()`, Error handling, Status code

database.minorErrorCode() (Method)

Returns a supplementary error code for an error that may have happened in the database or the interface to it.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`database.minorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields an operating system error code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the severity level from SQL server.

For a status code value of 7 when using the Informix database, this yields the ISAM error code.

For a status code value of 7 when using the Sybase database, this yields the severity level of the error from the DB-Library.

See also:	`Connection.minorErrorCode()`, `DbPool.minorErrorCode()`, Error handling, Status code

database.minorErrorMessage() (Method)

Returns a supplementary error message text for an error that may have happened in the database or the interface to it.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`database.minorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields the Oracle server name.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server name.

For a status code value of 7 when using the Informix database, this yields a text string describing the ISAM error.

For a status code value of 7 when using the Sybase database, this yields the text of the operating system error from the DB-Library.

See also:	`Connection.minorErrorMessage()`, `DbPool.minorErrorMessage()`, Error handling, Status code

database.prototype (Property)

The prototype for the database object that can be used to extend the interface for all database objects.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`database object`	
JavaScript syntax:	NES	`database.prototype`

See also:	`Prototype` property

database.rollbackTransaction() (Method)

Undoes any changes made in the current transaction.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`database.rollbackTransaction()`

In the transaction based technique, this method provides a way to rollback the changes if you have not yet committed them.

Refer to the Status Code topic for a list of the status code values that are returned by this method.

See also:	`database.beginTransaction()`, `database.commitTransaction()`, Status code

database.SQLTable() (Method)

Creates an HTML table based on the results of the SQL query provided in the argument.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String` primitive	
JavaScript syntax:	NES	`database.SQLTable(`*`someSQL`*`)`
Argument list:	*`someSQL`*	A valid SQL query for the connected database

The select statement is passed to the database and the results are returned to the caller as a series of records formatted to appear as an HTML table.

database.storedProc() (Method)

Creates a stored procedure object and runs the specified stored procedure in the database.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 3.0	
Property/method value type:	`Stproc` object	
JavaScript syntax:	NES	`database.storedProc(`*`aProcName`*`, `*`aProcParm`*`)`
Argument list:	*`aProcName`*	The name of a stored procedure to call
	`aProcParm`	A parameter set to pass to the stored procedure

See also:	`ResultSet` object

database.storedProcArgs() (Method)

Creates a prototype for a stored procedure and controls the argument passing.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 3.0	
Property/method value type:	`Stproc` object	
JavaScript syntax:	NES	`database.storedProcArgs(`*`aProc`*`)`
	NES	`database.storedProcArgs(`*`aProc`*`, `*`someArgTypes`*`)`

Argument list:	*aProc*	The name of a stored procedure
	someArgTypes	Some argument types to define the API

The prototype stored procedure object supports input and output parameters. This prototype object is used to indicate the direction of values in these parameters.

See also:	`DbPool.storedProcArgs()`

database.toString() (Method)

Returns a string equivalent of the database object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`database.toString()`

The value of the object is converted to a string value that represents its value.

See also:	`DbPool.toString()`

dataTransfer object (Object/JScript)

An object used during drag and drop operations to provide access to data being dragged.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myDataTransfer* = *myEvent*.dataTransfer
Object properties:	`dropEffect, effectAllowed`	
Object methods:	`clearData(), getData(), setData()`	

This also assists with access to the clipboard while items are being dragged and dropped. You need to access this object via the `dataTransfer` property of the `event` object.

Operating this functionality is quite complex and you should check out the various examples covered in the documentation at the Microsoft developer web site.

See also:	`Event.dataTransfer`

Property	JavaScript	JScript	N	IE	Opera	Notes
`dropEffect`	-	5.0 +	-	5.0 +	-	-
`effectAllowed`	-	5.0 +	-	5.0 +	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
`clearData()`	-	5.0 +	-	5.0 +	-	-
`getData()`	-	5.0 +	-	5.0 +	-	-
`setData()`	-	5.0 +	-	5.0 +	-	-

dataTransfer.clearData() (Method)

Clears any data currently in the `transfer` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myDataTransfer*`.clearData()`

The contents of the `dataTransfer` object are discarded according to the values specified. To understand what this means requires a short discussion about clipboards and how they work.

The Microsoft Windows clipboard is modelled very closely on the clipboard mechanisms originally implemented in the Macintosh operating system in 1984, when it was first released. The Macintosh environment is constructed around a set of resource objects. When a selection is cut or copied to the clipboard, what is actually stored is a set of resources that describe the selection in a variety of different ways. This enables the target application that receives a paste command to select the most appropriate piece of data that it can understand.

For example, in a music application, the selected region of notation is copied to the clipboard as the following:

- Native application specific data
- A MIDI sequence
- A picture of the notation on screen

If you then goto a word processor and paste in the clipping, it won't understand the MIDI data or the application specific data. However, it could very well understand the picture data and would choose that as being the most appropriate.

This explains how data is lost when you cut and paste between several applications and back to the originating application. Some applications are quite good at preserving the entire contents of the clipboard even though they may only understand one of its component varieties. An example of that is the Macintosh Scrapbook application. It can only display a picture when music clippings are pasted in from a MIDI sequencer. However, it preserves all the component resources and if you copy an item from the scrapbook, you get the complete set again.

Going back to the MSIE browser and the `dataTransfer` object, the drag drop and clipboard mechanism carries a collection of related resources. Each is a copy of the source item in different forms. This `clearData()` method can be used to discard the forms that you no longer need.

It accepts the following values in its argument:

- Text
- URL
- File
- HTML
- Image

You can specify one or several of these to discard the values you no longer need.

This method should be called in an `onDragStart` event handler for maximum effect. If you need to override the default behavior of the target receiver, then you may want to use this in the `onDrop` event handler too.

See also:	`clipboardData` object, `onDragStart`, `onDrop`

dataTransfer.dropEffect (Property)

Set the effect when the element is dropped.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDataTransfer`*`.dropEffect`

This property defines the effect when the data item is dropped onto the receiving element. It needs to be used with the `effectAllowed` property. Controlling the drag drop operation at this level is quite complicated and you should consult the Microsoft developer web site for an in depth explanation of how it works.

This property accepts the following values:

- `copy`
- `link`
- `move`
- `none`

This value can be set during certain event handlers, during the drag operation. These events are likely candidates:

- `onDragEnter`
- `onDragOver`
- `onDrop`

See also:	`dataTransfer.effectAllowed`, `onDragEnter`, `onDragOver`, `onDrop`

Web-references:

http://msdn.microsoft.com/workshop/author/dhtml/reference/properties/dropeffect.asp

dataTransfer.effectAllowed (Property)

Indicates whether the drop effect is allowed or not.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myDataTRansfer`*`.effectAllowed`

You should set this property in the `onDragStart` event handler.

The following values can be assigned to this property, to control whether the drag drop is allowed to happen:

- copy
- link
- move
- copyLink
- copyMove
- linkMove
- all
- none
- uninitialized

Assigning values to this property must be done bearing in mind what you have assigned to the `dropEffect` property as the two work together.

See also:	`dataTransfer.dropEffect`, `onDragStart`

dataTransfer.getData() (Method)

Gets the data from the `transfer` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDataTRansfer`*`.getData()`

This is used to extract the data via the `dataTransfer`, or `clipboardData` objects. The value returned will be in the form of a string and will either be the textual content or a URL reference to a non-text item.

This mode of access preserves the various security needs when accessing values from one frame to another.

This method is most useful within the `onCopy` and `onCut` event handlers.

See also:	`clipboardData` object, `onCopy`, `onCut`

dataTransfer.setData() (Method)

Sets the data in the `transfer` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDataTransfer*`.setData(`*aType, aString*`)`
Argument list:	*aType*	The value `TEXT` or `URL` to indicate what kind of data is in aString
	aString	A text string to be added to the transfer object

You would use this method to put data into the clipboard. This is done by accessing the `clipboardData` or `dataTransfer` objects during an event handler. You can only store textual values into the clipboard with this method. However they may be the raw text data itself or a description of the URL where non-text data can be found.

The method takes two arguments. The first can be set to the value "`TEXT`" or "`URL`" to indicate which kind of data is being stored. The second argument is the data to be added to the `transfer` object.

This method returns a Boolean value indicating success or failure of the `setData()` call.

Date and time (Definition)

There is a variety of ways to work with dates and times.

Date and time values are manipulated by means of a `Date` object. You can instantiate a new copy of the built-in `Date` object with its constructor. The new instance will hold a fixed time value, which might be 'the time now' or may have been initialized with some other value.

You can get and set various components of the time and date values for a `Date` object. Note that, although you can use the set methods to set a `Date` object to the system time, this will not alter the system time of the machine you are running the script in.

It is possible that some implementations may provide that capability, but it is not defined as part of the standard.

See also:	Broken down time, Calendar time, Daylight savings time adjustment, Local time, Localization, Universal coordinated time

Date constant (Definition)

A constant date value.

Date constants are Date objects with predefined values. These need to be manufactured from component parts and parsed by the `Date` object constructor.

See also:	Constant expression, `Date()` constructor, `Date()` function, `Date.constructor`, `Date.parse()`

Date from time (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

ECMA compliant implementations use the extended Gregorian system for dates. These are all based on 01-January-1970 UTC as a starting point. Although the date handling in JavaScript is flexible and generally comprehensive, there may be additional date computations required in some implementations.

The formula for calculating day number is shown here:

```
t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.

msPerDay = 86400000

Day(t) = floor(t/msPerDay)
```

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non-leap years to adjust the day numbers, and yield the day number of the first day of the given year and then use that to work out the time in milliseconds from when the year started:

```
DayFromYear(y) =

365 * (y - 1970) +

floor((y - 1969) / 4) -

floor((y - 1901) / 100) +

floor((y - 1601) / 400)

TimeFromYear(y) = msPerDay * DayFromYear(y)

YearFromTime(t) = The largest integer y to make TimeFromYear(y) less than or equal
to t.

DayWithinYear(t) = Day(t) - DayFromYear(YearFromTime(t))
```

The month value is worked out with this formulaic framework:

`MonthFromTime(t) = lookup` according to `DayWithinYear(t)` falling into a range according to the following table:

Greater than	Less than	Month	Name
000	031	0	January
031	059 + InLeapYear(t)	1	February
059 + InLeapYear(t)	090 + InLeapYear(t)	2	March
090 + InLeapYear(t)	120 + InLeapYear(t)	3	April
120 + InLeapYear(t)	151 + InLeapYear(t)	4	May
151 + InLeapYear(t)	181 + InLeapYear(t)	5	June
181 + InLeapYear(t)	212 + InLeapYear(t)	6	July
212 + InLeapYear(t)	243 + InLeapYear(t)	7	August
243 + InLeapYear(t)	273 + InLeapYear(t)	8	September
273 + InLeapYear(t)	304 + InLeapYear(t)	9	October
304 + InLeapYear(t)	334 + InLeapYear(t)	10	November
334 + InLeapYear(t)	365 + InLeapYear(t)	11	December

The date within the month is worked out in a similar way, and could probably share a common table of month lengths or offsets.

`DateFromTime(t) = lookup` according to `MonthFromTime(t)` selecting a value to subtract according to the following table:

Month value	Subtract this
00	-1
01	30
02	58 + InLeapYear(t)
03	89 + InLeapYear(t)
04	119 + InLeapYear(t)
05	150 + InLeapYear(t)
06	180 + InLeapYear(t)
07	211 + InLeapYear(t)
08	242 + InLeapYear(t)
09	272 + InLeapYear(t)
10	303 + InLeapYear(t)
11	333 + InLeapYear(t)

Cross-references:

ECMA 262 edition 2 – section – 15.9.1.5

ECMA 262 edition 3 – section – 15.9.1.5

Date number (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

A date number is identified by an integer in the range 1 through 31, inclusive. The specific range depends on the month being considered and whether a leap year is in force.

See also:	Broken down time, Date from time, Day from year, Day number, Day within year, Month from time, Time from year, Time range, Year from time

Cross-references:

ECMA 262 edition 2 – section – 15.9.1.5

ECMA 262 edition 3 – section – 15.9.1.5

Date object (Object/core)

An object of the class "`Date`".

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myDate* = Date
	N	*myDate* = *myEvent*.timeStamp
	N	*myDate* = *myMouseEvent*.timeStamp
	N	*myDate* = *myMutationEvent*.timeStamp
	N	*myDate* = *myUIEvent*.timeStamp
	-	*myDate* = new Date()
Object properties:	constructor, length, prototype	
Class methods:	parse(), UTC()	

Object methods:	`getDate()`, `getDay()`, `getFullYear()`, `getHours()`, `getMilliseconds()`, `getMinutes()`, `getMonth()`, `getSeconds()`, `getTime()`, `getTimezoneOffset()`, `getUTCDate()`, `getUTCDay()`, `getUTCFullYear()`, `getUTCHours()`, `getUTCMilliseconds()`, `getUTCMinutes()`, `getUTCMonth()`, `getUTCSeconds()`, `getVarDate()`, `getYear()`, `parse()`, `setDate()`, `setFullYear()`, `setHours()`, `setMilliseconds()`, `setMinutes()`, `setMonth()`, `setSeconds()`, `setTime()`, `setUTCDate()`, `setUTCFullYear()`, `setUTCHours()`, `setUTCMilliseconds()`, `setUTCMinutes()`, `setUTCMonth()`, `setUTCSeconds()`, `setYear()`, `toDateString()`, `toGMTString()`, `toLocaleDateString()`, `toLocaleString()`, `toLocaleTimeString()`, `toSource()`, `toString()`, `toTimeString()`, `toUTCString()`, `valueOf()`

A `Date` object contains a number that denotes a particular instant in time that is accurate to within a millisecond. The number value may also contain `NaN`, which indicates that the `Date` object does not represent a valid instant in time.

The prototype for the `Date` prototype object is the `Object` prototype object.

Instances of the `Date` object have no special properties beyond those they inherit from the `Date.prototype` object.

JavaScript version 1.2 and the ECMAScript standard both mandate additional methods that the `Date` object should support. These are generally useful when computing year numbers higher than 1999.

Warnings:

- The `Date` object is particularly bug prone in Netscape 2. If this browser version is important, you may need to provide significant amounts of date correcting logic or avoid the use of date values altogether.

Example code:

```
<!-- Display time since document loaded --->
<HTML>
<HEAD>
<SCRIPT>
window.myDate1 = new Date();
</SCRIPT>
</HEAD>
<BODY>
<DIV ID="TEXTCELL">
0000
</DIV>
<FORM>
<INPUT TYPE="button" VALUE="CLICK ME" onClick="clickMe()">
</FORM>
<SCRIPT>
function clickMe()
{
   myDate2 = new Date();
```

```
    myDelta = myDate2 - window.myDate1;
    document.all.TEXTCELL.innerText = myDelta/1000;
}
</SCRIPT>
</BODY>
</HTML>
```

Date() (Constructor)

A `Date` object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
Property/method value type:	`Date` object	
JavaScript syntax:	-	`new Date()`
	-	`new Date(`*`aValue`*`)`
	-	`new Date(`*`aYear`*`, `*`aMonth`*`)`
	-	`new Date(`*`aYear`*`, `*`aMonth`*`, `*`aDate`*`)`
	-	`new Date(`*`aYear`*`, `*`aMonth`*`, `*`aDate`*`, `*`anHour`*`)`
JavaScript syntax:	-	`new Date(`*`aYear`*`, `*`aMonth`*`, `*`aDate`*`, `*`anHour`*`, `*`aMinute`*`)`
	-	`new Date(`*`aYear`*`, `*`aMonth`*`, `*`aDate`*`, `*`anHour`*`, `*`aMinute`*`, `*`aSecond`*`)`
	-	`new Date(`*`aYear`*`, `*`aMonth`*`, `*`aDate`*`, `*`anHour`*`, `*`aMinute`*`, `*`aSecond`*`, `*`aMillisecond`*`)`
Argument list:	*`aDate`*	An optional date within the month value
	`aMillisecond`	An optional value between 0 and 999 milliseconds
	`aMinute`	An optional value between 0 and 59 minutes
	`aMonth`	An optional 0 to 11 month value
	`anHour`	A value between 0 and 23 hours
	`aSecond`	An optional value between 0 and 59 seconds
	`aYear`	A full year value
	`aValue`	A time in UTC milliseconds

The result of calling this constructor is a `date` object with the indicated date and time value.

Calling the `Date()` constructor with the new operator creates a fresh object based on the `Date` prototype. The value of this new `Date` object depends on the parameters specified when the constructor was invoked.

This is not the same as simply calling the `Date()` function which would yield the current system date and time at the instant it was called.

The arguments to the `Date()` constructor are all optional, but they are also positional. This means that you must mark empty positions with comma separated null values to indicate that a parameter needs to be skipped. The time values are assumed to be measured in local time and not UTC.

The prototype of the new `Date` object is the built in `Date` prototype object.

Functionally, the algorithm that manufactures a new date value uses the internal `MakeDay()`, `MakeTime()`, and `MakeDate()` functions that we describe elsewhere.

If the year value is less than 99, then the date creation adds 1900 to it and assumes the date is in the 20th century. To avoid millennium problems, always specify a full year number.

The following rules apply where items are omitted from the right of the argument list.

Zero values are assumed for hours, minutes and seconds. When all three are missing, the time is assumed to be midnight.

The date value is assumed to be the first of the month, and the default month is not considered since a single value on its own is taken to mean a millisecond time value in UTC time coordinates.

When all arguments are omitted, the time value for the new object is set to the current time in UTC time coordinates.

Putting null values in place of the year month and date sets the time correctly but unpredictable date values are substituted.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define the date but assume the time is set to zero
// Note that month numbers start at zero
myDate1 = new Date(1954, 0, 19);
document.write(myDate1);
document.write("<BR>");
// Define the time in minutes but make up any old date
myDate2 = new Date(null, null, null, 12, 14);
document.write(myDate2);
document.write("<BR>");
// Fully qualified date value
myDate3 = new Date(1984, 9, 23, 1, 0, 0, 0);
document.write(myDate3);
document.write("<BR>");
// Output message of the day
</SCRIPT>
</BODY>
</HTML>
```

Date() (Function)

A function that returns the current date.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0
Property/method value type:	`String primitive`
JavaScript syntax:	- `Date()`

This function returns a string primitive representing the current UTC time value.

When the `Date()` constructor is called as a function rather than in a new expression, it returns a string representing the current time (in UTC time). Note that when calling it as a function the arguments are all ignored and it is not equivalent to calling the `Date()` constructor in a new expression at all.

Effectively, the function call to a `Date()` constructor behaves as if you had coded this fragment of JavaScript in the script source text:

```
(new Date()).toString()
```

Date.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition – 2

This is an internal property that describes the class that a `Date` object instance is a member of. The reserved words suggest that, in the future, this property may be externalized.

See also:	Class, `Date` object

Property attributes:

DontEnum, Internal.

Cross-references:

ECMA 262 edition 3 – section – 8.6.2

Date.constructor (Property)

A reference to a constructor object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0
Property/method value type:	`Date constructor object`
JavaScript syntax:	- `Date.constructor`

The initial value of the date prototype constructor is the built-in `Date` constructor.

You can use this as one way of creating `Date` objects although it is more popular to use the new `Date()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

Date.getDate() (Method)

Returns the day number within a month for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*`.getDate()`

This method returns a day number within a month from the date value of the receiving object. The value is 1 based and will not exceed 31 although the range is variable based on month and leap year contexts.

The date is computed according to local time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Create diary of special days per month
myDiary = new Array();
myDiary[1]  = "Pay into bank account";
myDiary[28] = "Invoice customers";
myDiary[14] = "Chase customers for payment";
myDiary[5]  = "Top up fuel in generator";
// Work out day number
myDate = new Date();
myDay = myDate.getDate();
// Output message of the day
document.write(myDiary[myDay]);
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.14

Date.getDay() (Method)

Returns the weekday number for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getDay()

A weekday number for the date value of the receiving object is returned. The value will be in the range 0 to 6, with 0 representing Sunday.

The value is computed according to Local time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sun", "Mon", "Tue", "Wed", "Thu", "Fri", "Sat");
myDate = new Date();
document.write(myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.12

ECMA 262 edition 3 – section – 15.9.5.16

Date.getFullYear() (Method)

Returns the full year for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*`.getFullYear()`

The full year number of the date value in the receiving object is returned as a four digit value. This is much preferred to the get`Year()` method which suffers from Y2K ambiguities and is now deprecated in favor of this method.

The year number is a local time value.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Calculate which century from the year number
myDate = new Date();
myCentury = 1 + myDate.getFullYear()/100;
switch (myCentury % 10)
{
case 1 : mySuffix = "st";
break;

case 2 : mySuffix = "nd";
break;

case 3 : mySuffix = "rd";
break;

default : mySuffix = "th";
break;

}
document.write(myCentury + mySuffix + " century");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getYear(),Date.prototype,Date.setFullYear(), Date.setUTCFullYear(),Date.setYear()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.6

ECMA 262 edition 3 – section – 15.9.5.10

Date.getHours() (Method)

Returns the hour value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getHours()

The hours of the time value contained in the receiving object. This is returned as an integer in the range 0 to 23 inclusive.

The value is computed according to local time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Generate a flag based on work or play time
myDate = new Date();
myHours = myDate.getHours();
if((myHours > 8) && (myHours < 17))
{
document.write("At work");
}
else
{
document.write("At play");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.prototype, Date.setHours(), Date.setUTCHours()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.14

ECMA 262 edition 3 – section – 15.9.5.18

Date.getMilliseconds() (Method)

Return the milliseconds value of a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getMilliseconds()

The milliseconds of the time value contained in the receiving object. The result will be an integer in the range 0 to 999 inclusive.

The value is computed according to local time coordinates.

In the example a timer is set up to trigger a function call every 1000 milliseconds. However, processing load may affect how accurately the timer is executed. By measuring the time on each call, we know that the millisecond value should be the same each time but you will probably observe a small and random perturbation in the value. You can compensate for this by making a small adjustment to the timer value to take this error into account. You will most likely need to reduce the value 1000 by a few milliseconds to get a more accurate timer.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<DIV ID="RESULT">000</DIV>
<SCRIPT>
// Check the accuracy of a timer by printing the milliseconds
setInterval("monitor()", 1000);
myOldMSecs = 000;
function monitor()
{
   myDate  = new Date();
   myMsecs = myDate.getMilliseconds();
   myErr = myMsecs - myOldMSecs;
   document.all.RESULT.innerText = myMsecs + " (" + myErr + " milliseconds of
error)";
   myOldMSecs = myMsecs;
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getMinutes() (Method)

Returns the minutes value of a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*`.getMinutes()`

The minutes of the time value contained in the receiving object. The result will be an integer in the range 0 to 59 inclusive.

The value is computed according to local time coordinates.

Example code:

```
<!-- A bar chart indicating minutes of the hour -->
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=0 CELLPADDING=0 CELLSPACING=0>
<TR HEIGHT=10>
<TD ID="LEFT"  WIDTH=100 STYLE="background-color:RED"> </TD>
<TD ID="RIGHT" WIDTH=500 STYLE="background-color:BLUE"> </TD>
</TR>
</TABLE>
<SCRIPT>
setBar()
setInterval("setBar()", 60000);
function setBar()
{
   myDate    = new Date();
   myMinutes = myDate.getMinutes();
   myOther   = 60 - myMinutes;
   document.all.LEFT.style.width  = 1+myMinutes*10;
   document.all.RIGHT.style.width = 1+myOther*10;
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getMonth() (Method)

Returns the month value of a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*`.getMonth()`

The month number for the receiving date object is returned. This is a zero based value in the range 0 to 11 inclusive. The value 0 represents January, and 11 represents December.

The value is in local time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate  = new Date();
myMonth = myDate.getMonth();
egyptianCalendar(myMonth);
// Generate attributes of the egyptian calendar based on month
function egyptianCalendar(aMonth)
{
   mySeasonArray = new Array("Akhet", "Peret", "Shemu");
   myMonthArray  = new Array("I", "II", "III", "IV");
   myNameArray   = new Array("Thoth", "Phaophi", "Athyr", "Choiak", "Tybi",
"Mechir",       "Phamenoth", "Pharmuthi", "Pachons", "Payni", "Epiphi", "Mesore");
   myDeityArray  = new Array("Tekhi", "Ptah-aneb-res-f", "Het-hert", "Sekhet",
"Amsu",           "Rekeh-ur", "Rekeh-netches", "Rennutet", "Khensu", "Kenthi",
"Apt", "Heru-khuti");
   myTypeArray   = new Array("F", "M", "F", "F", "M", "M", "M", "F", "M", "M",
"F", "M");
   mySeason = mySeasonArray[Math.floor(aMonth/4)];
   myMonth  = myMonthArray[aMonth%4];
   myName   = myNameArray[aMonth];
   myDeity  = myDeityArray[aMonth];
   switch(myTypeArray[aMonth])
```

```
        {
           case "F" : myType = "Goddess";
              break;
           case "M" : myType = "God";
              break;
        }
     document.write("Index : "  + aMonth   + "<BR>");
     document.write("Season : " + mySeason + "<BR>");
     document.write("Month : "  + myMonth  + "<BR>");
     document.write("Name : "   + myName   + "<BR>");
     document.write("Deity : "  + myDeity  + "<BR>");
     document.write("Type : "   + myType   + "<BR>");
  }
  </SCRIPT>
  </BODY>
  </HTML>
```

Date.getSeconds() (Method)

Returns the seconds value of a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*`.getSconds()`

The seconds of the time value contained in the receiving object. The result will be an integer in the range 0 to 59 inclusive.

The value is computed according to UTC time coordinates.

Example code:

```
<!-- A bar chart indicating seconds of the minute -->
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=0 CELLPADDING=0 CELLSPACING=0>
<TR HEIGHT=10>
<TD ID="LEFT"  WIDTH=100 STYLE="background-color:RED"> </TD>
<TD ID="RIGHT" WIDTH=500 STYLE="background-color:BLUE"> </TD>
</TR>
</TABLE>
<SCRIPT>
setBar()
setInterval("setBar()", 990);
function setBar()
{
myDate    = new Date();
mySeconds = myDate.getSeconds();
myOther   = 60 - mySeconds;
document.all.LEFT.style.width  = 1+mySeconds*10;
document.all.RIGHT.style.width = 1+myOther*10;
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.22

Date.getTime() (Method)

Returns the time value of a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Time value`
JavaScript syntax:	- *myDate*`.getTime()`

The time value of the receiving object. This will be an integer that represents the time in milliseconds since the time origin at midnight on January the first, 1970.

This method returns the time value of the receiving object.

Example code:

```
<!-- Hand and eye coordination and reaction timer -->
<HTML>
<HEAD></HEAD>
<BODY>
<DIV ID="ONE" STYLE="background-color:YELLOW">
Click button 1 then button two as quickly as you can

ECMA 262 edition 3 – section – 15.9.5.9

Date.getTimezoneOffset() (Method)

Returns the time zone offset for the date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*`.getTimezoneOffset()`

The difference between UTC time and local time measured in minutes.

The result of this method is a zero based integer equal to the time difference between GM reference time and the clock in the client system. The value is measured in minutes and will be in the range 0 to 59 inclusive.

Warnings:

- Note that international time zones are generally in 60-minute intervals. However, a very few are less than 60 minutes.
- There are deficiencies in the accuracy of this method in Netscape 2 and 3. You should test whether your scripts work properly on those browsers if backwards compatibility is important to your project.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myTZO = myDate.getTimezoneOffset();
if(myTZO == 0)
{
   document.write("Same time as London, England.");
}
else
{
   document.write(myTZO + " hours relative to London, England time.");
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.26

Date.getUTCDate() (Method)

Returns the UTC day of month value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getUTCDate()

This method returns a day number within a month from the date value of the receiving object. The value is 1 based and will not exceed 31 although the range is variable based on month and leap year contexts.

The date is computed according to UTC time coordinates.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Create diary of special days per month
myDiary = new Array();
myDiary[1]  = "Pay into bank account";
myDiary[28] = "Invoice customers";
myDiary[14] = "Chase customers for payment";
myDiary[5]  = "Top up fuel in generator";
// Work out day number
myDate = new Date();
myDay = myDate.getUTCDate();
// Output message of the day
document.write(myDiary[myDay]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.prototype, Date.setUTCDate()`

ECMA 262 edition 2 – section – 15.9.5.11

ECMA 262 edition 3 – section – 15.9.5.15

Date.getUTCDay() (Method)

Returns the UTC weekday number for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getUTCDay()

The result of this method is a weekday number for the date value of the receiving object. The value will be in the range 0 to 6 inclusive. The 0 value represents Sunday.

The value is computed according to UTC time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sun", "Mon", "Tue", "Wed", "Thu", "Fri", "Sat");
myDate = new Date();
document.write(myArray[myDate.getUTCDay()]);
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 2 – section – 15.9.5.13

ECMA 262 edition 3 – section – 15.9.5.17

Date.getUTCFullYear() (Method)

Returns the UTC full year value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getUTCFullYear()

The year number for the receiving object normalized to UTC time coordinates. The result is a full 4 digit year number value based on the UTC time value.

Warnings:

- If you are computing relative times or developing scripts that operate on very early dates, Netscape will not support negative year numbers, and cannot go any earlier than year zero. MSIE can, if necessary return a negative year number.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Calculate which century from the year number
myDate = new Date();
myCentury = 1 + myDate.getUTCFullYear()/100;
switch (myCentury % 10)
{
case 1 : mySuffix = "st";
break;

case 2 : mySuffix = "nd";
break;

case 3 : mySuffix = "rd";
break;

default : mySuffix = "th";
break;

}
document.write(myCentury + mySuffix + " century");
</SCRIPT>
</BODY>
</HTML>
```

Date.getUTCHours() (Method)

Returns the UTC hours value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `myDate.getUTCHours()`

The result of this method is the hours component of the time value contained in the receiving object. The value will be in the range 0 to 23 inclusive.

The value is computed according to UTC time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Generate a flag based on work or play time
myDate = new Date();
myHours = myDate.getUTCHours();
if((myHours > 8) && (myHours < 17))
{
document.write("At work");
}
else
{
document.write("At play");
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getUTCMilliseconds() (Method)

Returns the UTC milliseconds for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.getUTCMilliseconds()

The result of this method is the milliseconds of the time value contained in the receiving object. The value will be in the range 0 to 999 inclusive.

The value is computed according to UTC time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<DIV ID="RESULT">000</DIV>
<SCRIPT>
// Check the accuracy of a timer by printing the milliseconds
setInterval("monitor()", 1000);
myOldMSecs = 000;
function monitor()
{
myDate  = new Date();
myMsecs = myDate.getUTCMilliseconds();
myErr = myMsecs - myOldMSecs;
document.all.RESULT.innerText = myMsecs + " (" + myErr + " milliseconds of
error)";
myOldMSecs = myMsecs;
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getUTCMinutes() (Method)

Returns the UTC minutes value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `myDate.getUTCMinutes()`

The result is the minutes of the time value contained in the receiving object. The value will be in the range 0 to 59 inclusive.

The value is computed according to UTC time coordinates.

Example code:

```
<!-- A bar chart indicating minutes of the hour -->
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=0 CELLPADDING=0 CELLSPACING=0>
<TR HEIGHT=10>
<TD ID="LEFT"  WIDTH=100 STYLE="background-color:RED"> </TD>
<TD ID="RIGHT" WIDTH=500 STYLE="background-color:BLUE"> </TD>
</TR>
</TABLE>
<SCRIPT>
setBar()
setInterval("setBar()", 60000);
function setBar()
{
myDate    = new Date();
myMinutes = myDate.getUTCMinutes();
myOther   = 60 - myMinutes;
document.all.LEFT.style.width  = 1+myMinutes*10;
document.all.RIGHT.style.width = 1+myOther*10;
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getUTCMonth() (Method)

Returns the UTC month number for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*.getUTCMonth()

The result of this method is month number for the receiving `date` object. The value will be in the range 0 to 11 inclusive, with the value 0 representing January, and 11 representing December.

The month number is measured in UTC time coordinates.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate  = new Date();
myMonth = myDate.getUTCMonth();
egyptianSeasons(myMonth);
// Generate attributes of the egyptian calendar based on month
function egyptianSeasons(aMonth)
{
mySeasonArray = new Array("Akhet", "Peret", "Shemu");
myMonthArray  = new Array("I", "II", "III", "IV");
mySeason = mySeasonArray[Math.floor(aMonth/4)];
myMonth  = myMonthArray[aMonth%4];
document.write("Index : "  + aMonth   + "<BR>");
document.write("Season : " + mySeason + "<BR>");
document.write("Month : "  + myMonth  + "<BR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.prototype`, `Date.setUTCMonth()`

Date.getUTCSeconds() (Method)

Returns the UTC seconds value for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myDate*`.getUTCSeconds()`

The result of this method is the seconds part of the time value contained in the receiving object. The value will be in the range 0 to 59 inclusive.

The value is computed according to UTC time coordinates.

Example code:

```
<!-- A bar chart indicating seconds of the minute -->
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=0 CELLPADDING=0 CELLSPACING=0>
<TR HEIGHT=10>
<TD ID="LEFT"  WIDTH=100 STYLE="background-color:RED"> </TD>
<TD ID="RIGHT" WIDTH=500 STYLE="background-color:BLUE"> </TD>
</TR>
</TABLE>
<SCRIPT>
setBar()
setInterval("setBar()", 990);
function setBar()
{
myDate    = new Date();
mySeconds = myDate.getUTCSeconds();
myOther   = 60 - mySeconds;
document.all.LEFT.style.width  = 1+mySeconds*10;
document.all.RIGHT.style.width = 1+myOther*10;
}
</SCRIPT>
</BODY>
</HTML>
```

Date.getVarDate() (Method)

A special date format for use with ActiveX objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`VarDate value`	
JavaScript syntax:	IE	*`myDate`*`.getVarDate()`

This method is provided so that you can obtain a special date format called `VT_DATE`. This is used for communicating with ActiveX objects on the Windows platform.

This method is not standardized in ECMAScript and is not supported in Netscape, so you should use it with great caution. In any case, if you are likely to need it, then you'll likely be using an `ActiveX` object that is only available on the Windows platform.

Date.getYear() (Method)

Returns a 2 digit non-Y2K compliant year for a date/time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0 Deprecated from JavaScript 1.3	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myDate`*`.getYear()`

The result of this method is a 2 digit year number for the date contained in the receiving object.

The year number is a local time value.

However, in this case, the value 1900 is subtracted from the year on the assumption that a two digit year will result.

This can lead to year 2000 problems as the year value may be modulo 100 or it may carry over.

This is why the method is deprecated and should be replaced by `Date.getFullYear()` in your scripts.

As of ECMA edition 3 it is no longer included in the standard although implementations may still provide it for backwards compatibility.

Warnings:

- Although it is described in the ECMA standard, it is noted that this function is not formally part of the standard and an ECMA compliant implementation need not provide it. Instead, the `Date.getFullYear()` function should be used.
- Nevertheless, some implementations may support this function although it is strongly recommended that you avoid its use.

Date.length (Property)

The length of a `date` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*.length

The `length` property for a `Date` object returns the maximum number of arguments that the `Date()` constructor function accepts.

The length property always returns the value 7 for a `Date` object.

See also:	`Date` object, `Date.constructor`

Property attributes:

ReadOnly, DontEnum.

Cross-references:

ECMA 262 edition 2 – section – 15.9.4

ECMA 262 edition 3 – section – 15.9.4

Date.parse() (Method/static)

A class based factory method for converting strings to `Date` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`UTC time value`
JavaScript syntax:	- `Date.parse(`*`aString`*`)`
Argument list:	*`aString`* A string containing a meaningful date value

The argument used with the `Date.parse()` method should process any string containing a sequence of characters that represents a meaningful date value. The `parse()` method then tokenizes that string and converts the value to a number in UTC time coordinates corresponding to the date and time in the string.

The string may be interpreted as a local time, UTC time, or a time in some other time zone depending on the contents of the string.

The result of this method is a UTC time value.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT1">???</DIV>
<DIV ID="RESULT2">???</DIV>
<FORM>
<HR>

Date.prototype (Property)

The prototype for the `Date` object that can be used to extend the interface for all `Date` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Date object`	
JavaScript syntax:	-	`Date.prototype`
	-	*`myDate`*`.constructor.prototype`

The initial value of the prototype property refers to the built-in `Date` prototype object.

The value of the `Date` prototype object is `NaN`.

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the output capabilities of Date objects
function millennium()
{
   return this.getFullYear()/1000;
}
// Register the new function
Date.prototype.millennium = millennium;
// Create a date and test the Date.millennium() method
myDate = new Date();
document.write(myDate.millennium())
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

See also:	`prototype` property

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

ECMA 262 edition 3 – section – 15.9.4.1

Date.setDate() (Method)

Sets the day number within a month of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*myDate*.setDate(*aDateValue*)
Argument list:	*aDateValue*	A day number within the current month

The result of this method will be the new time value of the containing object having been adjusted by the values passed in as arguments.

The calculations are performed according to local time coordinates.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate = new Date();
myDate.setDate(1);
document.write("The first day of this month is a " + myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getDate(),Date.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.32

ECMA 262 edition 3 – section – 15.9.5.36

Date.setFullYear() (Method)

Sets the full year value of a date/time object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*myDate*.setFullYear(*aYearValue*)
	-	*myDate*.setFullYear(*aYearValue, aMonthValue*)
	-	*myDate*.setFullYear(*aYearValue, aMonthValue, aDateValue*)
Argument list:	*aDateValue*	An optional date within the month value
	aMonthValue	An optional 0 to 11 month value
	aYearValue	A full year value

The result returned by this method will be the new time value of the containing object, having been adjusted by the values passed in as arguments.

The computations are carried out in local time coordinates.

ECMA mandates that the month and date should be optional arguments. If the date value is omitted, the value is provided internally as if the `getDate()` method had been invoked to provide it. Likewise the month value will be replaced by internally calling the `getMonth()` method.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate = new Date();
myDate.setFullYear(myDate.getFullYear() - 1);
document.write("A year ago on today's date, it was a " +
myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getFullYear()`,`Date.getYear()`,`Date.prototype`, `Date.setUTCFullYear()`,`Date.setYear()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.36

ECMA 262 edition 3 – section – 15.9.5.40

Date.setHours() (Method)

Sets the hours of a date/time object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Time value`
JavaScript syntax:	- *myDate*.setHours(anHoursValue) - *myDate*.setHours(*anHoursValue, aMinutesValue*) - *myDate*.setHours(*anHoursValue, aMinutesValue, aSecondsValue*) - *myDate*.setHours(*anHoursValue, aMinutesValue, aSecondsValue, aMillisecondsValue*)

Argument list:		
	aMillisecondsValue	An optional value between 0 and 999 milliseconds
	aMinutesValue	An optional value between 0 and 59 minutes
	anHoursValue	A value between 0 and 23 hours
	aSecondsValue	An optional value between 0 and 59 seconds

The value is computed according to local time coordinates.

ECMA mandates that the minutes, seconds and milliseconds should be optional arguments. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getMilliseconds()` method. Likewise, the seconds value behaves as if it had been supplied by a `getSeconds()` method, and the minutes as if `getMinutes()` was used, if they are missing.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDay1 = myDate.getDay();
for(myEnum=1; myEnum<24; myEnum++)
{
myDate.setHours(myDate.getHours()+1);
myDay2 = myDate.getDay();
if(myDay1 != myDay2)
{
document.write("In "+myEnum+" hours time it will be tomorrow.<BR>");
}
else
{
document.write("In "+myEnum+" hours time it will still be today.<BR>");
}
}
</SCRIPT>
</BODY>
</HTML>
```

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.30

ECMA 262 edition 3 – section – 15.9.5.34

Date.setMilliseconds() (Method)

Sets the milliseconds value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*myDate*`.setMilliseconds(`*aMillisecondValue*`)`
Argument list:	*aMillisecondValue*	a value between 0 and 999 milliseconds

The computations are done based on extracting a local time value and changing the millisecond count for that, before storing it back again as a local time value.

The result of this method is the new time value having had the milliseconds component set according to the passed-in argument.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setMilliseconds(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest second is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getMilliseconds()`,`Date.prototype`, `Date.setUTCMilliseconds()`

Date.setMinutes() (Method)

Sets the minutes of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Time value`
JavaScript syntax:	- `myDate.setMinutes(aMinutesValue)` - `myDate.setMinutes(aMinutesValue, aSecondsValue)` - `myDate.setMinutes(aMinutesValue, aSecondsValue, aMillisecondsValue)`
Argument list:	`aMillisecondsValue` — An optional value between 0 and 999 milliseconds `aMinutesValue` — A value between 0 and 59 minutes `aSecondsValue` — An optional value between 0 and 59 seconds

The computation is done according to local time coordinates.

ECMA mandates that the seconds and milliseconds should be optional arguments. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getMilliseconds()` method. Likewise, the seconds value behaves as if it had been supplied by a `getSeconds()` method, if it is missing.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setMilliseconds(0);
myDate.setSeconds(0);
myDate.setMinutes(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest hour is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.32

Date.setMonth() (Method)

Sets the month number of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*myDate*`.setMonth(`*aMonthValue*`)`
	- (JavaScript 1.3 +)	*myDate*`.setMonth(`*aMonthValue*`,` *aDateValue*`)`
Argument list:	*aDateValue*	An optional value in days of the month
	aMonthValue	A value between 0 and 11 in months

The result returned by this method will be the new time value of the containing object having been adjusted by the values passed in as arguments.

The computations are carried out in local time coordinates.

ECMA mandates that the date should be an optional argument. If the date value is omitted, the value is provided internally as if the `getDate()` method had been called to provide it.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate  = new Date();
myDate.setDate(4);
myDate.setMonth(6);
document.write("The fourth of July this year is a " + myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getMonth(),Date.prototype,Date.setUTCMonth()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.34

ECMA 262 edition 3 – section – 15.9.5.38

Date.setSeconds() (Method)

Sets the seconds value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*`myDate`*`.setSeconds(`*`aSeconds Value`*`)`
	- (JavaScript 1.3 +)	*`myDate`*`.setSeconds(`*`aSeconds Value, aMillisecondsValue`*`)`
Argument list:	*`aMillisecondsValue`*	An optional value between 0 and 999 milliseconds
	`aSecondsValue`	A value between 0 and 59 seconds

The values are computed as local time coordinates.

ECMA mandates that the milliseconds value should be an optional argument. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getMilliseconds()` method.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setMilliseconds(0);
myDate.setSeconds(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest minute is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 2 – section – 15.9.5.26

ECMA 262 edition 3 – section – 15.9.5.30

Date.setTime() (Method)

Sets the time value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*myDate*`.setTime(`*aTimeValue*`)`
Argument list:	*aTimeValue*	A value measured in milliseconds since midnight on any date.

The time value is extracted by clipping off any overflow past 24 hours. This is done with the internal `TimeClip()` method. The value of the receiving object is set to the resulting value. That same value is returned as the result of the method.

The result is a time clipped to modulo 24 hours.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY onMouseMove="moved()">
Move mouse horizontally to change day number
<DIV ID="ONE" STYLE="background-color:YELLOW">?</DIV>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate = new Date();
function moved(anEvent)
{
myDate.setTime(event.x * 1000000);
document.all.ONE.innerText = myArray[myDate.getDay()];
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.27

Date.setUTCDate() (Method)

Sets the UTC day within a month of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Time value`	
JavaScript syntax:	-	*`myDate`*`.setUTCDate(`*`aDateValue`*`)`
Argument list:	*`aDateValue`*	A day number within the current month

The result returned by this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

The calculations are performed according to UTC time coordinates.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate = new Date();
myDate.setUTCDate(1);
document.write("The first day of this month is a " + myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getUTCDate()`,`Date.prototype`

ECMA 262 edition 2 – section – 15.9.5.33

ECMA 262 edition 3 – section – 15.9.5.37

Date.setUTCFullYear() (Method)

Sets the UTC full year value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Time value`
JavaScript syntax:	- `myDate.setUTCFullYear(`*`aYearValue`*`)` - *`myDate`*`.setUTCFullYear(`*`aYearValue, aMonthValue`*`)` - *`myDate`*`.setUTCFullYear(`*`aYearValue, aMonthValue, aDateValue`*`)`
Argument list:	*`aDateValue`* — An optional date within the month value *`aMonthValue`* — An optional 0 to 11 month value *`aYearValue`* — A full year value

The result returned by this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

The computations are carried out in UTC time coordinates.

ECMA mandates that the month and date should be optional arguments. If the date value is omitted, the value is provided internally as if the `getUTCDate()` method had been called to provide it. Likewise the month value will be replaced by internally calling the `getUTCMonth()` method.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate = new Date();
myDate.setUTCFullYear(myDate.getFullYear() - 1);
document.write("A year ago on today's date, it was a " +
myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date.getFullYear()`,`Date.getUTCFullYear()`, `Date.prototype`,`Date.setFullYear()`

ECMA 262 edition 2 – section – 15.9.5.37

ECMA 262 edition 3 – section – 15.9.5.41

Date.setUTCHours() (Method)

Sets the UTC hours of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Time value`
JavaScript syntax:	- *myDate*.setUTCHours(*anHoursValue*) - *myDate*.setUTCHours(*anHoursValue*, *aMinutesValue*) - *myDate*.setUTCHours(*anHoursValue*, *aMinutesValue*, *aSecondsValue*) - *myDate*.setUTCHours(*anHoursValue*, *aMinutesValue*, *aSecondsValue*, *aMillisecondsValue*)

Argument list:		
	aMillisecondsValue	An optional value between 0 and 999 milliseconds
	aMinutesValue	An optional value between 0 and 59 minutes
	anHoursValue	A value between 0 and 23 hours
	aSecondsValue	An optional value between 0 and 59 seconds

The value is computed according to UTC time coordinates.

ECMA mandates that the minutes, seconds and milliseconds should be optional arguments. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getUTCMilliseconds()` method. Likewise, the seconds value behaves as if it had been supplied by a `getUTCSeconds()` method, and the minutes value as if `getUTCMinutes()` was used, if they are missing.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDay1 = myDate.getDay();
for(myEnum=1; myEnum<24; myEnum++)
{
myDate.setUTCHours(myDate.getHours()+1);
myDay2 = myDate.getDay();
if(myDay1 != myDay2)
{
document.write("In "+myEnum+" hours time it will be tomorrow.<BR>");
}
else
{
document.write("In "+myEnum+" hours time it will still be today.<BR>");
}
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.35

Date.setUTCMilliseconds() (Method)

Sets the UTC milliseconds value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	`Time value`

JavaScript syntax:	-	*myDate*.setUTCMilliseconds(*aMillisecondValue*)
Argument list:	*aMillisecondValue*	a value between 0 and 999 milliseconds

The computations are done based on extracting a UTC time value and changing the millisecond count for that before storing it back, again as a UTC time value.

The result of this method is the new time value having had the milliseconds component set according to the passed-in argument.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setUTCMilliseconds(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest second is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

Date.setUTCMinutes() (Method)

Sets the UTC minutes of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0
Property/method value type:	Time value
JavaScript syntax:	- *myDate*.setUTCMinutes(*aMinutesValue*)
	- *myDate*.setUTCMinutes(*aMinutesValue*, *aSecondsValue*)
	- *myDate*.setUTCMinutes(*aMinutesValue*, *aSecondsValue*, *aMillisecondsValue*)

Argument list:	*aMillisecondsValue*	An optional value between 0 and 999 milliseconds
	aMinutesValue	A value between 0 and 59 minutes
	aSecondsValue	An optional value between 0 and 59 seconds

The computation is done according to UTC time coordinates.

ECMA mandates that the seconds and milliseconds should be optional arguments. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getUTCMilliseconds()` method. Likewise, the seconds value behaves as if it had been supplied by a `getUTCSeconds()` method, if it is missing.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setUTCMilliseconds(0);
myDate.setUTCSeconds(0);
myDate.setUTCMinutes(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest hour is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

Date.setUTCMonth() (Method)

Sets the UTC month number of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0

Property/method value type:	Time value	
JavaScript syntax:	-	*myDate*.setUTCMonth(*aMonthValue*)
	-	*myDate*.setUTCMonth(*aMonthValue, aDateValue*)
Argument list:	*aDateValue*	An optional value in days of the month
	aMonthValue	A value between 0 and 11 in months

The result returned by this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

The computations are carried out in UTC time coordinates.

ECMA mandates that the date should be an optional argument. If the date value is omitted, the value is provided internally as if the `getUTCDate()` method had been called to provide it.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myArray = new Array("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
"Friday", "Saturday");
myDate  = new Date();
myDate.setUTCDate(4);
myDate.setUTCMonth(6);
document.write("The fourth of July this year is a " + myArray[myDate.getDay()]);
</SCRIPT>
</BODY>
</HTML>
```

Date.setUTCSeconds() (Method)

Sets the UTC seconds value of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0

Property/method value type:	`Time value`	
JavaScript syntax:	- *myDate*.setUTCSeconds(*aSecondsValue*)	
	- *myDate*.setUTCSeconds(*aSecondsValue*, *aMillisecondsValue*)	
Argument list:	*aMillisecondsValue*	An optional value between 0 and 999 milliseconds
	aSecondsValue	A value between 0 and 59 seconds

The values are computed as UTC time coordinates.

ECMA mandates that the milliseconds value should be an optional argument. If the milliseconds value is omitted, the current milliseconds value is used as if the value had been supplied with a `getUTCMilliseconds()` method.

The result of this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myDate = new Date();
myDate.setUTCMilliseconds(0);
myDate.setUTCSeconds(0);
myTime = myDate.getTime();
document.write("The time rounded down to the nearest minute is "  + myTime + "
Milliseconds");
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.5.31

Date.setYear() (Method)

Sets a non-Y2K compliant year number of the `time` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0 Deprecated in JavaScript 1.3
Property/method value type:	`Time value`
JavaScript syntax:	- *myDate*.setYear(*aYearNumber*)
Argument list:	*aYearNumber* — If the year number is less than 100, then 1900 is added to it.

The result returned by this method is the new time value of the containing object having been adjusted by the values passed in as arguments.

The computation is carried out in local time coordinates.

This method has difficulties with properly resolving the century, which is why it is deprecated and should be replaced by `Date.setFullYear()` in your scripts.

As of ECMA edition 3 it is no longer included in the standard, although implementations may still provide it for backwards compatibility.

Warnings:

- Although it is described in the ECMA standard, it is noted that this function is not formally part of the standard and an ECMA compliant implementation need not provide it. Instead, the `Date.setFullYear()` function should be used.
- Nevertheless, some implementations may support this function although it is strongly recommended that you avoid its use.

See also:	`Date.getFullYear(),Date.getYear(),Date.prototype, Date.setFullYear()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.38

ECMA 262 edition 3 – section – B.2.5

Date.toDateString() (Method)

The value of the `Date` object is presented just as a date.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myDate.toDateString()`*

The time value is rounded off and only the date value is presented by this method.

Cross-references:

ECMA 262 edition 3 – section – 15.9.5.3

Date.toGMTString() (Method)

Converts a `Date` object to a string containing a GMT time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0 Deprecated in JavaScript 1.3	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myDate.toGMTString()`*

This method returns a string value containing a GMT representation of the date and time value in the receiving object. The contents of the string are implementation-dependent, but are intended to represent the date in a convenient, human-readable form. However, this method is now deprecated in favor of `Date.toUTCString()` which should be used in preference. It is provided merely for compatibility with older systems.

As of ECMA edition 3 it is no longer included in the standard although implementations may still provide it for backwards compatibility.

Warnings:

- This function is now deprecated and you should use to`UTCString()` instead.

See also:	`Cast` operator, Cookie expires, `Date.prototype`, `Date.toUTCString()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.41

ECMA 262 edition 3 – section – B.2.6

Date.toLocaleDateString() (Method)

The value of the `Date` object is presented just as a date taking the present locale into consideration.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDate*`.toLocaleDateString()`

The time value is rounded off, and only the date value is presented by this method. Any locale specific character encoding is performed as necessary. If the implementation is particularly well endowed with internationalization code, this is an opportunity to reorganize the order of the day, month and year components and also to substitute leading zeros if necessary. The month names may also be spelled differently.

Cross-references:

ECMA 262 edition 3 – section – 15.9.5.6

Date.toLocaleString() (Method)

Converts a `Date` object to a string with the locale specific time.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDate*`.toLocateString()`

A string representing the date taking the locale into account.

The contents of the string that is returned, is implementation dependent. This method is intended to represent the date in a convenient and human-readable form that is appropriate to the geographic or cultural locale that is defined for the hosting environment.

In the Macintosh environment, the format should conform to that set by the date/time control panel in accordance with the Apple guidelines for application developers.

See also:	`Cast` operator, `Date.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.9.5.39

ECMA 262 edition 3 – section – 15.9.5.5

Date.toLocaleTimeString() (Method)

The value of the `Date` object is presented just as a time taking the present locale into consideration.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myDate.toLocaleTimeString()`

The date value is removed and only the time value is presented by this method. Any locale specific character encoding is performed as necessary. If the implementation is particularly well endowed with internationalization code, this is an opportunity to substitute leading zeros if necessary.

Cross-references:

ECMA 262 edition 3 – section – 15.9.5.7

Date.toSource() (Method)

Outputs a date formatted as a `Date` literal contained in a string.

Availability:	ECMAScript edition – 3 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myDate`*`.toSource()`

This is an alternative way to deliver a string version of a date value. In this case, it is formatted as a `Date` literal and can then be used in an `eval()` function to assign another date.

If you run the example below (in N 4, or 6), it should yield something resembling this:

```
(new Date(961700949597))
```

Note that the date value is in milliseconds UTC time, and will vary, but you should see a very long number like that.

Example code:

```
// Create a date object and display its source
myObject = new Date();
document.write(myObject.toSource());
```

See also:	`Date.prototype`, `Date.toString()`

Date.toString() (Method)

Return a string primitive version of an object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDate*`.toString()`

This method returns a string primitive representation of the date value of the receiving object. The contents of the string are implementation-dependent, but are intended to represent the date in a convenient, human-readable form in the current time zone. This is likely to be a UTC time value but implementations may perform some localization.

Warnings:

- If you plan to process the date string, be aware that MSIE presents its date format differently to the Netscape browser. Here is the MSIE presentation style:
  ```
  Wed Jun 21 20:20:03 UTC 2000
  ```
- And this is how Netscape presents the same time value:
  ```
  Wed Jun 21 20:20:03 GMT-2300 (2000
  ```
- Note that one uses UTC time and the other uses GMT. There is a very odd time-zone offset with the Netscape example and it is also missing a closing parenthesis. This may be platform- and version-dependent.
- You can override this behavior by creating your own `toString()` method and associating it with the `Date.prototype`. The example demonstrates how to override `toString()` with your own custom handler that should yield the same result on all platforms.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that overrides toString()
function myToString()
{
myYear  = this.getFullYear();
myMonth = this.getMonth() + 1;
myDate  = this.getDate();

return (myDate + "-" + myMonth + "-" + myYear);
}
// Register the new function
Date.prototype.toString = myToString;
// Create a date and test the replacement Date.toString() method
myDate = new Date();
document.write(myDate.toString())
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

A class based factory method for converting numeric values to `Date` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`UTC time in milliseconds`	
JavaScript syntax:	-	`Date.UTC(`*aYear, aMonth*`)`
	-	`Date.UTC(`*aYear, aMonth, aDate*`)`
	-	`Date.UTC(`*aYear, aMonth, aDate, anHour*`)`
	-	`Date.UTC(`*aYear, aMonth, aDate, anHour, aMinute*`)`
	-	`Date.UTC(`*aYear, aMonth, aDate, anHour, aMinute, aSecond*`)`
	- (JavaScript 1.3 +)	`Date.UTC(`*aYear, aMonth, aDate, anHour, aMinute, aSecond, aMillisecond*`)`
	aDate	An optional date within the month value

Argument list:	*aMillisecond*	An optional value between 0 and 999 milliseconds
	aMinute	An optional value between 0 and 59 minutes
	aMonth	An optional 0 to 11 month value
	anHour	A value between 0 and 23 hours
	aSecond	An optional value between 0 and 59 seconds
	aYear	A full year value
	aValue	A time in UTC milliseconds

This method returns a date value with the indicated date and time value.

When the `Date.UTC()` method is called, it interprets the arguments as UTC time values and returns a number representing the UTC time in milliseconds.

The value stored in the new date object depends on the argument values that are supplied. The arguments are all optional but are positional so, if an argument is missing, it is assumed to be the last argument and so on.

Functionally, the algorithm that manufactures a new date value uses the internal `MakeDay()`, `MakeTime()` and `MakeDate()` methods that we describe elsewhere.

If the year value is less than 99, then the date creation adds 1900 to it and assumes the date is in the 20th century. To avoid millennium problems, always specify a full year number.

Where arguments are omitted, zero values are assumed for hours, minutes and seconds. When all three are missing, the time is assumed to be midnight.

An incomplete date with zero, one or two arguments will behave in an implementation dependent way and might yield a different result depending on the platform supporting the script interpreter.

Date.valueOf() (Method)

Returns a number that is the date and time value for the receiving `Date` object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDate*`.valueOf()`

This method returns a numeric value representing the date and time in milliseconds UTC.

See also:	Cast operator, `Date.prototype.valueOf()`

Day from year (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

We need to calculate a reference point for each year number to know when it starts. We do this by calculating the number of days since the timer started.

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non -eap years to adjust the day numbers, and yield the day number of the first day of the given year:

```
DayFromYear(y) =
365 * (y - 1970) +
floor((y - 1969) / 4) -
floor((y - 1901) / 100) +
floor((y - 1601) / 400)
```

This function will return the start day for the year number passed in as an argument. See the example code to see how to run this in a test harness.

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Test day from year
document.write("<TABLE BORDER=1>");
for(var ii=1980; ii<2009; ii++)
{
   document.write("<TR>");
   document.write("<TD>");
   document.write(ii);
   document.write("</TD>");
   document.write("<TD>");
   document.write(dayFromYear(ii));
   document.write("</TD>");
   document.write("</TR>");
}
document.write("</TABLE>");

// Day from year function
function dayFromYear(aYear)
{
   var myDay = 365 * (aYear - 1970)  +
      Math.floor((aYear - 1969) / 4)   -
      Math.floor((aYear - 1901) / 100) +
      Math.floor((aYear - 1601) / 400);
   return myDay;
}
</SCRIPT>
</BODY>
</HTML>
```

Day number (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Calculating day numbers uses the `Math.floor()` function. It is the largest integer remaining after the time value is divided by the number of milliseconds per day.

The formula for calculating day number is shown here:

t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.

```
msPerDay = 86400000

Day(t) = Math.floor(t/msPerDay)
```

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Measure time in milliseconds since 01-01-1970 and work
// out the day number
var myDate = Number(new Date());
document.write(dayNumber(myDate));
// Work out day number from milliseconds
function dayNumber(aMillisecondTime)
{
var msPerDay = 86400000
var myDay = Math.floor(aMillisecondTime/msPerDay);

return myDay;
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 2 – section – 15.9.1.2

ECMA 262 edition 3 – section – 15.9.1.2

Day within year (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

The day number within a year is calculated by subtracting the day at the start of the year from the target day being evaluated. The difference is the day number within its year.

The formula for calculating day number is shown here:

t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.

```
msPerDay = 86400000

Day(t) = floor(t/msPerDay)
```

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non-leap years to adjust the day numbers and yield the day number of the first day of the given year and then use that to work out the time in milliseconds when the year started:

```
DayFromYear(y) =

365 * (y - 1970) +

floor((y - 1969) / 4) -

floor((y - 1901) / 100) +

floor((y - 1601) / 400)

TimeFromYear(y) = msPerDay * DayFromYear(y)

YearFromTime(t) = The largest integer y to make TimeFromYear(y) less than or equal
to t.

DayWithinYear(t) = Day(t) - DayFromYear(YearFromTime(t))
```

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Work out a day number within the year
msPerDay = 86400000;
myMilliseconds = Number(new Date());
document.write(dayWithinYear(myMilliseconds));
// Work out day number within year based on time value
function dayWithinYear(aMilliseconds)
{
myDayNumber     = dayNumber(aMilliseconds);
myYearFromTime  = yearFromTime(aMilliseconds);
myDayFromYear   = dayFromYear(myYearFromTime);
myDayWithinYear = myDayNumber - myDayFromYear;

return myDayWithinYear;
}
// Return year number based on time value
function yearFromTime(aMilliseconds)
{
myStartYear = 1970;

while(timeFromYear(myStartYear) < myMilliseconds)
{
myStartYear++
}
```

```
return myStartYear-1;
}
// Work out milliseconds at start of year
function timeFromYear(aYear)
{
myTime = msPerDay * dayFromYear(aYear);
return myTime;
}
// Work out day number from milliseconds
function dayNumber(aMillisecondTime)
{
myDay = Math.floor(aMillisecondTime/msPerDay);

return myDay;
}
// Day from year function
function dayFromYear(aYear)
{
myDay = 365 * (aYear - 1970)             +
Math.floor((aYear - 1969) / 4)   -
Math.floor((aYear - 1901) / 100) +
Math.floor((aYear - 1601) / 400);
return myDay;
}
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.9.1.4

Daylight savings time adjustment (Definition)

An adjustment to the local time value.

Availability:	ECMAScript edition – 2

Daylight savings time is the practice of shifting the settings of your clock during the Summer or Winter months to move some daylight time from the morning to the evening. The nature of this shift is dependent on locality and cultural issues. The time may be shifted in the Summer relative to standard time or it may be shifted in the Winter. In the UK, during the Winter, time is shifted backwards by an hour. In the USA, clocks are shifted forwards in the Summer.

An ECMA compliant implementation is expected to be able to determine the correct daylight savings time algorithm.

The algorithm is used to determine the Daylight Savings Time Adjustment value (known internally as DaylightSavingTA). This value is measured in milliseconds and must depend only on the following factors:

- The time since the beginning of the year
- Whether the year is a leap year
- The week day of the beginning of the year
- The geographic location

The ECMAScript implementation should decide whether daylight saving time would be in effect according to the currently available algorithm. Historically, daylight saving time algorithms may be different according to local political decisions and it would be too complicated trying to take that into account.

It is possible that the underlying host environment provides some daylight savings time algorithm support and the standard allows that this can be used if it is available.

The standard does not specify any particular algorithm. It just mandates that the algorithm should only rely on a restricted sub-set of information.

Warnings:

- The standard suggests that daylight savings time support is really a matter for the host environment and should be considered implementation and platform dependent. There are portability implications in that respect.

ECMA 262 edition 3 – section – 15.9.1.8

Days in year (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

The number of days in a year depends on whether it is a leap year or not.

ECMA compliant implementations use an extended Gregorian system to map a day number to a year number and to determine the month and date within that year. In this system, leap years are summarized thus:

```
DaysInYear(y) =

365 if ((y modulo 4) != 0)

366 if ((y modulo 4) == 0) and ((y modulo 100) != 0)

365 if ((y modulo 4) == 0) and ((y modulo 400) != 0)

366 if ((y modulo 400) == 0)
```

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Test number of days in year
document.write("<TABLE BORDER=1>");
for(var ii=1980; ii<2009; ii++)
{
document.write("<TR>");
document.write("<TD>");
document.write(ii);
document.write("</TD>");
document.write("<TD>");
document.write(daysInYear(ii));
document.write("</TD>");
document.write("</TR>");
}
document.write("</TABLE>");
// Day from year function
function daysInYear(aYear)
{
if((aYear % 4) != 0)
{
return 365;
}

if(((aYear % 100) != 0) ||
((aYear % 400) == 0))
{
return 366;
}

return 365;
}
</SCRIPT>
</BODY>
</HTML>
```

DbPool object (Object/NES)

An object of the class "`DbPool`" which provides a means of pooling connections to multiple databases.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	`myDbPool = new DbPool();`
	NES	`myDbPool = new DbPool(aType, aServer, aUser, aPassword, aDb);`
	NES	`myDbPool = new DbPool(aType, aServer, aUser, aPassword, aDb, maxCon);`
	NES	`myDbPool = new DbPool(aType, aServer, aUser, aPassword, aDb, maxCon, aFlag);`
Argument list:	*aType*	A database type
	aServer	A data source name or server name
	aUser	A user identifier
	aPassword	A valid password for the user
	aDb	A database name if required by the data source
	maxCon	A number indicating maximum connections
	aFlag	Commit/rollback flag value
Object properties:	`prototype`	
Object methods:	`connect(), connected(), connection(), disconnect(), majorErrorCode(), majorErrorMessage(), minorErrorCode(), minorErrorMessage(), storedProcArgs(), toString()`	

In JavaScript 1.2, you can connect to multiple databases and reuse connections. Each database can have a pool of available and ready connections which can be created when needed.

A `DbPool` object is created in a similar way to when you connect a single `database` object to a database. In this case however, you create a new `DbPool` object each time so you could maintain connections to several databases which is not possible with a plain (JavaScript 1.1) `database` object.

To create an object instance of the `DbPool` class, use the new operator on the `DbPool()` constructor.

The database type would likely be one of:

- ORACLE
- SYBASE
- INFORMIX
- DB2
- ODBC

The server value would identify one of the available data source names.

The user and password details would correspond to valid users you have already created on your database server.

Likewise the database name, although for some databases such as Oracle this may be done through the data source description and so the argument should be left blank in that case.

The maximum number of connections depends on your licensing arrangements with your database supplier and the capacity of your server and whether it needs to share connections with other services.

The commit flag indicates whether to commit (`true`) or rollback (`false`) a pending transaction.

See also:	`database.connect()`, Netscape Enterprise Server, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
`prototype`	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
`connect()`	1.2 +	-	3.0 +	-
`connected()`	1.2 +	-	3.0 +	-
`connection()`	1.2 +	-	3.0 +	-
`disconnect()`	1.2 +	-	3.0 +	-
`majorErrorCode()`	1.2 +	-	3.0 +	-
`majorErrorMessage()`	1.2 +	-	3.0 +	-
`minorErrorCode()`	1.2 +	-	3.0 +	-
`minorErrorMessage()`	1.2 +	-	3.0 +	-
`storedProcArgs()`	1.2 +	-	3.0 +	-
`toString()`	1.2 +	-	3.0 +	-

DbPool() (Constructor)

Used for creating new pools of connections to a database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`DbPool` object	
JavaScript syntax:	NES	`new DbPool(`*`aType, aServer, aUser, aPassword, aDb, maxCon, aFlag`*`);`
Argument list:	*`aDb`*	The name of a database
	`aFlag`	Commit or roll back on close
	`aPassword`	A valid password for the user
	`aServer`	The name of a database server
	`aType`	A valid connection type
	`aUser`	A user registered for database access on the server
	`maxCon`	The maximum number of simultaneous connections

When creating a new `DbPool` object, you need to indicate the type of database you are connecting to. The following are examples of commonly available database types:

- ORACLE
- SYBASE
- INFORMIX
- DB2
- ODBC

Use one of these values in the first argument to this method.

You will also need to know the name of your target server, a valid username and password and, if multiple databases are supported by your database server, then you will need to know the name of the target database you want to connect to.

The last two arguments indicate the maximum number of connections available at once and a flag to indicate the commit policy on closure. You can elect to automatically commit any changes (dangerous) or roll back any uncommitted changes.

See also:	`database.connect()`

DbPool.connect() (Method)

Connects the `DbPool` object to a database.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	`myDbPool.connect(`*`aType, aServer, aUser, aPassword, aDb, maxCon, aFlag`*`);`
Argument list:	*aDb*	The name of a database
	aFlag	Commit or rollback on close
	aPassword	A valid password for the user
	aServer	The name of a database server
	aType	A valid connection type
	aUser	A user registered for database access on the server
	maxCon	The maximum number of simultaneous connections

When connecting to a database, you need to indicate the type of database you are connecting to. The following are examples of commonly available database types:

- ORACLE
- SYBASE
- INFORMIX
- DB2
- ODBC

Use one of these values in the first argument to this method.

You will also need to know the name of your target server, a valid username and password and, if multiple databases are supported by your database server, then you will need to know the name of the target database you want to connect to.

The last two arguments indicate the maximum number of connections available at once and a flag to indicate the commit policy on closure. You can elect to automatically commit any changes (dangerous) or roll back any uncommitted changes.

See also:	`database.connect()`

DbPool.connected() (Method)

A flag that indicates the connection status for this `DbPool` object.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	`myDbPool.connected()`

This method returns a Boolean value that tells you whether the `database` object is connected to a database or not.

See also:	`database.connected()`

DbPool.connection() (Method)

Requests a connection object from the pool of available connections.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`Connection object`	
JavaScript syntax:	NES	`myDbPool.connection(`*`aName, aTimeout`*`)`
Argument list:	*`aName`*	A connection name
	`aTimeout`	Timeout in seconds

The object returned by this method is used to maintain the connection state details between the Netscape Enterprise Server and the back end database it is retrieving data from.

See also:	`Connection` object

DbPool.disconnect() (Method)

Disconnect from the database discarding all connections in the pool in the process.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
JavaScript syntax:	NES	`myDbPool.disconnect()`

It is a good idea to disconnect from the database when you know you won't need it anymore. This is good practice and allows other processes to connect when resources are scarce.

Until the database is connected again, only the `connect()` and `connected()` methods have any meaning.

See also:	`database.disconnect()`

DbPool.majorErrorCode() (Method)

Returns an error code value for an error that happened in the database or the interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myDbPool`*`.majorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields a return code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server message number.

For a status code value of 7 when using the Informix database, this yields the Informix error code.

For a status code value of 7 when using the Sybase database, this yields the DB-Library error number.

See also:	`Connection.majorErrorCode()`, `database.majorErrorCode()`, Error handling

DbPool.majorErrorMessage() (Method)

Returns an error message text for an error that happened in the database or the interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myDbPool`*`.majorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields a text string describing the server error.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields a text string from SQL server.

For a status code value of 7 when using the Informix database, this yields the text string from the vendor error library.

For a status code value of 7 when using the Sybase database, this yields a text string from the DB-Library.

See also:	`Connection.majorErrorMessage()`, `database.majorErrorMessage()`, Error handling

DbPool.minorErrorCode() (Method)

Returns a supplementary error code value for an error that happened in the database or the interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myDbPool`*`.minorErrorCode()`

For a status code value of 5 when using the Oracle database, this yields an operating system error code from the Oracle Call-level interface.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the severity level from SQL server.

For a status code value of 7 when using the Informix database, this yields the ISAM error code.

For a status code value of 7 when using the Sybase database, this yields the severity level of the error from the DB-Library.

See also:	`Connection.minorErrorCode()`, `database.minorErrorCode()`, Error handling

DbPool.minorErrorMessage() (Method)

Returns a supplementary error message text for an error that happened in the database or the interface to it.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myDbPool`*`.minorErrorMessage()`

For a status code value of 5 when using the Oracle database, this yields the Oracle server name.

For a status code value of 5 when using SQL server through the ODBC database interface, this yields the SQL server name.

For a status code value of 7 when using the Informix database, this yields a text string describing the ISAM error.

For a status code value of 7 when using the Sybase database, this yields the text of the operating system error from the DB-Library.

See also:	`Connection.minorErrorMessage()`, `database.minorErrorMessage()`, Error handling

DbPool.prototype (Property)

The prototype for the `DbPool` object that can be used to extend the interface for all `DbPool` objects.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`DbPool` object	
JavaScript syntax:	NES	`DbPool.prototype`
	NES	*`myDbPool`*`.constructor.prototype`

Refer to:

prototype property

DbPool.storedProcArgs() (Method)

Creates a prototype for a stored procedure and controls the argument passing.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`Stproc` object	
JavaScript syntax:	NES	*`myDbPool`*`.storedProcArgs()`

The prototype stored `procedure` object supports input and output parameters. This prototype object is used to indicate the direction of values in these parameters.

See also:	`database.storedProcArgs()`

DbPool.toString() (Method)

Returns a string primitive version of the `DbPool` object.

Availability:	JavaScript – 1.2 Netscape Enterprise Server – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`myDbPool.toString()`

The value of the object is converted to a string value that represents its value.

See also:	`database.toString()`

DD object (Object/HTML)

An object that represents the `<DD>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myDD* = *myDocument*.all.*anElementID*
	IE	*myDD* = *myDocument*.all.*tags("DD")*[*anIndex*]
	IE	*myDD* = *myDocument.all*[*aName*]
	-	*myDD* = *myDocument*.getElementById(*anElementID*)
	-	*myDD* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myDD* = *myDocument*.getElementsByTagName ("*DD*")[*anIndex*]
HTML syntax:	`<DD> ... </DD>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object

Object properties:	`noWrap`
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`

This object represents the definition value of an item in a definition list. It corresponds to a related definition term maintained in an `DT` object. `DT` and `DD` objects are paired up and maintained together as a member of the `DL` collection.

The `<DD>` tag is a block-level tag. That means that it forces a line break before and after itself unless the `DL` is compacted.

See also:	`DL` object, `DT` object, `Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`noWrap`	-	3.0 +	-	4.0 +	-	-	-	Warning

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-

`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

DD.noWrap (Property)

A switch to control text wrapping within the <DD> block.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDD*.noWrap

This is a Boolean value that controls whether the textual content is wrapped at the right hand window border or not.

If the value `false` is assigned to this property, then words will wrap as the page is drawn. This is good and is the way you would expect a browser to behave. The text will flow according to the space available.

If the value `true` is assigned to this property, the line of text will continue to the right until a <BR> or other block level tag is encountered. This will force the horizontal width of the page to extremely large and the user will need to scroll furiously to be able to see the text and then scroll back again for the start of the next line.

Warnings:

- Only use this if you plan to place line breaks at frequent intervals yourself and really do need to control the line breaks manually.

Debugger (Definition)

A tool to help with the location of bugs in your script.

See also:	Constraint, Debugging – client side, Error handling, JavaScript debugger console

debugger (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

ECMA 262 edition 3 – section – 7.5.3

Debugging - client side (Advice)

How to debug faulty client-side scripts.

When you are trying to debug client-side code, there are not many ways you have available for seeing what is going on. Usually, you have to resort to placing a `document.writes()` into the body of the page or perhaps putting up an alert box when the script runs.

In Netscape, you can bring up a debugging console by typing the string '`javascript:`' into the location box and pressing `return`. Because you have not indicated any action to be passed to the interpreter, it opens the debugging window by default.

Another way to do some very effective debugging is to trap the `onError` event handler with your own debugger script. You would implement the debugging error handler as something that opens a window and places HTML into it. Then you attach the handler to the current window with the `self.onerror` property.

You might find it useful to open a document window with a "`text/plain`" MIME type so you can simply use `document.writeln()` actions to display some debugging text.

A useful technique when debugging form handlers is to loop through all the elements in the form, presenting them in an `alert()` box for inspection. Of course this is useful for all kinds of collections, not just forms.

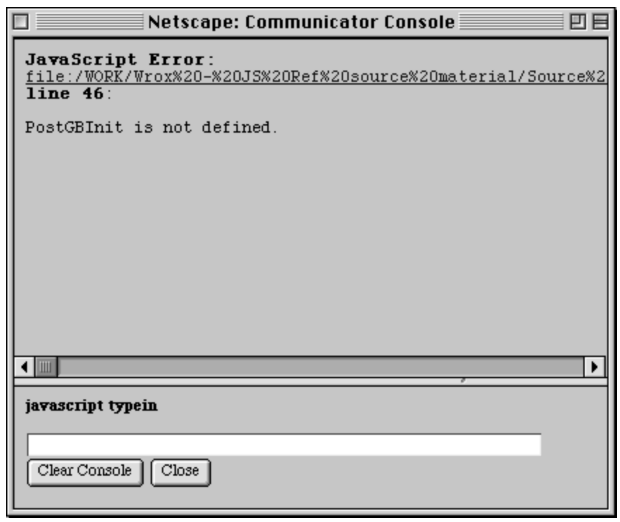
The example script illustrates three different ways to do debugging. There are lots of other techniques too.

The first example simply uses `document.write()` and `alert()` methods to feed information back to the user.

The second example is more sophisticated and attaches an error handler to the `onError` event hook. This works in MSIE. In Netscape, it was expected to work, but as of the pre-release version PR3 it still would not catch the errors. Since Netscape is very likely to undergo rapid and frequent updates for the foreseeable future, this might start to work quite soon. Nevertheless, Netscape provides the JavaScript console which may be helpful too.

The third example is based around a call to the embedded Java VM and requests that it prints a message on its console display surface. Again, whether this works may be browser and platform dependent but it is a starting point for custom building your own suite of debugging tools.

The fourth example shows how to debug form values without causing a form submit or page refresh.



Example code:

```
<!-- Simple debugging example -->
<HTML>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
// Write text into the document body at this point
document.write('Your text here');
// Present a dialog box with a message
alert('Your other text here');
</SCRIPT>
</BODY>
</HTML>
-----------------------------------------------------------------
<!-- Custom debugging example -->
<HTML>
<HEAD>
<SCRIPT>
function debugHandler(aMessage, aURL, aLineNumber)
{
   myText  = "An error has occurred\n\nThe message is\n\n";
   myText += aMessage + "\n\n at URL\n\n";
   myText += aURL + "\n\non line number ";
   myText += aLineNumber;

   alert(myText);

   return true;
}
</SCRIPT>
</HEAD>

<BODY>
<SCRIPT>
// Note that this may not work in Netscape Navigator
self.onerror = debugHandler("This is an example error", "local site", 21);
myError = null.open();
</SCRIPT>
</BODY>
</HTML>
-----------------------------------------------------------------
// Java console debugging
// Calls the Java console output to print a debug message
function consoleDebug(errMessage)
{
   java.lang.System.out.println(errMessage);
}

someError = "true";

// Call the console debug output like this
if(someError == true)
{
   consoleDebug("Display this text on the Java Console");
}
```

```
-----------------------------------------------------------------
// A form debugger provided by Jon Stephens
// This can pasted into the location window if it is prefixed
// with javascript: and if all the line breaks and extra
// spaces are removed
function formDebug()
{
   var output = "";
   for (var i = 0; i < document.forms.length; i++)
   {
      for (var j = 0; j < document.forms[i].elements.length; j++)
      {
         output +=  "Form: " + i
            +  " Elem: " + j
            +  " Type: "
            +  document.forms[i].elements[j].type  + "; "
            +  document.forms[i].elements[j].name  + ": "
            +  document.forms[i].elements[j].value + "<br>"
      }
   }
   var newWin = window.open("","newWin","width=350,height=350");
   with(newWin.document)
   {
      open();
      write(output);
      close();
   }
}

formDebug();
```

Debugging - server side (Definition)

How to debug faulty stand-alone scripts.

Debugging stand-alone, and server-side scripts is essentially the same.

You don't necessarily have a `document.write()` method but you will certainly have a means of printing text. In the case of a server-side script, that may be the way you construct the response so you can put debugging information in the response, so that it can be viewed by from the web browser.

You might not want to do that if you are debugging some security related services though. In that case, your web server probably has a logging capability and you might be able to write to the error log.

Example code:

```
// Nombas ScriptEase debugging is like thisClib.puts('Your message text here');
```

See also:	Debugging – client side, Input-output

Decimal point (.) (Delimiter)

A delimiter that marks the beginning of the fractional part of a floating point value.

Availability:	ECMAScript edition – 2 Opera – 3.0

A decimal point separates the integer and fractional parts of a floating point value. The character being used may need to alter depending on the locale of the hosting environment.

If your national language routines change the formatting of numbers, be aware that commas and dots mean different things.

A dot is really a decimal point. A comma is a thousands separator.

In some formatting regimes, thousands may be separated by a space character and a comma may be used in place of a dot (or vice versa).

Note also that it is a convention in financial reports to show negative values in parentheses but as a positive value.

All of this can make it difficult to parse numeric values that a user may enter into a text field.

Warnings:

- Localization of JavaScript implementations is still undergoing some development.

See also:	Floating point, Localization, Object property delimiter (.), Property accessor

Cross-references:

ECMA 262 edition 2 – section – 7.7.3

ECMA 262 edition 3 – section – 7.8.3

Decimal value (Definition)

A numeric value based on a radix of 10.

A decimal value is an integer composed of only the following characters:

```
0 1 2 3 4 5 6 7 8 9
```

Decimal values are never prefixed by a zero character.

The sequence carries over for the next increment when each column reaches the value 9. Thus:

```
0 1 2 3 4 5 6 7 8 9 10 11 12
```

Converting between decimal, hexadecimal, and binary values is quite complicated. Here are the first 16 values in all number bases:

Binary	Octal	Decimal	Hexadecimal
0000	00	0	0
0001	01	1	1
0010	02	2	2
0011	03	3	3
0100	04	4	4
0101	05	5	5
0110	06	6	6
0111	07	7	7
1000	10	8	8
1001	11	9	9
1010	12	10	A
1011	13	11	B
1100	14	12	C
1101	15	13	D
1110	16	14	E
1111	17	15	F

Warnings:

- Beware when you prefix decimal values with a zero character. You may want to justify a column of figures. If you add leading zero characters to a numeric string, if that string is subsequently parsed back to a numeric value, you may inadvertently export the value as a decimal but import it as an octal value. This can lead to an extremely difficult to diagnose fault in your software because the parsers sometimes add some intelligence and will correctly interpret the value as decimal if the characters 8 or 9 are present but otherwise interpret it as octal notation.
- Be careful that you remove any leading zero characters from the text strings that you plan to convert using the numeric parser.
- This may be implementation dependent behavior to some extent.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Create a 0-255 lookup table
document.write("<TABLE BORDER=1>");
document.write("<TR><TH>Index</TH>");
document.write("<TH>Binary</TH>");
document.write("<TH>Octal</TH>");
document.write("<TH>Hex</TH>");
document.write("<TH>Char</TH></TR>");
for(ii=0; ii<256; ii++)
{
```

```
    myBinary        = ii.toString(2);
    myBinaryPadding = "00000000".substr(1,(8-myBinary.length));

    myOctal         = ii.toString(8);
    myOctalPadding  = "0000".substr(1,(4-myOctal.length));

    myHex           = ii.toString(16);
    myHexPadding    = "00".substr(1,(2-myHex.length));

    myChar          = String.fromCharCode(ii);

    document.write("<TR ALIGN=RIGHT><TD>");
    document.write(ii);
    document.write("</TD><TD>");
    document.write(myBinaryPadding+myBinary);
    document.write("</TD><TD>");
    document.write(myOctalPadding+myOctal);
    document.write("</TD><TD>");
    document.write(myHexPadding+myHex.toUpperCase());
    document.write("</TD><TD>");
    document.write(" "+myChar);
    document.write("</TD></TR>");
}
document.write("</TABLE>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	Hexadecimal value, Integer constant, `Number.toString()`, Octal value

Declaration (Definition)

Declares the attributes of an identifier.

A declaration gives the type and scope of an identifier.

It specifies whether the identifier refers to a function or a variable and indicates what its name is. The scope is indicated by the placement. Variables are scoped globally if they are created outside of a function script source block.

When storage is being allocated, a declaration is sometimes called a definition. This means you might declare a function and define a variable. If you indicate the size of an array then that would be a definition.

See also:	Definition, Initialization, JavaScript language, Scope chain, Variable Declaration

Declared function (Definition)

A function can be declared in the script source text.

Availability:	ECMAScript edition – 2

Declared functions are added to the script source text to provide additional functions that are only needed while that script is being executed.

Declaring a function in a script requires a function declaration, which includes the name of the function, its arguments and a block of source script code to be executed when the function is called.

Through the Prototype Inheritance mechanism, this script code will be called in preference to any identically named function higher up the inheritance chain. This provides a way to override methods in parent object classes, which mimics (but is not identical to) the sub-class/super-class relationships in class-based languages.

See also:	Function object, function(...) ...

ECMA 262 edition 3 – section – 10.1.1

decodeURI() (Function)

This ECMA defined function can be used to decode an entire URI value that was encoded with the `encodeURI()` function.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`decodeURI(`*`anEncodedURI`*`)`
Argument list:	*`anEncodedURI`*	A previously encoded URI

This function is the complement of the `encodeURI()` function that we describe elsewhere.

A string that might have been encoded with the `encodeURI()` function either locally or remotely, can be converted back to a normal URI string with this function.

As far as ECMAScript is concerned, this supersedes the `unescape()` function, which is flagged as deprecated functionality in the JScript 5.5 documentation.

Note that the hash character (`#`) is not decoded.

See also:	`decodeURIComponent()`, `encodeURI()`, `encodeURIComponent()`, `escape()`, `unescape()`, URI handling functions

Cross-references:

ECMA 262 edition 3 – section – 15.1.3.1

decodeURIComponent() (Function)

This ECMA defined function can be used to decode a URI component value that was encoded with the `encodeURIComponent()` function.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`decodeURIComponent(`*`anEncodedComponent`*`)`
Argument list:	*`anEncodedComponent`*	A previously encoded component

This function is the complement of the `encodeURIComponent()` function that we describe elsewhere.

A string that might have been encoded with the `encodeURIComponent()` function either locally or remotely, can be converted back to a normal URI string with this function.

This enhances the encode/decode facilities of the compliant browser over and above what used to be available with `escape()/unescape()` functions.

See also:	`decodeURI(),encodeURI(),encodeURIComponent(), escape(),unescape()`, URI handling functions

Cross-references:

ECMA 262 edition 3 – section – 15.1.3.2

Decrement value (–) (Operator/postfix)

Pre or post decrementing operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`--anOperand`*
	-	*`anOperand--`*
Argument list:	*`anOperand`*	A numeric value that can be decremented

The operand is decremented by one.

A pre-fixing decrementor will subtract 1 from the operand value before it is used in the expression.

A post-fixing decrementor will subtract 1 from the operand after it is used in the expression.

Be careful how you use this pre/post placement as you can easily generate 'off by one' errors in your algorithms by placing the operator on the wrong side of the operand.

This operator is more or less functionally equivalent to:

```
anOperand -= 1
```

which is equivalent to:

```
anOperand = anOperand - 1
```

See also:	Additive expression, Additive operator, Increment value (++), Negation operator (-), Postfix decrement (--), Postfix expression, Postfix increment (++), Prefix decrement (--), Prefix expression, Prefix increment (++)

ECMA 262 edition 3 – section – 11.3.2

Deep copying (Definition)

Making a duplicate of objects, property by property.

See also:	`Array.toSource()`, Copying objects

default: (Label)

A target label for use with the switch statement as a catch-all for any unmatched cases.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 3.0

See also:	Label, Selection statement, switch(...) ... case: ... default: ...

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.2

ECMA 262 edition 3 – section – 12.11

defaultStatus (Property)

The default status text of the window.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`defaultStatus`
	-	`defaultStatus = aString`
	-	*`myWindow`*`.defaultStatus`
	-	*`myWindow`*`.defaultStatus = aString`
Argument list:	*`aString`*	A new value for the default status

Refer to:

Window.defaultStatus

DefaultValue() (Function/internal)

Internal private function.

Availability:	ECMAScript edition – 2

This internal function returns the default value for the object, given that the caller indicates a preferred result type in the hint argument.

The hint gives some suggestion to the receiving object about the preferred result type. This is a fairly ambiguous result. Generally if you ask for a string you will get a string. Asking for a number will generally yield a number. However, there are cases where the `DefaultValue` for an object cannot be rendered into the preferred type and you may generate a run-time error.

If you don't specify any hint value at all, the `DefaultValue` will first assume you want a Number unless the receiver is a `Date` object in which case it assumes a String is required.

See also:	Internal Method

Cross-references:

ECMA 262 edition 2 – section – 8.6.2.6

ECMA 262 edition 3 – section – 8.6.2.6

Defensive coding (Advice)

Allowing your scripts to be downwards compatible and coding for portability and robustness.

Coding defensively is to check for the existence of a feature before using it. Also to check that objects are defined before trying to modify their properties. You can check the version of the browser and switch various features of your scripts on and off accordingly.

With a little thought and planning, you can contrive your script design so that it degrades gracefully if it is run on less capable browser versions than that which you originally designed it for.

Defensive coding also covers cros- platform and cross-browser support. Running scripts in different browsers often exposes the differences between them. This may be simply a property value that is available in one context but not another. A more serious problem might be an entire object class that is missing from particular implementations.

Sometimes the differences are more subtle than that, and you may just find that a document object model needs to be traversed in a different way, depending on the browser being used.

Example code:

```
// Check for the existence of an object before using it
if(document.layers)
{
   document.write(document.layers);
}
else
{
   document.write("There is no layers array in this browser!");
}
```

See also:	Browser version compatibility, Compatibility, Cross browser compatibility

Definition (Definition)

Defines the storage for an identifier.

A definition is a declaration that also allocates storage for the item being declared.

For example:

```
new Array();
```

creates an empty `Array` object. As there is no indication of the likely size the array will require, no storage is allocated for array elements.

Now consider this:

```
new Array(10);

new Array("aaa", "bbb", "ccc");
```

Each of these declarations require some storage to be allocated. In the first entry, space for 10 elements is reserved in the array. In the second, there are three element pointers created and the storage for the three items as well.

Thus we have a definition.

See also:	Argument, Compliance, Compound statement, Constraint, Declaration, Deprecated functionality, Diagnostic message, `false`, Function, `function( ... ) ...`, Implementation, Object, Parameter, RValue, `true`, Variable Declaration

DEL object (Object/HTML)

An object that represents a `<DEL>` HTML tag within the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myDEL* = *myDocument*.all.*anElementID*
	IE	*myDEL* = *myDocument*.all.tags("DEL")[*anIndex*]
	IE	*myDEL* = myDocument.all[aName]
	-	myDEL = *myDocument*.getElementById(*anElementID*)
	-	*myDEL* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDEL* = *myDocument*.getElementsByTagName("DEL")[*anIndex*]
HTML syntax:	`<DEL> ... </DEL>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`cite, dateTime`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

You can add mark-up to a document to strike through text as if it were deleted. This deleted text block can also have a citation reference that links to a description of why the deletion took place.

The DOM level 1 specification includes this in the `ModElement` object functionality.

See also:	`Element` object, `INS` object, `ModElement` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

Inheritance chain:

Element object, Node object

DEL.cite (Property)

A URL that references a document that describes why the item was deleted.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- `myDEL.cite`

The URL of the document that describes why the text was marked as deleted is noted in this property.

DEL.dateTime (Property)

The date and time that the deletion occurred.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- `myDEL.dateTime`

This is the date and time value for when the deletion change occurred. If you are maintaining change control down to the sub-document level in a content management system, these values can be defined from change records in the database.

delete (Operator/unary)

Property deletion operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 3.0 Internet Explorer – 4.0 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	`delete anObject`
	-	`delete myArray[anIndex]`
	-	`delete myObject.aProperty`
Argument list:	*anIndex*	The index of the item to be deleted from the array.
	anObject	An object to be deleted
	aProperty	An object property to be removed

The delete operator is used to delete a property from an object or delete a reference to an object. It can also be used to delete an element from an array.

Using the new operator, a new object is created with a reference count of zero. Assigning that object creation to a variable increments the reference count. Saving it as an object property also increments the reference count. Storing it in an array does likewise.

All of these are simply references to the same object.

Deleting a variable containing a reference to an object decrements the reference count for that object.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

Warnings:

- The delete operator will not work with MSIE version 3.02 or earlier. It also won't work in Netscape 2.02.
- Netscape does not generate an error in version 3.0 if the delete operator is used but it is functionally ignored and does nothing.
- In JavaScript version 1.0 and version 1.1, the delete operator does not actually delete any object properties. Instead it sets them to null. If you then subsequently test for the existence of those properties, they might not prove `false` when you expect them to.
- In the JavaScript 1.2 implementation, in version 4 of Netscape , the behavior of the delete operator as it applies to variables is slightly different. Any variable declared with the `var` statement is considered to be permanent and cannot be deleted. This will generate an error if you try. This happens for the case when you enclose the script in `<SCRIPT LANGUAGE="JAVASCRIPT1.2">` tags.
- There is some difference between Netscape and MSIE as to whether global variables can be deleted. The safest assumption is that they cannot, so to remain portable, your script should not try.

Example code:

```
// Create a new object
myObject = new Object;
// Then delete a reference to it
delete myObject;
```

Delete() (Function/internal)

Internal private function.

Availability:	ECMAScript edition – 2

This internal function removes the named property from the object.

This function does not walk the prototype inheritance chain. If it did and a shared property got deleted, that property would disappear from ALL the objects that shared it.

If the property does not exist in the receiving object, the `Delete()` is assumed to have been successful anyway and `true` is returned.

If the property is present but has the `DontDelete` attribute, it cannot be removed so `false` is returned.

If the property can be deleted, then it is removed and `true` is returned.

Deprecated functionality (Pitfall)

Some language features are to be discontinued in later versions of the language.

Deprecated functionality describes a feature that is likely to be removed and should not be used in new developments.

There are various features that interpreter manufacturers add from time to time and which become standardized in a different and possibly better way, or that everyone agrees should be disregarded. Netscape's data tainting functionality is a good example of a dead end that was introduced and withdrawn soon after.

The following is a list of such deprecated functionality that should be avoided:

- Data tainting
- JavaScript extensions to HTML character entities

Warnings:

- If you use deprecated functionality, your script may fail when it is deployed on other platforms or when the platform it is hosted on is revised.

Desktop JavaScript (Definition)

Control of desktop automation with JavaScript.

You can install a JavaScript interpreter that you can use to automate activity on your desktop. On a Macintosh, this kind of activity has been possible for some time with HyperCard, AppleScript and the Macintosh Programmer's Workshop shell environment. Now you can install products such as Nombas ScriptEase.

On Windows, you could have used DOS batch files and if you had installed the NeXTStep developer tools in the past, a Bourne shell was possible. Other alternatives have also been available. Now, you can use JScript within the Windows Script Host environment. You can also use ScriptEase on Windows.

On UNIX, a variety of possibilities are available. ScriptEase again is useful but there are other freely available JavaScript interpreters that you can download and build yourself. It just depends how much work you want to do before you can start scripting.

Cross-references:

Wrox *Instant JavaScript* – page – 5

detachEvent() (Method)

A means of detaching events from windows and documents that were previously attached with the `attachEvent()` method.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	`detachEvent(`*`anEventName`*`)`
	IE	*`myWindow`*`.detachEvent(`*`anEventName`*`)`
Argument list:	*`anEventName`*	The name of an event to be handled

See also:	`.htc`, `<STYLE>`, `Document.attachEvent()`, `Document.detachEvent()`, `Window.attachEvent()`, Window.detachEvent()

Determining the object type (Useful tip)

To determine what kind of object type you have, this function may be useful.

This checks the type of the value passed in. If it is an object, then it looks at the constructor and returns the constructor's name. This works in Netscape 4.7 and MSIE version 5 and should work on other browsers, but check before deploying that it works on all the browsers you need it to.

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Determine object type
function what_kind(aValue)
{
var myType = typeof(aValue);
if (myType == "object")
{
return aValue.constructor.name;
}
else
{
return myType;
}
}
document.write(what_kind(1));
</SCRIPT>
</BODY>
</HTML>
```

Preferences

DFN object (Object/HTML)

An object representing the HTML content delimited by the `<DFN>` HTML tags.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myDFN* = *myDocument*.all.*anElementID*
	IE	*myDFN* = *myDocument*.all.tags("DFN")[*anIndex*]
	IE	*myDFN* = *myDocument*.all[*aName*]
	-	*myDFN* = *myDocument*.getElementById(*anElementID*)

JavaScript syntax:	-	*myDFN* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDFN* = *myDocument*.getElementsByTagName("DFN")[*anIndex*]
HTML syntax:	<DFN> ... </DFN>	
Argument list:	*anElementID*	The ID value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDblClick	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyPress	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyUp	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseDown	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseMove	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOver	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseUp	1.5+	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Element object

DHTML (Standard)

Dynamic HTML controlled by JavaScript. A fourth generation browser technology for dynamically altering the document that describes a web page.

You might be forgiven for thinking DHTML is a new kind of HTML. Actually it's not really. It's just plain old HTML code. What makes it dynamic are the supporting technologies that operate on it. Without them, there is nothing dynamic about HTML at all.

Principally, it's the JavaScript and CSS style sheet support that makes HTML dynamic and it's the access to the HTML through a Document Object Model that allows us to operate on the HTML in the document.

Things are complicated a little because the dynamism can be applied at the server-end and really what we mean by DHTML is a client-end activity. Server created HTML, even though it's done with JavaScript, is not really DHTML.

Perhaps a less ambiguous description is CSS and DOM scripting. That allows some differentiation of the appearance vs. structural things you can accomplish with script driven documents.

See also:	Dynamic HTML

DHTML Behavior (Definition)

A mechanism for enhancing the dynamic capabilities of HTML.

Refer to:

`Element.addBehavior()`

Diagnostic message (Definition)

A message from the interpreter warning you about a script error.

A diagnostic message is what the implementation presents when it detects an error.

These are normally presented as an `alert` box in web browsers.

In other implementations such as Web Server back ends, server-side JavaScript failures may be recorded in an error log or written into the pages being sent to the client. However, you should be careful to remove any debugging stubs before launching your service as these messages could potentially divulge some valuable security related information about your server (and how to hack it).

You should always know where the error logs are written for your implementation. On a UNIX platform, it is helpful to open an additional terminal console and pipe the output of the error log to the screen. This can be done with the tail command like this:

```
tail -f error.log
```

See also:	Constraint, Definition, Error, Error handling

Dialog boxes (Definition)

User communication is effected by means of several different dialog boxes.

Dialog boxes are generally modal. That means they need to be acted on and dismissed by the user. Some are scriptable and others are not. Your operating system will determine whether modality extends across the whole system or just to the application. If modality is system-wide, you won't be able to switch applications while a modal dialog is on display.

Here are a few that you might encounter routinely when scripting:

- `Window.alert()`
- `Window.confirm()`
- `Window.prompt()`
- `Window.showHelp()`
- `Window.showModalDialog()`
- `Window.showModelessDialog()`

One that you cannot script is the secure login panel presented to allow you to authenticate your access to a secure web page. That is controlled by the server, and your browser should not provide any script-driven interface to it.

See also:	Debugging – client side, `Window.alert()`,`Window.confirm()`, `Window.prompt()`,`Window.showHelp()`, `Window.showModalDialog()`,`Window.showModelessDialog()`

Dialog object (Object/JScript)

This is the `parent` object of a frame within a modal dialog window.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Inherits from:	`Window` object
JavaScript syntax:	IE *myDialog* = *myFrame*.parent IE *myDialog* = *myWindow*.parent
Event handlers:	`onAfterPrint, onBeforePrint, onBeforeUnload, onBlur, onDragDrop, onError, onFocus, onHelp, onLoad, onMouseMove, onMove, onResize, onScroll, onUnload`

To all intents and purposes this is a `window` object except that, because it is modal, it is placed on top of all other windows and, until it is disposed of, no other browser windows can be accessed.

Some early documentation suggests that there are dialog sizing properties for this window type but this has not been confirmed to work.

On the new version 6.0 Netscape browser, there is the tantalizing possibility that the appearance of dialog boxes can be affected by altering the 'skin' of the browser. As yet, this does not appear to be scriptable or accessible from HTML. It is highly likely that internally the appearance is JavaScript driven. Historically, much of the internal behavior of Netscape has been controlled by `.js` files so this may change.

See also:	`Window.alert()`,`Window.confirm()`,`Window.parent`, `Window.prompt()`,`Window.showHelp()`, `Window.showModalDialog()`,`Window.showModelessDialog()`

Event name	JavaScript	JScript	N	IE	Opera	Notes
onAfterPrint	-	5.0 +	-	5.0 +	-	-
onBeforePrint	-	5.0 +	-	5.0 +	-	-
onBeforeUnload	-	3.0 +	-	4.0 +	-	-
onBlur	-	3.0 +	-	4.0 +	-	Warning
onDragDrop	-	-	-	-	-	-
onError	-	3.0 +	-	4.0 +	-	Warning
onFocus	-	3.0 +	-	4.0 +	-	Warning
onHelp	-	3.0 +	-	4.0 +	-	Warning
onLoad	-	3.0 +	-	4.0 +	-	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	Warning
onMove	-	-	-	-	-	-
onResize	-	3.0 +	-	4.0 +	-	Warning
onScroll	-	3.0 +	-	4.0 +	-	-
onUnload	-	3.0 +	-	4.0 +	-	Warning

Inheritance chain:

`Window` object

dialogArguments (Property)

The arguments passed to a modal dialog window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogArguments`
	IE	`myWindow.dialogArguments`

Property attributes:

`ReadOnly`

Refer to:

`Window.dialogArguments`

dialogHeight (Property)

The height of a modal or modeless dialog window.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`dialogHeight`
	IE	*`myWindow`*`.dialogHeight`

Refer to:

`Window.dialogHeight`

dialogLeft (Property)

The offset to the left edge of a modal or modeless dialog window. In IE 4, the default measure is the `em`, in IE 5 it is the `pixel`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`dialogLeft`
	IE	*`myWindow`*`.dialogLeft`

Refer to:

`Window.dialogLeft`

dialogTop (Property)

The offset to the top edge of a modal or modeless dialog window. In IE 4, the default measure is the `em`, in IE 5 it is the `pixel`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`dialogTop`
	IE	*`myWindow`*`.dialogTop`

Refer to:

`Window.dialogTop`

dialogWidth (Property)

The width of a modal or modeless dialog window. In IE 4, the default measure is the `em`, in IE 5 it is the `pixel`.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Property/method value type:	Number primitive	
JavaScript syntax:	IE	dialogWidth
	IE	myWindow.dialogWidth

Refer to:

Window.dialogWidth

Dictionary object (Object/JScript)

A name-value collection object created by the Active X facilities.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myDictionary* = new ActiveXObject("Scripting.Dictionary");
Object properties:	Count	
Object methods:	Add(), Exists(), Item(), Items(), Key(), Keys(), Remove(), RemoveAll()	

A dictionary is a special kind of collection or array which allows you to access items using name and value pairs. This is functionally similar to using associative name indexing on a JavaScript array, so although this is not generally available, its fundamental usefulness is already provided in the native JavaScript implementation.

The Dictionary object provided by JScript and Active X, has a few extra properties and methods to help manage the contents of the dictionary. These could be simulated fairly easily and added to the Array prototype to create your own portable Dictionary-like object.

Warnings:

- As this object needs to be created with the Active X facilities, it is not supported outside of the Windows environment. It is odd that such a useful object can only be constructed in this way and that it does not have a native JavaScript constructor. That at least would make it available in all platforms that JScript runs in.
- Note that the properties and methods for the Dictionary object all start with an upper case letter. This is not the common practice in JavaScript and may cause you a few run-time errors if you forget.
- There are some unusual syntactical constructs in this object. In particular, item and key methods that behave like properties. These are intended to provide an interface to replace an item in the dictionary or to rename a key. These methods would normally be made with several arguments to a single method, but instead they use a method to retrieve a reference to a Dictionary pocket and you can then assign a value to the reference that was returned.

Example code:

```
// Create a new dictionary
var myDictionary = new ActiveXObject("Scripting.Dictionary");
// Store some items in the dictionary
// (Melting Points of fats/waxes)
myDictionary.Add("Butter",       "28");
myDictionary.Add("Lard",         "36");
myDictionary.Add("MuttonTallow", "44");
myDictionary.Add("Beeswax",      "61");
myDictionary.Add("Stearin",      "71.6");
myDictionary.Add("ParaffinWax",  "38");
// Display one item if it exists
if(myDictionary.Exists("ParaffinWax"))
{
document.write("Paraffin Wax melts at ");
document.write(myDictionary.Item("ParaffinWax"));
document.write(" degrees Centigrade.<BR>");
}
// Remove an item
if(myDictionary.Exists("Stearin"))
{
myDictionary.Remove("Stearin");
}
// Change an item and its key
if(myDictionary.Exists("MuttonTallow"))
{
myDictionary.Item("MuttonTallow") = "40";
myDictionary.Key("MuttonTallow") = "BeefTallow";
}
// List all the items
myArray = (new VBArray(myDictionary.Keys())).toArray();
for(myEnum=0; myEnum<myArray.length; myEnum++)
{
document.write("Key value: ");
document.write(myArray[myEnum]);
document.write("  Item value: ");
document.write(myDictionary.Item(myArray[myEnum]));
document.write("<BR>");
}
// Now discard the items in the array
myDictionary.RemoveAll();
```

See also:	ActiveX, `ActiveXObject` object

Property	**JavaScript**	**JScript**	**N**	**IE**	**Opera**	**Notes**
`Count`	-	3.0 +	-	4.0 +	-	ReadOnly.

Method	**JavaScript**	**JScript**	**N**	**IE**	**Opera**	**Notes**
`Add()`	-	3.0 +	-	4.0 +	-	-
`Exists()`	-	3.0 +	-	4.0 +	-	-

Table continued on following page

Method	JavaScript	JScript	N	IE	Opera	Notes
`Item()`	-	3.0 +	-	4.0 +	-	Warning
`Items()`	-	3.0 +	-	4.0 +	-	-
`Key()`	-	3.0 +	-	4.0 +	-	-
`Keys()`	-	3.0 +	-	4.0 +	-	Warning
`Remove()`	-	3.0 +	-	4.0 +	-	-
`RemoveAll()`	-	3.0 +	-	4.0 +	-	-

Dictionary.Add() (Method)

Adds a new item to the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myDictionary*.Add(*aKey, aValue*)
Argument list:	*aKey*	A textual key name
	aValue	A value to store for the key

This method adds a new item to the `Dictionary` associating it with the key name being passed.

Keys are meant to be strings but will be coerced as necessary during the addition. However, you cannot use an `Array` object to build the key name. If you do need to build a key name from an array, you must convert it to a string first.

The items being associated with `Dictionary` keys can be of any type.

You cannot replace an item with this method as a run-time error is caused by an attempt to add a new object where the key name has already been used.

Dictionary.Count (Property)

Returns a count of the number of items in the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myDictionary*.Count

This behaves like the `length` property of a native `JavaScript` Array or `Collection` object. Note that its name begins with an upper case letter.

Property attributes:

`ReadOnly`

Dictionary.Exists() (Method)

Returns a flag indicating whether a key has an item associated with it in the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myDictionary`*`.Exists(`*`aKey`*`)`
Argument list:	*`aKey`*	A textual key name

Dictionaries are a useful way to collect items together at random intervals. The `Dictionary` can then be tested later on after the items have been added. This method provides a way to test whether a specific name-value pair has been added to the `Dictionary`.

Dictionary.Item() (Method)

Returns a reference to the `Item` container for a key.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Reference to an item pocket`	
JavaScript syntax:	IE	*`myDictionary`*`.Item(`*`aKey`*`)`
	IE	*`myDictionary`*`.Item(`*`aKey`*`) = `*`aValue`*
Argument list:	*`aKey`*	A textual key name
	`aValue`	A value to store for the key

This method provides a way to extract an item from the `Dictionary` using its key name as an accessor.

This method can also be used as an alternative to the `Dictionary.add()` method although its syntax for doing so is unusual.

These two lines of code are syntactically different but functionally the same when creating a new name-value pair:

```
myDictionary.add("KEY1", "an item text");

myDictionary.item("KEY1") = "an item text";
```

This suggests that you can use the `add()` method to replace an item but in fact that will cause an error. The `item()`, method, used as if it were an `LValue` property is the only way to replace an item content.

Warnings:

- Although this is a method, because it has parentheses and therefore can be called, it also behaves as a property. This somewhat bends the syntax rules for JavaScript and looks like a badly formed expression when you see the variant that does an assignment.
- It is important to use this item within a conditional code block that tests for the existence of the key first. This is because an attempt to retrieve a named item from a `Dictionary` will create a named but empty item if it does not already exist.
- Note the capitalised name of the method.

Dictionary.Items() (Method)

Returns an array containing all Items in the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`VBArray object`	
JavaScript syntax:	IE	`myDictionary.Items()`

The entire set of items is returned in a `VBArray`. If you want to access this as a normal JavaScript array, you should use the `toArray()` method on the `VBArray` that is created by the `Items()` method.

Dictionary.Key() (Method)

Returns a reference to the named key container.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Reference to a key name pocket`	
JavaScript syntax:	IE	*`myDictionary`*`.Key(`*`anOldKey`*`) = `*`aNewKey`*
Argument list:	*`anOldKey`*	An existing key name
	`aNewKey`	A new name to rename the existing key to

This method provides a reference to the receptacle containing the key name. This 'by-reference' access to the key allows the key to be changed. You would not be able to do that if it accessed the key name by value.

Because you are referencing the container of the key, you can use this method as an `LValue` and assign a new value to the key. This is effectively a key rename mechanism.

If the key does not already exist, like the `Item()` method, this will create a new named but empty item in the `Dictionary`.

Dictionary.Keys() (Method)

Returns a collection of all the keys currently defined in the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`VBArray object`	
JavaScript syntax:	IE	*`myDictionary`*`.Keys()`

The entire set of key names is returned in a `VBArray`. If you want to access this as a normal JavaScript array, you should use the `toArray()` method on the `VBArray` that is created by the `Items()` method.

Warnings:

- This is not the same as a collection of `Items`. This is a list of key names.

Dictionary.Remove() (Method)

Remove a key name and its item value from the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*`myDictionary`*`.Remove(`*`aKey`*`)`
Argument list:	*`aKey`*	A textual key name

You should test that the key already exists before attempting to remove it. This will save you generating run-time errors if you attempt to remove items for non-existent keys.

Dictionary.RemoveAll() (Method)

Remove all key names and item values from the `Dictionary`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*`myDictionary`*`.RemoveAll()`

The dictionary is completely emptied and can be re-used instead of creating a new one.

Digit (Definition)

A decimal numeric character.

A digit is any of the following characters:

0 1 2 3 4 5 6 7 8 9

See also:	Identifier, Nondigit

DIR object (Object/HTML)

A somewhat deprecated object that is now superseded by the `<UL>` HTML tag and its object representation. This object represents the contents of a `<DIR>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myDIR* = *myDocument*.all.*anElementID*
	IE	*myDIR* = *myDocument*.all.tags("DIR")[*anIndex*]
	IE	*myDIR* = *myDocument*.all[*aName*]
	-	*myDIR* = *myDocument*.getElementById(*anElementID*)
	-	*myDIR* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDIR* = *myDocument*.getElementsByTagName("DIR")[*anIndex*]
HTML syntax:	`<DIR> ... </DIR>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`compact`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The DOM level 1 specification refers to this as a `DirectoryElement` object.

See also:	`Element` object, `UL` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`compact`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

DIR.compact (Property)

An attribute that controls the display of `<DIR>` items and the amount of space they require on the screen.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myDir*.compact

Refer to:

`DL.compact`

disableExternalCapture() (Method)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript – 1.2 Netscape – 4.0
Property/method value type:	`undefined`
JavaScript syntax:	N `disableExternalCapture()` N *myWindow*.disableExternalCapture()
See also:	`Window.enableExternalCapture()`, `Window.disableExternalCapture()`

DIV object (Object/HTML)

An object that represents a <DIV> block level element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myDIV* = *myDocument*.all.*anElementID*
	IE	*myDIV* = *myDocument*.all.tags("DIV")[*anIndex*]
	IE	*myDIV* = *myDocument*.all[*aName*]
	-	*myDIV* = *myDocument*.getElementById(*anElementID*)
	-	*myDIV* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDIV* = *myDocument*.getElementsByTagName("DIV")[*anIndex*]
HTML syntax:	`<DIV> ... </DIV>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align, dataFld, dataFormatAs, dataSrc`	
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDblClick, onDragStart, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onScroll, onSelectStart`	

A `DIV` object is a means of building a block structured organization of a document that is custom-designed. It is yet another means of building a hierarchical model if none of the existing models fits the structure you need. It is also a way of marking out blocks of a document to be treated as a styled area or perhaps a means of dynamically replacing or modifying document content in an easily controlled manner.

The <DIV> tag is a block-level tag. That means that it forces a line break before and after itself.

The example shows how to exchange the style values between two <DIV> blocks.

Warnings:

- In Netscape 4, a <DIV> object whose CSS style defines its positioning as absolute, is then enumerated in the layers collection at an appropriate position in the document/layer hierarchy. This is confusing because a <DIV> is not a <LAYER>. Refer to the discussion about `Layer` objects in a separate topic for further details.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="ONE" STYLE="background-color:RED">
The DIV block ONE
</DIV>
<DIV ID="TWO" STYLE="background-color:BLUE">
The DIV block TWO
</DIV>
<FORM>
<INPUT TYPE="button" VALUE="CLICK ME" onClick="clickMe()">
</FORM>
<SCRIPT>
function clickMe()
{
myStyle1 = document.all.ONE.style.cssText;
myStyle2 = document.all.TWO.style.cssText;

document.all.ONE.style.cssText = myStyle2;
document.all.TWO.style.cssText = myStyle1;
}
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Node` object

DIV.align (Property)

The alignment for content within a `<DIV>` block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	*`myDIV`*`.align`

The alignment of the `DIV` block object with respect to its containing parent object is defined in this property. The expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Divide (/) (Operator/multiplicative)

Divide one operand by another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`anOperand1 / anOperand2`
Argument list:	*`anOperand1`*	The dividend
	`anOperand2`	The divisor

The left-hand operand is divided by the right-hand operand and the quotient is returned.

The left operand is the dividend, and the right is the divisor. ECMAScript compliant interpreters do not perform integer division. The operand and results of all divisions are double-precision floating point numbers. All divisions are performed according to IEEE 754 specifications.

If either operand is `NaN` then the result is `NaN`.

The sign of the result is positive if both operands have the same sign and negative if the operands have different signs.

Division of an infinity by an infinity results in `NaN`.

Division of an infinity by zero results in an infinity. The sign is determined by the rule stated earlier.

Division of infinity by a non-zero finite value results in a signed infinity. The sign is determined as before.

Division of a finite value by infinity results in zero. The sign is determined as usual.

Division of a zero by a zero results in `NaN`.

Division of zero by any other finite value results in zero with the sign determined as normal.

Otherwise, where there is neither an infinity or zero involved and neither value is `NaN`, the quotient is computed and rounded to the nearest representable value. If the magnitude is too large to represent, it will overflow and become an infinity. If the magnitude is too small to represent, an underflow occurs and the result will be zero.

The associativity is from left to right.

Refer to the operator precedence topic for details of execution order.

See also:	Associativity, Divide then assign (/=), Double-precision, Multiplicative expression, Multiplicative operator, Operator Precedence, Remainder (%)

Cross-references:

ECMA 262 edition 2 – section – 11.5.2

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.5.2

Divide then assign (/=) (Operator/assignment)

Divide one operand by another and put the result in the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 /= anOperand2`*
Argument list:	*`anOperand1`*	The dividend
	`anOperand2`	The divisor

Divide the left operand by the right operand and assign the quotient to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 / anOperand2;
```

Although this is classified as an assignment operator, it is really a compound of an assignment and a multiplicative operator.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an `LValue`. That is, it should be able to take an assignment and store the value.

See also:	Assignment operator, Associativity, Divide (/), LValue, Multiplicative operator, Operator Precedence, Remainder (%)

ECMA 262 edition 3 – section – 11.13

DL object (Object/HTML)

An object that represents a definition list defined by a `<DL>` HTML tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	`myDL = myDocument.all.anElementID`
	IE	*myDL* = *myDocument*`.all.tags("DL")[`*anIndex*`]`
	IE	*myDL* = *myDocument*`.all[`*aName*`]`
	-	*myDL* = *myDocument*`.getElementById(`*anElementID*`)`
	-	*myDL* = *myDocument*`.getElementsByName(`*aName*`)[`*anIndex*`]`
	-	*myDL* = *myDocument*`.getElementsByTagName("DL")[`*anIndex*`]`
HTML syntax:	`<DL> ... </DL>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`compact`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Definition lists are collections of member definitions. The whole list is encapsulated in a `DL` object. Each member definition is constructed from a `DT` and a `DD` object which are maintained together.

The `<DL>` tag is a block-level tag. That means that it forces a line break before and after itself.

The DOM level 1 standard describes this as a `DListElement` object.

See also:	`DD` object, `DT` object, `Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`compact`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

DL.compact (Property)

An attribute that controls the display of <DD> and <DT> items and the amount of space they require on the screen.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myDL*.compact

The `DT` and `DD` objects are normally displayed on two consecutive lines. When the `DL` that owns a collection of `DT/DD` object pairs has the `compact` property set to `true`, the `DT/DD` pair are displayed on the same line to save space.

do ... while(...) (Iterator)

A variant of the `while` iterator that checks the condition after execution.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	`aLabel: do { someCode } while (aCondition );`
Argument list:	*aCondition*	This must prove true for a subsequent cycle to start
	aLabel	An optional identifier that names the loop
	someCode	The code that gets executed in the loop

A `do loop` is a variation on the `while` iterator. A `while` iterator checks the condition and only executes the code block if it is `true`. This means that a `while` loop may never execute even once. A `do` iterator checks the condition once the code has been executed. This ensures that a `do` iterator will perform at least one execution of the code block even if the condition proves `false` the first time it is tested.

ECMA edition 2 compliance merely states that it is a reserved word. At edition 3 of the ECMAScript standard, it is a fully supported requirement of compliance.

JavaScript version 1.2 anticipates this and provides it anyway.

If a labelled `continue` is used (available from version 1.2 of JavaScript), it is intended that execution should drop to the bottom of the loop and test the condition again before cycling or falling out.

Note carefully the line that increments the counter. If you leave it out, you create an endless loop and the browser locks you out. Maybe it will eventually crash but you may need to wait a long time.

Warnings:

- In Netscape 4, there is a bug with labelled `continue` statements and `do ... while` loops that causes the `continue` to vector to the top of the loop without testing the condition. This can set up an endless loop. You could work round this by creating a `while` loop and modifying the test condition.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myCounter = 10;
do
{
document.write(myCounter);
```

```
document.write("<BR>");
myCounter++;
}
while(myCounter < 35);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`continue`, Flow control, `for( ... ) ...`, `for( ... in ... ) ...`, Label, Off by one errors, `while( ... ) ...`

Doctype object (Object/DOM)

An object that represents the document type DTD.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Inherits from:	`Node` object	
JavaScript syntax:	IE	*myDoctype* = *myDocument*.all.*anElementID*
	IE	*myDoctype* = *myDocument*.all.tags("DOCTYPE")[*anIndex*]
	IE	*myDoctype* = *myDocument*.all[*aName*]
	-	*myDoctype* = *myDocument*.doctype
	-	*myDoctype* = *myDocument*.getElementById(*anElementID*)
	-	*myDoctype* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDoctype* = *myDocument*.getElementsByTagName("DOCTYPE")[*anIndex*]
HTML syntax:	`<!DOCTYPE>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`name`	
Collections:	`entities[], notations[]`	

Every document should own a `Doctype` object according to the DOM level 1 specification. This object encapsulates name and some collections that describe the DTD. Work is still underway on standardizing the XML and DTD requirements and this object is therefore likely to change in later versions of the DOM specification.

The DOM level 2 specification adds the following new properties:

- `publicId`
- `systemId`
- `internalSubset`

See also:	`Document.doctype`, `Element.document`, `Notation` object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`name`	1.5 +	5.5 +	6.0 +	5.5 +	-	1 +	ReadOnly

Inheritance chain:

Node object

Doctype.entities[] (Collection)

A named node map containing all the general entities within the DTD.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`NamedNodeMap object`	
JavaScript syntax:	-	*`myDoctype`*`.entities`

Property attributes:

`ReadOnly`.

Doctype.name (Property)

The name of the DTD that the Doctype encapsulates.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myDoctype.name`

Property attributes:

ReadOnly.

Doctype.notations[] (Collection)

A named node map containing the notations declared in the DTD encapsulated by the `Doctype` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0
Property/method value type:	`NamedNodeMap object`
JavaScript syntax:	- *myDoctype*.notations
See also:	`Notation` object

Property attributes:

`ReadOnly`

Document (Object model)

An organized collection of objects that represent a document.

The `document` object is the foundation around which a scriptable interface to an HTML or XML document is constructed. This is sometimes referred to as the DOM and is subject to its own standardization exercise being managed by W3C and other interested parties.

The DOM has its origins in the MSIE version 4 browsers. Version 3 of MSIE and versions of Netscape prior to version 6 implement a more miscellaneous collection of objects that behave a bit like a DOM but are not really a standards-compliant model.

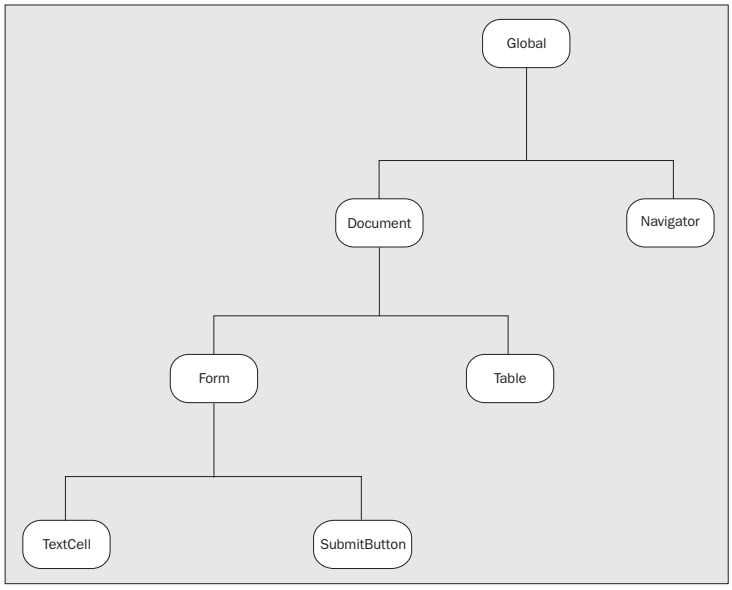
There are areas where the so called DOM support in each browser is so different as to render any script access to the document either problematical or virtually impossible with the same script. This means that you need to support parallel development of HTML and JavaScript to be able to cover both competing browsers.

Now that Netscape 6.0 converges on the same standard- based DOM model as MSIE, we can look forward to a much more portable future for our scripts. So long as we can disregard legacy versions and steer clear of the still quite large number of differences, we should be able to to do much more across different browsers without needing to code differently for each one. History suggests it is also equally likely that they will diverge in other areas where they introduce new features.

The starting point for the DOM hierarchy is the `<HTML>` HTML tag, although the `<BODY>` HTML tag is realistically the root of the DOM.

The basic approach to the DOM differs between the browsers on these points:

- Netscape prior to version 6.0 generally provides a constructor for every object type. MSIE only provides them for objects that you can reasonably instantiate. The new Netscape should comply with the DOM requirements and only provide constructors where they are mandated by the standard.
- MSIE implements an `Element` object on which most other DOM components are based. Netscape 6 implements a structured, DOM compliant model so this is implicit.
- The DOM hierarchy is organized in different ways. MSIE provides many reference vectors for locating parent and child objects to traverse the DOM tree. Netscape provides very few prior to version 6.0.
- MSIE provides an object to represent every tag. Its type is the tag name in upper case.
- On the down-side, MSIE supports a DOM structure that resembles the DOM standard quite closely. However, many of its class names are incorrect. Netscape 6.0 supports a similar structure but uses the correct names for object classes. If you need to use class names in your scripts, beware!



Warnings:

- This is not supported at all on Netscape 2 and 3 or MSIE version 3. You should at least check for these browsers and generate a helpful warning message or skip round the requirement somehow.

See also:	Compatibility, Document object, DOM, Event handler scope

Web-references:

http://msdn.microsoft.com/redirs/inetsdkredir.asphttp://www.w3.org/TR/WD-DOM/

document (Property)

The document within the current window.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`Document object`
JavaScript syntax:	- `document` - *`myWindow`*`.document`
See also:	`Window.document`, `Document object`

Property attributes:

`ReadOnly`

Document component (Definition)

A component object within a document object model.

Component objects within the document correspond to tags in the HTML or XML document. As tags, they may be given names with the `NAME="..."` HTML tag attribute. In the level 0 DOM, these names become properties of the `document` object, which can lead to pollution of the property/method namespace. This is likely to be changed in DOM level 1.

See also:	DOM

Document event handlers (Definition)

A property containing a reference to an event handler property.

Property/method value type:	Function object

There is a small set of event handler function properties created by default. You can assign your own handlers to these properties (if necessary creating the properties that don't already exist).

Here is a list of all the event handler property names that we discovered during our research:

Event	Handler	Usage
`Abort`	`onabort`	When image loading is aborted.
`AfterPrint`	`onafterprint`	When printing has just finished.
`AfterUpdate`	`onafterupdate`	When an update is completed.
`Back`	`onback`	The user has clicked on the [`BACK`] button in the toolbar.
`BeforeCopy`	`onbeforecopy`	Immediately before a copy to the clipboard.
`BeforeCut`	`onbeforecut`	Immediately before a cut to the clipboard.
`BeforeEditFocus`	`onbeforeeditfocus`	Immediately before the edit focus is directed to an element.
`BeforePaste`	`onbeforepaste`	Immediately before the clipboard is pasted.
`BeforePrint`	`onbeforeprint`	Immediately before printing begins.
`BeforeUnload`	`onbeforeunload`	Called immediately prior to the window being unloaded.
`BeforeUpdate`	`onbeforeupdate`	Called immediately before an update commences.
`Blur`	`onblur`	When an input element loses input focus.
`Bounce`	`onbounce`	Triggered when a marquee element hits the edge of its element area.
`Change`	`onchange`	When edit fields have new values entered or a popup has a new selection, this event's handler can check the new value.
`Click`	`onclick`	When the user clicks the mouse button on the `Element` object that represents the object on screen.
`ContextMenu`	`oncontextmenu`	Special handling for contextual menus.
`Copy`	`oncopy`	When a copy operation happens.
`Cut`	`oncut`	When a cut operation happens.
`DataAvailable`	`ondataavailable`	Some data has arrived asynchronously from an applet or data source.
`DataSetChanged`	`ondatasetchanged`	A data source has changed the content or some initial data is now ready for collection.
`DataSetComplete`	`ondatasetcomplete`	There is no more data to be transmitted from the data source.
`DblClick`	`ondblclick`	When the user double clicks on an object.
`Drag`	`ondrag`	When a drag operation happens.
`DragDrop`	`ondragdrop`	Some data has been dropped onto a window.
`DragEnd`	`ondragend`	When a drag ends.
`DragEnter`	`ondragenter`	When a dragged item enters the element.
`DragLeave`	`ondragleave`	When a dragged item leaves the element.
`DragOver`	`ondragover`	While the dragged item is over the element.

Table continued on following page

Event	Handler	Usage
DragStart	ondragstart	The user has commenced some data selection with a mouse drag.
Drop	ondrop	When a dragged item is dropped.
Error	onerror	Triggered if an error occurs when loading an image.
ErrorUpdate	onerrorupdate	An error has occurred in the transfer of some data from a data source.
FilterChange	onfilterchange	A filter has changed the state of an element or a transition has just been completed.
Finish	onfinish	A `marquee` object has finished looping.
Focus	onfocus	When the form element is selected for entry.
Forward	onforward	The user has clicked on the [`FORWARD`] button in the toolbar.
Help	onhelp	The user has pressed the [`F1`] key or selected [`help`] from the toolbar or menu.
KeyDown	onkeydown	When a key is pressed.
KeyPress	onkeypress	Pressing the key down and releasing it again elicits this event.
KeyUp	onkeyup	When a key is released.
Load	onload	When an object has completed loading.
LoseCapture	onlosecapture	When an element loses event capturing permission.
MouseDown	onmousedown	When the mouse button is pressed.
MouseDrag	onmousedrag	An event handler for mouse drag operations.
MouseMove	onmousemove	When the mouse pointer is moved.
MouseOut	onmouseout	When the mouse pointer leaves the active area occupied by the `Element` object that represents the object on screen.
MouseOver	onmouseover	When the mouse pointer enters the active area owned by the object.
MouseUp	onmouseup	When the mouse button is released.
Move	onmove	The browser window has been moved.
Paste	onpaste	When a paste operation happens.
PropertyChange	onpropertychange	When an object property is modified (similar to the Netscape `watch()` method).
ReadyStateChange	onreadystatechange	An object in the window has changed its ready state.
Reset	onreset	The user has clicked a reset button in a form.
Resize	onresize	As the window is resized, this event is triggered.
RowEnter	onrowenter	The data in a field bound to a data source is about to be changed.

Table continued on following page

Event	Handler	Usage
`RowExit`	`onrowexit`	The data in a field bound to a data source has been changed.
`Scroll`	`onscroll`	The window has been scrolled.
`Select`	`onselect`	Some textual content in the window has been selected.
`SelectStart`	`onselectstart`	A select action is beginning.
`Start`	`onstart`	A marquee element is beginning its loop.
`Stop`	`onstop`	When a stop action occurs.
`Submit`	`onsubmit`	The user has clicked on the submit button in a form.
`Unload`	`onunload`	Triggered when the document is unloaded.

See also:	`Document` object, `Element.onevent`

Document object (Object/HTML)

An object that represents the document currently loaded into the window. This exposes the contents of the HTML document through a variety of collections and properties.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Inherits from:	`Element` object

JavaScript syntax:		
	-	`myDocument = document`
	-	*`myDocument`*`= document.documentElement`
	IE	*`myDocument`*` = `*`myElement`*`.document`
	IE	*`myDocument`*` = `*`myElement`*`.offsetParent`
	-	*`myDocument`*` = `*`myElement`*`.ownerDocument`
	IE	*`myDocument`*` = `*`myElement`*`.parentElement`
	-	*`myDocument`*` = `*`myElement`*`.parentNode`
	-	*`myDocument`*` = `*`myFrame`*`.document`
	N	*`myDocument`*` = `*`myLayer`*`.document`
	-	*`myDocument`*` = `*`myWindow`*`.document`
	-	*`myDocument`*` = opener.document`
	-	*`myDocument`*` = self.document`

Argument list:	*`anIndex`*	An index that selects this document

Object properties:	<form_name>, activeElement, alinkColor, background, bgColor, body, characterset, charset, cookie, defaultCharset, designMode, doctype, documentElement, domain, expando, fgColor, fileCreatedDate, fileModifiedDate, fileSize, height, implementation, lastModified, linkColor, location, parentWindow, protocol, readyState, referrer, selection, title, uniqueID, URL, vlinkColor, width

The `document` object is the root of a hierarchy that describes the document in terms of objects, properties and methods that can operate on those objects.

The DOM level specification describes a core `Document` object and distinguishes that from the HTMLDocument that is a sub-class of it. However, the browsers do not make such a fine distinction and so Documents and HTMLDocuments are considered to be one and the same. This works because an HTMLDocument inherits the behavior of a DOM core `Document` object.

Documents and their child objects can respond to events by means of event handler functions. These are generally associated with one another by means of the HTML tag attributes that correspond to each event.

Although there is a superset of all event types, each object type only responds to a few of them.

The `document` object is based on the `Element` object, therefore it inherits all the properties and methods of that class and adds others itself.

The `document` object is basically derived initially from the `<BODY>` HTML tag, although it contains some properties that are associated with the `<HEAD>` HTML tag and others from the `<HTML>` HTML tag that encloses the entire file. The document type header also affects properties in the `document` object.

Traversing the document object model in MSIE is quite straightforward. In Netscape prior to version 6.0 it is so difficult as to be virtually impossible. You can access certain parts of the DOM in earlier Netscape browsers by virtue of the forms, applets, embeds and other collections but you cannot access other parts of the DOM at all.

Event handling support via properties containing function objects was added to `Anchor` objects at version 1.1 of JavaScript and is significantly extended in Netscape 6.0 where it supports DOM level 2 capabilities.

Because you might refer to documents in many ways, possibly by means of object properties or as a property belonging to another window, it is not safe to assume that the document property belonging to the `Global` object is always the `document` object you are trying to access. Indeed, a document may belong to a window, frame, layer or Iframe and several may be accessible at once. Because of this, the object references in the syntax examples assume the object is being referred to via a variable called `myDocument` or `myObject` etc. In the object descriptions, the value `myDocument` is shown being assigned as a variable from the many alternative sources that you can obtain a document reference.

The DOM level specification deprecates the following properties in favor of their counterparts belonging to the `BODY` object:

- `alinkColor`
- `background`
- `bgColor`
- `fgColor`
- `linkColor`
- `vlinkColor`

The DOM level 2 specification adds the following methods:

- `importNode()`
- `createElementNS()`
- `createAttributeNS()`
- `getElementsByTagNameNS()`
- `getElementById()`

A new suite of functionality relating to the way documents are viewed is introduced at DOM level 2. This is embodied in the following classes:

- `AbstractView`
- `DocumentView`

DOM level 3 expects to add the following properties to the `document` object:

- `actualEncoding`
- `encoding`
- `standalone`
- `strictErrorChecking`
- `version`

It is also expected to add the following methods:

- `adoptNode()`
- `getElementsByAttributeValue()`

Warnings:

- There are a number of properties that are defined in both Netscape and MSIE browsers. There are also a few that each defines while the other doesn't. There is at least one (`document.title`) that is defined with different behavior in both browsers. Likewise the same is true of the support for different methods across the two browsers.
- With each release, they tend to support the extensions that the other introduced with its previous release, but they also both introduce new and incompatible extensions each time as well.

Inheritance chain:

`Element` object, `Node` object

Document.<form_name> (Property)

The name of a form if the document contains a `<FORM>` tag.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`Form` object	
JavaScript syntax:	-	*myDocument*`.aFormName`
HTML syntax:	`<FORM NAME="aFormName">`	
Argument list:	*aFormName*	The unique name of a form

If a `<FORM NAME="ABCD">` tag is present in the document, then there will be a property of the document object called `document.ABCD`, named after the form. This means you can access the form object directly by name.

If there are several different forms, they will each have a named property according to their names.

Warnings:

- This is not supported in the same way on MSIE.
- Be careful not to use the same name more than once. Properties must be created according to the name HTML tag attribute in the `<FORM>` tag. If there are two `<FORM NAME="ABCD">` tags, there will only be one `ABCD` property but you cannot be sure which one of the two forms will be present in it. The individual forms will still be reachable via the `forms[]` array however.

See also:	`Document` object, `Form` object, `NAME="..."`

Document.activeElement (Property)

The input element that currently has input (keyboard and mouse) focus.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`An object that can receive input focus`	
JavaScript syntax:	IE	*myDocument*`.activeElement`

This property contains a reference to the `element` object that currently has the input focus.

This may refer to an input element but if there is no active `<FORM>` in the document then the active element will be the `window` object that the document is displayed in.

See also:	`Document` object, `Frame` object, `Window` object

Property attributes:

`ReadOnly`

Document.alinkColor (Property)

The color of a link on the page while it is being activated.

Availability:	DOM level – 0 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated	
Property/method value type:	`Color value`	
JavaScript syntax:	-	*myDocument*`.alinkColor`
	-	*myDocument*`.alinkColor = aColorValue`
HTML syntax:	`<BODY ALINK="aColorValue">`	
Argument list:	*aColorValue*	A hex color value or color name

This value controls the text of active links in the document body. You should use the normal color values to define the required color.

This property is equivalent to the `ALINK` attribute of the `<BODY>` HTML tag. This is color that is used while the mouse is over the link and the button is held down by the user.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape where style sheet controls do not.

The DOM level 1 standard deprecates the usage of this property in favor of `BODY.aLink` instead.

Warnings:

- This property can only be changed from JavaScript in the `<HEAD>` section. You cannot modify it after the `<BODY>` has commenced loading.

See also:	`BODY.aLink`, `BODY.link`, *`BODY.text`*, `BODY.vLink`, Color names, Color value, `Document` object, `Document.bgColor`, `Document.fgColor`, `Document.linkColor`, `Document.vlinkColor`

Document.all[] (Collection)

A collection object containing references to every object in the MSIE DOM.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	IE	*`myDocument`*`.all`

This is available by virtue of the document inheriting properties from an `Element` object.

Refer to the description of the `collection` object for details of how it enhances the capabilities of the basic built-in `Array` class.

Warnings:

- This function may not be available in a properly constructed level 1 DOM implementation. Therefore it may become deprecated after version 5 of MSIE.

See also:	`Collection` object, `Document` object, `Element` object, `Element.all[]`

Property attributes:

`ReadOnly`

Document.anchors[] (Collection)

An array of all the `anchor` objects in the document.

Availability:	DOM level – 1 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0
Property/method value type:	`AnchorArray object`
JavaScript syntax:	- `myDocument.anchors`
HTML syntax:	`<A>`

There is one anchor object for every `<A>` HTML tag in the page.

Prior to version 1.2 of JavaScript, this array simply contained a list of anchors but there were no anchor objects accessible until Netscape 4 implemented them. The only property that could be accessed prior to that was the length of the array.

Changing the name of an anchor in MSIE leaves the existing anchor available and adds a copy using the new name. This may be important if you are parsing the `anchors` array with an enumerator.

Refer to the description of the `AnchorArray` object for details of how it enhances the built-in `Array` class.

There is some difference between the browsers in the way they implement `anchor` and `link` objects. In MSIE the `anchor` and `link` objects are represented identically and the objects simply ignore properties they don't need. Netscape supports different objects according to whether they are links or anchors.

DOM level 1 requires that this collection contains only those objects instantiated by an `<A>` HTML tag which contain a `NAME="..."` HTML tag attribute. Any anchors that have an `ID="..."` HTML tag attribute but no `NAME="..."` attribute should not be included.

Warnings:

- Be aware that if you are not using some `NAME` or `ID` binding to the `<A>` tags, you may get unexpected results if new links are added and you are accessing elements of this array using numeric index values.
- The DOM standard mandates at level 1 that only the `A` tags that have a `NAME="..."` HTML tag attribute should be included in this collection. Anchors with an `ID="..."` HTML tag attribute but no `NAME="..."` attribute should not be included in the collection.

See also:	`Anchor` object, `Anchor.name`, `AnchorArray` object, `AnchorArray.length`, `Document` object, `Document.links[]`, `Element.all[]`, `LINK` object, `LinkArray` object

Property attributes:

`ReadOnly`

Document.applets[] (Collection)

An array containing a list of all the applets in the document.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0
Property/method value type:	`AppletArray object`
JavaScript syntax:	- `myDocument.applets`
HTML syntax:	`<APPLET>`

There is one `applet` object in this array for every `<APPLET>` tag. The applets are represented by `JavaObject` objects. These are wrappers around instances of the class `java.applet.Applet`. This is done with LiveConnect in Netscape and ActiveX in MSIE.

From Netscape 3 and MSIE version 3, your script is able to access the public methods and properties of the Java applets. Netscape supports better communication facilities between the two by virtue of its LiveConnect facility.

Every applet inherits some public properties and methods from its super-class. At least we can be certain that the applet supports the `start()` and `stop()` methods. In MSIE, the applets collection may contain references to intrinsic controls, images, embed and other non-Java objects as well. However other than those, you will need to examine the applet documentation on a case by case basis.

Refer to the description of the `AppletArray` object for details of how it enhances the built-in `Array` class.

DOM level 1 requires that this collection includes objects that are instantiated by `<OBJECT>` HTML tags. It also notes that `<APPLET>` HTML tags should be deprecated.

Warnings:

- Be aware that if you are not using some `NAME` or `ID` binding to the `<APPLET>` tags, you may get unexpected results if new applets are added and you are accessing elements of this array using numeric index values.
- In MSIE version 4, this returns a `Collection` object instead of an `AppletArray` object. MSIE 5 is more consistent with Netscape .

See also:	`Applet` object, `AppletArray` object, `Document` object, `Document.embeds[]`, `JavaObject` object, LiveConnect, `OBJECT` object

Property attributes:

`ReadOnly`

Document.attachEvent() (Method)

A means of attaching events to windows and documents.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDocument*`.attachEvent(`*anEventName*`,` *anEventHandler*`)`
Argument list:	*anEventHandler*	A reference to an event handler function
	anEventName	The name of an event to be handled

This is part of the behavior handling in MSIE which involves the use of style sheets and `.htc` files. It is a way of binding a function to an event so that when the event fires, the function is called. It can be applied in a more general way than just with behaviors.

See also:	`<STYLE>`, `Document.detachEvent()`, `Window.attachEvent()`, `Window.detachEvent()`

Document.background (Property)

DOM originally intended this to be the URL of a background image for the current document.

Availability:	DOM level – 0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myDocument*`.background`

The background image for the document which is defined in the `<BODY>` tag is actually stored in the `BODY` object in MSIE. You cannot access the background image directly in Netscape because the `BODY` object is not available.

DOM level 1 deprecates the use of this property in favor of the `BODY.background` property. Accessing this property in MSIE and Netscape returns the undefined value.

See also:	BODY.background

Document.bgColor (Property)

The background color of the document.

Availability:	DOM level – 0 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated
Property/method value type:	`color value`
JavaScript syntax:	- *myDocument*.bgColor - *myDocument*.bgColor = *aColorValue*
HTML syntax:	`<BODY BGCOLOR="aColorValue">`
Argument list:	*aColorValue* A hex color value or color name

This corresponds to the `BGCOLOR="..."` HTML tag attribute on the `<BODY>` tag.

You can modify this value at any time, the results of which will be to change the background color of the page.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape where style sheet controls do not.

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image, in case the image takes a long time to load or the browser is unable to display a background image.

Warnings:

- On the Unix platform, the Netscape browser versions 2 and 3 exhibit a bug when changing the background color. If you attempt to do this, the page content disappears until something causes the window to be redrawn. If you are using X-Windows, you may be able to alleviate this by changing the damage control policy; however, you would likely need to change it to a slower performing damage control model and that change would apply to all applications in the session. Alternatively, detect the platform and avoid the background color change.

See also:	`BODY` object, `BODY.aLink`, `BODY.bgColor`, `BODY.link`, `BODY.text`, `BODY.vLink`, Color names, Color value, `Document` object, `Document.alinkColor`, `Document.fgColor`, `Document.linkColor`, `Document.vlinkColor`, `style.backgroundColor`

Document.body (Property)

The contents of the <BODY> tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`BODY` object	
JavaScript syntax:	-	`myDocument.body`

In MSIE, this property is a reference to a `BODY` object. Early versions of Netscape are not DOM compliant and do not support this property since it has no `BODY` object implemented to refer to. This is corrected in Netscape 6.0 which implements full DOM level 1 compliance.

The DOM level 1 specification states that this property should yield an `HTMLElement` object. A `BODY` object is derived from an HTMLElement so that general rule is satisfied.

If the document is a frameset then it will return a `FRAMESET` object.

See also:	`BODY` object, `Document` object, `Window.pageXOffset`, `Window.pageYOffset`

Property attributes:

`ReadOnly`

Document.captureEvents() (Function)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myDocument`*`.captureEvents(`*`anEventMask`*`)`
Argument list:	*`anEventMask`*	A mask constructed with the manifest event constants

This is part of the event management suite which allow events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method allows you to specify what events are to be routed to the receiving `Document` object.

The events are specified by using the bitwise `OR` operator to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

A limitation of this technique is that ultimately, only 32 different kinds of events can be combined in this way and this may limit the number of events the browser can support. Since this is only supported by Netscape, the functionality is likely to be deprecated when the standards bodies agree on a standard way of handling events. Then we simply need to wait for the browser manufacturers to support the standardized behavior.

In the meantime, we shall have to implement scripts using this capability if we need to build complex event handling systems. A different script will be required for MSIE.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers and can call common handling routines that can be shared between MSIE and Netscape.

The example copes with cross browser execution in an interesting way (note; this doesn't work for Opera or N 6).

Warnings:

- Since a bit mask is being used, this must be an int32 value. This suggests that there can only be 32 different `Event` types supported by this event propagation model.
- This capability is deprecated and is not supported in Netscape 6.0 anymore. It never was supported by MSIE which implements a completely different event model. As it turns out the DOM level 2 event model converges on the MSIE technique.

Example code:

```
// A portable keyboard eventhandler
// Provided by Jon Stephens
function handleKeypress(event)
{
   var key;
   if(document.layers)
   {
      key = event.which;
   }
   if(document.all)
   {
      event = window.event;
      key = event.keyCode;
   }
   alert("Key: " + String.fromCharCode(key) + "\nCharacter code: " + key + ".");
}

if(document.layers)
{
   document.captureEvents(Event.KEYPRESS);
}

document.onkeypress = handleKeypress;
```

See also:	`captureEvents()`, `Document` object, `Document.releaseEvents()`, `Element.onevent`, Event management, Event propagation, Event type constants, `Frame` object, `Layer.captureEvents()`, `Layer.releaseEvents()`, `onMouseMove`, `Window` object, `Window.captureEvents()`, `Window.releaseEvents()`

Document.characterset (Property)

A Netscape 6.0 equivalent of the `Document.charset` property.

Availability:	JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myDocument*`.characterset`

Refer to:

`Document.charset`

Document.charset (Property)

The character set currently being used.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.charset`

This would contain the character set being used by the document. For example the value `"iso-8859-1"` is likely to be returned but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry.

See also:	`Document` object, `Document.defaultCharset`

Web-references:

ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets

Document.classes[] (Collection)

Part of the JSS style control model supported only by Netscape .

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated
Property/method value type:	`JSSClasses` object

This returns a collection of JSS classes. These are associative arrays that contain other associative arrays. They don't inherit properties and methods from the `Array` object class and are particularly difficult to operate on.

If you are working with JSS driven style sheets, for a start your project is not portable across browser. It will only work on Netscape. Secondly, you are using deprecated functionality. This will lead to your project code breaking at some time in the future when JSS support is no longer available.

Warnings:

- This functionality is removed from Netscape 6.0.

See also:	`Document` object, Document.contextual(), `Document.ids[]`, `Document.tags[]`,`JSSClasses` object

Property attributes:

ReadOnly.

Document.clear() (Method)

A deprecated method that clears the document.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 5.0 Deprecated	
JavaScript syntax:	-	`myDocument.clear()`

This is a method that was implemented early in the life of the Netscape browser. It is only provided for backwards compatibility with older projects and should not be used in any new work you do.

Warnings:

- This method is deprecated as of JavaScript version 1.2 from which point you simply need to use `document.open()` to create a fresh (and empty) document.

See also:	`Document` object

Document.close() (Method)

Close a document body after you have finished writing to it.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myDocument*.close()

Calling the `document.close()` method will cause the output buffer to be flushed, stop the rotating loading icon and force the display of any HTML you have written. In some browsers this may happen automatically when the script exits and in others you will need to do it explicitly. It is good coding style to close a stream when you have finished writing to it. This is analogous to the `fflush()` call that C programmers make to force the buffered output to be sent through an I/O stream.

If you close a document stream and then proceed to write to it again, the document will be implicitly cleared and reopened. That is as if you had performed a `document.clear()` and then a `document.open()`. Any content that you had just written and then terminated with the `document.close()` will be discarded and a new document body started.

The DOM level 1 specification suggests that this method may be deprecated in the future.

See also:	`Document` object, `Document.open()`, `Document.write()`, `Document.writeln()`

Document.contextual() (Method)

Returns a style object that represents the contextual style for the receiver.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated	
Property/method value type:	`JSSTag` object	
JavaScript syntax:	N	*myDocument*.contextual(*aStyle, ...*)
Argument list:	*aStyle*	One or more style objects to clone

This method is used to instantiate a new `style` object for when tags occur within the tags or classes of other types. For example, you can build a contextual `style` object that combines two tag types and specifies that when, and only when, they are used in that context, a certain style appearance is defined.

This fragment of JavaScript will yield a `style` object that is relevant to the contents of an `<H1>` tag:

```
myStyle1 = document.tags.H1;
```

This fragment will yield a `style` object relevant to text inside a `<B>` tag (bold text):

```
myStyle2 = document.tags.B;
```

Now we can combine the two to yield a `style` object that applies only to content between the `<B>` tags when they are inside `<H1>` tags:

```
myStyle3 = document.contextual(myStyle1, myStyle2);
```

Finally, we can set some attribute of that style:

```
myStyle3.color = "Blue";
```

So, any text inside `<B>` tags inside `<H1>` tags will be blue.

This needs to be executed in a `<SCRIPT>` block in the `<HEAD>` portion of the document and cannot be executed after the body has commenced loading.

The result of this method call is a `style` object that operates within a particular context.

Warnings:

- Because this is part of the JSS support, its use is deprecated and likely to become redundant now that Netscape is orienting its style sheet capabilities towards the open standards from W3C.

See also:	`Document` object, `Document.classes[]`, `Document.tags[]`, `JSSTag` object

Document.cookie (Property)

Access to a cookie for the current document.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDocument*.cookie

A cookie is a small fragment of textual data that is associated with the current page. It is not modelled particularly well for access by JavaScript and you will need to use some scripting to disassemble and reassemble the name-value pairs that are concatenated together to make the cookie.

The `cookie` property for a document returns a string containing ALL the cookies that apply to the document. You will need to split them into individual cookies by separating them at semi-colon boundaries. From that you will for each cookie obtain a `name=value` construct that you can further dismantle and process.

Note that you will not get any of the special attributes of the cookie since they are write-only. The only thing you can get back is its `value` property. This means that although the `cookie` property is available for read and write access, it is unlike all other properties it is not symmetrical. You don't get back out what you put in.

Warnings:

- MSIE version 3 will only return cookie data for documents that were requested using the `http:` protocol.

Example code:

```
// Define a cookie for the current document
document.cookie = "cookiename=value";
// Define a cookie from a variable using URL escape()
document.cookie = "cookiename=" + escape(myValue);
// Setting an expiry date on the cookie
myCookieValue   = "cookiename=value";
myCookieExpires = "expires="+myDate.toGMTString();
myCookie = myCookieValue + "; " + myCookieExpires;
```

See also:	Cookie, `Document` object

Document.createAttribute() (Method)

Creates an `Attribute` object that can then set on an Element with the `setAttributeNode()` method.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Attribute` object	
JavaScript syntax:	N	*myDocument*`.createAttribute(`*aName*`)`
Argument list:	*aName*	The name of the attribute to create

This is a new feature introduced with the DOM level 1 standard and currently available only in fully DOM compliant browsers.

The example function shows how a new `attribute` object can be created and set on an element. Because this is standardized at the DOM document level and is not dependent on HTML, it could work in non-web browser implementations.

This is where browser implementations of DOM functionality tend to blur the facts slightly. DOM describes a generic `Document` and then sub-classes that to describe an `HTMLDocument`. Browsers merge the two areas of functionality and simply call it a `Document`.

Example code:

```
// A code fragment that creates an attribute and sets it on
// an element object that is passed in:
function attachMyAttrib(anElement, aName, aValue)
{
var myNewAttr = createAttribute(aName);
var myOldAttr = anElement.setAttributeNode(myAttr);
}
```

See also:	`Attr` object, `Attribute` object

Document.createCDATASection() (Method)

Creates a new `CDATASection` object whose value is the string passed as an argument.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0
Property/method value type:	`CDATASection` object
JavaScript syntax:	N *myDocument*`.createCDATASection(someData)`
Argument list:	*someData* The data content for the new object

See also:	`CDATASection` object

Document.createComment() (Method)

Creates a new comment `node` object containing the data passed in the string argument.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0
Property/method value type:	`COMMENT` object
JavaScript syntax:	N *myDocument*`.createComment(`*someData*`)`
Argument list:	*someData* The content of the comment block

See also:	`COMMENT` object

Document.createDocumentFragment() (Method)

Creates a new and empty document fragment.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`DocumentFragment` object	
JavaScript syntax:	N	*myDocument*`.createDocumentFragment(`*someData*`)`
Argument list:	*someData*	The content of the document fragment

See also:	`DocumentFragment` object

Document.createElement() (Method)

A method to create a new element within a document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Element` object	
JavaScript syntax:	-	*myDocument*`.createElement(`*aTagName*`)`
Argument list:	*aTagName*	An HTML tag name

The result of calling this method is a new `Element` object as if it had been freshly instantiated by an HTML tag.

This is a means of creating new objects which you can then assign to various properties. It is effectively a constructor which is driven by the HTML tag names.

Internally, the MSIE browser maintains objects that are associated with HTML tags as members of a class named after the tag that created them. It's as if there were a class that corresponded to each HTML tag. This means that a call like `createElement()` can use them as if they were constructor objects.

The internal mechanisms in Netscape 6.0 follow the DOM level 1 specification more closely and use the correct class names as defined in the standards. MSIE may support these in the future and you should be careful when writing any script that needs to be aware of the object class names it is operating on.

See also:	`Document` object, `Element` object

Document.createEntityReference() (Method)

A new `EntityReference` object is created. It may acquire the same child list as the entity it refers to.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`EntityReference` object	
JavaScript syntax:	N	*myDocument*`.createEntityReference(`*aName*`)`
Argument list:	*aName*	The name of the entity reference to be created
See also:	*EntityReference* object	

Document.createProcessingInstruction() (Method)

A new processing instruction node is created. Its name and content are specified by the arguments.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`ProcessingInstruction` object	
JavaScript syntax:	N	*myDocument*`.createProcessingInstruction (`*aTarget*`,`*someData*`)`
Argument list:	*aTarget*	The target for the instruction
	someData	The data for the instruction
See also:	`ProcessingInstruction` object	

Document.createStyleSheet() (Method)

A style sheet factory method.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`styleSheet` object	
JavaScript syntax:	IE	*myDocument*`.createStyleSheet()`
	IE	*myDocument*`.createStyleSheet(`*aURL*`)`
	IE	*myDocument*`.createStyleSheet(`*aURL*`, `*anIndex*`)`
Argument list:	*aURL*	The URL to load the style sheet from
	anIndex	A location within the stylesheet list to insert this stylesheet

This is a means of adding a style sheet to a document from the JavaScript context.

When you create the style sheet, you have the choice of simply creating an empty `styleSheet` object or calling one in from a URL document source location.

You can also specify where in the hierarchy of currently loaded style sheets this new one should be placed by specifying its index location within the styleSheets collection.

If you can locate this `styleSheet` object once it has been installed, you can carry out further modifications on it by means of the `addRule()` method. This may be somewhat problematic on some browser versions and platforms since you don't get an object reference handle back from this method. You might be able to code around that, however, since you can specify a target index position in the `styleSheets` collection. That may mean you can get a reference to it indirectly once it has been added.

Warnings:

- Although this method is supposed to return a `styleSheet` object, on the Macintosh platform it returns a `null` value in some versions of the MSIE browser.

See also:	`Document` object, `StyleSheet` object, `StyleSheet.addRule()`

Document.createTextNode() (Method)

A means of constructing a new `textNode` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`textNode` object	
JavaScript syntax:	-	*myDocument*`.createTextNode(`*someData*`)`
Argument list:	*someData*	The textual content of the node

You may need to create additional text nodes to be placed between other objects you create when modifying a document object model. Text nodes are placed interstitially between object nodes within a document hierarchy.

See also:	Hierarchy of objects, `textNode` object

Document.defaultCharset (Property)

The default character set of the document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.defaultCharset`

This would contain the character set being used by the document when it was first opened. That may have changed but this value should always be the same as it was at the start. For example the value `"iso-8859-1"` is likely to be returned but the local variant of the browser and OS may affect the value you get.

Warnings:

- Netscape does not support this.

See also:	`Document` object, `Document.charset`

Document.designMode (Property)

Part of a page authoring control system built into the MSIE browser.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDocument*`.designMode`

This is a means of editing objects manually within the browser. While the browser is in this state, editable elements acquire a UI for modification by means of the `enter` key. When the `designMode` property is set to `"on"` you cannot execute scripts.

The following values can be assigned to this property:

- `On`
- `Off`
- `Inherited`

Warnings:

- Whether this works may depend on platform and browser versions. It does not appear to be functional on MSIE for Macintosh despite the Microsoft documentation saying that it should work.

Document.detachEvent() (Method)

A means of detaching events from windows and documents that were previously attached with the `attachEvent()` method.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myDocument*.detachEvent(anEventName)
Argument list:	*anEventName*	The name of an event to be handled

This is part of the behavior handling in MSIE which involves the use of style sheets and `.htc` files.

See also:	<STYLE>, Document.attachEvent(), Window.attachEvent(), Window.detachEvent()

Document.doctype (Property)

The current document type of the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Doctype object	
JavaScript syntax:	-	*myDocument*.doctype
HTML syntax:	<!DOCTYPE aDocumentDescription>	
Argument list:	*aDocumentDescription*	A reference to a DTD for this document

The <!DOCTYPE> tag at the top of the document is instantiated into a `Doctype` object and a reference to it is stored here. This tag describes a DTD statement that identifies the type of document.

Here is a properly formed DTD statement:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0 FINAL//EN">
```

This is represented by an object whose type is a single exclamation mark. As this tag should be on the first line of a document, the object will be at index 0 in the `document.all[]` array.

Support for this is still somewhat patchy as of Netscape 6.0 and MSIE 5.5. Netscape 6.0 returns a `DocType` object (note the class name capitalization) but its string value is not defined. MSIE returns an undefined value.

Warnings:

- There is apparently no access to this value in Netscape and MSIE only provides limited access.

See also:	`!` object, `!.tabIndex`, `Doctype` object, `Document` object, `Element` object

Property attributes:

`ReadOnly`

Document.documentElement (Property)

An HTML element that represents the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`Element` object
JavaScript syntax:	- *myDocument*`.documentElement`
HTML syntax:	`<HTML>`

This property contains a reference to an `Element` object that corresponds to the `<HTML>` tag at the top of the document.

Warnings:

- Traversing this object with a `for( ... in ... )` loop in MSIE 5 may lead to a browser crash. This is unfortunately still true for version 5.5 of MSIE.

See also:	`Document` object, `Element` object, `HTML` object

Property attributes:

`ReadOnly`

Document.domain (Property)

A means of allowing web servers that trust one another to allow normally insecure access from one another's documents.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myDocument`*`.domain`

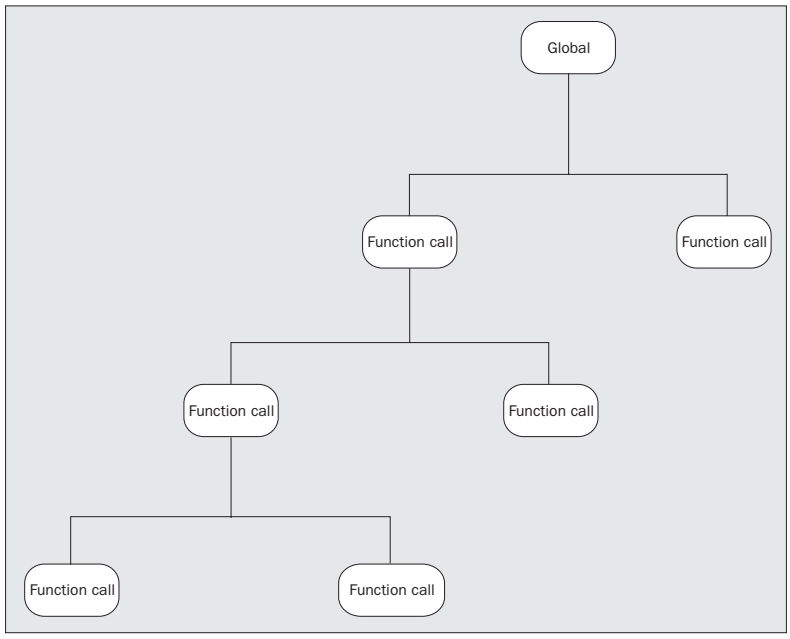
This is part of the Netscape security model that allows unsigned scripts to communicate with one another as long as they belong to the same domain.

Normally, documents may not always be able to communicate with one another because they come from different servers. This can be alleviated by specifying a domain that is shared by several servers.

The initial value of this property is the complete host name of the server that provided the document when it was loaded.

A script is able to set a domain value that is a suffix of the existing domain. So, `aaa.bbb.ccc.com` can become `bbb.ccc.com` but cannot become `another.domain.com` which allows you to serve documents from several hosts in the same domain but not access content served by other domains.

Once any two documents have the same domain setting, they can exchange property values with one another even though they may have originated on different hosts.



Warnings:

- This is not supported on the WebTV platform.

See also:	`Document` object, JellyScript, Security policy

Property attributes:

`ReadOnly`

Document.elementFromPoint() (Method)

Determines which element is under a particular `x, y` location.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Object` object	
JavaScript syntax:	IE	*myDocument*`.elementFromPoint(`*xCoordinate*`,` *yCoordinate*`)`
Argument list:	*xCoordinate*	The X-coordinate value
	yCoordinate	The Y-coordinate value

The result of this method will be a reference to the `Element` object under the `x,y` point.

The document is inspected and the browser works out the topmost `Element` object at the indicated `x,y` location. That `Element` object is then returned as the result. This is very much like executing a mouse click at a location in the document window, and then extracting the target `Element` object from the `event` object. However this is far simpler.

See also:	`Document` object

Document.embeds[] (Collection)

An array of all the `<EMBED>` tag objects within the document.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`EmbedArray` object	
JavaScript syntax:	-	*myDocument*`.embeds`
HTML syntax:	`<EMBED>`	

Each <EMBED> tag is represented here by an object. The embeds are encapsulated in the same JavaObject objects as are used for the Java applets.

Every embedded plugin will respond to different suites of property and method messages although there may be some similarities between some plugins that serve the same purpose.

Warnings:

- Be aware that if you are not using some NAME or ID binding to the <EMBED> tags, you may get unexpected results if new embeds are added and you are accessing elements of this array using numeric index values.
- In Netscape, your JavaScript code interacts with them courtesy of LiveConnect in a very similar way. MSIE interacts with the embeds by means of ActiveX. This can lead to some differences in the way the plugins are supported and the things they can do in each browser environment.
- In MSIE on the Windows platform, plugins are often recommended for use with the <OBJECT> tag rather than the <EMBED> tag. This can lead to portability issues in your scripts and web pages.
- In MSIE version 4, this returns a Collection object instead of an EmbedArray object. MSIE 5 is more consistent with Netscape .
- Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the EMBED class. In Netscape they are objects commonly referred to as belonging to the Plugin class although they are really implemented as JavaObject objects. In MSIE, this is an ActiveX object.
- There is additional confusion in that there is a plugins[] array that belongs to the document and another that belongs to the navigator object. They both contain collections of objects but of different types. This is further confused by the fact that the document.plugins[] array is another name for the document.embeds[] array.
- Because of this confusing situation, the best recommendation is that we refer to document.embeds[] and navigator.plugins[] and quietly ignore the document.plugins[] array. Furthermore we shall refer to Plugin objects as being something the browser can use to play embedded content and Embed objects will be an instance of a plugin that is alive and running in a document.

See also:	<EMBED>, Document object, Document.applets[], Document.plugins[], Embed object, EmbedArray object, JavaObject object, LiveConnect

Property attributes:

ReadOnly

Document.execCommand() (Method)

Part of an MSIE special document command handling mechanism. A method for executing commands.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	Boolean primitive

JavaScript syntax:	IE	*myDocument*.execCommand(*aCommand*)
	IE	*myDocument*.execCommand(*aCommand*, *aUIFlag*)
	IE	*myDocument*.execCommand(*aCommand*, *aUIFlag*, *aParameter*)

Argument list:	*aCommand*	An MSIE command to execute
	aParameter	Parameter value to the command
	aUIFlag	Display or inhibit UI appearance

The MSIE browser supports a special command handling interface that hooks through the browser's user interface. It allows you to automate user actions in a way that other browsers and non-Windows platform users cannot take advantage of.

Although this is a method that applies to a `document` object, many of the commands that are executed through this mechanism will require that a `TextRange` object is created and available first.

The result returned by this method, is a Boolean `true` if the action succeeded, and a Boolean `false` if it failed in someway.

The flag parameter provides a way to suppress any user interface changes that may appear as a result of executing the command.

Name	Description
`2D-Position`	Absolutely positioned elements can be moved by dragging.
`AbsolutePosition`	Sets an element's position property to "`absolute`"
`BackColor`	The background color for the current selection is set to the color value passed in the parameter argument.
`Bold`	The selected text has `<B>` and `</B>` tags placed at either end.
`Copy`	The `TextRange` is copied to the clipboard.
`CreateBookmark`	Carries out modifications to an existing `<A>` tag or creates one, then adds the item to the bookmarks list. The parameter provides the `NAME` value. The `<A>` tag is removed if there is no parameter.
`CreateLink`	Wraps an `<A HREF="...">` tag around the selected text. The parameter contains the URL value for the HREF.
`Cut`	Performs a cut to clipboard.
`Delete`	The text range is deleted. This is not the same as a `Cut` command.
`FontName`	Wraps `<FONT>` tags round the selection. The required font face is passed in the parameter.
`FontSize`	Wraps `<FONT>` tags round the selection and defines the fonts size from the parameter value.
`ForeColor`	Redefines the foreground `btext` color for the selection taking the color value from the parameter.
`FormatBlock`	Wraps a `<BLOCK>` tag round the `TextRange`.
`Indent`	The `TextRange` is indented
`InsertButton`	A `<BUTTON>` tag is placed at the current insertion point in the document. Its `ID` value is defined by the parameter.

Table continued on following page

Name	Description
InsertFieldset	A <FIELDSET> tag is inserted with the ID value being taken from the parameter
InsertHorizontalRule	An <HR> tag is added at the current insertion point.
InsertIFrame	A new <IFRAME> is inserted with the content URL being provided in the parameter.
InsertImage	Overwrites an image on the current selection.
InsertInputButton	An <INPUT TYPE="Button"> is added with its ID value coming from the parameter.
InsertInputCheckbox	An <INPUT TYPE="Checkbox"> is added with its ID value coming from the parameter.
InsertInputFileUpload	An <INPUT TYPE="FileUpload"> is added with its ID value coming from the parameter.
InsertInputHidden	An <INPUT TYPE="Hidden"> is added with its ID value coming from the parameter.
InsertInputImage	An <INPUT TYPE="Image"> is added with its ID value coming from the parameter.
InsertInputPassword	An <INPUT TYPE="Password"> is added with its ID value coming from the parameter.
InsertInputRadio	An <INPUT TYPE="Radio"> is added with its ID value coming from the parameter.
InsertInputReset	An <INPUT TYPE="Reset"> is added with its ID value coming from the parameter.
InsertInputSubmit	An <INPUT TYPE="Submit"> is added with its ID value coming from the parameter.
InsertInputText	An <INPUT TYPE="Text"> is added with its ID value coming from the parameter.
InsertMarquee	A new <MARQUEE> is added with the ID being taken from the parameter.
InsertOrderedList	A new <OL> is added with the ID being taken from the parameter.
InsertParagraph	A new <P> is added with the ID being taken from the parameter.
InsertSelectDropdown	A new <SELECT TYPE="select-one"> is added with the ID being taken from the parameter.
InsertSelectListbox	A new <SELECT TYPE="select-multiple"> is added with the ID being taken from the parameter.
InsertTextArea	A new <TEXTAREA> is added with the ID being taken from the parameter.
InsertUnorderedList	A new <UL> is added with the ID being taken from the parameter.
Italic	The TextRange is enclosed with <I> tags.
JustifyCenter	The TextRange is centered within its parent object.
JustifyFull	The TextRange is fully justified.
JustifyLeft	The TextRange is left justified.
JustifyRight	The TextRange is right justified.

Table continued on following page

Name	Description
LiveResize	Causes the MSHTML Editor to update an element's appearance continuously during a resizing or moving operation, rather than updating only at the completion of the move or resize.
MultipleSelection	Allows for the selection of more than one site selectable element at a time when the user holds down the SHIFT or CTRL keys.
Outdent	The complement of the Indent command.
OverWrite	The input-typing mode is set to overwrite if the parameter value is true and insert if it is false.
Paste	The contents of the clipboard are pasted into the TextRange.
PlayImage	If an image represents a video clip, then it starts playing.
Refresh	The document is reloaded.
RemoveFormat	The complement of the FormatBlock command.
SaveAs	Saves the current Web page to a file.
SelectAll	The entire document text is selected.
StopImage	The complement of the PlayImage command.
UnBookmark	The complement of the CreateBookmark command.
Underline	Places <U> tags around the TextRange.
Unlink	The complement of the CreateLink command.
Unselect	Unselects whatever was selected to create the TextRange. Many commands are now inappropriate until a new TextRange has been created.

None of these commands provide any greatly significant functionality as far as dynamic HTML is concerned. A few of them allow you to manage the clipboard and bookmark lists. It is probably best to avoid using these commands and use the more usual ways of accessing the document internals.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	Document object, Document.queryCommandEnabled(), Document.queryCommandIndeterm(), Document.queryCommandState(), Document.queryCommandSupported(), Document.queryCommandText(), Document.queryCommandValue(), FileUpload.select(), TextRange.execCommand()

Document.expando (Property)

A means of locking objects to prevent new properties being added.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myDocument*.expando
	IE	*myDocument*.expando = aSwitch
Argument list:	*aSwitch*	A boolean value to turn this feature on or off

When the `document.expando` property is set to `false`, it inhibits the creation of new properties if they do not already exist. This can sometimes help find bugs in your scripts. Imagine that you may have misspelled a property name. Setting this property so that it generates a runtime error when a new property is created may help you to isolate the fault.

See also:	`Document` object

Document.fgColor (Property)

The foreground color for text in the current document.

Availability:	DOM level – 0 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated	
Property/method value type:	Color value	
JavaScript syntax:	-	*myDocument*.fgColor
	-	*myDocument*.fgColor = aColorValue
HTML syntax:	<BODY TEXT="aColorValue">	
Argument list:	*aColorValue*	A hex string or color name

This value controls the foreground text in the document body. You should use the normal color values to define the required color.

This is the default text color for the document. It corresponds to the `TEXT` attribute in the `<BODY>` tag.

Default foreground text is colored according to this setting unless it is in an `<A>` tag when the `alinkColor`, `linkColor` and `vlinkColor` values override it. The foreground text color can be changed inline with the `<FONT COLOR="...">` HTML tag attribute.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape where style sheet controls do not.

DOM level 1 deprecates the use of this property in favor of the `BODY.text` property.

Warnings:

- This property can only be changed in the `<HEAD>` section. You cannot modify it after the `<BODY>` has commenced loading.

See also:	BODY.aLink, BODY.link, BODY.text, BODY.vLink, Color names, Color value, Document object, Document.alinkColor, Document.bgColor, Document.linkColor, Document.vlinkColor

Document.fileCreatedDate (Property)

The date that the document file was created.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myDocument*.fileCreatedDate

Where it is possible to distinguish properties of document source files, this can tell you about the history of the document.

This read-only property describes the date that a file was created. With this you can calculate the age of the file by subtracting that date from the date and time now.

See also:	IMG.fileCreatedDate

Property attributes:

ReadOnly

Document.fileModifiedDate (Property)

The date that the document file was last modified.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myDocument*.fileModifiedDate

Where it is possible to distinguish properties of document source files, this can tell you about the history of the document.

This read-only property describes the date that a file was last modified. With this you can calculate the age of the file content by subtracting that date from the date and time now.

Because this is MSIE specific functionality, you should use the Document.lastModified property for portable script code.

See also:	Document.lastModified, IMG.fileModifiedDate

Property attributes:

`ReadOnly`

Document.fileSize (Property)

The size in bytes of the file that was received by the browser.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myDocument*`.fileSize`

This is the exact length of the received HTTP body portion of the document. This does not count any HTTP headers that the web server may have sent prior to the HTTP body. If you edit a document in a text file and then load it into the web browser, this is the exact length of that text file in characters.

On the Macintosh operating system, some text editors hide additional resource data in the file. This is not included and on that platform, the `fileSize` property is a measurement of the data fork of the file and does not include the resource fork.

See also:	`Document` object, `IMG.fileSize`

Property attributes:

ReadOnly

Document.forms[] (Collection)

An array containing a list of all the forms in the document.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 3.0 Internet Explorer – 4.0 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`FormArray` object	
JavaScript syntax:	-	`myDocument.forms`
HTML syntax:	`<FORM>`	

Every `<FORM>` element in the document corresponds to an object in the `forms[]` array.

Warnings:

- Be aware that if you are not using some `NAME` or `ID` binding to the `<FORM>` tags, you may get unexpected results if new forms are added and you are accessing elements of this array using numeric index values.
- In MSIE version 4, this returns a generic untyped object instead of an `AppletArray` object. MSIE 5 is more consistent with Netscape .
- Following some experiments, it seems that in Netscape (version 4.75) the length of the `forms[]` array indicates only the number of numerically indexed items in the array. There are additional items added to the array to refer to the same `Form` objects by name.

Example code:

```
// Referring to the first form of a document
myFirstForm = document.forms[0];
// Referring to the last form of a document
myLastForm = document.forms[document.forms.length-1];
```

See also:	`Document` object, `Element.all[]`, `Form` object, `FormArray` object

Property attributes:

`ReadOnly`

Document.frames[] (Collection)

An array containing references to all the frame objects within a document.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Frames` object	
JavaScript syntax:	IE	*myDocument*`.frames`
HTML syntax:	`<FRAME>`	

In the MSIE browser, you can define in-line frames with the `<IFRAME>` tag. The `frame` property of a document contains a reference to a `Frames` object which is a collection of `Frame` or `Window` objects that enumerate the child frames within the current document.

Aside from the fact that the frame inlined into the HTML and can appear like an image embedded in the text, in all other respects it is like `<FRAME>` in a `<FRAMESET>` and is instantiated as a `Window` object.

To locate the objects representing these in-line frame, use the normal DOM navigation techniques based on object `ID` values and collections belonging to the document.

Warnings:

- Be careful not to confuse this property with the `Window.frames` property.

See also:	`Document` object, `Frame` object, `Frames` object, `Window` object, `Window.frames[]`

Property attributes:

`ReadOnly`

Document.getElementById() (Method)

An accessor method for retrieving objects from within the DOM hierarchy specifically according to their `ID` value.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`Element` object	
JavaScript syntax:	-	*myDocument*`.getElementById(anID)`
Argument list:	*anID*	The ID value of an object to locate in a string

Sometimes, it can be inconvenient to walk the document hierarchy to locate an object by its `ID`. One alternative is to search the `all[]` collection on the MSIE browser but this is a linear search that takes place serially through the document object collection from beginning to end. It can take quite a while to locate the object.

There may also be some conflict in locating objects. The `ID` and `NAME` attributes are different and yet often the two namespaces are combined and searched together.

This method is a faster way of locating object specifically by its `ID` value and ignoring its NAME value. It searches the only unmerged namespace for the `ID` value.

The DOM level 1 specification notes that the behavior is undefined if more than one item shares the same `ID`. Running a short test on MSIE on the Macintosh platform yields the first occurring element with a matching `ID` value. It is likely that this is the generic behavior for versions of MSIE across all other platforms too. For now at least Netscape 6.0 seems to do the same thing.

As there is undefined behavior in the specification, you may find that some browsers return a different object. Indeed, because this is undefined, the behavior may change from one browser version to the next.

Document.getElementsByName() (Method)

An accessor method for retrieving objects from within the DOM hierarchy specifically according to their `NAME` value.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`NodeList` object	
JavaScript syntax:	-	*myDocument*`.getElementsByName(`*aName*`)`
Argument list:	*aName*	The name of the element to be retrieved

Sometimes, it can be inconvenient to walk the document hierarchy to locate an object by its `NAME`. One alternative is to search the `all[]` collection but this is a linear search that takes place serially through the document object collection from beginning to end. It can take quite a while to locate the object.

There may also be some conflict in locating objects. The `ID` and `NAME` attributes are different and yet often the two namespaces are combined and searched together.

This method is a faster way of locating an object specifically by its `NAME` value and ignoring its `ID` value. It searches the only unmerged namespace for the `NAME` value.

Warnings:

- This always yields an empty collection on MSIE 5 for Macintosh.

Document.getElementsByTagName() (Method)

A node list is returned that contains references to all the child elements having the specified tag name.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`NodeList` object	
JavaScript syntax:	-	*myDocument*`.getElementsByTagName(`*aTagName*`)`
Argument list:	*aTagName*	The name of an HTML tag

See also:	`Element.getElementsByTagName(),NodeList` object

Document.getSelection() (Method)

Return the currently selected text string.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myDocument*`.getSelection()`

If you have selected a piece to text, in Netscape this method will return the raw unformatted text within the selection. If there are any HTML tags in the selection, they will be stripped out.

The MSIE browser employs a completely different technique that involves `Selection` objects and `TextRange` objects as a means of access to the selected text.

As it is easy to deselect the highlighted text by clicking on some other active object in the page, you will need to access the selection inside an event handler that is triggered by the selection action itself. This might be done quite effectively in an `onSelectStart` handler.

Warnings:

- On MSIE, use the selection property of the document object.

See also:	`Document` object, `Document.selection`, `Selection` object

Document.handleEvent() (Function)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myDocument*`.handleEvent(`*anEvent*`)`
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`Document` object, `handleEvent()`

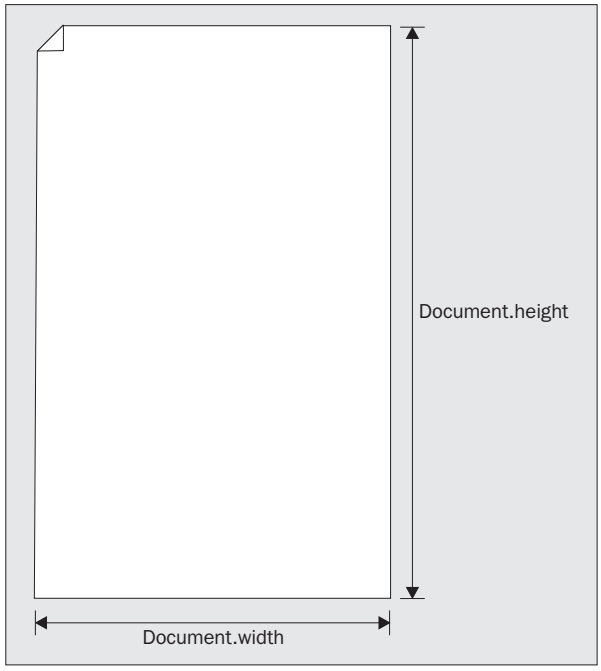
Document.height (Property)

The height of the document.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myDocument*`.body.offsetHeight`
	N	*myDocument*`.height`

The current height of the document measured in pixels. This value constantly changes as the document content is rendered into the page. You can measure this value during document loading and then measure it later to find the page has grown in size.

On MSIE, this property is not supported and you need to do a little work to access the appropriate `Element` object properties of the `body` object.



Warnings:

- This is not supported by MSIE, however you could use the `document.body.offsetHeight` property instead.
- This value can be read by an unsigned script in another window.

See also:	`Document` object, `Document.width`

Document.ids[] (Collection)

Part of the JSS model supported only by Netscape 4.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated	
Property/method value type:	`JSSTags` object	
JavaScript syntax:	N	*myDocument*`.ids`

This yields a `JSSTags` associative array which contains a `style` object for each `Element` object in the page which has an `ID="..."` HTML tag attribute.

The `ID` value is used as an associative array reference to reach the `style` object.

This property does not show up when the document properties are enumerated in a `for( ... in ... )` loop.

Refer to the `JSSTags` topic if you need to operate on these objects.

Warnings:

- This is only supported by Netscape 4 and is part of the JSS support and therefore to be deprecated and should not be used on new projects.
- If you plan to use this, the style settings can only be done during the `<HEAD>` portion of the document and cannot be modified once the document body begins to load.
- This functionality is removed from Netscape 6.0.

See also:	`Document` object, `Document.classes[]`, `ID="..."`, `JSSTags` object

Property attributes:

`ReadOnly`, `DontEnum`.

Document.images[] (Collection)

An array containing a list of all the images in the document.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0
Property/method value type:	`ImageArray` object

JavaScript syntax:	-	*myDocument*.images
HTML syntax:	<IMG>	

Every image in the document corresponds to an element in this array. There is a one for one relationship between these elements and <IMG> tags.

The MSIE and Netscape browsers each maintain an ImageArray object which is just a special case of the Array object. However, although they both store objects that represent images in that array, those image objects are quite different. For a start in Netscape they are of the class "Image" while in MSIE they are of the class "IMG" named after the HTML tag. Perhaps this is fortunate in that you may be able to detect what kind of object you are operating on if you need to perform complex image management activities. This might change however if browsers become more standards compliant in their object class naming, so it may not be true of all versions of all browsers.

The DOM level 1 specification requires that only those images referenced by <IMG> HTML tags should be included in this list.

Warnings:

- Be aware that if you are not using some NAME or ID binding to the <IMG> tags, you may get unexpected results if new images are added and you are accessing elements of this array using numeric index values.

See also:	Document object, Element.all[], Image object, ImageArray object

Property attributes:

ReadOnly

Document.implementation (Property)

A reference to a DOM Implementation object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	Implementation object	
JavaScript syntax:	-	*myDocument*.implementation

This object is used to find out about the DOM implementation in a web browser in the same way that the navigator object tells you about the browser version and its capabilities.

The most useful item belonging to this object is the hasFeature() method. With that you can establsih whether your script is running in an environment that supports the capabilities that you need.

Warnings:

- This may not be implemented in all version of the MSIE browser. It has been reported as being undefined in MSIE 5.0 and 5.5 for Windows.

See also:	`Document` object, `Implementation` object

Property attributes:

`ReadOnly`

Document.lastModified (Property)

The modification date of the document is stored in this property.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDocument*`.lastModified`

This value is obtained by inspecting the HTTP headers as they arrive in the browser. The value of this header is defined by the web server, which probably used the modification date of the file in the `htdocs` directory that it served the content from.

You can check that this is a valid date by handing it to the `Date.parse()` method as an argument. If `Date.parse()` yields a zero value, then it is invalid unless the file was last modified in January 1970 which is extremely unlikely.

See also:	`Document` object, `Document.fileModifiedDate`, `Document.location`, `Document.referrer`, `Document.title`

Property attributes:

`ReadOnly`

Document.layers[] (Collection)

An array containing a list of layers in the document.

Availability:	JavaScript – 1.2 Netscape – 4.0
Property/method value type:	`LayerArray` object
JavaScript syntax:	N *myDocument*`.layers`

HTML syntax:	<LAYER>

Each item in this array corresponds to a <LAYER> tag in the document. This array also includes layers that are created in Netscape by setting the position attribute of an HTML <DIV> block to absolute.

The layers in this array are ordered according to the order in which they appear in the document. Layers can be accessed associatively if they have been given an ID with the ID="..." or NAME="..." tag attribute. This means you can refer to an element whose ID is set to ABC by its unique name. Either as document.ABC or document layers["ABC"].

Warnings:

- Netscape 6.0 completely removes layer support. If you use layers, your pages will break.
- Be aware in Netscape 4 that if you are not using some NAME or ID binding to the <LAYER> or <DIV> tags, you may get unexpected results if new layers are added and you are accessing elements of this array using numeric index values.
- Unnamed layers will not be added to the array, although the array length will correctly reflect the existence of the layers in its count. The count will be wrong and there will be too few objects in the array when you enumerate them in a loop.

See also:	Document object, ID="...", Layer.layers[], LayerArray object, style.position

Property attributes:

ReadOnly, DontEnum

Document.linkColor (Property)

The color of links that have not yet been visited.

Availability:	DOM level – 0 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated	
Property/method value type:	Color value	
JavaScript syntax:	-	*myDocument*.linkColor
	-	*myDocument*.linkColor = *aColorValue*
HTML syntax:	<BODY LINK="aColorValue">	
Argument list:	*aColorValue*	A hex color value or color name

This value controls the text of active links in the document body. You should use the normal color values to define the required color.

This property is equivalent to the `LINK` attribute of the `<BODY>` HTML tag. This is the color that is used for as yet unvisited links.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape where style sheet controls do not.

DOM level 1 deprecates this property in favor of the `BODY.link` property.

Warnings:

- This property can only be changed in the `<HEAD>` section. You cannot modify it after the `<BODY>` has commenced loading.
- On MSIE 5 for Macintosh, the color of the link remains set to its default color until a mouse rolls over it whereupon it changes to the value defined in the script. This is probably a bug.
- Some suggested work arounds include using `document.write()` to output the `<BODY>` tag as the document is loaded. This might work for some applications although I have experienced significant problems with complex pages that are being built with `document.write()` calls. The problems seem to stem from the internal document structure being incomplete and, once the page is loaded, some object references crash the browser. This is particularly problematic with `<OBJECT>` tags in MSIE for Windows and because the `<BODY>` tag is so fundamental to a document, you may want to check that a page composed in this way really does work on all browsers and platforms.

See also:	`BODY.aLink`, `BODY.bgColor`, `BODY.link`, `BODY.text`, `BODY.vLink`, Color names, Color value, `Document` object, `Document.alinkColor`, `Document.bgColor`, `Document.fgColor`, `Document.vlinkColor`

Document.links[] (Collection)

An array of links in the document.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`LinkArray` object
JavaScript syntax:	- *myDocument*`.links`
HTML syntax:	`<A><AREA>`

This is a collection of `link` objects, each one corresponding to an `anchor` or `area` tag in the document. This array may be identical to the `anchors[]` array if there are no `<AREA>` tags present.

Note that in Netscape , the class type for these link objects is actually `Url` and so they are described in detail at that point in the lexically sorted topics.

Objects are added to this array if they are hyperlinks. Simple named anchors do not qualify for addition to this array although they would be added to the array accessible via the `document.anchors` property. The `anchors`, and `links` arrays allow you to distinguish easily between internal and external HREF values. It is slightly confusing in that all `<A>` tags will be members of the `anchors` array while only externally linking `<A>` tags and all `<AREA>` tags will be in the `links` array.

DOM level 1 requires that this collection should include all objects instantiated by `<AREA>` and `<A>` HTML tags which contain an `HREF="..."` HTML tag attribute.

Warnings:

- Be aware that if you are not using some `NAME` or `ID` binding to the `<A>` and `<AREA>` tags, you may get unexpected results if new links are added and you are accessing elements of this array using numeric index values.
- There are security limitations to what you can do when accessing the links property of a document in another frame. So long as both documents came from the same server, you can access one from the other. Documents from the same domain can access one another as can signed documents according to the security policy in force at run-time.
- It isn't proven conclusively but Netscape 6.0 may have some incipient bugs that prevent `write-access` to properties of objects in this collection. That may be corrected quite quickly as the browser is more widely released.

See also:	`Anchor` object, `Document` object, `Document.anchors[]`, `Element.all[]`, `LinkArray` object, `LinkArray.length`, Security policy, `Url` object, `Url.name`

Property attributes:

`ReadOnly`

Document.location (Property)

This is another name for the `Document.URL` property.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated
Property/method value type:	`Location` object
JavaScript syntax:	- *myDocument*`.location`

This is deprecated now in favor of using the `Document.URL` property to access a `Url` object.

In version 1.0 of JavaScript this was a simple string primitive value that contained the actual location of a window. It was not necessarily the same value as the `Window.location.href` value which always contained the requested location.

As of version 1.1 of JavaScript, this is now a reference to the same object that `Window.location` points at. However at the same time its use became deprecated.

Warnings:

- This `location` property is not the same as the `location` property that belongs to a window. The `document.location` property is a string containing the URL that the document was loaded from. The `window.location` property is a reference to the requested URL encapsulated in an object. Because of this, the `document.location` property is not preferred and you should use the `document.URL` property to avoid confusion.
- This property is supposed to be read-only. However, Netscape 4 allows this property value to be changed. This is not recommended practice and you should use the `Window.location.href` property to change the page in the window.

See also:	`Document` object, `Document.lastModified`, `Document.referrer`, `Document.URL`, `Location` object, `Window.location`

Document.open() (Method)

Open a document body ready for writing.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0

JavaScript syntax:	-	*myDocument*`.open()`
	-	*myDocument*`.open(`*aMimeType*`)`
	-	*myDocument*`.open(`*aMimeType, aReplaceFlag*`)`

Argument list:	*aMimeType*	A text string describing a valid mime types for the document
	aReplaceFlag	A string containing the word "replace"

This opens and prepares the document in readiness for a `document.write()` action.

Although the `document.close()` is required, the `document.open()` may be omitted. Some browsers may be permissive enough to allow the `document.write()` actions to work without a `document.open()` first but occasionally a browser may fail. It is good coding style to observe the discipline of opening a stream before writing to it.

The optional parameter describes the MIME type of the document to be opened. By default this will be "text/html". The "text/plain" MIME type is useful too. You can, in theory, open any kind of document but most binary formats are just not practical.

Refer to the MIME type topic for details of some available MIME type values.

The DOM level 1 specification suggests that this method may be deprecated in the future.

Warnings:

- MSIE does not support the MIME type parameter.

See also:	Debugging – client side, Document object, Document.close(), Document.write(), Document.writeln(), MIME types, Window.open()

Document.parentWindow (Property)

The window object that contains the document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	Window object	
JavaScript syntax:	IE	*myDocument*.parentWindow

This is the parent window in which the document is currently being viewed. This window parent-child hierarchy is the nearest analogy that MSIE has to the Netscape layers facility.

If you write code to manage layers or parent-child windows (such as documents containing in-line frames), you will need to take account of browser differences and code accordingly.

See also:	Document object, Frame object, Window object, Window.document, Window.frame

Property attributes:

ReadOnly

Document.plugins[] (Collection)

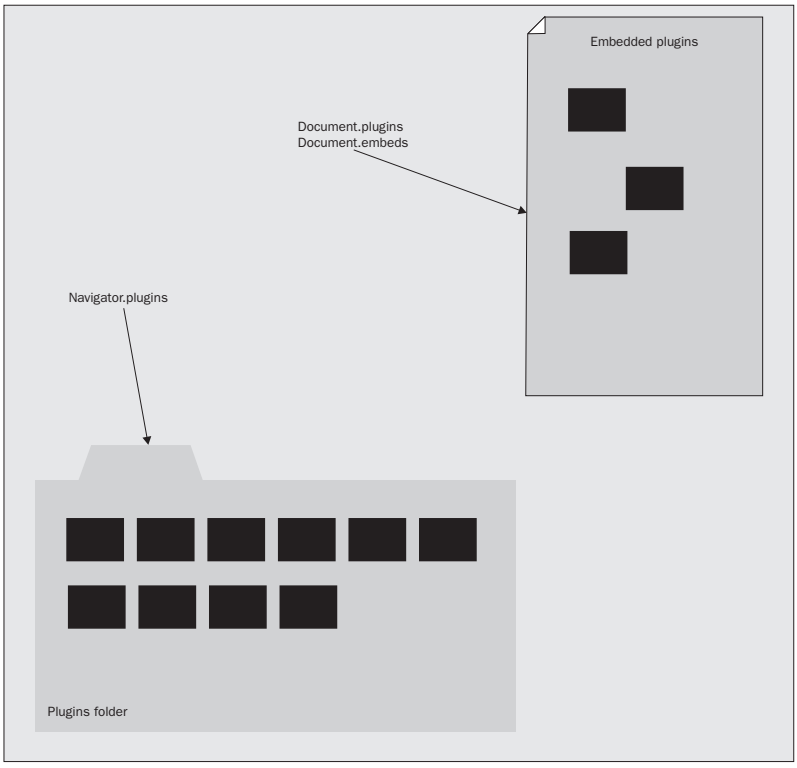
Another (confusing) name for the `document.embeds` property and NOT the `navigator.plugins` property.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0 Deprecated
Property/method value type:	`EmbedArray` object
JavaScript syntax:	- *myDocument*`.plugins`

Each `<EMBED>` tag is represented here by an object. The embeds are encapsulated in the same `JavaObject` objects as are used for the Java applets.

Every embedded plugin will respond to different suites of property and method messages although there may be some similarities between some plugins that serve the same purpose.

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the EMBED class. In Netscape they are objects commonly referred to as belonging to the `Plugin` class although they are really implemented as `JavaObject` objects. In MSIE, this is an `ActiveX` object.



There is additional confusion in that there is a `plugins[]` array that belongs to the document and another than belongs to the `navigator` object. They both contain collections of objects but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.

Due to this confusing situation, the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` array. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and `Embed` objects will be an instance of a plugin that is alive and running in a document.

Warnings:

- In MSIE version 4, this returns a `Collection` object instead of an `EmbedArray` object. MSIE 5 is more consistent with Netscape .
- Because of the confusion between embedded and installed plugins, it is highly recommended that you use the `document.embeds` array for scripts that operate on objects instantiated by the `<EMBED>` tag. Then, use the `navigator.plugins` array for operations on the installed and available plugins that may not yet be embedded into a page.

See also:	`Document` object, `Document.embeds[]`, `EmbedArray` object

Property attributes:

`ReadOnly`

Document.protocol (Property)

The protocol that was used when the document was loaded.

Availability:	JScript – 1.0 Internet Explorer – 3.02	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.protocol`

This should yield the value HTTP or FILE or one of the other available protocols according to how the document was accessed. This allows you to build script code that can behave differently according to how the document was loaded.

See also:	`IMG.protocol`, URL

Property attributes:

`ReadOnly`

Document.queryCommandEnabled() (Method)

Part of an MSIE special document command handling mechanism. Indicates if a command is available for a document or text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	IE `myDocument.queryCommandEnabled(aCommandName)`
Argument list:	`aCommandName` An MSIE command name

This method returns a Boolean value that indicates whether the named command is enabled. Many factors can affect the result of this command. It may depend on the ready state of the document or whether a selection is in force.

Refer to the `document.execCommand()` method for a list of the available commands.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandEnabled()`

Document.queryCommandIndeterm() (Method)

Part of an MSIE special document command handling mechanism. Indicates whether the command is in the indeterminate state.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	IE `myDocument.queryCommandIndeterm(aCommandName)`
Argument list:	`aCommandName` An MSIE command name

If the document is not fully loaded (you can check the `readyState`), or if a command might not be available due to some of its prerequisites not being set (such a selection creating a `TextRange`), this method will return a Boolean `true` value. If it returns a Boolean `false`, then the command may be available as determined by the enabled test.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandIndeterm()`

Document.queryCommandState() (Method)

Part of an MSIE special document command handling mechanism. The current state of a command for the document or text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive or Null`	
JavaScript syntax:	IE	*myDocument*`.queryCommandState(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

This will return one of the following values:

- Boolean `true` if the command has completed.
- Boolean `false` if it is still in progress.
- Null if the state cannot be determined.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandState()`

Document.queryCommandSupported() (Method)

Part of an MSIE special document command handling mechanism. Indicates whether the document or text range supports a command.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDocument*`.queryCommandSupported(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

Some commands are not supported by the `document` object but may be supported by the `TextRange` object.

This method returns a Boolean `true` value if the command is supported by the document object.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandSupported()`

Document.queryCommandText() (Method)

Part of an MSIE special document command handling mechanism.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.queryCommandText(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

Some commands support the extraction of text from the document or `TextRange`. If the command does support the extraction of text, it will be returned by this method.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandText()`

Document.queryCommandValue() (Method)

Part of an MSIE special document command handling mechanism. The value of a command for a document or text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.queryCommandValue(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

The value of a command depends on the command itself and what is selected. This method returns a value according to those criteria.

Warnings:

- This is only supported by the 32 bit Windows version of MSIE.

See also:	`Document` object, `Document.execCommand()`, `TextRange.queryCommandValue()`

Document.readyState (Property)

The current downloading status disposition of the document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.readyState`

Sometimes, you can design scripts to execute while the document is downloading. In-line scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

If it is important that the document has completed loading, you can check this property for one of the following values:

State	Value
`uninitialized`	The object is first instantiated but has not begun loading.
`loading`	The object has commenced loading.
`loaded`	The object has completed loading.
`interactive`	The object is loaded but not yet closed but is ready to handle interaction.
`complete`	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the `ActiveX` object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`Document` object, `onReadyStateChange`, `XML` object

Property attributes:

`ReadOnly`

Document.recalc() (Method)

A special MSIE supported method that sends a recalculation event to a document.

Availability:	JScript – 5.0 Internet Explorer – 5.0		
JavaScript syntax:	IE	*myDocument*`.recalc()`	
	IE	*myDocument*`.recalc(`*aFlag*`)`	
Argument list:	*aFlag*		A flag to force the recalculation

All dynamic properties in the document will be recalculated when this method is called.

The flag value is optional and is assumed to be `false` if it is missing. Setting this flag to `false` only recalculates those dynamic properties that have changed.

Setting the flag to the `true` value forces the browser to recalculate all of the dynamic properties regardless of whether they have changed or not.

Document.referrer (Property)

The URL of the document that was displayed when the user clicked on a link to request this document.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myDocument*`.referrer`

The referrer value indicates the page that was being viewed when the user clicked on a link to request this document.

The referrer data is often used in log analysis to trace a click stream that the user traversed your web site with. This property allows you to do similar things at the client end and build all kinds of history trees and back button simulations.

If you are prepared to do a little work to dismantle the referring link, you can detect when someone has a link to one of your internal pages. What you do then is up to you but you could redirect to an error page or simply bump the user to your front page. This would mean that whatever they did to bookmark one of your pages, they would always end up at your front door instead.

Warnings:

- This does not work in MSIE version 3.
- In Netscape, the referrer only contains a value if the document is different. If a document refers to itself in an anchor, clicking on that anchor effectively reloads the document. The referrer will be an empty string. It continues to to be suspect at Netscape 6.0 as well.
- Some log analysis studies suggest that the referrer value is empty in MSIE when documents are loaded into frames.
- Also as a result of studying log results, book-marked links or link values typed into the location box or drag/dropped into the browser will also not yield a meaningful referrer value.

See also:	`Document` object, `Document.lastModified`, `Document.location`, `Document.URL`, `Window.location`

Property attributes:

`ReadOnly`

Document.releaseEvents() (Function)

An alias for the `window.releaseEvents()` method.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myDocument`*`.releaseEvents(`*`anEventMask`*`)`
Argument list:	*`anEventMask`*	A mask defined with the manifest event constants

This is part of the Netscape 4 event management suite which allows events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method provides a means of indicating which events are no longer needing to be captured by the receiving `Document` object.

The events are specified by using the bitwise `OR` operator to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

Since this is only supported by Netscape prior to version 6.0, the functionality is likely to be deprecated when the standards bodies agree on a standard way of handling events. In the meantime, we shall have to implement scripts using this capability if we need to build complex event handling systems that work on legacy browsers. A different script will be required for MSIE although it may be possible for Netscape 6.0 to share the same one.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers, and can call common handling routines that can be shared between MSIE and Netscape.

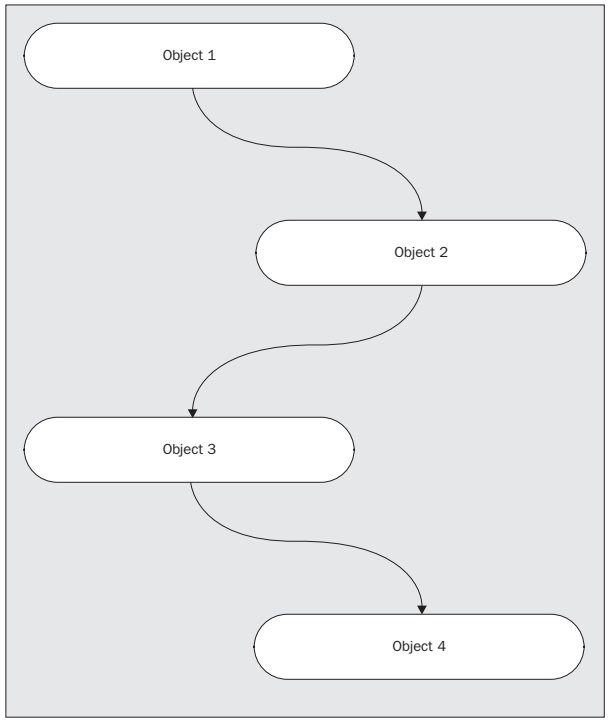
See also:	`captureEvents()`, `Document` object, `Document.captureEvents()`, `Element.onevent`, Event propagation, Event type constants, `Event.modifiers`, `Frame` object, `Layer.captureEvents()`, `Layer.releaseEvents()`, `onMouseMove`, `Window` object, `Window.releaseEvents()`

Document.routeEvent() (Function)

Part of the Netscape event propagation complex.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myDocument`*`.routeEvent(`*`anEvent`*`)`

Argument list:	*anEvent*	An event to be routed



See also:	`Document` object, `Document.handleEvent()`, Window.routeEvent()

Document.scripts[] (Collection)

An array of all the `<SCRIPT>` blocks in a document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`ScriptArray` object	
JavaScript syntax:	IE	*myDocument*`.scripts`
HTML syntax:	`<SCRIPT>`	

This is an array with references to a collection of objects that represent the `<SCRIPT>` blocks in the current document.

Unnamed `<SCRIPT>` blocks are placed into the array with numbered index values. `<SCRIPT>` having an `ID="..."` HTML tag attribute will be added to the array associatively. The `NAME="..."` HTML tag is not reflected in this associative naming scheme and does not work with `<SCRIPT>` blocks.

Warnings:

- In MSIE version 4, this returns a generic `Collection` object instead of a `ScriptArray` object.
- If you interrogate this array in-line while the document is loading, you will not see any script blocks that follow the one containing the script that inspects the array. That suggests this should be used once the document has completed loading.

See also:	`<SCRIPT ID="...">`, `<SCRIPT>`, `Document` object, `ID="..."`, `SCRIPT` object, `ScriptArray` object

Property attributes:

`ReadOnly`.

Document.selection (Property)

The selected text within the object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Selection` object	
JavaScript syntax:	IE	*myDocument*`.selection`

This is the MSIE equivalent functionality to the Netscape `document.getSelection()` method.

Any selected text is returned by a request for this property.

Warnings:

- On Netscape use the `document.getSelection()` method instead.
- On the Macintosh MSIE 5.0 browser, the selection property consistently returns `null` even when there is some text selected. This may be because the Macintosh implementation of MSIE does not support text ranges.

See also:	`Document` object, `Document.getSelection()`, `Selection` object

Property attributes:

`ReadOnly`.

Document.styleSheets[] (Collection)

An array containing a list of style sheets in an MSIE document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`styleSheets` object
JavaScript syntax:	- *myDocument*`.styleSheets`
HTML syntax:	`<LINK>`

This property yields a `styleSheets` array that contains a collection of objects that represent any style sheets currently used by the document. These style sheets are called into the document with the `<LINK>` tag.

The core style sheet model for both MSIE and Netscape is fundamentally the same. However, the style sheet management is done in a completely different way in MSIE and Netscape, prior to version 6.0.

The MSIE technique appears to be far easier to operate on and you can quite easily build algorithmic techniques to locate exactly the `style` object you want to. In Netscape 4, the CSS styling appears to have been added as an interface to an underlying JSS styling model that is far more cumbersome.

As of Netscape 6.0, the JSS support is deprecated and a DOM-based `Style` object like the one in MSIE now provides a more consistent way to operate on styles.

Warnings:

- The entire style management complex is different between the two browsers.

See also:	`Document` object, `rule` object, `StyleSheet` object, `StyleSheetList` object

Property attributes:

`ReadOnly`.

Document.tags[] (Collection)

Part of the JSS model supported only by Netscape 4.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated
Property/method value type:	`JSSTags` object
JavaScript syntax:	N *myDocument*`.tags`

Prior to Netscape 6.0, this was one of the ways into the style sheet manipulation process. It is now deprecated and should not be used in any forward looking new projects unless they really need to operate with legacy browsers. Even then, compared with the MSIE and Netscape 6.0 capabilities, this is quite limited in its scope.

This roughly corresponds to the `Document.styleSheets[]` property in MSIE and is the root of the style control mechanism in Netscape .

Since you cannot enumerate this value and it does not translate easily into a primitive type it is difficult to examine from JavaScript.

Warnings:

- This is not available in MSIE and is part of the Netscape 4 JSS style support and therefore to be deprecated and not used in new projects.
- Although this is supposed to be an associative array, it is really a factory class that manufactures `JSSTag` objects on demand. If you specify a non-existent HTML tag as a property to this object, you should get an error. Unfortunately you just get a new `JSSTag` object.
- This whole JSS style complex is deprecated, and unless you are simply keen to amuse yourself examining it and doing some experiments, it is of little practical use.
- Netscape 6.0 provides a much more capable and portable interface by means of the `Style` object and removes all the JSS functionality.

See also:	`Document` object, `Document.classes[]`, `Document.contextual()`, `JSSTags` object

Property attributes:

`ReadOnly`, `DontEnum`.

Document.title (Property)

The title text for the document.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.all.tags("`*TITLE*`")[0].text`
	-	*myDocument*`.title`
HTML syntax:	`<HEAD><TITLE>aTitleText</TITLE><HEAD>`	
Argument list:	*aTitleText*	Some text in the title heading block

The document title is yielded by this property. The property is not enumerable in the Netscape browser but it is in MSIE. In Netscape this property value is read-only but in MSIE you can modify it whenever you want by assigning a new value to one of the property references that point at the string containing the title text.

This is the text placed inside the `<TITLE>` tags. It exists inside the`<HEAD>` portion of the document, which suggests the document is really rooted at the `<HTML>` tag rather than the `<BODY>` tag. There are minor hierarchical inconsistencies like this.

In the MSIE browser, a special `TITLE` object is also created to help construct a DOM hierarchy inside the browser. The text attribute of that object references the same value as this property.

Warnings:

- For most other objects, this value represents the `TITLE="..."` tag attribute for the tag that constructs the object. Beware when using title attributes that you get the value you really wanted.
- In the MSIE browser, for objects other than the `document` object, the `title` property is used as `ToolTip` text, that automatically appears when the mouse moves over an `Element` object and pauses there.

See also:	`<TITLE>`, `Document` object, `Document.lastModified`, `Element.title`, `HTML` object, `HTML.title`, `LINK.title`, `TITLE` object, `TITLE.text`

Document.uniqueID (Property)

A unique `ID` value for this document.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDocument*`.uniqueID`

Some server side support provides a way to give each document a unique `ID` value. this property reflects such a value for access at the scripting interface.

Document.URL (Property)

This is the actual URL that was loaded for the document.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myDocument*`.URL`

Most of the time, the `document.URL` value will be the same as the `window.location.href` value. However if a server redirect happened, then *`document.URL`* will contain the actual page that was loaded while `window.location.href` will contain the requested URL.

This property should be used in place of the `document.location` property which used to be a string but is now a reference to the same object as the `window.location` property.

See also:	`Document` object, `Document.location`, `Document.referrer`, URL, `Window.location`

Property attributes:

`ReadOnly`.

Document.vlinkColor (Property)

The color of a visited link in the current document.

Availability:	DOM level – 0 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0 Deprecated in DOM level 1	
Property/method value type:	`Color value`	
JavaScript syntax:	-	*`myDocument`*`.vlinkColor`
	-	*`myDocument`*`.vlinkColor = `*`aColorValue`*
HTML syntax:	`<BODY VLINK="aColorValue">`	
Argument list:	*`aColorValue`*	A hex color value or color name

This value controls the text of visited links in the document body. You should use the normal color values to define the required color.

This corresponds to the `VLINK` attribute in the `<BODY>` tag.

Now that the style control facilities are more sophisticated, this tag attribute is likely to fall into disuse. On the other hand it does work consistently on both MSIE and Netscape where style sheet controls do not.

DOM level 1 deprecates the use of this property in favor of the `BODY.vLink` property.

Warnings:

- This property can only be changed in the `<HEAD>` section. You cannot modify it after the `<BODY>` has commenced loading.

See also:	`BODY.aLink`, `BODY.link`, `BODY.text`, `BODY.vLink`, Color names, Color value, `Document` object, `Document.alinkColor`, `Document.bgColor`, `Document.fgColor`, `Document.linkColor`

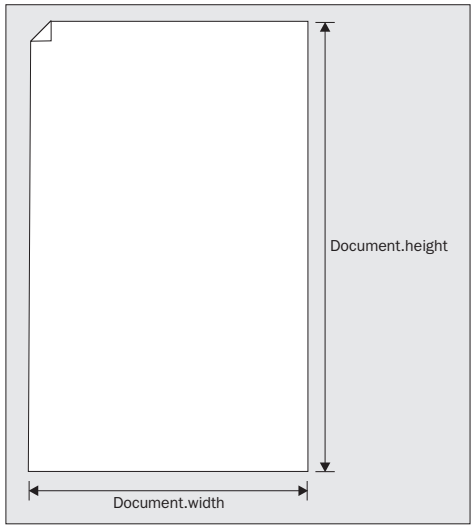
Document.width (Property)

The width of the document.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myDocument*`.body.offsetWidth`
	N	*myDocument*`.width`

The current width of the document measured in pixels. This value constantly changes as the document content is rendered into the page. You can measure this value during document loading and then measure it later to find the page has grown in size.

On MSIE, this property is not supported and you need to do a little work to access the appropriate `Element` object properties of the body object.



Warnings:

- This is not supported by MSIE, however you could use the `document.body.offsetWidth` property instead.
- This value can be read by an unsigned script in another window.

See also:	`Document` object, `Document.height`

Document.write() (Method)

A method for writing HTML into the document body.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myDocument*.write(*anArgument*)
	-	*myDocument*.write(*anArgument, ...*)
Argument list:	*anArgument*	A value to be written out to the document

In a client-side script, you would use `document.write()` to generate some HTML.

This is a host method. It belongs to the `document` object. Its argument values are converted to a string value and are then appended to the content of the document window and then interpreted as HTML.

This is the primary means of generating HTML as a document is parsed and the scripts are executed. Everything that is output by the `document.write()` method is streamed into the page at the execution point where it is called. That means if you place a `<SCRIPT>` block in the middle of the page and it has a `document.write()` in its global code (that is not inside a function declaration), the output will be inserted into the document in place of the `<SCRIPT>` block.

This is a useful technique for creating dynamically changing pages where the dynamism happens at the client end.

Although writing to the current document in an event handler will destroy the document, you can perform `document.write()` actions in other windows to replace their document content. You will need to invoke the `document.write()` method belonging to the target window or frame you want the write to happen in. Here is a `document.write()` that is targeted at a frame somewhere in a frame-set:

```
top.frames[4].document.write("Some target content");
```

When writing across frames like this, you should call the `document.open()` method before the `document.write()` and then call `document.close()` afterwards. The animated browser loading icon will continue to revolve until you close the target document.

The `document.write()` method takes a variable number of arguments which it will concatenate in the output. You can do the concatenation manually but all that is needed is to comma separate the individual items for the `document.write()` to perform this step automatically.

The DOM level 1 specification suggests that this method may be deprecated in the future.

Warnings:

- Beware if you use `document.write()` at any time other than during the document parsing. If you use it in an event handler, you will overwrite the entire documents. Once you have overwritten the document, even the event handler has gone and there is no trace of the original document so when you subsequently refresh again, you may get a blank page.

- Destroying the document content with a `document.write()` will crash Netscape 2 browsers. It may lead to unexpected behavior in Netscape 3 browsers.
- Beware that if you were to use a `with` statement to add the document object to the scope chain, your script would look very much like the server side scripts which use the `write()` method on its own.
- If the output that you write does not immediately appear, it may have been buffered by the browser. There is no way to flush this buffer out to the screen and keep the document open. The only way to flush the buffer is to call the `document.close()` method. However any subsequent `document.write()` will implicitly call `document.open()` and clear the page as it starts a new empty document.
- If you need to change the HTML at that time, you will need to resort to the following dynamic HTML techniques:
  - `<DIV>` blocks
  - `<SPAN>` blocks
  - `innerHTML` and `innerText` properties of elements
  - `createElement()` and its related DOM support.

See also:	Comma operator (,), `Document` object, `Document.close()`, `Document.open()`, Input-output, `response.write()`

Document.writeln() (Method)

A method for writing HTML into the document body.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myDocument*`.writeln(`*anArgument*`)`
	-	*myDocument*`.writeln(`*anArgument, ...*`)`
Argument list:	*anArgument*	A value to be written out to the document

The `document.writeln()` method is very similar to the `document.write()` method. The difference is that `document.writeln()` will place a carriage return after the written value.

This is of little consequence when writing HTML because the browser ignores any line breaks in the HTML.

However, it can be useful when writing other kinds of output such as plain text for example.

The DOM level 1 specification suggests that this method may be deprecated in the future.

See also:	Comma operator (,), `Document` object, `Document.close()`, `Document.open()`, Input-output, `response.write()`

DocumentEvent (Object/DOM)

An interface that extends the `Document` object to support a DOM compliant event structure.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myDocumentEvent = myDocument*
Object methods:	`createEvent()`	

This is not an object class that exists on its own. Rather it is an extension to the underlying `Document` object. It could be considered to be a sub-class of `Document` that inherits all the properties and methods of the `Document` class. Objects of this type are likely to report that they belong to the `Document` class rather than the `DocumentEvent` class although that may be implementation dependent.

The syntax listing shows that a `DocumentEvent` object is equal to a `Document` object although as is the case with Document, you cannot be certain which one of several possible documents you may have been passed if several windows, frames or layers are in use at once.

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`createEvent()`	1.5 +	-	6.0 +	-	-	2 +	-

DocumentEvent.createEvent() (Method)

A method to create a new `event` object ready to be dispatched to an `EventTarget`.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Event` object	
JavaScript syntax:	N	`myDocumentEvent.createEvent(aType)`
Argument list:	*aType*	A string containing an event type

The only argument to this method contains the event type value. This is discussed fully in the `Event.type` topic elsewhere. The method returns a freshly manufactured but uninitialized `Event` object.

The DOM specification describes how the event should be initialized by an appropriate initialization method.

During the execution of this method, it is possible to raise a DOM exception. The only one enumerated in DOM level 2 is the `NOT_SUPPORTED_ERR` value.

The following event types are defined in DOM level 2:

Value	Event object type
`HTMLEvents`	HTML `Element` objects
`MouseEvents`	`MouseEvent` object
`MutationEvents`	`MutationEvent` object
`UIEvents`	`UIEvent` object

See also:	`Event.type`, `UIEvent.initUIEvent()`

DocumentFragment object (Object/DOM)

The DOM specification calls this a lightweight or minimal document object. It can be used as a temporary store for a part of the document hierarchy.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0
Inherits from:	`Node` object
JavaScript syntax:	N *myDocumentFragment* = *myDocument*`.createDocumentFragment()`

See also:	`Document.createDocumentFragment()`, `Node` object

Inheritance chain:

`Node` object

DocumentStyle object (Object/DOM)

Added at DOM level 2 to support document related stylesheets.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0
JavaScript syntax:	N *myDocumetStyle* = new DocumentStyle()

This is a major upgrade in progress. At present the DOM level 2 standards run to several hundred pages and are extremely powerful.

The event model is supported by the Netscape 6.0 browser. Some (probably most) of the style model is supported by MSIE and Netscape 6.0 but there are some shortcomings. For instance, MSIE incorrectly names some properties and object types and it introduces some non-compliant extra methods and properties which are not portable.

The document styling interface is likely to be an area of major amounts of work on the next round of browser upgrades.

DOM mandates that this object should have a single property:

- `styleSheets`

Note that MSIE takes that property name and uses it as an object type. DOM mandates that the property should point at a `StyleSheetList` object and not a `styleSheets` object.

DocumentType object (Object/DOM)

This is implemented in MSIE as a Doctype object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Inherits from:	`Node` object	
JavaScript syntax:	-	`myDocumentType = new DocumentType()`

Inheritance chain:

`Node` object

Refer to:

`Doctype` object

DOM (Standard)

A standardized model of a document built with objects.

The DOM standard is concerned with mapping document components to an object model which reflects the values defined in HTML tag attributes. These are visible to the script writer as object properties. In case of conflicts with reserved words and object names in the JavaScript context, any conflicting names will have the"`html`" prefix. An example is the "`for`" attribute which becomes the "`htmlFor`" property. The HTML tag that instantiated an object is reflected in the `tagName` property of each element object. All document elements derived from HTML tags are sub-classed from the `Element` class.

The W3C Document Object Model standard is being reviewed and updated to enhance the support of the document in the browser. There are several levels to this standard:

- Level 0 – The more or less de-facto situation with the version 4 browsers.
- Level 1 – Text, elements and attributes of HTML and XML.
- Level 2 – Views, traversals, events and stylesheets standardized.
- Level 3 – More work on events and the content model introduced.
- Future – Potential standardization of the security model and standardization of the context and environment in which the document exists.

Thankfully now that browsers are converging on the same standards the amount of duplicated effort will diminish over time as the older browsers are replaced. Netscape 6.0 is just beginning to ship. Beta versions of MSIE version 6.0 are imminent and Opera version 5 is likely to be similarly capable as regards DOM compliance. DOM level 1 seems to be roughly where we are at present.

Browser manufacturers make grand claims to be ECMAScript compliant as well as DOM compliant. This claim is somewhat suspect. Providing objects with the functionality of DOM specified classes but having different class names does not completely satisfy the requirements for DOM compliance. We may ultimately end up with objects being mirrored into duplicate instances under different class names to satisfy DOM class naming and to preserve legacy support.

MSIE at version 5 supports a DOM like object model with Microsoft specific class names. Netscape 6 supports a highly DOM compliant object model with correct object class names. When testing the PR3 beta version of Netscape 6.0, it looked like several HTML tags instantiated objects of the same class when they should have been different but this may have gone away in the final release.

As browser manufacturers support more standardized interfaces, we may be better off in some areas but are also likely to be inconsistent between the browsers in some new areas.

As the new levels are introduced and add new modules, they often extend the interfaces of existing classes. The DOM standard accomplishes this by defining new classes as if they were a sub-class of the object they extend. This provides some opportunity for implementors to name object classes incorrectly in early version of their DOM support. For example, event handling extends the `Document` object to allow it to create new events. This would really be an extension of the `Document` object and would likely not be implemented by sub-classing `Document` to create a `DocumentEvent` object. Were that the way the implentor had chosen, we would have a DOM hierarchy model that had been structurally altered by the insertion of a new sub-class between Document and HTMLDocument and we already have enough confusion between those two object classes across browsers.

Warnings:

- The support for DOM in Netscape 4 is so vestigial that it cannot really be called a DOM implementation at all. This is corrected in Netscape 6.0 which supports DOM level 1 and additionally supports some DOM level 2 features to do with Event handling.

Web-references:

http://www.w3c.org/DOM/

DOM - Level 0 (Standard)

The initial collation of document objects and properties from the de-facto HTML & JavaScript implementations.

The level 0 version of the DOM standard was compiled from the available functionality of the Netscape 3.0 and MSIE version 3.0 functionality. The principal input was derived from the HTML support provided by the browsers. As it stands, some attributes and methods are provided to support backwards compatibility with these older browsers. Those items will likely become deprecated features and will in due course be withdrawn.

DOM - Level 1 (Standard)

A standardized model of a document built with objects.

The level 1 version of the DOM standard defines the complete content structure of the document.

This is implemented in the standard in two parts:

- DOM core functionality
- HTML functionality

The core functionality should apply to documents of a variety of types while the HTML functionality should only be supported in implementations that use HTML marked up documents.

In a fully compliant browser, you can expect to access all of the attributes, names and values of each and every tag. There should be a high degree of consistency between HTML tag attribute sets and object properties and methods.

The document should then be represented as a tree of objects starting at the outermost `<HTML>` tag and all subsequent items being contained in a logical tree structured parent and child arrangement.

With the consistent compliance between HTML attributes and JavaScript object properties, there may still be a few catch-outs. For example, the namespaces may collide. An HTML attribute may correspond to a JavaScript reserved word and therefore it should not be used as a property or method name since they exist in the identifier namespace. Identifiers and JavaScript reserved words must not collide.

To work around this, some prefix will be added to the property names.

The Level 1 DOM support should also include some API support to locate objects by name without necessarily walking the document tree.

Warnings:

- The level 1 DOM specification is similar to but may be somewhat incompatible with the MSIE version 4 DOM implementation. Netscape 6.0 provides the most accurate and compliant implementation of DOM level 1 at the time of writing.

See also:	`NamedNodeMap` object

DOM - Level 2 (Standard)

A standardized model of a document built with objects.

The level 2 DOM is an enhancement on the level 1 support. It introduces additional properties and styles for `document` objects.

The standard is composed of the following modules:

- DOM core functionality
- HTML functionality
- Event handling

- Style specification
- Document views
- Traversal and range specification

The DOM level specification is now a 500 page document that maps the HTML specification to the ECMAScript and Java language bindings. Many additional objects are provided to assist in navigating the DOM hierarchy.

In general, the MSIE version 5 browser on Windows and Macintosh is the best and most complete implementation of DOM released for general use so far.

Netscape 5 never saw the light of day, and with Netscape 6, the development teams have a stated goal of going very aggressively for DOM standardization. Running the same inspection scripts on MSIE 5 and Netscape 6 reveals that the DOM implementations are structurally similar but that the DOM compliance is more robust in Netscape . This is because MSIE does not use the standardized class names `fpr` objects although the entity relations are more or less correct.

The differences between level 1 and level 2 basic support for DOM are as follows:

- Some new methods added to the existing DOM interfaces and exceptions. This extends to about 30 minor changes.
- Many wholly new interfaces are added. These provide access to the HTML implementation, views on the document, additional `StyleSheet` support, new CSS support, `Event` handling support, traversals and ranges.

See also:	ECMAScript, `MutationEvent` object

DOM - Level 3 (Standard)

An improved model of the document object structure.

The level 3 DOM is an enhancement on the level 2 support. It introduces additional properties and interfaces for `document` objects.

The standard is composed of the following modules:

- DOM core functionality
- HTML functionality
- Event handling
- Style specification
- Document views
- Traversal and range specification
- Content model and archiving

The DOM level specification has grown again although not as much as it did at the level 2 version. Some changes to the `Core` and `Events` modules have taken place and a new module has been introduced to support content models and the ability to export and import documents between implementations.

Level 3 standardization is still very much a work in progress and as a whole the DOM standardization process is somewhat held back by work in other groups to do with XML and internationalization among other things. Progress is still being made and although there is much to do, many aspects of the DOM standard are now reasonably well defined and not likely to change.

It still remains for the browser manufacturers to catch up with the standard and in particular to use the same naming conventions for object classes instead of continually inventing their own.

See also:	ECMAScript

DOM Events (Standard)

A new modular part of the DOM standard introduced at level 2 and implemented in Netscape 6.

The DOM level 2 event model has been designed to be platform and language neutral. The standard describes bindings for Java and ECMAScript and it is applicable to other environments too.

The foundation on which DOM Events are constructed requires that DOM Core and DOM views are available too.

There are three main types of events:

- User interface related events such as those triggered by an input device. A key press or mouse click is an example.
- Logical events that may have been triggered via the UI but are more abstract. A focus change or element notification event is an example.
- Mutation events which are caused by some action that modified the structure of the document.

Events are captured in several ways depending on the implementation and context. For example, server-side events would be captured in a different way to those in a web browser.

In a structured document, a target element that receives an event may handle it or may choose to pass it upwards through the document hierarchy to its parent node. This is called event bubbling and was first provided in a web browser by MSIE. As of version 6, the same event model is used in Netscape which attempts to implement the entire DOM level 2 event capabilities as described in the standard.

Events can be cancelled. This can prevent them from bubbling upwards or from exercising some default behavior.

As an alternative to implementing an event bubbling technique, the DOM level 2 event model also provides for an event capturing approach where the highest ancestor object that registers a listener will receive the event before the target object. This traverses the document hierarchy from top to bottom and is the opposite of the bubbling technique which traverses from bottom to top.

`EventTarget` objects are not really objects in their own right although it is convenient to describe them thus in the DOM specification. An `EventTarget` is actually one of the already existing classes but when the DOM level 2 event model is implemented, the `element` objects that can react to events become `EventTargets` by inheriting the properties and methods of the `EventTarget` class as well as any others they inherit from their superclass.

Events are handled by registering `EventListener` functions. These are registered by the potential `EventTargets`. An `EventTarget` is simply an HTML instantiated object, or one that has been manufactured by script and placed into the display for the user to interact with.

See also:	`Element` object, Event, Event management, Event model, `MutationEvent` object

Domain error (Definition)

An error in computation that would normally crash a compiled program.

Refer to:

Minima-maxima

DOMImplementation object (Object/DOM)

MSIE implements this class as the `Implementation` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
JavaScript syntax:	- *myDOMImplementation* = new DOMImplementation - *myDOMImplementation* = myDocument.implementation

Refer to:

Implementation object

DontDelete (Property attribute)

An internal property attribute that prevents a property from being deleted.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

This attribute is set internally on properties by the host environment that the interpreter implementation is running in. When this attribute is set on a property, that property cannot be deleted by the script writer. This attribute is not normally exposed to the script level code.

See also:	DontEnumerate, ReadOnly

Cross-references:

ECMA 262 edition 2 – section – 11.4.1

DontEnumerate (Property attribute)

An internal property attribute that prevents a property from being enumerated.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

This attribute is set internally on properties by the host environment that the interpreter implementation is running in. When this attribute is set on a property, that property cannot be enumerated by the script writer. This attribute is not normally exposed to the script level code.

See also:	DontDelete, `for( ... in ... ) ...`, ReadOnly

Cross-references:

ECMA 262 edition 2 – section – 12.6.3

ECMA 262 edition 3 – section – 12.6.4

double (Reserved word)

Reserved for future language enhancements.

Providing `double` as a reserved keyword suggests stronger data typing may be available in later versions of the ECMA standard.

This keyword also represents a Java data type and the `double` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	float, Integer, `java.lang.Double`, LiveConnect, long, Reserved word, short

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

Double-precision (Definition)

A type of number value.

Double precision numbers use twice the number of bits to represent the value and this increases the range of values that can be resolved by the numeric computations.

See also:	Divide (/), JellyScript

Drive object (Object/JScript)

A special JScript object to represent a disk drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0
JavaScript syntax:	IE `myDrive = myFileSystem.GetDrive()`
Object properties:	`AvailableSpace, DriveLetter, DriveType, FileSystem, FreeSpace, IsReady, Path, RootFolder, SerialNumber, ShareName, TotalSize, VolumeName`

This is an object that represents the disk drive that a `file` object is stored on in the Windows environment. This object is accessed via the `GetDrive()` method belonging to the `FileSystem` object.

See also:	`FileSystem.GetDrive(),Folder.Drive`

Property	JavaScript	JScript	N	IE	Opera	Notes
`AvailableSpace`	-	3.0 +	-	4.0 +	-	-
`DriveLetter`	-	3.0 +	-	4.0 +	-	-
`DriveType`	-	3.0 +	-	4.0 +	-	-
`FileSystem`	-	3.0 +	-	4.0 +	-	-
`FreeSpace`	-	3.0 +	-	4.0 +	-	-
`IsReady`	-	3.0 +	-	4.0 +	-	-
`Path`	-	3.0 +	-	4.0 +	-	-
`RootFolder`	-	3.0 +	-	4.0 +	-	-
`SerialNumber`	-	3.0 +	-	4.0 +	-	-
`ShareName`	-	3.0 +	-	4.0 +	-	-
`TotalSize`	-	3.0 +	-	4.0 +	-	-
`VolumeName`	-	3.0 +	-	4.0 +	-	-

Drive.AvailableSpace (Property)

The amount of free space on the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Number primitive`
JavaScript syntax:	IE `myDrive.AvailableSpace`

The amount of total capacity on the drive may be useful to a server-side script developer who needs to store some information during a session. Refer to the `FreeSpace` property for details of the remaining space available on the drive.

See also:	`Drive.FreeSpace,Drive.TotalSize`

Drive.DriveLetter (Property)

The name of the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDrive*`.DriveLetter`

The abbreviated letter name of the drive in the Windows file system hierarchy.

If the `Drive` object was supported on file-systems other than Windows, the behavior of this property would be unclear, as only Windows names its drives by letters.

Drive.DriveType (Property)

The kind of disk media in the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myDrive*`.DriveType`

This returns a string describing the kind of media that the drive supports. These drive types are currently supported:

Type	Description
0	Undefined
1	Removable volume
2	Fixed disk
3	Network mounted drive
4	CD-ROM
5	RAM disk in memory

If you know the type of drive being used, you can write scripts in a more informed manner. If you are aware that the drive may be volatile, then you can make sure things are backed up, and you can also establish whether the volume is updateable from its type.

Drive.FileSystem (Property)

The kind of file system on the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.FileSystem`

A disk drive is mapped via a file-system. This property returns a reference to an object that encapsulates the file system on the drive.

See also:	`FileSystem` object

Drive.FreeSpace (Property)

The amount of free space left on the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myDrive`*`.FreeSpace`

The amount of spare capacity on the drive may be useful to a server-side script developer who needs to store some information during a session.

See also:	`Drive.AvailableSpace`, `Drive.TotalSize`

Drive.IsReady (Property)

Whether the drive is ready to be used.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myDrive`*`.IsReady`

The behavior of this property will depend on the hardware you have in your system. If you use a hard disk drive, it is likely to always yield `true` for this property. Other drive types may need to be spun up or mounted. They may yield a `false` value. Some may yield a `false` value that changes to true after a short while.

Drive.Path (Property)

The path for the specified drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.Path`

If the drive is mounted into a file system at some location other than the root, this is the path to reach its root directory.

Drive.RootFolder (Property)

A `folder` object that represents the root folder for the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.RootFolder`

Drives have a root folder. This property yields the path to reach the root folder for the drive that this object encapsulates.

Drive.SerialNumber (Property)

The serial number of the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.SerialNumber`

Not all drives will provide a serial number. Some removable cartridge drives support this as a means of identifying cartridges when they are used in multiple drives or systems.

Drive.ShareName (Property)

If the drive is shared, then this is its shared name.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.ShareName`

If a disk drive is shared for use by other users on a network, this property reflects the name it was given when it was set up for sharing.

Drive.TotalSize (Property)

The total space available on the disk if it were empty.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myDrive`*`.TotalSize`

This is the total space available on the drive. There appears to be some redundancy here given that we also have `AvailableSpace` and `FreeSpace` properties.

See also:	`Drive.AvailableSpace`, `Drive.FreeSpace`

Drive.VolumeName (Property)

Access to the volume name of the drive.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myDrive`*`.VolumeName`

If the disk drive supports volume naming, this may be an alternative way to identify a disk drive as opposed to the `DriveLetter` property value.

Drives object (Object/JScript)

A collection of drives belonging to a file system.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myDrives* = myFileSystem.Drives
Object properties:	count	

The `Drives` object is a collection that needs to be used with an enumerator to access the individual drive items.

Example code:

```
// Instantiate a file system object
myFileSystem = new ActiveXObject("Scripting.FileSystemObject");

// Create an enumerator
myEnum = new Enumerator(myFileSystem.Drives);

// Traverse the Drives collection via the enumerator
for(; !myEnum.atEnd(); myEnum.moveNext())
{
  processDrive(myEnum.item());
}

//A function to do something with each disk drive
function processDrive(aDrive)
```

See also:	FileSystem.Drives[]

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
count	-	3.0 +	-	4.0 +	-	-	-	-	-	-	-

DropShadow() (Filter/visual)

A visual filter for creating drop shadows.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Filter – `DropShadow()`

DT object (Object/HTML)

An object that represents the content of a <DT> tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myDT* = *myDocument*.all.*anElementID*
	IE	*myDT* = *myDocument*.all.tags("DT")[*anIndex*]
	IE	*myDT* = *myDocument*.all[*aName*]
	-	*myDT* = *myDocument*.getElementById(*anElementID*)
	-	*myDT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myDT* = *myDocument*.getElementsByTagName("DT")[*anIndex*]
HTML syntax:	<DT> ... </DT>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	noWrap	
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

This object represents the definition term of an item in a definition list. It corresponds to a related definition contained in a `DD` object. `DT` and `DD` objects are paired up and maintained together as a member of the `DL` collection.

The <DT> tag is a block-level tag. That means that it forces a line break before and after itself unless its enclosing <DL> tag uses its compact property.

See also:	`DD` object, `DL` object, `Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
noWrap	-	3.0 +	-	4.0 +	-	-	-	Warning

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
OnFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

DT.noWrap (Property)

Controls the wrapping of text within a `<DT>` block.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myDT*`.noWrap`

This is a Boolean value that controls whether the textual content is wrapped at the right hand window border or not.

If the value `false` is assigned to this property, then words will wrap as the page is drawn. This is good and is the way you would expect a browser to behave. The text will flow according to the space available.

If the value `true` is assigned to this property, the line of text will continue to the right until a `<BR>` or other block level tag is encountered. This will force the horizontal width of the page to extremely large and the user will need to scroll furiously to be able to see the text and then scroll back again for the start of the next line.

Warnings:

- Only use this if you plan to place line breaks at frequent intervals yourself and really do need to control the line breaks manually.

DVB-MHP (Standard)

Digital Video Broadcasting – Multimedia Home Platform.

An emerging Digital TV platform standard, which may achieve some dominance in the future. Of interest to JavaScript users because it is being developed by Sun Microsystems as a platform in which a web browser could be hosted.

If that is the case, there may, by implication, be a JavaScript interpreter available for use.

See also:	Interpret

Dynamic HTML (Definition)

A fourth generation browser technology for dynamically altering the document that describes a web page.

Dynamic HTML is a term that collectively describes the DOM (Document Object Model) and the script activated mechanisms for changing the content of a web page either interactively or not. The content of the page can be animated or modified as a result of the user moving the mouse or clicking on items in the page. The event model is also a contributing factor as is Style sheet support for abstraction of content and appearance by means of CSS (Cascading Style Sheets) and the absolute positioning of HTML elements.

Really the term Dynamic HTML should be deprecated in favor of "DOM scripting" and "CSS scripting".

See also:	CSS, DHTML, DOM, Event model

Dynamic positioning (Definition)

Cascading style properties for positioning objects within the page.

Dynamic positioning in MSIE is accomplished with the `style` object that belongs to each `Element` object in the MSIE DOM. This means that every tag pretty much corresponds to an object in the MSIE DOM. This gives a very fine-grain approach to style and position attributes.

Netscape prior to version 6.0 had to accomplish dynamic positioning by means of layers. This is a bit more complicated than the CSS positioning now available in the new version.

Warnings:

- The JavaScript API that Netscape and MSIE provide to support dynamic positioning differ from one another.

See also:	CSS level 2, CSS-P, style.position

E-mail containing JavaScript (Advice)

You can embed JavaScript into e-mail messages composed using HTML.

When you compose and send an e-mail message, you may use HTML as a way to improve the presentation. This means you can include some JavaScript to be executed in the client mail reader application.

Not all mail clients can support HTML, let alone JavaScript. However, if your recipient does, then you can do some creative things to generate auto reply messages (security permitting). You can also do animation, play audio, present a form for a survey etc. You simply construct your HTML document in the normal way.

Server-generated mail-outs could use this technique to determine how well targeted the mailing is. Perhaps you could put a subscribe/unsubscribe button on the form and tie that to a user ID. That would get round one of the major difficulties of unsubscribing people, which is to do with the mutations that mail addresses undergo. Periodically, a mail server may move or a domain name may change, and this means that unsubscribing from the new address does not locate the subscription record that was made under an old address. Passing an ID back and forth solves this major headache.

Warnings:

- There are significant security and virus related risks with JavaScript enabled e-mail. The possibilities are so catastrophic that the best recommendation is to deactivate JavaScript and Java in any mail reading client application.
- Just because something is possible does not mean it is advisable or good to do.
- On the other hand, within the confines of a closely controlled Intranet or workgroup, this could find many useful applications. Just so long as you know where the mails came from and you can absolutely trust that they have not been compromised.
- Personally, I'd recommend that you turn it off. I've not yet been convinced of the need to support HTML in e-mail correspondence other than for demonstrating how hip and trendy I can be.

ECMA (Standard)

An international standards organization.

The European Computer Manufacturers Association (ECMA) has be developing standards for computing systems for many years.

You can obtain printed copies of their standards and in most cases you can download an electronic copy for your own use.

You should explore the ECMA web site for details of their activities and standards if you are developing compliant implementations or scripts.

See also:	Compliance, Conformance, ECMAScript, Implementation, Opera, Overview, Topic classification

Web-references:

ftp://ftp.ecma.ch/mailto://documents@ecma.ch/http://www.ecma.ch/

ECMAScript (Background)

An international standard that describes JavaScript.

ECMAScript is an object oriented programming language for performing computations and manipulating computational objects within a host environment.

It defines the central or core capabilities of the language and does not define any of the host defined capabilities.

As defined in the standard, ECMAScript is not intended to be self-sufficient, but should provide core functionality on top of which host objects need to be added.

Scripting languages are intended to be used by both experienced programmers and non-programmers. This means a scripting language will tend to be less formal than a compiled language and will relax the rules a little. Basically you can get away with more things than a compiler would permit.

Scripting languages are generally used to automate existing capabilities of a hosting environment. Those facilities may be already accessible under manual operation via a Graphical User Interface.

ECMAScript was originally designed to be a web scripting language to provide facilities to add dynamics to client-side browser displayed web pages.

Some of the facilities provided by ECMAScript interpreters are similar to those available in other languages such as Java, Perl and C.

Here is an extract from the ECMA second edition standard:

"This ECMA Standard is based on several originating technologies, the most well-known being JavaScript and JScript. The language was invented by Brendan Eich at Netscape and first appeared in the Netscape Navigator version 2.0 browser. It has appeared in all subsequent Netscape Navigator browsers and in all browsers from Microsoft starting with MSIE version 3.0."

Warnings:

- The browser manufacturers go to great lengths to stress how well they comply with a standard. Microsoft and Netscape both claim compatibility with ECMAScript.
- It is not always clear which revision of ECMAScript they are claiming compliance with. It is hoped that they mean edition 3 of the standard. However if they don't make this clear, they may only be edition 2 compliant.
- If all the browsers you are using were 100% compliant with ECMAScript edition 3, would this then mean that you could write one version of your script and deploy it everywhere?
- Unfortunately not. ECMAScript only defines the core language. It allows for the browser manufacturers adding host specific features in a compliant fashion, but it does not specify what they should be. Because the DOM implementations are so different, claiming ECMAScript compliance is almost meaningless in terms of whether you can really build portable scripts to run in web browsers.
- That is not to diminish the importance of ECMAScript at all. It is the foundation on which every JavaScript interpreter should be based – without question. However, for your script to be truly portable, every other facet of the implementation must also conform strictly to the same standard.
- At least we could expect browser manufacturers to comply with ECMAScript and the W3C DOM definition. That still leaves many holes in security standardization and event handling. Not to mention the new directions regarding mobile devices and TV set-top boxes, which will all lead to diverging implementations.
- The event handling is being rigorously worked out as part of the DOM level 2 and level 3 standardization work.

Cross-references:

ECMA 262 edition 2 – section – 4

ECMA 262 edition 3 – section – 4

Wrox *Instant JavaScript* – page – 12

ECMAScript – edition 2 (Standard)

Specific conformance for ECMAScript at its second edition.

The character encoding support described in the second edition of the standard is very specific:

"A conforming implementation of the International standard shall interpret characters in conformance with the Unicode Standard, Version 2.0, and ISO/IEC 10646-1 with UCS-2 as the adopted encoding form, implementation level 3. If the adopted ISO/IEC 10646-1 subset is not otherwise specified, it is presumed to be the BMP subset, collection 300."

Other than typographical and editorial changes, little was added between the first and second editions of the ECMA standard. That means this edition becomes the foundation specification for the core language.

The principle features of this edition include:

- Arithmetic, string and logical operators
- Global and local variables managed via scope chains
- Core data types and objects (`Number`, `String`, `Boolean`)
- Core object types (`Date` and `Array`)
- Core numeric library support by means of the `Math` object
- Language flow control and keywords
- Object instantiation by means of constructors
- Inheritance supported via prototype chains

The Unicode Standard, Version 2.0, Addison-Wesley Publishing Co. ISBN: 0-201-48345-9

ECMAScript – edition 3 (Standard)

Specific conformance for ECMAScript at its third edition.

The character encoding support described in the third edition of the standard is somewhat more advanced than that in the second edition:

"A conforming implementation of this International standard shall interpret characters in conformance with the Unicode Standard, Version 2.1 or later, and ISO/IEC 10646-1 with either UCS-2 or UTF-16 as the adopted encoding form, implementation level 3. If the adopted ISO/IEC 10646-1 subset is not otherwise specified, it is presumed to be the BMP subset, collection 300. If the adopted encoding form is not otherwise specified, it presumed to be the UTF-16 encoding form."

The third edition adds to the earlier versions in the following areas:

- Regular expressions
- Richer control statements
- Better string and array handling
- Exception handling improvements with `try/catch`
- Internationalization facilities
- Error objects for managing exceptions

ECMAScript edition 3 support is a feature of the MSIE/Jscript 5.5. upgrade and the new Netscape 6.0 release.

Unicode Technical Report #8, The Unicode Standard, Version 2.1.

ECMAScript version (Standard)

The version history for ECMAScript.

The version history of ECMAScript is slightly behind the current browser implementations. Versions of ECMAScript are defined as editions 2 and 3 of the standard. Edition 1 was superseded by edition 2, which made few functional changes. There were not enough to warrant revising the level of functionality.

ECMA edition 2 is roughly equivalent to JavaScript version 1.1, minus any HTML document modelling.

ECMA edition 3 is roughly equivalent to JavaScript 1.5 and JScript 5.5.

Element object (Object/HTML)

A common name for an object that represents an HTML tag or container.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Inherits from:	`Node` object

JavaScript syntax:	IE	*myElement* = document.all(*anIndex*)
	IE	*myElement* = document.all.*anElementID*
	IE	*myElement* = document.all[*anIndex*]
	IE	*myElement* = document.children(*anIndex*)
	IE	*myElement* = document.children.*anElementID*
	IE	*myElement* = document.children[*anIndex*]
	-	*myElement* = *myChildNodes*[*aName*]
	-	*myElement* = *myChildNodes*[*anIndex*]
	-	*myElement* = *myDocument*.getElementById(*anElementID*)
	-	*myElement* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myElement* = *myDocument*.createElement(*aTagName*)
	-	*myElement* = *myDocument*.documentElement
	-	*myElement* = *myDocument*.getElementsByTagName(*aTagName*)[*anIndex*]
HTML syntax:	<*anHTMLTag*>	
Argument list:	*anElementID*	The ID value for the required element
	anHTMLTag	A tag that represents a realizable concrete object
	anIndex	An index location in the collection
	aTagName	The name of an HTML tag to create an element for
	aName	An associative array reference
Object properties:	canHaveChildren, canHaveHTML, className, clientHeight, clientLeft, clientTop, clientWidth, contentEditable, currentStyle, dir, document, firstChild, hideFocus, id, innerHTML, innerText, isContentEditable, isDisabled, isTextEdit, lang, language, lastChild, nextSibling, nodeName, nodeType, nodeValue, offsetHeight, offsetLeft, offsetParent, offsetTop, offsetWidth, outerHTML, outerText, ownerDocument, parentElement, parentNode, parentTextEdit, previousSibling, readyState, recordNumber, runtimeStyle, scopeName, scrollHeight, scrollLeft, scrollTop, scrollWidth, sourceIndex, style, tagName, tagUrn, title, uniqueID	
Object methods:	addBehavior(), applyElement(), blur(), clearAttributes(), click(), componentFromPoint(), contains(), doScroll(), focus(), getAdjacentText(), getAttribute(), getAttributeNode(), getElementsByTagName(), getExpression(), insertAdjacentHTML(), insertAdjacentText(), mergeAttributes(), normalize(), releaseCapture(), removeAttribute(), removeAttributeNode(), removeBehavior(), removeExpression(), replaceAdjacentText(), scrollIntoView(), setAttribute(), setAttributeNode(), setCapture(), setExpression()	
Functions:	handleEvent()	

Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`
Collections:	`all[]`, `attributes[]`, `behaviorUrns[]`, `childNodes[]`, `children[]`, `filters[]`

The standard DOM hierarchy model specifies a variety of properties that should be available across the entire collection of objects. This suggests that all objects in the document would generally behave as if they were sub-classes of a master DOM `element` object.

DOM level 1 describes an `Element` object and an `HTML` object and makes a distinction between the two. JavaScript considers them to be one and the same within a web browser context.

In JavaScript 1.2 and MSIE 4, many HTML tags are represented as objects that have similar methods and properties. It is convenient also to model these as if they were sub-classes of a single super-class. Actually, Netscape at revision 4 does not really support this model very consistently, although it is a sound concept when studying the internals of the MSIE browser. Netscape 6.0 implements a much more robust and complete set of the DOM level 1 capabilities.

The `Element` object described here includes the behavior of the DOM `Element` object with some additional properties and methods that are common to many objects in the various browsers.

We call these `Element` objects. In other reference works they may be called DOM objects, DOM elements or HTML Elements. Trying to work out what kind of element you have is not always easy. Some objects will provide this with their `toString()` method. Others will need some inspection. You can look at `constructor` properties for help. Sometimes `object.constructor.name` will tell you what you need. This is not consistent across all the different kinds of objects, nor is the same technique applicable across all browsers.

By considering all the DOM and HTML Element objects as sub-classes of the `Element` object class, we can document their common behavior collectively and then deal with any specific behavior they may implement on a case by case basis.

We attempt to de-clutter the object descriptions by abstracting properties, methods, collections and events into a super-class wherever possible. This `Element` class does not really exist as a concrete class but it helps to understand the internals of the MSIE and Netscape 6.0 browsers in particular to model it like this. A couple of notable exceptions are the `document` object and `window` object classes which share some properties etc. with the `Element` class, but cannot easily be considered to be sub-classes of the `Element` class. Those properties and methods etc. are used in a contextually different way and may exhibit slightly different behavior, and so they merit being covered in separate (but similar) topics to the ones described as members of the `Element` topic set.

There is another special class and that is the `FormElement` object. These are sub-classes of the fundamental `Element` class, but are a super-class of all `Form` elements which represent `<INPUT>` tags. Many of these share common methods and properties in addition to the `Element` object functionality. Properties, methods, collections and events that relate to the `Input` object class are discussed under topics beginning with the phrase "Input" and are not duplicated here. However, they are listed here in the summary.

If you are inspecting objects with an enumeration loop, you may want to eliminate `Element` object properties so that your enumerator only lists special properties of the object you are inspecting. There is actually no object of the `Element` object type. We explored a great deal of the internal browser model by writing small fragments of JavaScript to walk through the properties of each object type. This yielded some properties that were hitherto undocumented and highlighted some differences between platforms and browsers.

In MSIE, there is a class for each type of HTML tag. There is also an `array` class for collections of each type of tag. For example, for an imaginary tag called `<XXXX>`, there will be an object class with the name `XXXX` which represents tags of that type regardless of whether they are upper or lower cased. There will also be an `XxxxArray` collection for that class which is yielded by this expression:

```
document.all.tags("XXXX")
```

If you create imaginary tags in your documents, MSIE won't render them nor will it create objects to represent them. However, the expression shown above will yield an empty collection of an appropriate type.

Versions of Netscape prior to 6.0 do not implement this mechanism because they manage its content with a different DOM construction technique. Netscape 6.0 and MSIE support a more consistent interface to all of the tags in a document. No version of Netscape provides the `all[]` collection.

If you want to examine the properties of `Element` objects you need to be able to isolate those properties that are inherited and those that are not. The example code for MSIE includes a function that you can use to exclude items that are inherited from `Element` objects as you enumerate the properties of an object. We used this to examine the undocumented structures within web content viewed in the browsers. There is also an attribute accessor function demonstrated here. The rest of the example demonstrates a framework for examining object properties.

The DOM level 2 specification adds the following new methods to support namespaces:

- `getAttributeNS()`
- `setAttributeNS()`
- `removeAttributeNS()`
- `getAttributeNodeNS()`
- `setAttributeNodeNS()`
- `getElementsByTagNameNS()`
- `hasAttribute()`
- `hasAttributeNS()`

DOM level 2 moves the `normalize()` method to the `Node` object but it is still available here through inheritance.

As the DOM standards advance and proliferate and the browser become more DOM standards compliant, a standards based approach to the documentation may become more appropriate. We have structured our coverage around a browser centric approach.

`Element` objects will have other properties and methods not included here because they are not yet implemented or fall outside the standard. The following properties are present in some implementations for example:

- `onOffBehavior`
- `hasMedia`
- `syncMaster`

These are part of the SMIL and HTML+TIME standards which are still in a state of evolution and therefore the behavior of the implementation may change.

Warnings:

- Be careful how you operate on these objects. Traversing the properties in a `for( ... in ... )` loop can recursively lock up your browser for some objects that represent high level parts of the DOM hierarchy.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY >
<IMG ID="IMAGE1" SRC="wrox.gif">
<TABLE CELLPADDING=2 CELLSPACING=2 BORDER=1>
<SCRIPT>
var myObject = document.getElementById("IMAGE1");
document.write(displayProperties(myObject));

// Display a table of enumerated properties
function displayProperties(anObject)
{
   var myOut = "";
   myOut += '<TR BGCOLOR="ANTIQUEWHITE">';
   myOut += "<TD>Object type</TD><TD>";
   myOut += typeof anObject;
   myOut += "</TD><TD>";
   myOut += anObject;
   myOut += "</TD><TD>Name</TD><TD>Specified</TD>";
   myOut += "<TD>Value</TD></TR>";

   for(myProp in anObject)
   {
      // Place a not symbol on this condition to see
      // non inherited properties
      if(isElementProperty(myProp))
      {
         myOut += "<TR><TD>";
         myOut += myProp;
         myOut += "</TD><TD>";
         myOut += typeof anObject[myProp];
         myOut += "</TD><TD>";
         myOut += displayableValue(myProp, anObject[myProp]);
         myOut += "</TD><TD>";
         myOut += getPropAttr(anObject, myProp, "name");
         myOut += "</TD><TD>";
         myOut += getPropAttr(anObject, myProp, "specified");
         myOut += "</TD><TD>";
         myOut += getPropAttr(anObject, myProp, "value");
         myOut += "</TD></TR>";
      }
   }

   return myOut;
}
```

```
// Prevent recursive displays

Inheritance chain:

`Node` object

Element.addBehavior() (Method)

Attach a behavior to an object in MSIE.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*`.addBehavior()`

MSIE supports an extension to style sheet handling that provides for scripts to be called as part of the style. These are called behaviors. The script source text is stored in a special and separate file with an `.htc` (or `.HTC`) file extension. It stands for HTml Component.

This augments the already available event handler support which provides for handlers to be registered with individual objects or with a particular instance of a tag. Behaviors allow a handler to be registered with all occurrences of a tag with only one registration being necessary.

Here is the contents of a simple HTC file taken from the Wrox book *Professional JavaScript*.

```
<SCRIPT LANGUAGE="JScript">attachEvent("onclick", event_onclick);function
event_onclick(){   alert("Read the manual.");}</SCRIPT>
```

This can be defined in a style sheet or in a `<STYLE>` tag. Here is how it would be invoked with an inline `<STYLE>` defined in the `<HEAD>` of a document:

```
<STYLE>   .help{behavior:url(help.htc)}</STYLE>
```

Having defined the style, you can now apply this to any element. For example, it could apply to the entire contents of a `<DIV>` block like this:

```
<DIV CLASS="help" DELAY="2000">Click for help</DIV>
```

The `DELAY` HTML tag attribute provides a way to delay the presentation of the `<DIV>` block contents until the browser has had a chance to load the HTC file content.

There are more complex ways to use behaviors that involve the use of XML mark-up and which can avoid the use of `attachEvent()` methods. Refer to the Microsoft web site for further details.

See also:	`.htc`, Behavior, `Element.removeBehavior()`

Web-references:

http://msdn.microsoft.com/workshop/essentials/versions/IE5behave.asp

Element.all[] (Collection)

An array containing references to all elements within this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	IE	*`myElement`*`.all`

This property yields a collection of objects that are descendants within the DOM hierarchy of the receiver.

The collection (Array) contains a reference to all the objects that represent the contents of the HTML contained within the current `Element` object. If the `Element` object is the document, then this array will contain every single object within the document. If it represents a `<TABLE>` then it will contain references to objects within that table and none that live outside it.

The objects are listed strictly in the order in which they appear in the document source.

You can access the items by index number or you can operate on the collection with the `item()` or `tags()` methods. If you use index number access, MSIE allows you to use either square brackets or parentheses to delimit the index value. Associative references may also work if the target item has a `NAME` or `ID` value defined.

Refer to the topic that describes the `Collection` object for further details.

The event handling is also dealt with in a generic manner via the `Element` object. However some object sub-classes also support additional event types. Event types and handlers are dealt with in topics pertaining to each type of event.

Warnings:

- Be careful that when you traverse this collection you avoid the possibility of creating a recursive reference. This can lead to a script lockup that could crash your browser.
- Netscape does not support the `all[]` collection for document objects. Versions prior to Netscape 6.0 also do not consistently support access via an `ID` value.

See also:	`Anchor` object, `Collection` object, `Document.all[]`, `Document.anchors[]`, `Document.forms[]`, `Document.images[]`, `Document.links[]`, `Element` object, `Form` object, `FormElement` object, Hierarchy of objects, `HyperLink` object, `Image` object, `LINK` object

Property attributes:

`ReadOnly`.

Element.applyElement() (Method)

A way of defining an `Element` object as the child or parent of another element.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*.applyElement(*anObject*)
	IE	*myElement*.applyElement(*anObject*, *aLocation*)
Argument list:	*anObject*	An object to be referenced
	aLocation	The relationship to construct

When the element is applied, you must specify the `element` object to which it is to become attached.

There is an optional second parameter to define whether it should become the parent or the child of that object. If the second parameter is not specified, then the element becomes the parent of the target object.

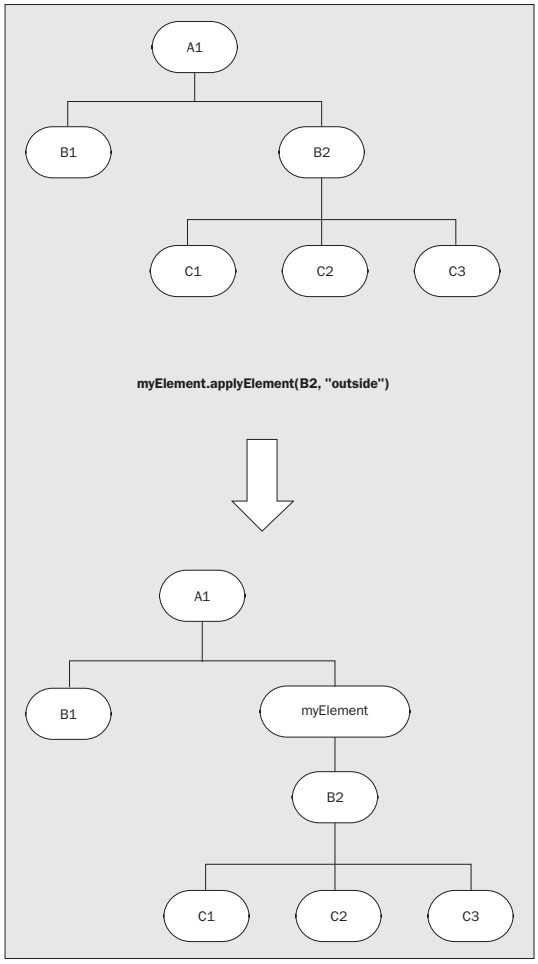
The second parameter can be any of these values:

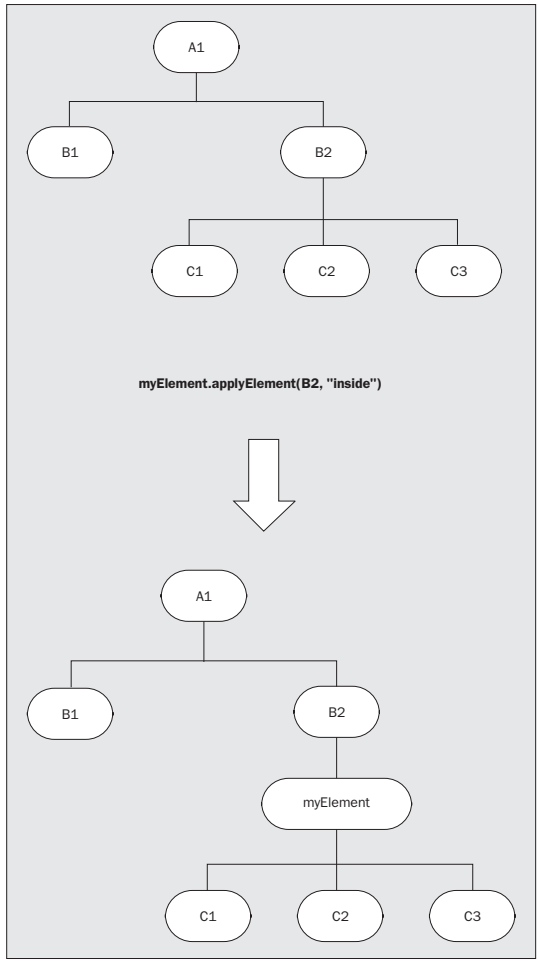
- `outside`
- `inside`

Warnings:

- Although this can be used at run-time when the page is being constructed, any removal of elements during this process may leave the page in a state where it cannot be properly rendered.

See also:	`Function.apply()`





Element.attributes[] (Collection)

A reference to a collection of `attribute` objects for the HTML tag that the `Element` object represents.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Attributes object`	
JavaScript syntax:	-	*`myElement`*`.attributes`

This property yields an `attributes` object which is a collection of `attribute` objects belonging to the object instantiated by an HTML tag.

The `attributes` object contains properties that JavaScript can inspect to obtain the value of HTML tag attributes for the tag that instantiated the `Element` object.

Structurally, the `attributes` object is an array whose elements correspond to properties of the `Element` object, each containing a name, a value and a flag. The `Flag` value is set `true` only when the property has a meaningful value. That value is reflected in the `value` property of the `attribute` object.

So, to find out all about an `Element` object property, you can get the value of the property by enquiring for its contents directly. However, if you use the property name to index the `attributes` array for that `Element` object, you can find out other information about that property by inspecting the `attribute` properties.

Access a property of an object like this:

myObject`["propertyName"]`

or like this:

myObject`.propertyName`

To access its corresponding attributes use this:

myObject`.attributes["propertyName"].name`

myObject`.attributes["propertyName"].specified`

myObject`.attributes["propertyName"].value`

However you should test for the existence of the *myObject*`.attributes[`*myProp*`]` object first because an `attribute` object is not created for every property of an `Element` object but only those that correspond to valid HTML tag attributes for the parent tag.

Any `Element` objects that represent HTML tags will have a `nodeType` of 1. Other node types supported by their `attributes` property will contain the null value.

The example code shows how this attribute access might be provided with a function.

Example code:

```
// An attribute accessor function
function getPropertyAttribute(anObject, aProp, anAttrib)
{
   if(anObject.attributes[aProp])
   {
      return anObject.attributes[aProp][anAttrib];
   }
   else
   {
      return "";
   }
}
```

See also:	Attributes object, Element object, Element.mergeAttributes(), Node.attributes[]

Property attributes:

ReadOnly.

Element.behaviorUrns[] (Collection)

A collection of all the behaviors attached to an element (as a set of URN strings).

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*.behaviorUrns

This lists all the URN values that point at HTC files from within the current document.

Property attributes:

ReadOnly.

Element.canHaveChildren (Property)

A Boolean flag indicating whether this element may have child Nodes associated with it.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myElement*.canHaveChildren

If an element is able to own child Nodes and hence populate its childNodes[] collection and its children[] and all[] collections, then this property should be set true.

Element.canHaveHTML (Property)

A flag property that indicates whether the element can contain HTML.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myElement*.canHaveHTML

If an element is able to respond to `innerHTML` set and get accessors and hence display some visible onscreen content, this property should yield `true`.

See also:	`Element.innerHTML`, `Element.innerText`

Property attributes:

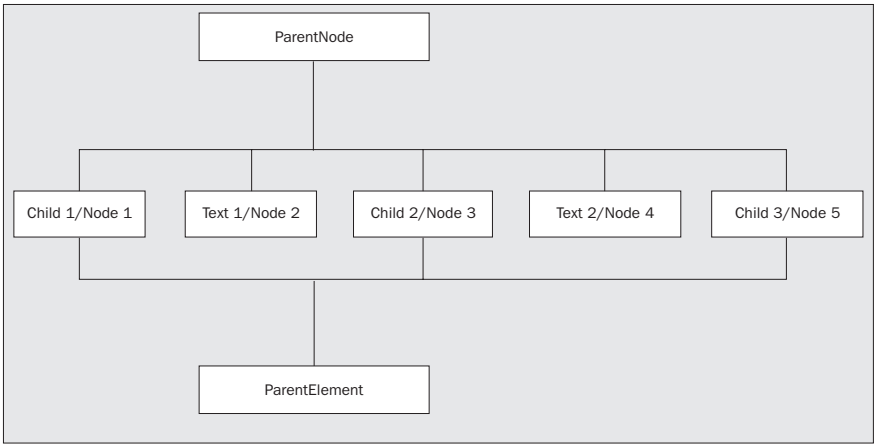
`ReadOnly`.

Element.childNodes[] (Collection)

A list of object nodes within the DOM that are direct children of the `node` object that owns this collection.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`ChildNodes` object
JavaScript syntax:	- *myElement*`.childNodes`

This is part of the internal management of the DOM that browsers use to manage the document content. There are additional nodes here that map to fragments of text in between HTML tags. So there may be more items in this array than in the `children[]` property.



See also:	`ChildNodes` object, `Element` object, Hierarchy of objects, `Node.childNodes[]`

Property attributes:

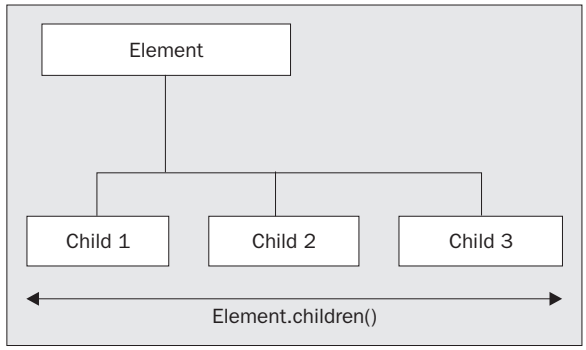
`ReadOnly`.

Element.children[] (Collection)

The elements that are direct children of this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	IE	*myElement*`.children`

A collection of objects which are the immediate children of the receiving `Element` object. These objects generally represent HTML tags but there are other objects that are linked in to the DOM hierarchy that represent the fragments of text between the HTML tags.



See also:	`Collection` object, `Element` object, Hierarchy of objects

Property attributes:

`ReadOnly`.

Element.className (Property)

The value of the `CLASS` tag attribute for the HTML tag that represents this element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myElement*`.className`
	-	*myElement*`.className = `*aClassName*
Argument list:	*aClassName*	A new class name that exists in the cascading style sheet

This property contains the name of the cascading style sheet class for the tag that the `Element` object represents. Because MSIE implements its tag objects so consistently as sub-classes of the `Element` object class, it is possible to apply `CLASS` tag attributes to tags that really shouldn't have style sheets associated with them. The `<HTML>` and `<HEAD>` tags for example. Nevertheless, you can still define a `CLASS` tag attribute and its value will be reflected and accessible in this property.

You can read or write this value to manipulate the style attributes of the object.

The value is specified as a String primitive, but is case sensitive. If you specify multiple items, they must be space separated.

Changing this value can be a way to change a whole range of style settings on an object in a single hit rather than modifying the individual settings one by one.

Warnings:

- This property used to be called `Element.class` but has been renamed as of DOM level 1 to avoid namespace conflicts with a possible future `object.class` property.
- This is not the name of the object class that is associated with the tag. In Netscape, you can usually figure out the class of an object by accessing the `constructor` property to get an object that represents the class and then you can obtain the `name` property of the constructor to find the class name. This doesn't work in MSIE in general. However, you can get a string version of an object in MSIE in many cases that is of the form "[object XXXXX]" where XXXXX is the class name. You will need to dismantle the string with a fragment of script.
- There can be a conflict of style settings where the same attribute is controlled from several class settings. The following precedence rules are applied:

  1. Styles defined in the Element's HTML tag.
  2. Styles applied to the Element with the `CLASS` HTML tag attribute.
  3. Styles applied using the `ID` value of an Element.
  4. Inline styles defined within the script environment.

See also:	`CLASS="...",Element` object

Element.clearAttributes() (Method)

Clear the attributes from an `element` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*`.clearAttributes()`

Any attribute values that are associated with an element can be cleared using this method.

Warnings:

- This may not be supported on all platforms that MSIE runs on. In particular, under testing it failed to work on a Macintosh and generated a run-time error.

Element.click() (Method)

Sends a click event to the receiving object to trigger its `onclick` event handler.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*`myElement`*`.click()`

This is supported by most objects on MSIE but only `input` objects on Netscape, and this is still true in version 6.0.

It simulates the effect of a mouse click on the object. This should trigger the event handler for the `onclick` event. That handler would be a function object and a reference to it should be available in the `onclick` property of the receiving object.

The handler function may have been registered by assigning the function object reference to the property user script control or it may have been registered with the `onClick` HTML tag attribute in the tag that instantiates the object.

See also:	`onClick`

Element.clientHeight (Property)

The height in pixels of the object on the client display surface.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.clientHeight`

The height of the extent rectangle around the `element` object as it appears on screen. This value is measured in pixels.

Warnings:

- This property does not operate consistently across different platforms, and in any case is only available in MSIE. This somewhat limits its usefulness.

Property attributes:

`ReadOnly`.

Element.clientLeft (Property)

The offset in pixels of the object on the client display surface relative to its parent object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.clientLeft`

The pixel coordinate of the left edge of the extent rectangle around the `element` object as it appears on screen.

Warnings:

- This property does not operate consistently across different platforms and in any case is only available in MSIE. This somewhat limits its usefulness.

Property attributes:

`ReadOnly`.

Element.clientTop (Property)

The offset in pixels of the object on the client display surface relative to its parent.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.clientTop`

The pixel coordinate of the top edge of the extent rectangle around the `element` object as it appears on screen.

Warnings:

- This property does not operate consistently across different platforms and in any case is only available in MSIE. This somewhat limits its usefulness.

Property attributes:

`ReadOnly`.

Element.clientWidth (Property)

The width in pixels of the object on the client display surface.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.clientWidth`

The width of the extent rectangle around the `element` object as it appears on screen. This value is measured in pixels.

Warnings:

- This property does not operate consistently across different platforms and in any case is only available in MSIE. This somewhat limits its usefulness.

Property attributes:

`ReadOnly`.

Element.componentFromPoint() (Method)

Determines what object is under a particular pixel coordinate in the window.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Element` object	
JavaScript syntax:	IE	*`myElement`*`.componentFromPoint(`*`anX, aY`*`)`
Argument list:	*`anX`*	A horizontal coordinate
	`aY`	A vertical coordinate

Return a reference to an `element` object that is the upper most in the Z order at the corresponding X-Y coordinate point measured in pixels relative to the upper left of the receiving object.

Element.contains() (Method)

A test to see if the element contains another element.

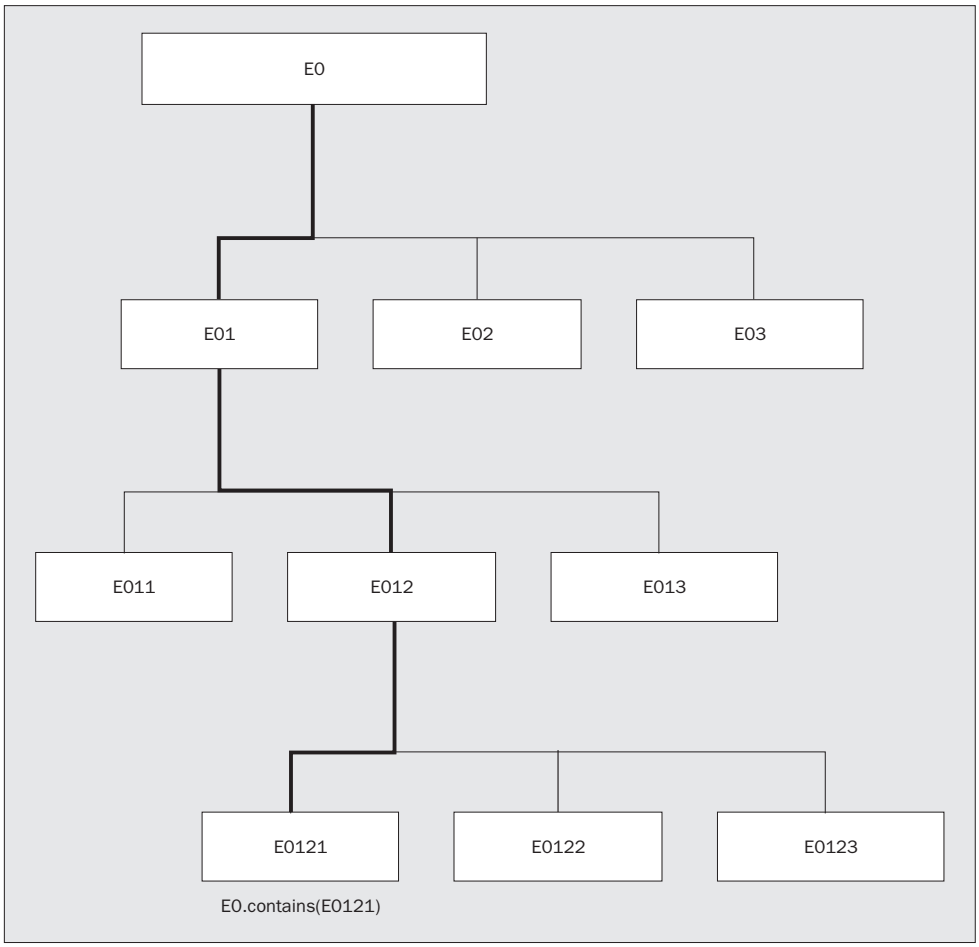
Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0
Property/method value type:	`Boolean primitive`

JavaScript syntax:	IE	*myElement*.contains(*anElement*)
Argument list:	*anElement*	An Element object to check for

The receiving element hierarchy is checked to see if the element that is passed as an argument exists by reference within it.

The result of this method will be `true` if the element referred to by its argument is contained in the receivers node descendants. If by traversing the child nodes of the receiver the indicated element cannot be found, a `false` value is returned.

The functionality of this method is similar to that provided by the DOM level 1 compliant `Node.hasChildNodes()` method which should provide a more portable solution.



See also:	Element object, Node.hasChildNodes()

Element.contentEditable (Property)

A property that determines whether the content of an element can be changed.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.contentEditable`
	IE	*myElement*`.contentEditable = `*aSetting*
Argument list:	*aSetting*	One of `true`, `false` or `inherit`

This property can be set under script control. The following values are appropriate for use with it:

- `inherit`
- `true`
- `false`

When set to `false`, the content cannot be changed. When set to `inherit`, the ability to change the content depends on the setting of this property in the parent Node.

You cannot set this property on the following element types:

- TABLE
- COL
- COLGROUP
- TBODY
- TD
- TFOOT
- TH
- THEAD
- TR

However you can work around this by placing `<DIV>` and `<SPAN>` elements inside the table cells and then setting their `contentEditable` property as needed.

Element.currentStyle (Property)

A reference to a `style` object that contains the current style settings for the `Element` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0
Property/method value type:	`Style` object

JavaScript syntax:	IE	*myElement*.currentStyle
	IE	*myElement*.currentStyle = *aStyleObject*
Argument list:	*aStyleObject*	A new style object to associate with the element

Because the style values are cascaded from style sheet to style sheet and may include some inline styles as well as some explicit styles, objects need to maintain a current style value that is the result of all the inheritances applied on top of one another.

In addition they maintain a run-time style which reflects dynamic changes as well. The run-time style is based on the current style in the first place.

The value of this property is a reference to a `style` object. However it does not refer to the same `style` object as the `style` property. You can test for this with the `isObjectEqual()` function that we have covered elsewhere.

Warnings:

- Note that in MSIE, the object that is returned is of the class "`style`" rather than "`Style`". The upper and lower case spelling may differ between browsers. However since you are likely to access the object by reference you may never need to know the specific class name.

See also:	`currentStyle` object, `Element` object, `Element.runtimeStyle`, `Element.style`, `isObjectEqual()`, `runtimeStyle` object, `style` object (2)

Element.dir (Property)

The text direction of the `Element` object content.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myElement*.dir
	-	*myElement*.dir = *aDirection*
Argument list:	*aDirection*	A value that indicates leftwards or rightwards text drawing

The `dir` property may be set to indicate a left to right or right to left parsing direction.

This is part of the localization support and represents the contents of the `DIR` tag attribute.

If you assign a value to this property it is case sensitive and must be either "`ltr`" or "`rtl`".

This property works in conjunction with the `lang` property to control the direction of text flow.

On MSIE 5.0 for Macintosh, this can reverse the order of the table columns so they are drawn right to left, but present the items in the cells still written left to right. This may be because tables block the inheritance of style attributes from the outer containing elements into the table cells.

See also:	`BDO.dir`, `Element` object, `NOFRAMES.dir`, `NOSCRIPT.dir`

Element.document (Property)

The document containing this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Document` object	
JavaScript syntax:	IE	*`myElement`*`.document`

This is the document in which the `Element` object is instantiated. Although this is not generally available as an object property in Netscape, it is supported by the `Window` object by virtue of it being a global value. This means that for most cases, the scope chain adds the `document` object to all objects, or at least it appears as if they have the property. However, in Netscape, the `document` property is shared by all objects in the window rather than each having its own private `document` property that refers to the same `document` object. The difference is subtle.

Warnings:

- Be careful when blindly using the properties of `Element` objects, as a property such as this can lead you into a recursive loop situation.

See also:	`Doctype` object, `Document` object, `Element` object, `Element.ownerDocument`, `Layer.document`, `Window.document`

Property attributes:

`ReadOnly`.

Element.doScroll() (Method)

Simulates a mouse click on a scroll bar.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*`myElement`*`.doScroll()`
	IE	*`myElement`*`.doScroll(`*`aKeyword`*`)`
Argument list:	*`aKeyword`*	Define the scroll item to click on

This emulates the action of the user having clicked on a scrollbar item with the mouse. The scroll controller that is clicked on depends on the keyword used in the method call.

Keyword:	Description:
`down`	Composite reference to `scrollbarDown`.
`left`	Composite reference to `scrollbarLeft`.
`pageDown`	Composite reference to `scrollbarPageDown`.
`pageLeft`	Composite reference to `scrollbarPageLeft`.
`pageRight`	Composite reference to `scrollbarPageRight`.
`pageUp`	Composite reference to `scrollbarPageUp`.
`right`	Composite reference to `scrollbarRight`.
`scrollbarDown`	Down scroll arrow is at the specified location.
`scrollbarHThumb`	Horizontal scroll thumb or box is at the specified location.
`scrollbarLeft`	Left scroll arrow is at the specified location.
`scrollbarPageDown`	Page-down scroll bar shaft is at the specified location.
`scrollbarPageLeft`	Page-left scroll bar shaft is at the specified location.
`scrollbarPageRight`	Page-right scroll bar shaft is at the specified location.
`scrollbarPageUp`	Page-up scroll bar shaft is at the specified location.
`scrollbarRight`	Right scroll arrow is at the specified location.
`scrollbarUp`	Up scroll arrow is at the specified location.
`scrollbarVThumb`	Vertical scroll thumb or box is at the specified location.
`up`	Composite reference to `scrollbarUp`.

The default value is `scrollbarDown`.

Element.filters[] (Collection)

Filters are supported by MSIE and provide some stylistic control over presentation. This collection contains all the filters associated with an `Element`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Filters` object	
JavaScript syntax:	IE	*`myElement`*`.filters`

This is a reference to a filter collection object that contains details of objects that represent a DHTML filter effect that is invoked during event handling.

See also:	Behavior, `Element` object, Filter, `Filter` object, `style.filter`, Transition

Property attributes:

`ReadOnly`.

Element.firstChild (Property)

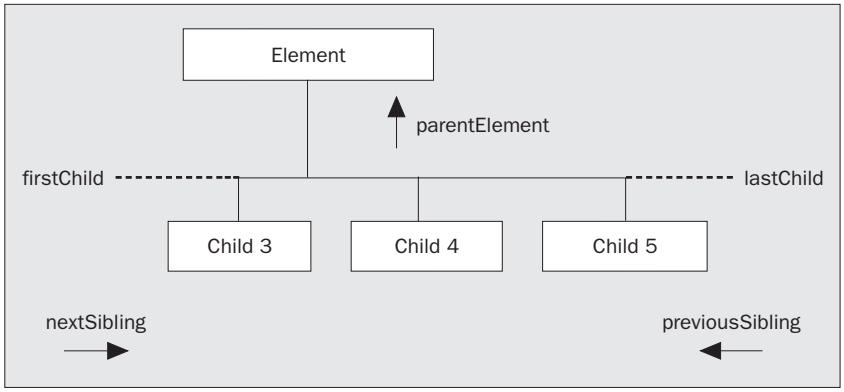
The first object in the collection of direct children of this element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`Element` object
JavaScript syntax:	- *`myElement`*`.children[0]` - *`myElement`*`.firstChild`

The `Element` objects are instantiated as the HTML tags are parsed within the document source. They are added to several collections and can be navigated in a variety of ways.

Each `Element` object has an array of `Element` objects that are considered to be its direct descendants (that is children). This collection will not contain its children's children. The first element in this collection can be referred to by index and its siblings by means of an enumerator or `for( ... in ... )` loop. However you can access it directly with this property.

If the element has no children, then this property will contain a null value.



See also:	`Element` object, `Element.lastChild`, `Element.nextSibling`, `Element.parentElement`, `Element.previousSibling`, `Node.firstChild`, `Node.hasChildNodes()`

Element.getAdjacentText() (Method)

Obtains the text adjacent to the object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.getAdjacentText(`*aRelativePosition*`)`
Argument list:	*aRelativePosition*	An indication of where the new HTML is to be placed

Using the same locational techniques as `insertAdjacentText()`, this method retrieves the text adjacent to the element.

See also:	`Element.insertAdjacentHTML()`, `Element.insertAdjacentText()`, `Element.replaceAdjacentText()`

Element.getAttribute() (Method)

An accessor for reading named custom attributes.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myElement*`.getAttribute(`*anAttribName*`)`
	-	*myElement*`.getAttribute(`*anAttribName*`,` *aCaseSense*`)`
Argument list:	*aCaseSense*	A flag to indicate a case-sensitive lookup
	anAttribName	An attribute of an `Element` object

This is an accessor method which is used to access named attributes of an `Element` object. Attributes are not properties in the strict sense of the word, but may be accessible as if they were in some implementations.

This accessor is intended to provide a means of managing custom attributes.

It would be logical to assume that attributes are named uniquely but if several share the same name, differing only in case sensitivity, then if a case-insensitive search is used you may not retrieve the one you expect. It is likely that you'll be given the last one that occurs, but this may be implementation-dependent.

The case-sensitive flag should be set to the Boolean `true` value to force a case-sensitive search and `false` to ignore the case of letters in the attribute name.

The following values can be passed in the optional case-sensitive flag argument:

- `true` – A case-sensitive search is carried out.
- `false` – A case-insensitive search is carried out.
- 0 – A case-insensitive search of property values is carried out by default. If several instances are located, then only the last is returned.
- 1 – A case-sensitive search is carried out.
- 2 – The value is returned exactly as was originally defined in the document source regardless of subsequent `setAttribute()` calls.

The result will be value of the attribute. If the element does not have an attribute of the specified name, a `null` value is returned.

Warnings:

- If a case-sensitive search is carried out using a property name stored in a variable, you should make sure that the same setting was defined for a corresponding `setAttribute()` call. If you don't, then it is possible that the name may have a case change if the 0 value was used in the `setAttribute()` call. After that case change, the value in the variable will no longer match the property defined for the receiving object.

See also:	`Element` object, `Element.removeAttribute()`, `Element.setAttribute()`,`style.getAttribute()`

Element.getAttributeNode() (Method)

Given its name, this will retrieve an `Attribute` node for the `Element` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Attribute` object	
JavaScript syntax:	-	*`myElement`*`.getAttrbuteNode(`*`aName`*`)`
Argument list:	*`aName`*	The name of an attribute node

See also:	`Attribute` object

Element.getElementsByTagName() (Method)

Obtain a collection of elements that have the same tag name.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`NodeList` object	
JavaScript syntax:	-	*myElement*`.getElementsByTagName(`*aTagName*`)`
Argument list:	*aTagName*	The name of a tag

Modern browsers are implementing a DOM standard architecture that represents a document in the same way regardless of the browser you are running. This means that the focus of script development will move away from a browser-centric view to a standards-centric approach. Using DOM will lead to you developing a much more portable script product.

One of the important "gateway" methods to this DOM model is `getElementsByTagName()`. This can be applied to a document or to an individual HTML element within it.

The `getElementsByTagName()` method returns a collection of elements that are children of the receiving element so long as they were instantiated by the specified tag name.

Many HTML tags create a container within which other tags are placed. `<HTML>` contains `<HEAD>` and `<BODY>` as its immediate children. A `<BODY>` tag might contain a `<TABLE>` which contains `<TR>` row elements, each of which has its own collection of `<TD>` elements. Within those table cells, further parent- child relationships are constructed.

The `getElementsByTagName()` method will walk down that parent-child tree structure and collect a reference to each `Element` object that was instantiated by the HTML tag name you specify. Then on return, it passes back a `Collection` object with them organized for easy access with the `item()` method or by array index.

Since you can apply this search to an individual HTML element, the traversal of the document tree can be very efficient because you only need to walk the portion local to the objects you want to find.

Warnings:

- Netscape 6.0 is forgiving of non-existent tag names. It will instantiate an `Element` object and you can access it using this DOM method even though the tag is not a valid HTML item. MSIE does not do that. It won't parse incorrect tags into DOM objects and therefore this is not a portable workaround for hiding data in documents.
- Beware that `item()` methods that are used to access individual members of a collection come in several varieties with different argument values. In the case of the MSIE `Collection` object, the method name is capitalised so you need to call `Item()` and not `item()` on those collections.

See also:	`Document.getElementsByTagName()`, `NodeList` object

Element.getExpression() (Method)

Obtains an expression value from within a style rule.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myElement`*`.getExpression()`

The rules that are used to construct a style are comprised of multiple expressions. You can use this method to extract the value of an expression from a style item.

Given the rule might contain a line such as:

```
width:200px
```

the `getExpression()` method can be applied to the `style` object containing the rule with that expression like this:

```
myStyle.getExpression("width:")
```

The value 200px would be returned.

See also:	`Element.removeExpression(), Element.setExpression(),style.getExpression(), style.removeExpression(),style.setExpression()`

Element.hideFocus (Property)

This property controls whether there is any visible effect of acquiring focus on an object.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myElement`*`.hideFocus`
	IE	*`myElement`*`.hideFocus = `*`aSwitch`
Argument list:	*`aSwitch`*	A Boolean value

This simply controls the visible effect of having focus. To control whether an object can receive focus or not, the `tabIndex` property should be modified instead.

Setting the property `true` inhibits the visible focus effect. Setting it `false` restores the visible effect of receiving focus to the normal behavior.

See also:	`onFocus`

Element.id (Property)

The value of the `ID` tag attribute in the HTML tag that represents this element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *`myElement`*`.id`
HTML syntax:	`<ELEMENT_TAG ID="anIDValue">`
Argument list:	*`anIDValue`* A valid (and unique within the document) ID value

DOM level 1 specifies this property as a member of the `HTMLElement` object.

HTML elements in MSIE are often identified using their `ID` value. This is a textual name added with the `ID` HTML tag attribute. Netscape 6.0 should support this more reliably than earlier versions of the browser.

The value of the `ID` HTML tag attribute is stored in this property. This is also used as a means of locating elements by `ID` value.

You can change the `ID` value of an element by setting this property since it has read and write access. However it is hard to think of a circumstance where that might be useful. It is really meant to be a read-only property.

DOM provides some help when searching for elements and you can use the `getElementsById()` method on the `document` object in a DOM compliant implementation. Note that a `getElementsById()` method is not supported on the individual HTML elements. This does mean that DOM compliant searches by `ID` will traverse the entire document if necessary.

DOM provides several other mappings and you can traverse a node hierarchy as well, so this is not likely to prove a severe limitation.

Warnings:

- You must make sure that any value you assign to this property is unique within the document since it is used as part of the document navigation mechanism.
- If you use the same `ID` value for more than one element, it is not clear which one will be located first when the document hierarchy is traversed, although it is likely to be the first one that was defined.
- In the case of objects with the same `ID`, you may be presented with a collection or array of objects rather than a single object. This can make it difficult to write general purpose scripts.

See also:	`Element` object, `ID="..."`

Element.innerHTML (Property)

The inner HTML of a tag in the document.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myElement*.innerHTML
	-	*myElement*.innerHTML = *someHTML*
Argument list:	*someHTML*	Some new HTML content to place inside the object

The HTML in between but not including the tags that define the element is extracted. The resulting content complete with tags and text is returned when this property is being read.

When the property is being written to, the start and end tags remain intact but everything between them is replaced with a sequence of HTML content.

This property contains the text and any HTML tags that are contained in the body of the element. If you only want the text, then use the `innerText` property.

If you want to include the containing tags, then use the `outerHTML` or `outerText` properties instead.

You can assign new text to be displayed in the HTML element by using this property as an LValue.

The `innerHTML` property of an HTML `Element` object is supported in Netscape 6.0 although it is not mandated in the DOM specification. However Netscape 6.0 does not also support `innerText`, `outerHTML` or `outerText`. You should be able to accomplish what you need with `innerHTML` though.

Warnings:

- Be careful if you extract the `innerHTML` of an element and `document.write()` it back to the same document. You can create recursive loop situations if you are evaluating in global code during the document loading process.
- You cannot set this property while the document is loading.
- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.

See also:	`Element` object, `Element.canHaveHTML`, `Element.innerText`, `Element.insertAdjacentHTML()`, `Element.outerHTML`, `Element.outerText`

Element.innerText (Property)

The inner text of a tag in the document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.innerText`
	IE	*myElement*`.innerText = `*aString*
Argument list:	*aString*	Text to replace the inner text

The HTML in between but not including the tags that define the element is extracted and any tags are removed. The resulting text is returned when this property is being read.

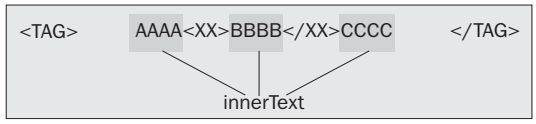
When the property is being written to, the start and end tags remain intact but everything between them is replaced with a text string. To place HTML tags between the tags, use the innerHTML property.

For some objects, this is equivalent to the text property that Netscape supports.

It is effectively the same as `anElement.innerHTML` as long as there is no mark-up on the text between the beginning and ending tags.

If you want to include the containing tags, then use the `outerText` or `outerHTML` properties instead.

You can assign new text to be displayed in the HTML element by using this property as an LValue.



Warnings:

- This is not supported by Netscape although the `text` property may be supported by some objects. You can probably do all you need to do by means of the `innerHTML` property which Netscape 6.0 does support.
- You will need to detect the browser type before attempting to use this property.
- Be careful if you extract the `innerText` of an element and `document.write()` it back to the same document. You can create recursive loop situations if you are evaluating in global code during the document loading process.
- You cannot set this property while the document is loading.
- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.
- Netscape does not support it at all.

See also:	Anchor.text, Element object, Element.canHaveHTML, Element.innerHTML, Element.insertAdjacentHTML(), Element.outerHTML, Element.outerText

Element.insertAdjacentHTML() (Method)

Inserts some HTML into the document adjacent to this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	undefined	
JavaScript syntax:	IE	*myElement*.insertAdjacentHTML (*aRelativePosition*, *someHTML*)
Argument list:	*aRelativePosition*	An indication of where the new HTML is to be placed
	someHTML	The new fragment of HTML to be inserted

This is quite similar to an expression that assigns a new value to the `innerHTML` property of an `Element` object. In this case, the new HTML leaves the existing HTML intact.

The relative positions where the adjacent HTML can be introduced determine where the new HTML is to be inserted. The following relative positions can be specified:

Position:	Description:
AfterBegin	Immediately after the opening tag and before any other content
AfterEnd	Immediately after the closing tag and before any other content
BeforeBegin	Immediately before the opening tag
BeforeEnd	Immediately before the closing tag

Warnings:

- You cannot call this method while the document is loading.
- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.

See also:	Element object, Element.getAdjacentText(), Element.innerHTML, Element.innerText, Element.insertAdjacentText(), Element.outerHTML, Element.outerText

Element.insertAdjacentText() (Method)

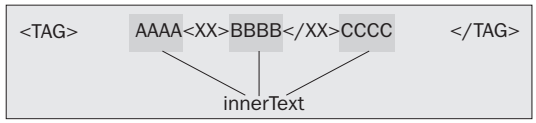
Inserts some text into the document adjacent to this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*`myElement`*`.insertAdjacentHTML(`*`aRelativePosition, aString`*`)`
Argument list:	*`aRelativePosition`*	An indication of where the new HTML is to be placed
	`aString`	The new fragment of text to be inserted

This is quite similar to an expression that assigns a new value to the `innerText` property of an `Element` object. In this case, the new text leaves the existing text and HTML content intact.

The relative positions where the adjacent text can be introduced determine where the new text is to be inserted. The following relative positions can be specified:

Position:	Description:
`AfterBegin`	Immediately after the opening tag and before any other content
`AfterEnd`	Immediately after the closing tag and before any other content
`BeforeBegin`	Immediately before the opening tag
`BeforeEnd`	Immediately before the closing tag



Warnings:

- You cannot call this method while the document is loading.
- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.

See also:	`Element` object, `Element.getAdjacentText()`, `Element.insertAdjacentHTML()`, `Element.replaceAdjacentText()`,`Node.insertBefore()`

Element.isContentEditable (Property)

Returns a Boolean value indicating whether the content of the element can be altered.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myElement`*`.isContentEditable`

It is necessary to have this property because the `Element.contentEditable` property may have the value "inherited" assigned to it. To determine whether the content was in fact editable would require you to walk up the document hierarchy to a parent node whose `contentEditable` property was set explicitly.

Property attributes:

`ReadOnly`.

Element.isDisabled (Property)

A flag property that indicates whether the user can interact with the object or not.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myElement`*`.isDisabled`

This is especially applicable to `input` objects or those other objects that may not be sub-classes of the `Input` object but can be clicked on by the user. For example, `Anchor` objects.

The property yields the current state of the disabled setting for the receiving object.

A separate property to the object's `disabled` property is necessary because it might depend on the context in which an object is used and whether that context (such as a form or window) is disabled. The implication is then that all child objects within that context would be disabled too. It's also necessary because some objects are not members of the `Input` object family but can still be disabled even though they do not have a `disabled` property of their own.

Property attributes:

`ReadOnly`.

Element.isTextEdit (Property)

A Boolean indication of the text editing capabilities of this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myElement`*`.isTextEdit`

This property contains a Boolean flag to indicate whether the object can be used to create a `TextRange` object. This is done with the `createTextRange()` method. Only the following object classes should yield a true value for this property:

- `BODY`
- `BUTTON`
- `TextCell`
- `TextArea`

If the HTML element represents an `<INPUT>` tag whose type is `TEXT` for example, then this value will yield true. Most of the time it will yield false. It is useful for writing generic accessors and handlers for objects which may or may not have selectable or editable text in them.

Logically you would only want to read from this property.

The value yielded by this property will be true if the element represents an editable text field and false if is not.

Example code:

```
// An example showing how a text range can be created//
conditionallyif(myElement.isTextEdit){   myElement.createTextRange();}
```

See also:	// An example showing how a text range can be created
	// conditionally
	if(myElement.isTextEdit)
	{
	  myElement.createTextRange();
	  alert("TextRange object created");
	}

Property attributes:

`ReadOnly`.

Element.lang (Property)

The value of the `LANG` tag attribute of the HTML tag that represents this element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myElement*`.lang`
	-	*myElement*`.lang = `*aNationality*
Argument list:	*aNationality*	An indication of the national language required

This property controls the locale specific text rendering. It allows special characters to be handled appropriately and special character sets to be supported properly according to the national language variants.

Refer to the Language codes topic for a list of the available language codes.

See also:	`Element` object, `LANG="..."`, `Navigator.language`, `Navigator.systemLanguage`, `Navigator.userLanguage`

Cross-references:

RFC 1766

http://www.ics.uci.edu/pub/ietf/http/related/iso639.txt

http://www.chemie.fu-berlin.de/diverse/doc/ISO_3166.html

Element.language (Property)

The required scripting language for fragments of script associated with this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.language`
	IE	*myElement*`.language = `*aScriptLanguage*
HTML syntax:	`<SCRIPT LANGUAGE="...">`	
Argument list:	*aScriptLanguage*	One of the available scripting languages

This does not affect scripting contained within script tags, but provides a way to select a script language interpreter for use with event handlers for example.

The following scripting languages are supported in MSIE (Netscape does not support this facility):

- JAVASCRIPT
- JSCRIPT
- VBS
- VBSCRIPT

The values are case-insensitive in the MSIE browser.

With this property available, it is conceivable that other languages could be supported in the future. For example, client-side Perl and Python are feasible. Search out the PerlScript and ActivePython projects for further details.

See also:	`<SCRIPT LANGUAGE="...">`, `Element` object

Element.lastChild (Property)

The last child object contained within the DOM hierarchy that descends from this element.

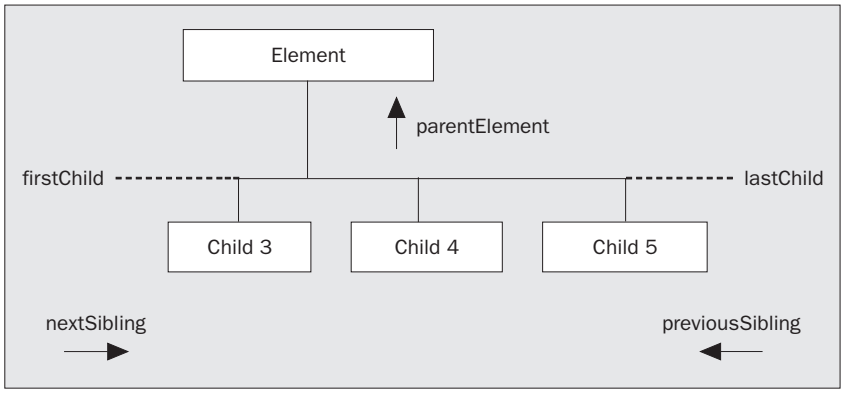
Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`Element` object
JavaScript syntax:	- *myElement*`.children[`*anIndex*`]` - *myElement*`.lastChild`
Argument list:	*anIndex* — A value equal to the length of the array minus 1

The `Element` objects are instantiated as the HTML tags are parsed within the document source. They are added to several collections and can be navigated in a variety of ways.

Each `Element` object has an array of `Element` objects considered to be its direct descendants (that is children). This collection will not contain its children's children. The last element in this collection can be referred to by index and its siblings by means of an enumerator or `for( ... in ... )` loop. However you can access it directly with this property.

Accessing the object at the end of the collection with this property is more convenient than measuring the length of the collection and accessing by array index.

If the element has no children, then this property will contain a `null` value.



See also:	`Element` object, `Element.firstChild`, `Element.nextSibling`, `Element.parentElement`, `Element.previousSibling`, `Node.lastChild`

Element.mergeAttributes() (Method)

Merge the attributes from one object with another.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*`myElement`*`.mergeAttributes(`*`anElement`*`)`
	IE	*`myElement`*`.mergeAttributes(`*`anElement`*`, `*`aCaseSense`*`)`
Argument list:	*`aCaseSense`*	A flag indicating whether name lookup is case sensitive
	`anElement`	A source element to merge attributes from

The attributes from the source object are merged with the attributes of the receiving object. This may replace some attribute values or may add to the set of attributes if similarly named attributes are present in both but only differ in their case sensitivity.

See also:	`Element.attributes[]`, `Element.removeAttribute()`, `Element.setAttribute()`

Element.nextSibling (Property)

An HTML element at the same level within the document hierarchy.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	`Element` object	
JavaScript syntax:	-	*myElement*.nextSibling
	-	*myElement*.parentElement.children[*anIndex*]
Argument list:	*anIndex*	An enumerated position in the collection

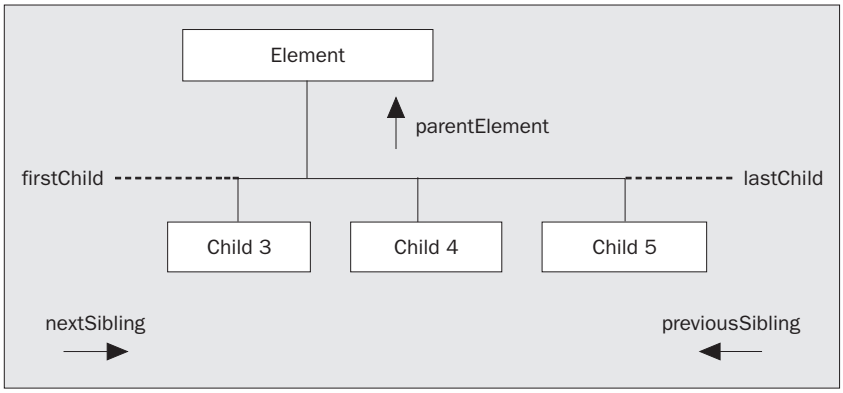
The `Element` objects are instantiated as the HTML tags are parsed within the document source. They are added to several collections and can be navigated in a variety of ways.

Each `Element` object has an array of `Element` objects considered to be its direct descendants (that is children). This collection will not contain its children's children. All elements in this collection can be referred to by index and all siblings by means of an enumerator or `for( ... in ... )` loop. However you can access them directly with this property.

Accessing the next object in the collection belonging to the parent by means of this property is more convenient than traversing back to the parent and working through the children property's collection.

The next sibling will be the object following this one in the children property's collection of the same parent element.

If there is no next sibling then the `null` value will be returned.



See also:	`Element` object, `Element.firstChild`, `Element.lastChild`, `Element.parentElement`, `Element.previousSibling`, `Node.nextSibling`

Element.nodeName (Property)

Part of the internal document hierarchy management.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myElement*.nodeName

The nodeName property is part of the browser's internal DOM management. It contains a value that is the name of the HTML tag that instantiated the object. This is also reflected as the tagName property.

When the object is a Text object, the nodeName value is "#text" because there is no HTML tag to represent plain text and a text node is placed between HTML Element objects. It's like the mortar between the bricks in a wall.

See also:	Element object, Node.nodeName

Property attributes:

ReadOnly.

Element.nodeType (Property)

Part of the internal document hierarchy management.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myElement*.nodeType

The nodeType property is part of the browser's internal DOM management.

By inspecting the properties of various objects with an enumeration loop, you can determine some values for this property. If you know the node type, you may be able to take advantage of this when you write more sophisticated scripts. Here is a partial list of node types defined by the DOM specification:

Constant:	Type:	Description:
undefined	null	A member of the attributes collection
ELEMENT_NODE	1	HTML element object node
ATTRIBUTE_NODE	2	HTML tag attribute object
TEXT_NODE	3	Text object node
CDATA_SECTION_NODE	4	CDATA section
ENTITY_REFERENCE_NODE	5	Entity reference
ENTITY_NODE	6	Entity node

Table continued on following page

Constant:	Type:	Description:
PROCESSING_INSTRUCTION_NODE	7	Processing instruction node
COMMENT_NODE	8	Comment node
DOCUMENT_NODE	9	Document object
DOCUMENT_TYPE_NODE	10	Doctype object
DOCUMENT_FRAGMENT_NODE	11	Document fragment node
NOTATION_NODE	12	Notation node

The DOM standard is quite large at level 1 and defines a lot of ways in which you can traverse a document structure. The level 2 capabilities are even more extensive. Scripts than can understand node types and DOM document trees will be able to accomplish some amazingly powerful things.

See also:	`Element` object, `Node.nodeType`

Property attributes:

`ReadOnly`.

Element.nodeValue (Property)

Part of the internal document hierarchy management.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *`myElement`*`.nodeValue`

This object is part of the browser's internal DOM management.

The value of this attribute always seems to be the `null` object for objects that represent HTML tags. This is probably because all the other attributes of the tags can be stored in named properties of the `Element` object or in attributes of those properties collected into the `Attributes` object that belongs to it.

When the node is a `#text` value, the text itself is stored here.

See also:	`Element` object, `Node.nodeValue`

Element.normalize() (Method)

Processes all of the `textNode` objects that are children of the receiving element and prepares the document for save and restore.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	`Element.normalize()`

There are implications here for the way `CDATASection` objects are handled and are most likely to be used when XPointer lookups are required.

This begins to move in the direction of XML support, which the DOM actively facilitates and which is a very large and complicated topic. For now we shall concentrate on HTML documents.

Element.offsetHeight (Property)

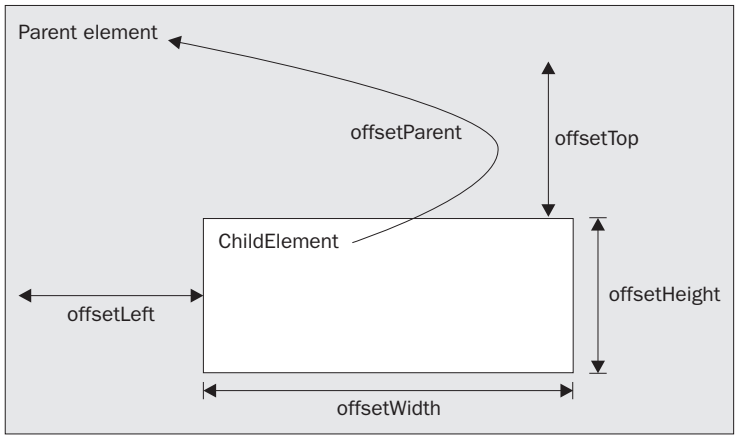
The height of this element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.offsetHeight`

The height of the element in pixels. This value is read-only but for some objects such as images the `height` property should be used instead if you need to modify the physical size of the item. The changes will be reflected in this property but you cannot make the changes by altering the value of this property from your script.

The value in this property is not supposed to include any padding, border or margin widths.

Although the name of this property implies its value is related to a parent object, in fact it is a measure of the element's height and the parentage has no bearing on that whatsoever.



Warnings:

- The offset properties are implemented very inconsistently across platforms and versions of MSIE. Use them with caution. In any case, they are available for read access only so they are of limited use in position control.
- MSIE 4 for Windows incorrectly includes padding widths around the object when calculating the size value in here. The correct value will be yielded on both Macintosh and Windows versions of MSIE 4 if you don't specify any padding at all.

See also:	`Element` object, `Element.offsetWidth`

Property attributes:

`ReadOnly`.

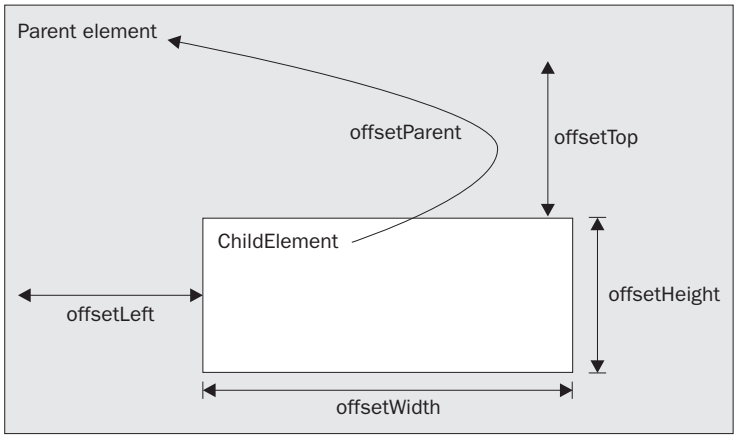
Element.offsetLeft (Property)

The X coordinate of the HTML element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.offsetLeft`

The position of the object in pixels offset horizontally from its parent. This value is read-only.

The `offsetParent` property contains a reference to the parent object that the relative positions are measured with respect to.



Warnings:

- The offset properties are implemented vary inconsistently across platforms and versions of MSIE. Use them with caution. In any case, they are available for read access only so they are of limited use in position control.

See also:	`Anchor.x`, `Element` object, `Element.offsetParent`, Measurement units, `style.pixelLeft`, `style.posLeft`

Property attributes:

`ReadOnly`.

Element.offsetParent (Property)

A reference to the parent object that is the reference point for offset positioning values.

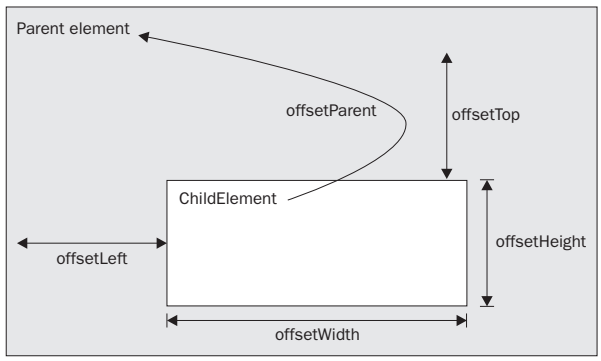
Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Element` object	
JavaScript syntax:	IE	*myElement*`.offsetParent`

The parent object whose position provides a datum for the element to be offset away from.

This could refer to the `document` object for the current window. In many cases it will be the `BODY` object for the document. However you may have used `<TABLE>` tags to control the layout and these might be the parent objects for the content of the table while the parent of the `TABLE` objects would be the `BODY` object.

The parent-child hierarchy of `element` objects within the document is dependent on how you construct it when the document source is authored.

This is not the same as the `parentElement` property. That property reflects the true document hierarchy in all its fine detail. The `offsetParent` property reflects the spatial relationships between objects. Objects that show up in the `parentElement` hierarchy will likely be omitted from the `offsetParent` hierarchy model on account of them not contributing any spatial offset to the contained elements.



Warnings:

- The offset properties are implemented very inconsistently across platforms and versions of MSIE. Use them with caution. In any case, they are available for read access only so they are of limited use in position control.

See also:	`BODY` object, `Document` object, `Element` object, `Element.offsetLeft`, `Element.offsetTop`, `Element.parentElement`, Hierarchy of objects, `TABLE` object

Property attributes:

`ReadOnly`.

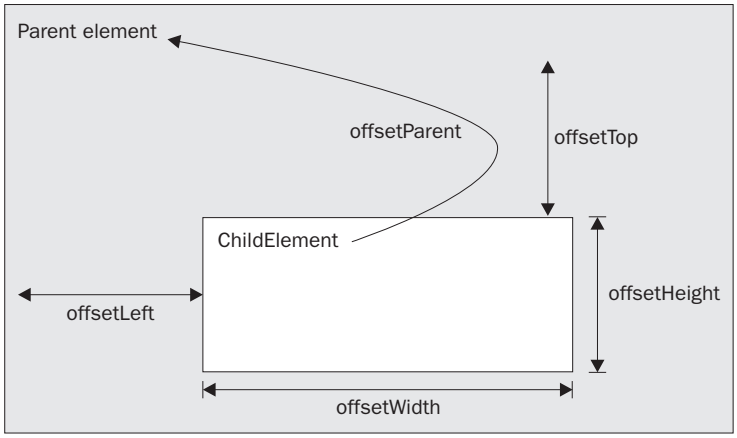
Element.offsetTop (Property)

The Y coordinate of the HTML element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.offsetTop`

An offset value in the vertical access from the origin of the parent to the top of the receiving `Element` object. This value is read-only.

The `offsetParent` property contains a reference to the parent object that the relative positions are measured with respect to.



Warnings:

- The offset properties are implemented very inconsistently across platforms and versions of MSIE. Use them with caution. In any case, they are available for read access only so they are of limited use in position control.

See also:	`Anchor.y`, `Element` object, `Element.offsetParent`, Measurement units, `style.pixelTop`, `style.posTop`

Property attributes:

`ReadOnly`.

Element.offsetWidth (Property)

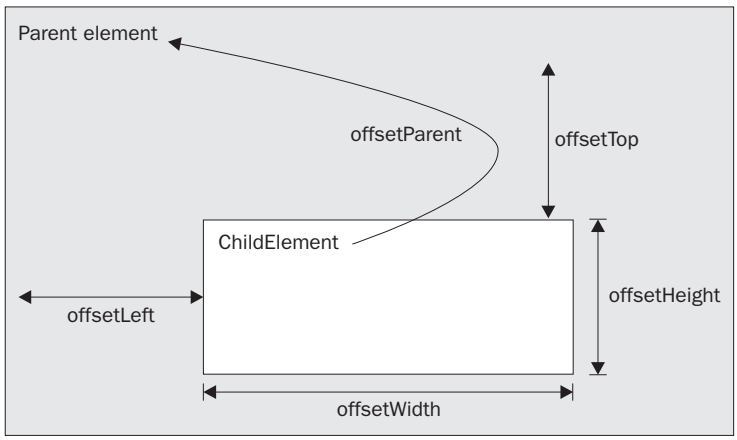
The width of the HTML element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.offsetWidth`

The width of the element in pixels. This value is read-only, but for some objects such as images the `width` property should be used instead if you need to modify the physical size of the item. The changes will be reflected in this property but you cannot make the changes by altering the value of this property from your script.

The value in this property is not supposed to include any padding, border or margin widths.

Although the name of this property implies its value is related to a parent object, in fact it is a measure of the element's width and the parentage has no bearing on that whatsoever.



Warnings:

- The offset properties are implemented very inconsistently across platforms and versions of MSIE. Use them with caution. In any case, they are available for read access only so they are of limited use in position control.
- MSIE version 4 for Windows incorrectly includes padding widths around the object when calculating the size value in here. The correct value will be yielded on both Macintosh and Windows versions of MSIE 4 if you don't specify any padding at all.

See also:	`Element` object, `Element.offsetHeight`

Property attributes:

`ReadOnly`.

Element.onevent (Property)

A property containing a reference to an event handler property.

Availability:	JavaScript – 1.2 JScript – 5.0 Internet Explorer – 5.0 Netscape – 4.0	
Property/method value type:	`Function` object	
JavaScript syntax:	- *myElement*`.onevent`	
	- *myElement*`.onevent = `*aFunctionObject*	
HTML syntax:	`< ... onEvent="...">`	
Argument list:	*aFunctionObject*	An event handler function

There is a small set of event handler function properties created by default. Some sub-classes of the `Element` object will add others as needed. You can assign your own handlers to these properties (if necessary creating the properties that don't already exist).

Here is a list of all the event handler property names discovered during our research. These are collated from a variety of documentation sources. Some were discovered by inspecting objects with scripts:

Event:	Handler:	Usage:
Abort	`onabort`	When image loading is aborted.
AfterPrint	`onafterprint`	When printing has just finished.
AfterUpdate	`onafterupdate`	When an update is completed.
Back	`onback`	The user has clicked on the [BACK] button in the toolbar.
BeforeCopy	`onbeforecopy`	Immediately before a copy to the clipboard.
BeforeCut	`onbeforecut`	Immediately before a cut to the clipboard.

Table continued on following page

Event:	Handler:	Usage:
BeforeEditFocus	`onbeforeeditfocus`	Immediately before the edit focus is directed to an element.
BeforePaste	`onbeforepaste`	Immediately before the clipboard is pasted.
BeforePrint	`onbeforeprint`	Immediately before printing begins.
BeforeUnload	`onbeforeunload`	Called immediately prior to the window being unloaded.
BeforeUpdate	`onbeforeupdate`	Called immediately before an update commences.
Blur	`onblur`	When an input element loses input focus.
Bounce	`onbounce`	Triggered when a marquee element hits the edge of its element area.
Change	`onchange`	When edit fields have new values entered or a popup has a new selection, this event's handler can check the new value.
Click	`onclick`	When the user clicks the mouse button on the `Element` object that represents the object on screen.
ContextMenu	`oncontextmenu`	Special handling for contextual menus.
Copy	`oncopy`	When a copy operation happens.
Cut	`oncut`	When a cut operation happens.
DataAvailable	`ondataavailable`	Some data has arrived asynchronously from an applet or data source.
DataSetChanged	`ondatasetchanged`	A data source has changed the content or some initial data is now ready for collection.
DataSetComplete	`ondatasetcomplete`	There is no more data to be transmitted from the data source.
DblClick	`ondblclick`	When the user double clicks on an object.
Drag	`ondrag`	When a drag operation happens.
DragDrop	`ondragdrop`	Some data has been dropped onto a window.
DragEnd	`ondragend`	When a drag ends.
DragEnter	`ondragenter`	When a dragged item enters the element.
DragLeave	`ondragleave`	When a dragged item leaves the element.
DragOver	`ondragover`	While the dragged item is over the element.
DragStart	`ondragstart`	The user has commenced some data selection with a mouse drag.
Drop	`ondrop`	When a dragged item is dropped.
Error	`onerror`	Triggered if an error occurs when loading an image.
ErrorUpdate	`onerrorupdate`	An error has occurred in the transfer of some data from a data source.
FilterChange	`onfilterchange`	A filter has changed the state of an element or a transition has just been completed.
Finish	`onfinish`	A marquee object has finished looping.
Focus	`onfocus`	When the form element is selected for entry.

Table continued on following page

Event:	Handler:	Usage:
Forward	`onforward`	The user has clicked on the [FORWARD] button in the toolbar.
Help	`onhelp`	The user has pressed the [F1] key or selected [help] from the toolbar or menu.
KeyDown	`onkeydown`	When a key is pressed.
KeyPress	`onkeypress`	Pressing the key down and releasing it again elicits this event.
KeyUp	`onkeyup`	When a key is released.
Load	`onload`	When an object has completed loading.
LoseCapture	`onlosecapture`	When an element loses event capturing permission.
MouseDown	`onmousedown`	When the mouse button is pressed.
MouseDrag	`onmousedrag`	An event handler for mouse drag operations.
MouseMove	`onmousemove`	When the mouse pointer is moved.
MouseOut	`onmouseout`	When the mouse pointer leaves the active area occupied by the `Element` object that represents the object on screen.
MouseOver	`onmouseover`	When the mouse pointer enters the active area owned by the object.
MouseUp	`onmouseup`	When the mouse button is released.
Move	`onmove`	The browser window has been moved.
Paste	`onpaste`	When a paste operation happens.
PropertyChange	`onpropertychange`	When an object property is modified (similar to the Netscape Navigator `watch()` method).
ReadyStateChange	`onreadystatechange`	An object in the window has changed its ready state.
Reset	`onreset`	The user has clicked a reset button in a form.
Resize	`onresize`	As the window is resized, this event is triggered.
RowEnter	`onrowenter`	The data in a field bound to a data source is about to be changed
RowExit	`onrowexit`	The data in a field bound to a data source has been changed.
Scroll	`onscroll`	The window has been scrolled.
Select	`onselect`	Some textual content in the window has been selected.
SelectStart	`onselectstart`	A select action is beginning.
Start	`onstart`	A marquee element is beginning its loop.
Stop	`onstop`	When a stop action occurs.
Submit	`onsubmit`	The user has clicked on the submit button in a form.
Unload	`onunload`	Triggered when the document is unloaded.

You can usually discover what events an object supports by enumerating all its properties in a `for( ... in ... )` loop. The event handler hooks will be listed with the other enumerable properties of the object.

Element.outerHTML (Property)

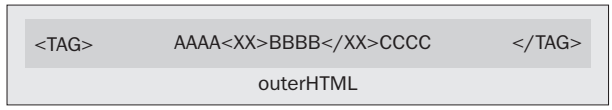
The outer HTML of a tag in the document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.outerHTML`
	IE	*myElement*`.outerHTML = `*someHTML*
Argument list:	*someHTML*	Some new HTML content to place outside the object

The outer HTML of an HTML element is that fragment of HTML that completely contains the start and end tags of the element. The `outerHTML` of an `<A>` tag would be the complete anchor and any styled text or image tags between the `<A>` and `</A>` tags.

You can read this value to extract a fragment of HTML and you can write to this value to redefine a section of HTML within the page.

Because this property is not DOM compliant, you may want to refer to the DOM `Text` object and DOM `CharacterData` object which provide a compliant set of accessors to the content of a DOM component. The implementation of this is still somewhat vague and ambiguous and some more work needs to be done to bring the DOM compliant capabilities up to the same level of functionality. This can probably best be simulated by walking up the tree to a containing element and using `innerHTML` on that object.



Warnings:

- Be careful if you extract the `outerHTML` of an element and `document.write()` it back to the same document. You can create recursive loop situations if you are evaluating in global code during the document loading process.
- You cannot set this property while the document is loading.
- If you replace the outer HTML, you will also be replacing the containing tags of the object. If you do not keep the `ID` or `NAME` properties intact, you may not be able to locate the object again in the way you might expect to later.
- Conceptually, changing the `outerHTML` property of an object might imply that the object's class is being changed as well. This is not truly consistent with the rules of object oriented programming as you would not normally 'cast' objects in the way you might 'cast' pointers in the C-Language context. The effects of this are not documented and you may find that the behavior varies from one implementation to another.

- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.
- Netscape does not support it at all.

See also:	`Element` object, `Element.innerHTML`, `Element.innerText`, `Element.insertAdjacentHTML()`, `Element.outerText`

Element.outerText (Property)

The outer text of a tag in the document.

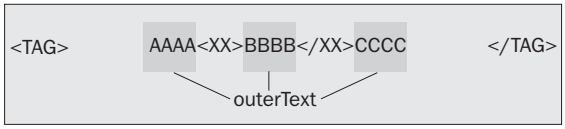
Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myElement`*`.outerText`
	IE	*`myElement`*`.outerText = `*`aString`
Argument list:	*`aString`*	Some new text content to place outside the object

The HTML from the start tag to the end tag, including the tags that define the element, is extracted and any tags are removed. The resulting text is returned when this property is being read.

You can read this value to extract a fragment of text, and you can write to this value to redefine a section of text within the page.

When the property is being written to, the start and end tags are destroyed because everything between them and the tags is replaced with a text string. To place new HTML tags as replacements for the ones you are about to destroy, use the `outerHTML` property.

DOM standardization provides access to the content of a `Text` and `CharacterData` object. These are special cases of the `Node` object which is also the parent of the `Element` object. We really need the `Element` object to inherit the data accessors of the `CharacterData` object as well and for now at least it doesn't. So long as you want to access text in between `Element` objects, you may be able to navigate the Node hierarchy and access properties of the `Text` objects between each `Element`.



Warnings:

- Be careful if you extract the `outerText` of an element and `document.write()` it back to the same document. You can create recursive loop situations if you are evaluating in global code during the document loading process.
- You cannot set this property while the document is loading.

- It is not clear what the intent of this property is when used as an `LValue`. Assigning a new string to this property when it's on the left of an expression implies that the containing HTML tags could be removed. Some experimentation may be necessary to ensure you get predictable behavior across the various browser implementations. Removing the containing HTML tags could cause an object to be removed from the document tree and discarded. Because the container is no longer there, any child objects will also have been destroyed and there is no handle by which you can locate the object again because there is no HTML tag with a `NAME` or `ID` attribute to find.
- If the implementation is smart, it will let you retain the parent object by reference, but will mutate it from an HTML Element that represents a tag and change it into a text node. That way you could then reassign some `outerHTML` to it to re-establish the HTML containment again.
- MSIE version 4 for Macintosh does not support this as widely as the Windows version or later versions of MSIE for Macintosh.
- Netscape does not support it at all.

See also:	`Element` object, `Element.innerHTML`, `Element.innerText`, `Element.insertAdjacentHTML()`, `Element.outerHTML`

Element.ownerDocument (Property)

A reference to the `document` object that the element is contained within.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`Document` object
JavaScript syntax:	- *myElement*`.ownerDocument`

This is another name for the `document` property of an `Element` object. They both refer to the same object.

This is provided by MSIE 5 and Netscape 6.0 as a convenience property. Accessing a containing document object in this way is far easier than walking down a `document.childElement` sequence to locate a contained document.

See also:	`Document` object, `Element` object, `Element.document`, Hierarchy of objects, `Node.ownerDocument`

Property attributes:

`ReadOnly`.

Element.parentElement (Property)

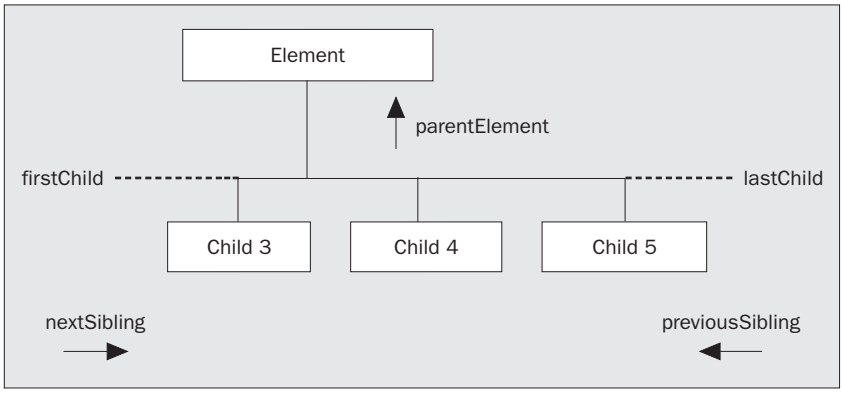
The element that is the owner or parent of the current object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Element` object	
JavaScript syntax:	IE	*`myElement`*`.parentElement`

This is the object that contains the receiving `Element` object. For example, an `Element` object that represents a `<TABLE>` tag is the parentElement of the `Element` objects that represent the `<TR>` tags within that table. If you want to add a row to a table, you may select the row that needs to be replaced or that it can be inserted after. You can then locate its `parentElement` and modify that if necessary.

This is not the same as the `offsetParent`. This property reflects the true document hierarchy in all its fine detail. The `offsetParent` property reflects the spatial relationships between objects. Objects that show up in the `parentElement` hierarchy will likely be omitted from the `offsetParent` hierarchy model on account of them not contributing any spatial offset to the contained elements.

Access to a `parentElement` is especially useful when driving the generation of `styleSheet` properties. You might have a series of nested containers which cascade a relative font size. By checking the fonts size property belonging to the `style` object associated with the `parentElement`, you can set a limit on this cascading effect to prevent the font sizes from becoming too small.



See also:	`Document` object, `Element` object, `Element.firstChild`, `Element.lastChild`, `Element.nextSibling`, `Element.offsetParent`, `Element.parentNode`, `Element.previousSibling`, Hierarchy of objects

Property attributes:

`ReadOnly`.

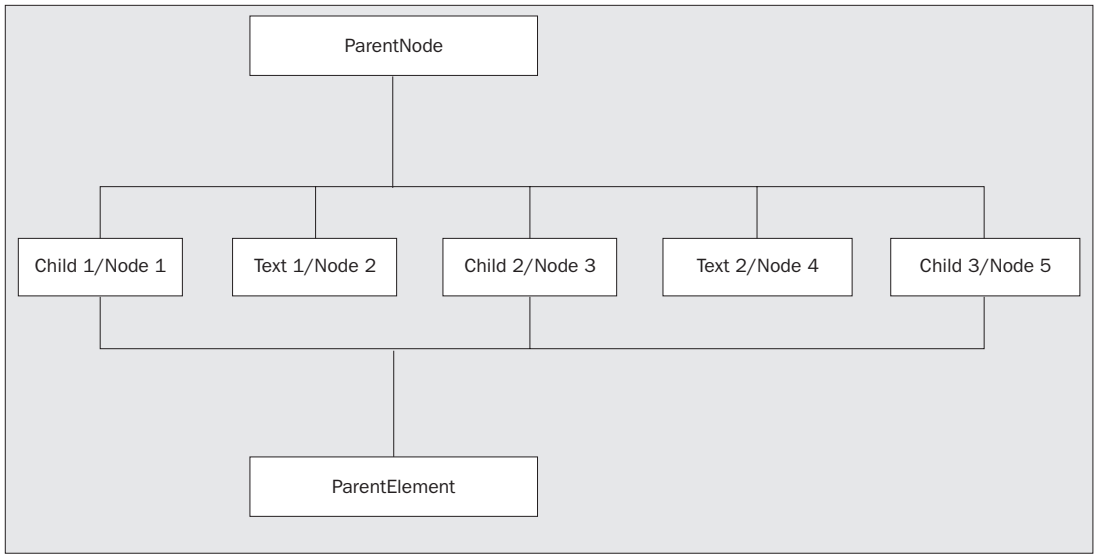
Element.parentNode (Property)

Part of the internal DOM hierarchy management.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`Element` object	
JavaScript syntax:	-	*`myElement`*`.parentNode`

This is part of the internal DOM management provided by the browser. Although the functionality is similar to `parentElement`, it is not quite the same since there are two hierarchies superimposed on one another. One hierarchy simply contains objects representing the HTML tags. The other contains additional objects that help the browser maintain the text between the HTML tags.

The `parentElement` property is not DOM compliant whereas `parentNode` is.



See also:	`Document` object, `Element` object, `Element.parentElement`, Hierarchy of objects, `Node.parentNode`

Property attributes:

`ReadOnly`.

Element.parentTextEdit (Property)

A reference to the next highest object in the hierarchy that allows a `TextRange` to be created.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Element` object	
JavaScript syntax:	IE	*`myElement`*`.parentTextEdit`

`TextRange` objects can only be created for a limited sub-set of the available objects in the MSIE browser. Only objects that can receive input focus are appropriate.

An object somewhere higher up in the hierarchy is referred to by this property. The document hierarchy may have to be traversed upwards for some considerable distance before a suitable object is found, so this hierarchical model is much more sparsely populated than any of the others.

Warnings:

- Because text ranges are not supported in the Macintosh, MSIE returns a `null` value when text ranges and the `parentTextEdit` property is accessed.

Example code:

```
// Locate a textEdit capable parent object and create an all enclosing text range.
myParentTextEdit = myElement.parentTextEdit;
myTextRange = myParentTextEdit.createTextRange();
alert ("TextRange object created for " + myParentTextEdit.tagName);
```

See also:	`Element` object, Hierarchy of objects, `TextRange` object

Property attributes:

`ReadOnly`.

Element.previousSibling (Property)

An HTML element at the same level within the document hierarchy.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Element` object	
JavaScript syntax:	-	*`myElement`*`.parentElement.children[`*`anIndex`*`]`
	-	*`myElement`*`.previousSibling`

Argument list:	*anIndex*	An enumerated position in the collection

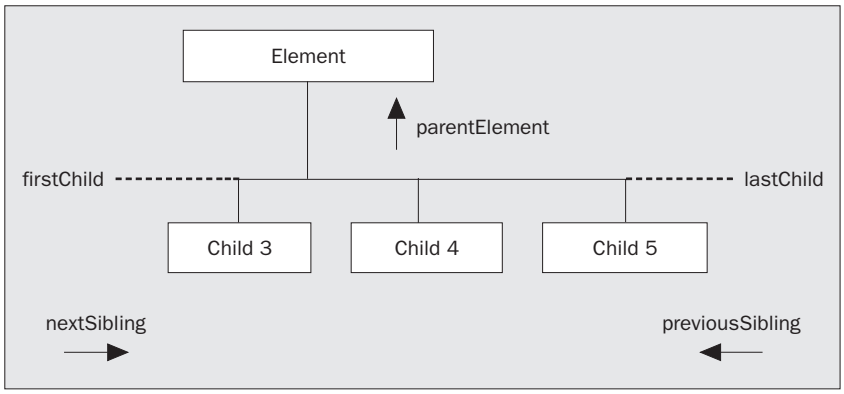
The `Element` objects are instantiated as the HTML tags are parsed within the document source. They are added to several collections and can be navigated in a variety of ways.

Each `Element` object has an array of `Element` objects that are considered to be its direct descendants (that is children). This collection will not contain its children's children. All elements in this collection can be referred to by index and all siblings by means of an enumerator or `for( ... in ... )` loop. However you can access them directly with this property.

Accessing the next object in the collection belonging to the parent by means of this property is more convenient than traversing back to the parent and working through the children property's collection.

The previous sibling will be the object prior to this one in the children property's collection of the same parent element.

If there is no previous sibling, then the `null` value will be returned.



See also:	`Element` object, `Element.firstChild`, `Element.lastChild`, `Element.nextSibling`, `Element.parentElement`, `Node.previousSibling`

Element.readyState (Property)

The `readyState` of an object contains a value indicating whether it is currently loading or is ready to use.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myElement*`.readyState`

This property contains the current disposition of the `element` object.

You might use this in a timed event to watch the status of a document being loaded into a window or frame. Then when it has completed loading, you could activate some script within it.

Here is a list of the ready state values:

State:	Value:
uninitialized	The object is first instantiated, but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed. However, it is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

Note that these are string values. Some references describe a numeric value for ready states. According to the Microsoft documentation however, they are strings.

Sometimes, you can design scripts to execute while the document is downloading. Inline scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the `ActiveX` object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`onReadyStateChange`

Property attributes:

`ReadOnly`.

Element.releaseCapture() (Method)

Part of the event handling mechanism in MSIE.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*`.releaseCapture()`

If event capture was established with the `setCapture()` method, this relinquishes such event capturing.

See also:	`Element.setCapture()`

Element.removeAttribute() (Method)

An accessor method to delete a named custom attribute.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myElement*`.removeAttribute(`*anAttribName*`)`
	-	*myElement*`.removeAttribute(`*anAttribName*`, `*aCaseSense*`)`
Argument list:	*aCaseSense*	A flag indicating whether lookup is case sensitive or not
	anAttribName	An attribute of an `Element` object

This is an accessor method which is used to remove named attributes of an `Element` object. Attributes are not properties in the strict sense of the word but may be accessible as if they were in some implementations. They are gathered together into an `Attributes` collection which you can access like any other `Array` or `Collection` object to retrieve the individual `Attribute` objects. The accessor methods provide some additional modes of access for convenience.

This accessor is intended to provide a means of managing custom attributes.

If the `false` value is returned, it may mean that either the attribute did not exist and could not be removed or that the attribute was locked in some way preventing it from being removed. The `true` value returned by this method indicates the attribute was successfully removed.

Note also that you can only remove attributes that were added with the `setAttribute()` method. Some attributes may have been added by the browser and may not be removed by scripts.

Warnings:

- Note that the DOM level 1 standard defines this method as returning no meaningful value. Other implementations may concur so you should not rely on the value being returned.
- However, Netscape 6.0 and MSIE 5.5 do return a meaningful value.

See also:	`Attribute` object, `Attributes` object, `Element` object, `Element.getAttribute()`, `Element.mergeAttributes()`, `Element.setAttribute()`

Element.removeAttributeNode() (Method)

Removes an attribute node from the element hierarchy. If the attribute has a default value, that will be used subsequently.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Attribute` object	
JavaScript syntax:	-	*`myElement`*`.removeAttributeNode(`*`anAttribute`*`)`
Argument list:	*`anAttribute`*	An `attribute` object to be removed

See also:	`Attribute` object

Element.removeBehavior() (Method)

Removes a behavior that was previously added to the object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*`myElement`*`.removeBehavior()`

Part of the MSIE behaviors control suite.

See also:	Behavior, `Element.addBehavior()`

Element.removeExpression() (Method)

Removes an expression from an object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*`myElement`*`.removeExpression()`

This is used for removing expressions from the `style` object that have previously been put there by the `setExpression()` method call.

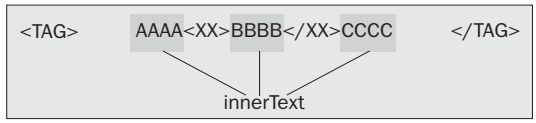
See also:	`Element.getExpression()`, `Element.setExpression()`, `style.getExpression()`, `style.removeExpression()`, `style.setExpression()`

Element.replaceAdjacentText() (Method)

Replace some text adjacent to the `element` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*`myElement`*`.replaceAdjacentText (`*`aRelativePosition`*`, `*`aString`*`)`
Argument list:	*`aRelativePosition`*	An indication of where the new HTML is to be placed
	`aString`	The new fragment of text to be inserted

This is a close relation to the `insertAdjacentText()` method. This method will replace the text adjacent to an object rather than add to it.



See also:	`Element.getAdjacentText()`, `Element.insertAdjacentText()`

Element.runtimeStyle (Property)

The style settings for the object, taking into account any cascaded styles and changes to the styles that may have happened dynamically.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Style` object	
JavaScript syntax:	IE	*`myElement`*`.runtimeStyle`

Because the style values are cascaded from style sheet to style sheet and may include some inline styles as well as some explicit styles, objects need to maintain a current style value that is the result of all the inheritances applied on top of one another.

In addition they maintain a runtime style which reflects dynamic changes as well. The runtime style is based on the current style in the first place.

The value of this property is a reference to a `style` object. However, it does not refer to the same `style` object as the `style` property. You can test for this with the `isObjectEqual()` function that we have documented elsewhere.

See also:	`currentStyle` object, `Element.currentStyle`, `Element.style`, `runtimeStyle` object

Element.scopeName (Property)

The name of a scope chain.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myElement`*`.scopeName`

The MSIE browser allows different scope chains to be built and referred to by name. These are called namespaces. This is a very esoteric property and its coverage is quite sparse in the Microsoft developer documentation. However, you should refer to the MSDN web site for further details.

Web-references:

http://msdn.microsoft.com/workshop/author/dhtml/reference/properties/scopename.asp

Element.scrollHeight (Property)

An MSIE property for measuring sizes of objects when they have been scrolled.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.scrollHeight`

This functionality is not well supported across platforms and means different things for different objects. Generally, it is taken as the height of an object when its scroll position is taken into account. Objects scrolled entirely off the screen have a `scrollHeight` of zero.

Warnings:

- This functionality is sufficiently unportable as to preclude its use from any useful purpose.

Property attributes:

`ReadOnly`.

Element.scrollIntoView() (Method)

Set the scroll of the document to bring the element into view.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*`myElement`*`.scrollIntoView()`
	IE	*`myElement`*`.scrollIntoView(`*`aReferencePoint`*`)`
Argument list:	*`aReferencePoint`*	Indicates the desired scroll to location

This method scrolls the window to bring the receiving element into view. The argument is an optional Boolean value that indicates whether the receiving `Element` object should be scrolled to the top (`true`) or the bottom (`false`) of the window.

By default, the value true is assumed if no value is specified.

See also:	`Element` object

Element.scrollLeft (Property)

An MSIE property for measuring position of objects when they have been scrolled.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.scrollLeft`

This functionality is not well supported across platforms and means different things for different objects. Generally, it is taken as the distance an object has been scrolled in the horizontal axis.

Warnings:

- This functionality is sufficiently unportable as to preclude its use from any useful purpose.

Element.scrollTop (Property)

An MSIE property for measuring position of objects when they have been scrolled.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.scrollTop`

This functionality is not well supported across platforms and means different things for different objects. Generally, it is taken as the distance an object has been scrolled in the vertical axis.

Warnings:

- This functionality is sufficiently unportable as to preclude its use from any useful purpose.

Element.scrollWidth (Property)

The width of a scrolling region.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myElement`*`.scrollWidth`

This functionality is not well supported across platforms and means different things for different objects. Generally, it is taken as the width of an object when its scroll position is taken into account. Objects scrolled entirely off the screen have a `scrollWidth` of zero.

Warnings:

- This functionality is sufficiently unportable as to preclude its use from any useful purpose.

Property attributes:

`ReadOnly`.

Element.setAttribute() (Method)

An accessor method to set a named custom attribute value.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*`myElement`*`.setAttribute(`*`anAttribName`*`,` *`aValue`*`)`
	-	*`myElement`*`.setAttribute(`*`anAttribName`*`,` *`aValue`*`,` *`aCaseSense`*`)`
Argument list:	*`aCaseSense`*	A flag indicating whether name lookup is case sensitive
	`anAttribName`	An attribute of an `Element` object
	`aValue`	A new value for the custom attribute

An attribute is added to the `attributes` collection for the object. Some attributes are presented as properties as well which is simply an alternative means of access to the same value. If that is the case then setting the attribute will also alter the property setting as well.

If the case sensitivity flag is set to true, then the name of the attribute must exactly match the name used in the HTML tag attribute, otherwise the results are uncertain.

See also:	`Element` object, `Element.getAttribute()`, `Element.mergeAttributes()`, `Element.removeAttribute()`

Element.setAttributeNode() (Method)

A new attribute node is added to the element. If one with the same name already exists, it will be replaced.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Attribute` object	
JavaScript syntax:	-	*myElement*`.setAttributeNode(`*anAttribute*`)`
Argument list:	*anAttribute*	An attribute node object to be set

See also:	`Attribute` object

Element.setCapture() (Method)

Part of the event handling mechanism in MSIE.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*`.setCapture()`

If an event capture is established with this method, it can be relinquished with the `releaseCapture()` method.

See also:	`Element.releaseCapture()`

Element.setExpression() (Method)

Part of the behavior handling mechanisms in MSIE.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myElement*.setExpression(*aProperty*, *anExpression*, *aLanguage*)
Argument list:	*aProperty*	The name of a property to be modified
	anExpression	An expression to assign
	aLanguage	The language the expression is defined in

The rules that are used to construct a style are comprised of multiple expressions. You can use this method to assign a new value to an expression within a style item with that value being generated by a callback to a script function.

The rule might contain a line such as:

```
width:200px
```

The `setExpression()` method can be applied to the `style` object containing the rule with that expression like this:

```
myStyle.setExpression("width:", "callBack()", "JavaScript")
```

The value of the width parameter would be defined by the result of calling the `callBack()` function in the JavaScript context.

The language argument can be one of the following:

- JavaScript
- JScript
- VBScript

See also:	`Element.getExpression()`, `Element.removeExpression()`,`style.getExpression()`, `style.removeExpression()`,`style.setExpression()`

Element.sourceIndex (Property)

The index value of this element in the `document.all[]` array.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myElement*.sourceIndex

In MSIE, all `Element` objects are available in the `all[]` array object for the document. If you need to know the element's position within that order, this property tells you what the index value for the object is. This will change as objects are created and destroyed in the page.

This is useful to be able to tell the relative position of objects in the page, perhaps so that you can scroll forwards or backwards to reach them.

Warnings:

- This value may change if new objects are added to the document.

See also:	`Element` object

Property attributes:

`ReadOnly`.

Element.style (Property)

A `style` object that can be modified for the element.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0
Property/method value type:	`Style` object
JavaScript syntax:	- *`myElement`*`.style`

This property is an important reference to a DOM level 2 `style` object which can be accessed from script to dynamically alter the appearance of an HTML element.

The `Element.style` property yields an object that contains the style settings for the HTML element. By modifying the properties of this `style` object belonging to the HTML element, you can affect the display of the element. It is as if the element owned a miniature style sheet of its own. This may be affected by the settings of the `CLASS` tag attribute on the HTML tag that instantiates the `Element` object; we will come back to that in a little while.

You can replace the `style` object with another you have created separately or defined in the style sheet, and by doing this you can effect a considerable change in appearance of an object in one hit without needing to change several properties individually.

Style management is quite complex and offers many more capabilities than using HTML tags and attributes. You should be able to completely abstract any appearance related controls away from the HTML document at the cost of it not working on older browsers.

The complexity stems from there being an inheritance mechanism and the possibility of having many `style` objects attached to a document at different points. There is a hierarchy of `style` objects, each overriding another. Ultimately the appearance you see is the accumulation of all of those style controls cascaded down to your element.

You can try to alter a style property on an object only to see it remain the same as it was before. Styles are attached to objects at different points in the DOM tree and some style properties are inherited. So you could be altering a style property that is being masked. This can be quite frustrating.

Each HTML element in the DOM structure has a `style` property that points at a `style` object. `Style` objects may be shared by referring to the same one from several elements.

The `style` object is documented extensively elsewhere with a topic describing each of its properties. For now, let's look at some simple style manipulation. You can access the style properties of an element as simply as this:

```
myElement.style.color = "red";
```

That's it, aside from learning about all of the different style properties that are available and their values. You'll need to look at how styles are inherited down the DOM document tree.

Styles can be put into style sheets and pulled in from a shared document in a `<LINK>` tag. Access to those `style` objects is a little more complicated because you need to locate the object representing that `<LINK>` tag, then navigate through the `StyleSheet` object to find the rules that describe each named style block. Those rules are associated with your element by means of the `CLASS` HTML tag attribute. Having located the rule for your `element` object (and these would be shared between many objects), you can examine the rule object and access it's `style` property. That points at a `style` object that is just like the one your `Element.style` property would have pointed at.

You can also specify the styles inline, that is you can add a `STYLE` HTML tag attribute to the tag that instantiates your `element` object. That would be reflected in the properties of a private `style` object that your `Element.style` property refers to.

MSIE supports two additional properties that relate to the cascaded style on an element. They are called `currentStyle` and `runtimeStyle`. The `currentStyle` property points at an object that holds the accumulated style, taking into account linked stylesheets, tag attributes and anything else that can affect style appearance apart from any script driven changes. The `runtimeStyle` property takes the `currentStyle` property and accumulates appearance changes when styles are modified on an object, so it represents the visual style as it is now. Neither of these are portable though, and they are not part of the DOM standard and so they should be avoided.

To learn more about styles and how they work you might want to go through this learning sequence:

- Build a document with HTML tag driven appearance, just like you always used to.
- Now remove all its appearance control and introduce `STYLE` HTML tag attributes and put in some CSS style control.
- If you prefer, use a `<LINK>` tag to call in a style sheet and build some even more complex style controls.

- Now explore the document hierarchy by looking at individual HTML Elements and inspecting their `style` objects.
- Try enumerating the `style` objects to inspect their properties.
- Then try modifying those properties.
- By this stage, you should now be pretty much an expert at modifying style and appearance.

Support for styles is part of the DOM level 2 specification which the MSIE and Netscape 6.0 browsers support (at least in part). While it's at recommendation stage, it could change. Browsers may implement it incorrectly or introduce bugs inadvertently. Because of that uncertainty, we have covered what seems to work and what we expect to become available, but things may change with new browser versions. There is a lot still to explore and test with Netscape 6.0, and MSIE 6.0 is on the horizon too.

See also:	`CLASS="..."`, `Element` object, `Element.currentStyle`, `Element.runtimeStyle`, `style` object (2), `StyleSheet` object

Element.tagName (Property)

The name of the HTML tag that instantiated this object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myElement*`.tagName`

This property contains a text string with the HTML tag name in upper case for the tag that instantiated the object. This is also some indication of the object class, which will help you to write generic functions that can operate on many kinds of objects in an intelligent way.

The tag name is returned without any left and right carets (greater/less than signs) and in fully DOM compliant implementations will be the same value as the class name of the object. There are a few inconsistencies that prevent this being used reliably as a class name for non DOM specified objects, but within some constraints, it may be useful in that context for determining what kind of object a script is operating on.

It is possible that the `Element` represents a text node. Text nodes are placed between the elements that represent HTML tags. We can then operate on the text in between adjacent HTML tags. With this capability, we probably don't need `innerHTML`, `OuterHTML`, `innerText` and `outerText` properties anymore. However, we will need to get a little bit smarter with our navigation of document trees to locate these text nodes.

If the element does represent a text node, then the `tagName` value is meaningless. Typically a browser will respond with an undefined value which could be difficult to handle. An empty space would have been easier to cope with. You should check the value you get back from this property, unless you are absolutely certain it relates to an HTML tag. If you suspect it might be a text node, then check it before using it or your script will crash.

See also:	`Attribute.nodeName`, `Element` object

Property attributes:

`ReadOnly`.

Element.tagUrn (Property)

The URN value for a tag.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myElement`*`.tagUrn`

This is part of the XMLNS support in MSIE 5.0 and returns a URN value specified in a namespace declaration. This is highly MSIE specific functionality and not standardized for use in other browsers. It is not portable.

Element.title (Property)

The value of the `TITLE` tag attribute for the HTML tag that created this object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myElement`*`.title`
	-	*`myElement`*`.title = `*`aToolTip`
HTML syntax:	`<LINK TITLE="...">`	
Argument list:	*`aToolTip`*	A text string

This is the text that is presented as a 'ToolTip' when the mouse rolls onto an object and pauses there for a few moments. The MSIE browser and the Netscape 6.0 browser will display this text as a small popup comment box. Earlier versions of Netscape prior to version 6.0 did not support this capability, so it should be considered somewhat implementation dependent until the penetration of newer browsers increases.

When aural style sheet support is provided by a browser, this value might be spoken as the mouse rolls over it.

Warnings:

- This property is not the name of the object. The `ID` tag attribute is a more reliable way of making that association, since it assists with the `document.all[]` array construction and indexing on MSIE, and is more portable across browsers when accessing objects associatively.
- Another recommended technique is the DOM compliant `getElementById()` method which in the longer term will become more prevalent.
- This is also not the same as the `altText` on an image, which may also appear as a ToolTip in some browsers.

See also:	`Document.title`, `Element` object, `LINK.title`

Element.uniqueID (Property)

An automatically generated unique ID value for an object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myElement`*`.uniqueID`

You may go to great lengths to map ID values to objects in your documents and still have ID conflicts. This property generates a guaranteed unique ID value which will be static for that object as long as it exists.

However, reloading a page and requesting a unique ID again from objects within it will not yield the same values.

You cannot assign a value to this property.

Property attributes:

`ReadOnly`.

else ... (Keyword)

Part of the `if ... else` conditional code execution mechanism.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0

JavaScript syntax:	-	`if(aCondition){someCode1} else{someCode2}`
Argument list:	*aCondition*	A condition that tests `true` or `false`
	someCode1	Code to be executed if the condition tests `true`
	someCode2	Code to be executed if the condition tests `false`

This is an optional additional statement that can be added to an `if()` condition test to allow for some alternative code to be executed when the condition tests `false`. The `true` case will cause the first block of code to be executed, the `false` case will execute the second (that which follows the `else` keyword).

See also:	`else if( ... ) ...`, Flow control, `if( ... ) ...`, `if( ... ) ... else ...`, Selection statement, `switch( ... ) ... case: ... default: ...`

ECMA 262 edition 2 – section – 12.5

ECMA 262 edition 3 – section – 12.5

Wrox *Instant JavaScript* – page – 23

else if(...) ... (Idiom)

A technique for stacking `if` conditions in a script.

Although there is no '`else if`' keyword, because the `if` follows the `else` and is separated by a space, the `if` block is treated as if it were a single statement. Here we omit the braces surrounding the statement executed in the `else` condition of a leading `if` block. We then place another in its `else` statement and so on. Like this:

```
if(aCondition){   some code}else if(aCondition){   some code}else if(aCondition){
some code}else{   some code}
```

By putting in the braces, it becomes clearer. Actually, what we have really done is this:

```
if(aCondition){   some code}else{   if(aCondition)   {      some code   }   else
{      if(aCondition)      {         some code      }      else      {
some code      }   }}
```

It is really just a plain old `if() else` block nested several times. By leaving off the braces (against our recommendations otherwise), in this circumstance it actually makes the code clearer.

See also:	Code block delimiter {}, `else ...`, `if( ... ) ...`, `if( ... ) ... else ...`

EM object (Object/HTML)

An object representing the HTML content delimited by the `<EM>` tags.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myEM* = *myDocument*.all.*anElementID*
	IE	*myEM* = *myDocument*.all.tags("EM")[*anIndex*]
	IE	*myEM* = *myDocument*.all[*aName*]
	-	*myEM* = *myDocument*.getElementById(*anElementID*)
	-	*myEM* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myEM* = *myDocument*.getElementsByTagName("EM")[*anIndex*]
HTML syntax:	`<EM> ... </EM>`	
Argument list:	*anElementID*	The ID value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

`<EM>` tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

See also:	`Element` object

Inheritance chain:

Element object, Node object

<EMBED> (HTML Tag)

A mechanism for adding plugin functionality to a web browser.

Inherits from:	Element object

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the EMBED class. In Netscape they are objects commonly referred to as belonging to the Plugin class.

Because of this, and because each browser supports different properties and methods for them, they will be discussed here as Embed objects for MSIE and Plugin objects for Netscape.

Warnings:

- Note that Netscape can talk to the plugins that are encapsulated with an <EMBED> tag, but the MSIE browser cannot. However MSIE will talks to plugins that are encapsulated with the <OBJECT> tag. Netscape has supported <OBJECT> tags, but somewhat unreliably. Version 6 should be more robust.
- The Macintosh platform does not support the <OBJECT> tag because the MSIE browser really expects and hopes that it will be used to encapsulate an ActiveX object. Since ActiveX objects are written to be compiled into X86 machine code, they can only be used on a Wintel platform.
- Because of this, the MSIE browser on the Macintosh does support some limited communication with <EMBED> tag plugins.
- Trying to find a platform and browser portable compromise for embedding plugins (especially for video playback) is an utterly lost cause right now. You will have to write browser specific modules and use the appropriate one.

See also:	Document.embeds[], Embed object, EmbedArray object, Plugin events, Plugin object

Inheritance chain:

Element object, Node object

Embed object (Object/HTML)

An object that represents an embedded item in MSIE.

Availability:	JavaScript – 1.0 JScript – 3.0 Internet Explorer – 4.0 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myEmbed* = *myDocument*.all.*anElementID*
	IE	*myEmbed* = *myDocument*.all.tags("EMBED")[*anIndex*]
	IE	*myEmbed* = *myDocument*.all[*aName*]
	-	*myEmbed* = *myDocument*.*anElementName*
	-	*myEmbed* = *myDocument*.embeds[*anIndex*]
	-	*myEmbed* = *myDocument*.getElementById(*anElementID*)
	-	*myEmbed* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myEmbed* = *myEmbedArray*[*aName*]
	-	*myEmbed* = *myEmbedArray*[*anIndex*]
	-	*myEmbed* = *myDocument*.getElementsByTagName("EMBED")[*anIndex*]
HTML syntax:	<EMBED>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an `Element` object
Object properties:	accessKey, align, height, hidden, name, palette, pluginspage, readyState, src, tabIndex, units, width	
Event handlers:	onBlur, onClick, onDblClick, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the `EMBED` class. In Netscape they are objects commonly referred to as belonging to the `Plugin` class, although they are really implemented as `JavaObject` objects. In MSIE, this is an `ActiveX` object.

There is additional confusion in that there is a `plugins[]` array that belongs to the `document` and another that belongs to the `navigator` object. They both contain collections of objects, but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.

Because of this confusing situation, the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` object. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and `Embed` objects will be an instance of a plugin that is alive and running in a document.

Warnings:

- Interacting with the properties of `Embed` objects in MSIE seems to work quite reliably. This is not the case with Netscape, which is prone to all kinds of strange behavior. However that may be version and platform specific and could depend greatly on the quality of what you are embedding.
- As an example, Video plugins work really well on one particular platform and are generally less optimal on others. Windows media player is great on Windows and lacking in reliability and quality on other platforms. QuickTime is brilliant on Macintosh and good on Windows, but it still suffers some instability. Real player is pretty good everywhere, but it works better as a player than it does as a plugin. Windows media player works well as a plugin on MSIE. QuickTime is good as both a plugin and a player, but its JavaScripting control is somewhat behind Real player. None of them share the remotest similarity as far as properties, parameters or JavaScript API calls are concerned. If only we could have some compatible video players, we could solve a lot of the embedding problems.

Inheritance chain:

`Element` object, `Node` object

Embed.align (Property)

Controls the alignment of an embedded plugin relative to its surrounding objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*.align

The alignment of the `plugin` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Embed.height (Property)

The height of a plugin's extent rectangle.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*`.height`

The space reserved for the plugin is defined by an extent rectangle that surrounds the space occupied by it even before it is loaded. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

Embed.hidden (Property)

A flag indicating whether a plugin is hidden or not.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myEmbed*`.hidden`

Setting this property to `true` will hide the plugin, and a `false` value will reveal it.

Embed.name (Property)

This corresponds to the `NAME` attribute of the `<EMBED>` tag.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myEmbed*`.name`

Objects are identified either by the `NAME` HTML tag attribute or by the `ID` HTML tag attribute.

Netscape 4 shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However, in many cases, both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace. Netscape 6.0 is DOM based and works well with `ID` values.

Embed.palette (Property)

The palette for use with a plugin.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*.palette

In the Windows environment, there are two alternative palettes that you can apply to an embedded object. This property reflects the value of the `PALETTE` HTML tag attribute on the `<EMBED>` tag that instantiates this object.

It should contain one of these values to indicate which palette is being used:

- foreground
- background

Property attributes:

`ReadOnly`.

Embed.pluginspage (Property)

The URL of a page where the plugin can be obtained if it is not yet installed in the browser.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*.pluginspage

This contains a URL value where the plugin can be obtained if you do not have it installed in your browser.

Property attributes:

`ReadOnly`.

Embed.readyState (Property)

The downloading status disposition of the plugin associated with the `<EMBED>` tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*.readyState

This property reflects the loading status of an `EMBED` object.

Sometimes, you can design scripts to execute while the document is downloading. Inline scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

If it is important to know when the document has completed loading, you can check this property for one of the following values:

State:	Value:
uninitialized	The object is first instantiated but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed, and is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the `ActiveX` object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`onReadyStateChange`

Property attributes:

`ReadOnly`.

Embed.src (Property)

The URL of an external file that the plugin may use.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myEmbed`*`.src`

Some plugins may need to access a supplementary data file from the server. It is good practice to abstract such data values from the code itself and so a means of passing this parameter value in from outside is necessary. The `SRC` HTML tag attribute is reflected into this property and is provided as a somewhat standardized means of passing one of the parameter values most likely to be defined.

Embed.units (Property)

The unit of measure for the height and width of the plugin extent rectangle.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*`.units`

This value appears to be derived from the measurement units used in style sheets.

However, it does not appear to work at all and has no observable effect on the browsers. There are several possible values for this, but they are not supported uniformly across all browsers and platforms. This may be better supported in the future.

The best solution for now is to omit this attribute and always measure `<EMBED>` tag objects in pixels.

The following values are allegedly available:

- pixels
- en
- em

Embed.width (Property)

The width of the plugin extent rectangle.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEmbed*`.width`

The space reserved for the plugin is defined by an extent rectangle that surrounds the space occupied by it even before it is loaded. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

EmbedArray object (Object/browser)

A more appropriate name for a `PluginArray` that contains a collection of plugins within the current document.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0

Inherits from:	`Object` object
JavaScript syntax:	- *myEmbedArray* = *myDocument*.embeds
	- *myEmbedArray* = myDocument.*plugins*
Object properties:	`length`

A collection of objects, each one representing a plugin that is embedded in the current page. The object being referred to is not the embedded data, but the plugin module that plays it.

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the `EMBED` class. In Netscape they are objects commonly referred to as belonging to the `Plugin` class although they are really implemented as `JavaObject` objects. In MSIE, this is an `ActiveX` object.

There is additional confusion in that there is a `plugins[]` array that belongs to the `document` and another that belongs to the `navigator` object. They both contain collections of objects but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.

Because of this confusing situation the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` object. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and `Embed` objects will be an instance of a plugin that is alive and running in a document.

Warnings:

- Beware of confusion between `document.plugins` and `navigator.plugins`. The former relates to the plugins currently used in the document while the latter lists the plugins currently available and supported by the browser.

See also:	`<EMBED>`, `Collection` object, `Document.embeds[]`, `Document.plugins[]`, `Embed` object, `JavaObject` object, `Plugin` object, `PluginArray` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly

Inheritance chain:

`Object` object

EmbedArray.length (Property)

The number of `plugin` objects in the document.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myDocument*`.embeds.length` - *myDocument*`.plugins.length`
See also:	`EmbedArray` object, `Collection.length`

Property attributes:

`ReadOnly`.

Embedded JavaScript (Definition)

JavaScript available inside your application.

Embedded interpreters are available to buy or download as open source projects.

With an embedded interpreter, you can break your application into components and integrate them together with fragments of JavaScript. This allows you to flexibly reconfigure and extend an application very easily.

See also:	Host environment, Platform

Cross-references:

Wrox *Instant JavaScript* – page – 5

Emboss() (Filter/visual)

Displays the image content of the HTML element as if it were an embossed effect.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

filter – `Emboss()`

Empty statement (;) (Statement)

A no-op 'do-nothing' statement.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0
JavaScript syntax:	- ;

An empty statement is signified by a semi-colon on a line by itself or a semi-colon following a semi-colon with no executable statements in between them.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

Warnings:

- If you intentionally place an empty statement into your script, you should put a comment adjacent to it to make sure people realize you did it on purpose. They may remove it otherwise and you may have had a functional reason for putting it there such as to aid the parsing of the text inside a `SCRIPT` object.
- This sails awfully close to the territory of self-modifying code which programmers have always loved to do and preachers of good programming style have said is a very bad thing.
- On the other hand, JavaScript supports the `eval()` function and you can't get closer to self modifying code than that.

See also:	Associativity, Operator Precedence, Semi-colon (;), Statement

ECMA 262 edition 2 – section – 12.3

ECMA 262 edition 3 – section – 12.3

enableExternalCapture() (Method)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`enableExternalCapture()`
	-	*`myWindow`*`.enableExternalCapture()`

Refer to:

`Window.enableExternalCapture()`

encodeURI() (Function)

This ECMA defined function can be used to encode an entire URI value that can then be decoded with the `decodeURI()` function.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`encodeURI(`*`aURI`*`)`
Argument list:	*`aURI`*	An unencoded URI

The `encodeURI()` function computes a new version of the string value it is passed. The new version has certain characters replaced with hexadecimal escape sequences. The string is expected to conform to the UTF-8 profile.

All character codes other than letters, numbers or a small set of special characters will be escaped.

These special characters are not transformed:

- Minus
- Underscore
- Period
- Exclamation-mark
- Tilde
- Single quote
- Opening and closing parentheses

Note that the hash character is also not encoded by this function.

Cross-references:

ECMA 262 edition 3 – section – 15.1.3.3

encodeURIComponent() (Function)

This ECMA defined function can be used to encode a URI component value that can then be decoded with the `decodeURIComponent()` function.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- `encodeURIComponent(`*`aComponent`*`)`
Argument list:	*`aComponent`* A URI component to be encoded

The `encodeURIComponent()` function is used to encode individual components belonging to a URI. You will need to deconstruct the URI yourself if you intend to call this function from your own scripts.

See also:	`decodeURI()`, `decodeURIComponent()`, `encodeURI()`, `escape()`, `unescape()`, URI handling functions

Cross-references:

ECMA 262 edition 3 – section – 15.1.3.4

Engrave() (Filter/visual)

An effect that is the opposite of the embossed image appearance.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

filter – `Engrave()`

Enquiry functions (Definition)

A means of determining value types.

The following enquiry functions are built in:

- `isFinite()`
- `isNaN()`

This operator can behave as if it were a function:

- typeof

These enquiry functions are available in other languages and we have documented them elsewhere with example scripts to simulate their functionality:

- `isalnum()`
- `isalpha()`
- `iscntrl()`
- `isdigit()`
- `isgraph()`
- `islower()`
- `isodigit()`
- `isprint()`
- `ispunct()`
- `isspace()`
- `isupper()`
- `isxdigit()`

See also:	`isAlnum(),isAlpha(),isCtrl(),isDigit(),isFinite(), isGraph(),isLower(),isNaN(),isODigit(),isPrint(), isPunct(),isSpace(),isUpper(),isXDigit(),typeof`

Entity object (Object/DOM)

An entity is an item in an XML document. This object encapsulates the XML entity.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Inherits from:	`Node` object

JavaScript syntax:	-	*myEntity* = new Entity()
Object properties:	notationName, publicId, systemId	

DOM level 3 is expecting to add the following properties:

- actualEncoding
- encoding
- version

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
notationName	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly.
publicId	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly.
systemId	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly.

Inheritance chain:

Node object

Entity.notationName (Property)

If an entity is unparsed, then this will be the name of the notation for that entity, otherwise it is null.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myEntity*.notationName

Property attributes:

ReadOnly.

Entity.publicId (Property)

The public identifier associated with the entity if it was specified when the entity was instantiated.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myEntity*.publicId

Property attributes:

ReadOnly.

Entity.systemId (Property)

The system identifier associated with the entity if it was specified when the entity was instantiated.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myEntity*.systemId

Property attributes:

ReadOnly.

EntityReference object (Object/DOM)

A reference to an entity object in an XML document.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Inherits from:	Node object	
JavaScript syntax:	N	*myEntityReference* = *myDocument*.createEntityReference(*aName*)
Argument list:	*aName*	The name of the entity to reference

See also:	Document.createEntityReference()

Inheritance chain:

Node object

enum (Reserved word)

Reserved for future language enhancements.

The provision of this keyword suggests that future versions of ECMAScript may support enumerated data types.

See also:	Reserved word, Type

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

Enumeration constant (Definition)

Possible future functionality to provide enumerated data types.

Refer to:

`enum`

Enumerator object (Object/JScript)

A special object supported by MSIE for processing collections of objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myEnumerator* = Enumerator
	IE	*myEnumerator* = new Enumerator(*aCollection*)
Argument list:	*aCollection*	The collection to be enumerated
Object properties:	constructor	
Object methods:	atEnd(),item(),moveFirst(),moveNext()	

An `Enumerator` object provides a way to enumerate through all the objects in a collection (aka Array). You can create a new `Enumerator`, giving it your collection as an argument and can then access the items in the collection in a more sophisticated way than simply using a `for` loop.

You can use the `enumerator` to cycle through the items in a collection in much the same way as a `for( ... in ... )` loop would enumerate the properties. However, in some collections, objects have more than one entry. They may have an indexed entry and an associative entry. An `enumerator` should traverse the collection visiting each item only once. A `for` loop may visit objects several times.

The available set of methods and properties is somewhat limited compared with `enumerator` objects in other languages.

Because this is only available on MSIE and is severely dysfunctional on the Macintosh version of MSIE 5, its use is somewhat limited from the portability point of view. It is recommended that you avoid using it for the time being. Later, when it is more widely and reliably available, it may be more useful.

Do not confuse DOM `NodeList` arrays with `Enumerator` or `Collection` objects. The `NodeListitem()` method is subtly different to the `Enumerator.Item()` method.

Warnings:

- When tested on MSIE 5 for Macintosh, this object exhibited some very odd behavior.
- When passed a `FormArray`, it complained that it was not a `Collection` object. When passed a `Collection` object (`document.all`) it still complained. However, when passed an `Array` object, it was happy to accept it. It would allow a new `Enumerator` to be created with no argument being passed to its constructor function.
- When examined, its constructor reported that it was a reference to a `Date` object.
- The object may only be usable on MSIE on the Windows platform until a later version of MSIE supports a corrected implementation.
- The naming convention for methods and properties of this object are capitalized in a very untypical way and you need to be aware of this in case you have trouble getting your `enumerator` to work properly.

Example code:

```
// Instantiate a file system object
myFileSystem = new ActiveXObject("Scripting.FileSystemObject");

// Create an enumerator
myEnum = new Enumerator(myFileSystem.Drives);

// Traverse the Drives collection via the enumerator
for(; !myEnum.atEnd(); myEnum.moveNext())
{
   processDrive(myEnum.item());
}

// A function to do something with each disk drive
function processDrive(aDrive){...}
```

See also:	`Collection` object, `Files` object, `NodeList` object

Property	JavaScript	JScript	N	IE	Opera	Notes
`constructor`	-	3.0 +	-	4.0 +	-	Warning

Method	JavaScript	JScript	N	IE	Opera	Notes
`atEnd()`	-	3.0 +	-	4.0 +	-	-
`item()`	-	3.0 +	-	4.0 +	-	-
`moveFirst()`	-	3.0 +	-	4.0 +	-	-
`moveNext()`	-	3.0 +	-	4.0 +	-	-

Enumerator() (Constructor)

A constructor function for creating new `Enumerator` objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Enumerator` object	
JavaScript syntax:	IE	`new Enumerator()`
	IE	`new Enumerator(`*`aCollection`*`)`
Argument list:	*`aCollection`*	A collection of objects to be enumerated

This is the constructor function for creating new `enumerator` objects. Use it with the `new` operator to manufacture an `Enumerator` and then store the reference to it in a variable.

Enumerator.atEnd() (Method)

A method that returns a flag indicating the end of the collection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myEnumerator`*`.AtEnd()`

In your enumeration loop, you can test this method and exit the loop if it returns the Boolean `true` value.

Enumerator.constructor (Property)

A reference to the `constructor` object for the `Enumerator`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Enumerator` object	
JavaScript syntax:	IE	*`myEnumerator`*`.constructor`

You can access the constructor for an existing `Enumerator` object here.

You can use this as one way of creating `Enumerator` objects, although it is more popular to use the `new Enumerator()` technique.

This property is useful if you have an object that you want to clone, but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

Warnings:

- On the Macintosh version of MSIE 5, this property yields a reference to the `Date()` constructor object. This is obviously a bug and renders the `Enumerator` unusable on this platform.

Enumerator.item() (Method)

A reference to the current item in the collection. This method returns the object from the collection that the `enumerator` is currently accessing.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	*myEnumerator*.item(*anIndex*)
	IE	*myEnumerator*.item(*aSelector*)
	IE	*myEnumerator*.item(*aSelector*, *anIndex*)
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

Enumerator.moveFirst() (Method)

Resets the enumerator to point at the first item in the collection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myEnumerator*.MoveFirst()

This relocates the enumerator so that it accesses the first item in the collection.

Enumerator.moveNext() (Method)

Moves the enumerator to the next item in the collection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myEnumerator*.MoveNext()

This indexes the `enumerator` onwards to the next item in the collection that has not yet been visited.

Environment (Definition)

The environment is the computing context in which the script is executed.

There are a variety of different environments in which a script may be executed. At the time of writing, a JavaScript script could be operating in any of these distinctly different environments:

- A Netscape web browser
- A MSIE browser
- Several other new web browsers
- A server CGI environment
- A desktop application environment
- A UNIX shell
- A WebTV set top box
- A Liberate TV Navigator set top box
- A WAP/WScript mobile phone
- An Adobe PDF file reader
- An embedded web browser built-into consumer products

Each of these has certain advantages and constraints. Most offer special facilities native and unique to that hosting environment.

In general, you should be able to determine which of these environments you are operating in. However, there is no standardized way to detect this at present.

There may be range limits on values in certain environments and certainly there will be 'bugs' in the implementations that are platform specific. It is also very likely that functionality will be more or less incomplete in some environments – mostly depending on the maturity of the implementation.

Wrox *Instant JavaScript* – page – 5

Equal to (==) (Operator/equality)

Compares two operands for equality.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`anOperand1 == anOperand2`*
Argument list:	*`anOperand1`*	A value that can reasonably be compared
	`anOperand2`	A value that can reasonably be compared with *`anOperand1`*

The result is the Boolean value `true` if `anOperand1` is numerically or lexically equal to `anOperand2`, otherwise `false` is returned.

The equality operator is not always transitive. For example, two string objects may represent the same string value. Comparing the objects for equality will yield `false` because the references to the objects are being compared and not the object values themselves. However, forcing a string comparison may in fact yield a `true` value when testing for equality. Do this by converting the objects as part of the comparison process by type conversion or `valueOf()` methods.

Numeric values may require rounding to take place and testing for equality may be accurate down to a precision finer than your script cares about. You can set a precision value in a variable, then subtract the value you are comparing with from the absolute value of the comparee. If the difference is smaller than your precision value, then the two values are close enough to yield a match.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

Refer to the Equality expression topic for a discussion on the ECMA standard definition of the equality testing rules.

Warnings:

- Be careful not to confuse the single equals with the double equals. Placing a single equals in place of a test for equality will assign the right hand value to the left hand operand and clobber the value accidentally. It will also force the relational expression to yield `true` as well. The interpreter may be forgiving enough that a run-time error isn't generated, but the side effects could be subtle and make it hard to diagnose the cause.
- A triple equals sign further complicates things as it is a test for identical type as well as equal value.

Example code:

```
// Fuzzy matching of numeric values
function almost_equal(aValue1, aValue2)
{
   var myPrecision = 1e-10;
   if((Math.abs(aValue1 - aValue2)) < myPrecision)
   {
      return(true);
   }
   return(false);
}
```

Wrox *Instant JavaScript* – page – 36

Equality expression (Definition)

An expression that tests for equality or not.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

Equality expressions are a special case of Relational expressions. They deal strictly with equality or non-equality.

There are two equality operators that you can use to make an equality expression:

- The == operator tests for equality.
- The != operator tests for inequality.

As a general rule, equality expressions will yield a `true` or `false` result in a more forgiving way than relational expressions. Passing `NaN`, undefined and `null` values to relational expressions may yield undefined values as results, where an equality expression would still return a Boolean value.

The comparisons between objects are likely to be a shallow comparison. If you are comparing two objects of the same type, the comparison logic will check to see if you are referring to the same instance. That is a test for identity and not equality. A deeper comparison might compare two similar objects on a property by property basis. They wouldn't be identical, but they may be equivalent. You could simulate this with a script function that returns `true` or `false` having done a deep comparison.

Tests for equality require further deductive reasoning on the part of the interpreter. The values are converted to their preferred types. If the types are the same, then the values can be compared easily either as Numbers or Strings. If the types are different, the further conversion is necessary before the comparison can be completed. In that case, Boolean become Numbers as do any other non-numeric values and numeric comparison predominates.

Comparing `null` with undefined values does not require any conversion and they will compare equal.

Comparing values with `null` can expose some bugs in earlier implementations. It may be safer to rely on Boolean conversions and simply test for `true` or `false`.

The ECMA standard (edition 3) sets out the rules for testing two values for equality (somewhat simplified):

- If they are of different types, they are unequal – return `false`.
- If the type of the first argument is undefined or `null` return `true`.
- For numeric values `NaN` in either case return `false`.
- Positive and negative zeros are represented differently internally but are equal.
- Otherwise equal numbers return `true` and unequal numbers return `false`.
- For strings, the two values must contain the same sequence of characters for them to be equal.
- Boolean values must be equal and they have no special states to consider.
- Object references must refer to the same object instance.
- The values `null` and undefined are considered to be equal.
- If necessary, `ToNumber()` and `ToPrimitive()` functions are called to coerce objects when one value is a primitive and the other is an object.
- If all of the above fail to match equal then a false value is returned.

It seems odd to assume equality to be true if the type of the arguments is not absolutely clear, but this may be necessary to allow implementations some flexibility in the internal representation of values which may not have a defined type.

It might also be strange to see that if either value is `NaN` then a `false` value is returned. This is necessary because `NaN` is indeterminate. It is not a specific value and can be caused by a variety of circumstances when an expression yields an out of bounds value. There is no guarantee that two individual `NaN` values resulted from the same circumstance and hence they are assumed to be unequal.

Referring to the same object also includes joined objects which are an internal mechanism for sharing functionality between objects. This is not exposed to the script interface.

Warnings:

- Earlier versions of MSIE and Netscape exhibited bugs in the comparison logic between the results of comparisons involving `NaN`, `null` and `0`, where type conversions led to inconsistent behavior.
- Since historically there are known bugs in comparisons involving `null` values, you should avoid using them. The following:

```
if(a){   someCode}
```

may be more reliable in some implementations than:

```
if(a != null){   someCode}
```

Example code:

```
// Force a string comparison
myResult = (a+'' == b+'');
alert(myResult);

// Force a numeric comparison
myResult = (a-0 == b-0);
alert(myResult);

// Force a boolean comparison
myResult = (!a == !b);
```

ECMA 262 edition 3 – section – 11.9

Wrox *Instant JavaScript* – page – 39

Equality operator (Definition)

An operator that tests for equality or not.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

There are two equality operators:

- The == operator tests for equality.
- The `!=` operator tests for inequality.

Equality operators deal exclusively with the test for the operands being equal to one another. They yield a `true` or `false` result and are generally considered as part of the relational operator set since they are most often used in the same circumstances.

Testing two operands for equality follows these basic rules:

If the native types of the two operands are not the same, then the values are not equal unless a numeric coercion yields equal values from both sides or the operands both yield `null`/undefined values.

If the type of the left operand is undefined or `null`, it is assumed to be equal to the right operand.

If either of the operands is `NaN`,then they are assumed to be not equal.

Positive and negative zero are equal values.

Boolean values must be identical values to be considered equal.

Two strings of the same length containing the same character sequence (identical copies of one another in terms of Unicode character code points) are assumed to be equal.

References to the same object test as equal. References to two objects containing the same property values, even though they may be copies of one another, are not equal.

Comparing different types of operands can use coercion techniques to force the comparison to be conducted according to string, numeric or Boolean rules.

If one of the operands is an object and the other is not, then the object is converted to a primitive.

String comparisons can be by concatenating values of other types to an empty string. It may help to use the parentheses to guarantee that precedence is established as you intend it to be. Here is a forced string comparison:

```
("" + a) == ("" + b)
```

Numeric comparisons can be forced by subtracting zero. Again, grouping operators help to establish the desired precedence:

```
(a - 0) == (b - 0)
```

Boolean comparisons can be forced by performing a logical NOT on both operands, in which case precedence control with grouping operators may not be as necessary as it is with the addition and concatenation operators:

```
!a == !b
```

The values `null` and `undefined` are generally considered to be equal although they are distinctly different values. This is because early implementations did not support an explicit `undefined` value and allowed for it to have the same meaning as the `null` value.

Comparing strings is done simply according to the Unicode character code point values and does not take into account any of the more subtle semantic meanings of those characters as defined in the Unicode version 2.0 specification.

Refer to the identity operators for a more exact comparison taking data type into account.

Warnings:

- Be careful not to miss one of the equals signs when testing for equality. You can accidentally assign to an LValue and not realize it.

ECMA 262 edition 3 – section – 11.9

Error (Definition)

That which happens when your script fails to execute properly.

Availability:	ECMAScript edition – 2

The ECMA standard dictates that a compliant implementation will detect and alert on all errors in the code even if the error is in a section of code that is not executed. Such dead code might be in a conditional block for which the condition could never be true. Nevertheless, a compile time warning should be generated.

This means that you should not rely on placing code within an `if(false)` block to prevent its execution. Instead, you should comment out the code to achieve the same effect.

This behavior is generally implementation dependent due to the different ways that compilers and interpreters may be designed and built. It also changes as browser versions evolve and of course the kind of error that is thrown can also affect when and how it is detected and managed.

ECMA 262 edition 2 – section – 16

ECMA 262 edition 3 – section – 16

Error events (Definition)

A class of events that are triggered by errors.

HTML syntax:	`<IMG onError="...">`

There is an `onError` event defined as part of the set of events supported by JavaScript. However, as of JavaScript version 1.2, the `onError` event is actually only supported by `Image` objects when defined in HTML tag attributes. You can add an error handler to a `window` object with the `onerror` property.

The `<IMG onError="...">` tag element allows an error during image loading to be handled gracefully.

Attaching an error handler to a `window` with the `window.onerror` property allows JavaScript errors to be intercepted.

Error events have a slightly different parameter passing API so although they are events, they are slightly different to the rest of the event model.

See also:	Error handler, Event handler, Event model, `onError`, `Window.onerror`

Error handler (Interface)

Triggered by an error in the JavaScript execution.

JavaScript syntax:	- `function` *`anErrorHandler`*`(`*`aMessage`*`, `*`aURL`*`, `*`aLine`*`) { `*`someCode`*` };`	
Argument list:	*`aLine`*	The line number where the error occurred
	`aMessage`	The text of the error message
	`anErrorHandler`	An identifier name for the function
	`aURL`	The URL of the document containing the error
	`someCode`	The script source for the error handler

This is a means of trapping the errors in any script. You can activate an error handler in various ways. Placing this line at the top of your script will trap all errors within that script:

```
self.onerror = function() { return true };
```

Because the script always returns true, no error dialog will ever be displayed.

Here is a pseudo code example of a better technique.

```
function HandleErrors(aMessage, aURL, aLine){   //If we can handle the error with
a piece of code      return true;   //Else we can't do anything      return
false;}self.onerror = HandleErrors;
```

An error handler should return true if the host environment can safely ignore the error and `false` if the environment needs to handle the error as normal.

See also:	Error, Error events, Semantic event, `Window.onerror`

Error handling (Definition)

A mechanism for dealing with errors.

Error handling in compiled languages happens in two stages.

First, compile time messages tell you about syntax errors. Secondly, when you run the application, you get run-time errors. These are generally semantic problems.

JavaScript is an interpreted language and as such compilation and run-time happen one after the other when the script is executed. Some implementations parse and tokenize the entire script before executing any of it, others may parse and execute a line at a time.

If you are handling errors in server-side code, you may be able to make use of the following methods/properties of the Netscape Enterprise Server's server-side objects. These will tell you about errors that have just occurred:

- `majorErrorCode()`
- `majorErrorMessage()`
- `minorErrorCode()`
- `minorErrorMessage()`

The status codes returned by NES database calls imply that you should inspect these error code values when the status code is 5 or 7 (depending on the database type).

Warnings:

- In an effort to make the Internet more accessible to inexperienced users, you may find some browsers, especially those in TV set-top boxes, handle errors silently. A fatal error in a script may halt the script and indeed stop any others executing on the page. However, the user will not receive any warning that this has happened. This is certainly the case with the WebTV set-top box and may be true of others.

Error object (Object/core)

An object that represents a custom error condition.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

JavaScript syntax:	-	*myError* = new Error()
	-	*myError* = new Error(*aNumber*)
	-	*myError* = new Error(*aNumber*, *aText*)
Argument list:	*aNumber*	An error number
	aText	A text describing the error
Object properties:	constructor, description, message, name, number, prototype	
Object methods:	toString()	

This object is provided to create custom error codes for your application. The ECMA standard (edition 3) describes them as objects that are thrown as exceptions when a run-time error occurs.

These objects are passed as the first argument of the `catch()` function in a `try ... catch` structure where you can inspect them and deal with the error.

Example code:

```
// Force an error condition
myError = new Error(100, "My user defined error text")
try
{
   throw myError;
}
catch(anErr)
{
   confirm(anErr.description);
}
finally
{
   alert("Sorted");
}
```

See also:	`catch( ... )`, `EvalError` object, `RangeError` object, `ReferenceError` object, `SyntaxError` object, `throw`, `try ... catch ... finally`, `TypeError` object, `URIError` object

Error() (Constructor)

An `Error` object constructor.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	`new Error()`
	-	`new Error(`*`aNumber`*`)`
	-	`new Error(`*`aNumber`*`, `*`aText`*`)`
Argument list:	*`aNumber`*	An error number
	`aText`	A text describing the error

The `Error()` constructor can be called with the `new` operator or as a function.

The initial value of `Error.prototype.constructor` is the built-in `Error()` constructor.

The two arguments supplied to the `Error()` constructor describe the error number and a textual description. They are all optional.

A `prototype` property is automatically created in case the `Error` object is used as a constructor at some future time.

See also:	Constructor function, `constructor` property, `Error.prototype`

Cross-references:

ECMA 262 edition 3 – section – 15.11.2

Error() (Function)

An `Error` object constructor.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	`Error()`
	-	`Error(`*`aNumber`*`)`
	-	`Error(`*`aNumber`*`, `*`aText`*`)`
Argument list:	*`aNumber`*	An error number
	`aText`	A text describing the error

When the `Error()` constructor is called as a function, it creates and initializes a new `Error` object. The function call `Error()` is equivalent to the expression `new Error()` with the same arguments.

See also:	`Error.prototype`

Cross-references:

ECMA 262 edition 3 – section – 15.11.1

Error.constructor (Property)

A reference to a constructor object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Error` object	
JavaScript syntax:	-	*`myError`*`.constructor`

The initial value of `Error.prototype.constructor` is the built-in `Error()` constructor.

You can use this as one way of creating `Error` objects, although it is more appropriate to use the `new Error()` technique.

This property is useful if you have an object that you want to clone, but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`Error.prototype`

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 3 – section – 15.11.4.1

Error.description (Property)

A property that corresponds to the description argument in the constructor function.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myError`*`.description`

A human readable textual description of the custom error is available in this property. You can assign a new value if you wish. Reading the property yields the value that was passed in the description argument to the constructor function unless it has been changed since then.

Warnings:

- The ECMA standard describes this property as `Error.message`. MSIE supports it as the `description` property.

Error.message (Property)

A property that corresponds to the message argument in the constructor function.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myError`*`.message`

A human readable textual description of the custom error is available in this property. You can assign a new value if you wish. Reading the property yields the value that was passed in the description argument to the constructor function unless it has been changed since then.

Warnings:

- The ECMA standard describes this property as `Error.message`. Netscape 6.0 claims to be completely compliant and therefore should support this property.
- MSIE supports the `description` property which is functionally identical.

Cross-references:

ECMA 262 edition 3 – section – 15.11.4.3

Error.name (Property)

The name of an `Error` object can be accessed with this property.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	- *myError*.name	
	- *myError*.name = *aString*	
Argument list:	*aString*	The new name value for the `Error` object

The initial value for this property is the string primitive "`Error`". The ECMA standard suggests that this property can be assigned with a different name for each instance of the `Error` object.

For native errors that are subclassed from this `Error` object, the `name` property will be the name of that object class and will be one of the following:

- `EvalError`
- `RangeError`
- `ReferenceError`
- `SyntaxError`
- `TypeError`
- `URIError`

Cross-references:

ECMA 262 edition 3 – section – 15.11.4.2

Error.number (Property)

A property that corresponds to the number argument in the constructor function.

Availability:	JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myError`*`.number`

This is the error number your custom error will be registered under. Unless you change it by assigning a new value to this property, it will contain the value that was passed in the number argument to the constructor function.

The number is a 32 bit value consisting of a facility code and an error number. The upper 16 bits is the facility code and the lower 16 bits the error number within that facility.

Error.prototype (Property)

The prototype for the `Error` object that can be used to extend the interface for all `Error` objects.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Error` object	
JavaScript syntax:	-	`Error.prototype`
	-	*`myError`*`.constructor.prototype`

This is the `Error` prototype object belonging to the `global` object and from which all `Error` objects are descended.

The initial value of `Error.prototype` is the built-in `Error` prototype object.

The value of the `prototype` property of an `Error` object is used to initialize child objects when that `Error` object is used as a constructor.

The following properties are inherited from the `Error.prototype`:

- `Error.prototype`
- `Error.constructor`
- `Error.name`

- `Error.message` (according to ECMA)
- `Error.description` (according to Microsoft)

The following methods are inherited from the `Error.prototype`:

- `Error.toString()`

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object to emulate the ECMA standard message property that is lacking in some implementations.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that provides ECMA compliance
function message()
{
   return this.description;
}

// Register the new function
Function.prototype.message = message;

// Create an Error object and test the new property accessor
var myError = new Error(100, "My error message");
document.write(myError.message);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Error()`, `Error()`, `Error.constructor`, `Error.toString()`, `prototype` property

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 3 – section – 15.11.3.1

Error.toString() (Method)

Returns a string primitive version of an `Error` object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myBoolean*.toString()

The value of the object is converted to a string value that represents its value. The value returned is implementation dependent.

See also:	`Cast` operator, `Error.prototype`, `toString()`

Cross-references:

ECMA 262 edition 3 – section – 15.11.4.4

Escape sequence (\) (Definition)

A means of defining characters that cannot easily be typed on a keyboard.

Availability:	ECMAScript edition – 2 Opera – 3.0

The string delimiter characters present problems if you need to include them inside a string. Typically you may want to include a single quote as an apostrophe, as in the contraction of do not to don't. Or you may want to enclose a spoken comment inside double quotation marks.

Because the single and double quotes are generally interchangeable in JavaScript, in most cases the problem is easy to solve.

To use " inside a string, you can do it like this:

```
myString = 'A man said "hello" to me';
```

Using a double quote to include single quotes in your string, you might do this:

```
myString = "Don't do that";
```

Using the backslash escape delimiter we can safely use any combination of quotes inside either sort. Like this:

```
myString = "A man said \"hello\" to me";

myString = 'Don\'t do that';
```

A further use for this is to escape a single dot character in regular expressions. This allows you to search for full stops in the source text because a dot in a Regular Expression is a wildcard character match. This technique is useful for other meta symbols in the regular expression set. Refer to the regular expression topic for more details.

Just to illustrate here is a simple example. This regular expression matches any single character at the start of a line:

```
/^./
```

This variant matches only full stops or periods at the start of the line:

```
/^\./
```

An escape sequence is a series of characters that taken together describe a character that cannot normally be represented in the code set that the source is written in, or may be difficult to type on keyboards that are not specially designed for international character sets.

Escape Sequence	Name	Symbol
\"	Double Quote	"
\'	Single Quote (Apostrophe)	'
\\	Backslash	\
\a	Audible alert (MSIE displays the letter a)	<BEL>
\b	Backspace (ignored silently in MSIE)	<BS>
\f	Form Feed (ignored silently in MSIE)	<FF>
\n	Line Feed (Newline – MSIE inserts a space)	<LF>
\r	Carriage Return (MSIE inserts a space)	<CR>
\t	Horizontal Tab (MSIE inserts a space)	<HT>
\v	Vertical tab (MSIE displays the letter v)	<VT>
\0nn	Octal escape	-
\042	Double Quote	"
\047	Single Quote (Apostrophe)	'
\134	Backslash	\
\xnn	Hexadecimal escape	-
\x22	Double Quote	"
\x27	Single Quote (Apostrophe)	'
\x5C	Backslash	\
\unnnn	Unicode escape	-

Table continued on following page

Escape Sequence	Name	Symbol
\u0022	Double Quote	"
\u0027	Single Quote (Apostrophe)	'
\u005C	Backslash	\
\uFFFE	A special Unicode sentinel character for flagging byte reversed text	-
\uFFFF	A special Unicode sentinel character	-

Here are some examples of escape sequences for the apostrophe character.

In HTML apostrophe characters are escaped like this:

```
&#039;
```

In C language characters are escaped like this for octal values:

```
\047
```

And like this for hexadecimal values:

```
\x27
```

And in JavaScript, Unicode characters can be escaped like this:

```
\u0027
```

Where the `\u` is followed by a four digit hexadecimal value.

O'Reilly *JavaScript Definitive Guide* – page – 38

escape() (Function/global)

URL escaping a text string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	- `escape(anInputString)`	
	- `escape(anInputString, aSwitch)`	
Argument list:	*anInputString*	A string of un-escaped (normal) characters.
	aSwitch	A switch that allows plus signs to be encoded or not

The `escape()` function computes a new version of the string value it is passed. The new version has certain characters replaced with hexadecimal escape sequences.

All character codes from zero to 32 (decimal) will be escaped.

All character codes above 126 will be escaped.

The table summarizes the characters below 127 that will be escaped.

Escape	Character
%09	Tab
%0A	Line feed
%0D	Carriage return
%20	space
%21	!
%22	"
%23	#
%24	$
%25	%
%26	&
%27	'
%28	(
%29	)

Table continued on following page

Escape	Character
%3A	:
%3B	;
%3C	<
%3D	=
%3E	>
%3F	?
%5B	[
%5C	\
%5D	]
%5E	^
%60	`
%7B	{
%7C	|
%7D	}
%7E	~
%7F	Delete

For those characters that are replaced whose Unicode encoding is 0xFF or less, a two digit escape sequence of the form %xx is used. For those characters that are replaced whose Unicode character value is greater than 0xFF, a four-digit escape sequence of the form %uxxxx is used.

The encoding is partly based on the encoding described in document RFC1738. However the entire coding scheme goes beyond the scope of that RFC document.

Most non-alphanumeric characters will be escaped. All control codes are and also the upper 128 of the 255 character codes that are normally used in a web browser will be escaped too. The example script generates a table of character codes that show how they are escaped. Note that control characters will be represented by a 'missing character' box, but on some platforms special characters are mapped for display in these lower code points (0-31).

MSIE version 4 introduces Unicode support.

Netscape supports the optional second parameter to switch on the encoding of plus signs. You should place an integer 1 in this argument to activate plus encoding.

As far as ECMAScript is concerned, this is superceded in edition 3 with a set of generalized URI handling functions. The JScript 5.5 documentation refers to the `escape()` function as a deprecated feature.

Example code:

```
// Create a 0-255 lookup table of escapes
document.write("<TABLE BORDER=1>");
document.write("<TR><TH>Index</TH>");
document.write("<TH>Char</TH>");
document.write("<TH>Escape</TH></TR>");
for(ii=0; ii<256; ii++)
{
   myBinary        = ii.toString(2);
   myBinaryPadding = "00000000".substr(1,(8-myBinary.length));

   myOctal         = ii.toString(8);
   myOctalPadding  = "000".substr(1,(3-myOctal.length));

   myHex           = ii.toString(16);
   myHexPadding    = "00".substr(1,(2-myHex.length));

   myChar          = String.fromCharCode(ii);

   document.write("<TR ALIGN=RIGHT><TD>");
   document.write(ii);
   document.write("</TD><TD>");
   document.write(" "+myChar);
   document.write("</TD><TD>");
   document.write(escape(myChar));
   document.write("</TD></TR>");
}
document.write("</TABLE>");
```

Escaped JavaScript quotes in HTML (Pitfall)

Closing quotes may appear when you least expect them.

If you are generating JavaScript calls from a database, you might use one particular field as a quote delimited text parameter like this:

```
<A HREF="javascript:alert('Some text');">Click me</A>
```

Since the JavaScript call is inside a tag attribute, it is enclosed in double quotes. This means for starters that double quotes are a problem in your data if they appear.

You can get round this by enclosing any string constants in the JavaScript domain by using single quotes. JavaScript doesn't mind either. However, that means you get a problem when a single quote turns up in your data.

You might think that your output routines that get data from the database are doing very well by detecting the apostrophe and replacing it with `&#039;`, however you might still be in trouble. Likewise if you escaped the double quote by using the HTML character entity descriptor. This is because the browser unescapes the page as it is loaded. This is extremely hard to diagnose because when you view the source, you see the character entities and not the characters they become.

You must ensure that your data extraction/insertion code places the database generated items into this scenario with JavaScript escapes and not HTML escapes.

Of course everywhere else in the document you need to escape things as HTML and not JavaScript.

This all applies vice-versa by swapping the quotes around, although the escaped character entity value changes.

The example code illustrates a set of quoted strings that break and another set that work fine.

When they break, they cause a run-time error. In some cases they even prevent the status line from displaying the right thing.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Watch the status bar as you roll over the link.<BR>
<HR>
Examples of broken quotes:<BR>
<BR>
<A HREF="javascript:alert('xxx'xxx');">Test 1.1</A><BR>
<A HREF="javascript:alert('xxx&#039;xxx');">Test 1.2</A><BR>
<A HREF='javascript:alert("xxx"xxx");'>Test 1.3</A><BR>
<A HREF='javascript:alert("xxx&#034;xxx");'>Test 1.4</A><BR>
<A HREF='javascript:alert("xxx\'xxx");'>Test 1.5</A><BR>
<A HREF="javascript:alert('xxx\"xxx');">Test 1.6</A><BR>
<HR>
These work fine:<BR>
<BR>
<A HREF="javascript:alert('xxx\'xxx');">Test 2.1</A><BR>
<A HREF='javascript:alert("xxx\"xxx");'>Test 2.2</A><BR>
<A HREF="javascript:alert('xxx&#034;xxx');">Test 2.3</A><BR>
<A HREF='javascript:alert("xxx&#039;xxx");'>Test 2.4</A><BR>
<A HREF="javascript:alert('xxx\047xxx');">Test 2.5</A><BR>
<A HREF="javascript:alert('xxx\x27xxx');">Test 2.6</A><BR>
<A HREF="javascript:alert('xxx\u0027xxx');">Test 2.7</A><BR>
<A HREF="javascript:alert('xxx\042xxx');">Test 2.8</A><BR>
<A HREF="javascript:alert('xxx\x22xxx');">Test 2.9</A><BR>
<A HREF="javascript:alert('xxx\u0022xxx');">Test 2.10</A><BR>
<HR>
</BODY>
</HTML>
```

Eval code (Definition)

Script source executed by an `eval()` function call.

Availability:	ECMAScript edition – 2

Eval code is the source text that is supplied to the built-in `eval()` function.

When the `eval()` function is called, it expects a string as an argument value. The contents of that string should be syntactically correct executable script source text.

On initialization, the scope chain is based on the caller's scope chain. The variable object and its '`this`' property value are also inherited. If there is no calling context, then the global object is used instead. The scope chain is identical to the caller's. Variable instantiation is performed by using the variable object belonging to the caller, but with empty property attributes. The caller provides its own value.

Eval code therefore executes very much as if it were part of the caller's execution context.

See also:	`eval()`, Executable code, Execution context, `JSObject.eval()`

Cross-references:

ECMA 262 edition 2 – section – 10.1.2

ECMA 262 edition 3 – section – 10.2.2

eval() (Function/global)

Execute some script source passed as an argument.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	Depends on the script source passed as an argument	
JavaScript syntax:	-	`eval(`*`aSourceText`*`)`
Argument list:	*`aSourceText`*	A string value containing some syntactically correct script source code.

When the `eval()` function is called, it expects a string to be passed to it as its single argument value. The contents of that string should be syntactically correct executable script source text.

The script code gets executed and any result it generates is returned. That value must be explicitly returned, otherwise the result will be undefined.

Warnings:

- If the script source passed to the `eval()` function cannot be parsed without failure, a run-time error will result.
- Be careful how you let people pass values from outside into this function. It is feasible to provide a way for a user to type in some valid JavaScript and to then execute it for them in an `eval()` function. This can be dangerous, not only because it exposes all the variables in the script but also it may be possible to construct a JavaScript that when executed, talks back to the server that provided the page in the first place.
- It would be an unusual thing to do anyway, but the possibility may be there to compromise your server security. It rather depends on the security in the hosting environment. Possibly an `eval()` action is not permitted to do things that a non-user-modifiable script embedded in a web page can do. However, this is likely to be very implementation specific.

Example code:

```
// Create some script source
var scriptCode = "c = a * b";
var a = 5;
var b = 10;
var c = 2;
document.write(c);
document.write("<BR>");
eval(scriptCode);
document.write(c);
```

Wrox *Instant JavaScript* – page – 28

EvalError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 Netscape – 6.0	
Inherits from:	`Error` object	
JavaScript syntax:	N	*myError* = new EvalError()
	N	*myError* = new EvalError(*aNumber*)
	N	*myError* = new EvalError(*aNumber*, *aText*)
Argument list:	*aNumber*	An error number
	aText	A text describing the error

This sub-class of the `Error` object is used when an exception is caused by using the global `eval()` function incorrectly.

See also:	`catch( ... )`, `Error` object, `RangeError` object, `ReferenceError` object, `SyntaxError` object, `throw`, `try ... catch ... finally`, `TypeError` object, `URIError` object

Inheritance chain:

`Error` object

Cross-references:

ECMA 262 edition 3 – section – 15.11.6.1

Event-driven model (Definition)

A contextual manner in which script functions are executed.

Events are generated by all kinds of occurrences. For example, an event is generated when a web page has finished loading.

Some events are triggered as a result of some user interaction, for example, clicking a mouse button or passing a mouse pointer across the screen. As the mouse crosses over an item on the screen, it generates an event signifying that the mouse has entered the region occupied by the screen item. Similarly, an event is generated when the mouse moves away from the item.

Other events can be generated by plugins as they execute some special dynamic animated or audio/visual presentation.

Sometimes these events may be useful to trap a form submission or maybe a user has entered some data into a text cell and you want to check it right away before the user does something else.

Sometimes, events might be generated on a regular basis with an interval timer.

There are other more subtle events such as errors, property changes and focus changes. Some of these are derived and are triggered as a consequence of other events.

There is an association between an event and an event handler. The handler is a JavaScript function having the same or a similar name as the event. If an event handler is not present, then the event is discarded and the browser continues interacting with the user.

See also:	`Element.onevent`, `MutationEvent` object

Event (Definition)

A trigger that may occur at any time.

Event mechanisms are good way to add functionality to the user interaction. Rather than let the browser handle the user's mouse clicks, you can intervene with JavaScript and add all kinds of sophisticated behavior to each user-driven trigger.

An event is simply a trigger generated manually by the user or as a consequence of something happening in the host environment. Events can be generated at the following times:

- When a user clicks on something
- When something finished being loaded from the web server
- When an error occurs
- When a Java exception happens
- When a timer runs out
- When a page is closed
- When a page needs to be refreshed
- When a plugin calls back to its parent page
- When a property changes while it has a `watch()` active on it
- Server-side initiation

Each of these is associated with a handler. Most of them are triggered as HTML intrinsic events.

By default, the triggers behave as if a `null` handler is assigned to the event so it appears that nothing happens when the event fires. It's likely that inside the interpreter the event is processed and simply calls a handler that returns straight away. You can replace that handler whenever you want to as the page content is processed.

MSIE version 4 implements virtually every event on every object. We describe each of those events in its own topic.

Trying to integrate both MSIE and Netscape browser event models into a single unified concept is something that is vexing the W3C experts as they deliberate over higher level functionality in the DOM. This is not likely to be resolved for some time.

Even the documentation from Netscape is inconsistent as to which event and object combinations are supported on different platforms, and you should attempt to test any portable scripts and event handlers on a variety of system configurations before deployment. Netscape 6.0 is far more standards based and consistent with MSIE as far as event handling is concerned. It implements the DOM level 2 event support. Documentation on the new version is still scarce, even on the Netscape web sites.

Draft DOM level 3 documents describing an MSIE-like event model have been published and the relevant topics are included here because that event model is supported by Netscape 6.

You may be able to establish what events are supported by an object if you write an inspection script to enumerate and print out the names of any properties of that object. You should see place holder properties for each event handler. These will be undefined unless you have registered a handler function with them.

See also:	DOM Events, Script execution

Cross-references:

Wrox *Instant JavaScript* – page – 52

event (Property)

During event handling, MSIE stores a reference to an `Event` object in this variable.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Event` object	
JavaScript syntax:	IE	`event`
	IE	*`myWindow`*`.event`

Example code:

```
// Browser portable event handler
function myEventHandler(anEvent)
{
   if(navigator.appName.indexOf("Microsoft") != -1)
   {
      anEvent = window.event;
      anEvent.srcElement = target;
      anEvent.button = which;
      anEvent.keyCode = which;
      anEvent.altKey = anEvent.modifiers & Event.ALT_MASK;
      anEvent.ctrlKey = anEvent.modifiers & Event.CONTROL_MASK;
      anEvent.shiftKey = anEvent.modifiers & Event.SHIFT_MASK;
      anEvent.clientX = pageX;
      anEvent.clientY = pageY;
   }
   // Portable event code goes here.
}
```

See also:	`Element.onevent`,`Window.event`

Property attributes:

`ReadOnly`.

Event bubbling (Definition)

A mechanism whereby MSIE and Netscape 6.0 pass events up a hierarchy of objects until they find a handler.

Event bubbling was introduced in version 4.0 of MSIE and provides a structured and hierarchical way of handling events. This is somewhat more object oriented in its approach than that provided by the Event Management suite in Netscape prior to version 6.

Functionally, this is very similar to the event hierarchy model found in HyperCard. Other hyper-linking and events-driven systems have modelled their event handling on this same technique since it became popularized in HyperCard in 1987.

The event bubbling technique hands an event to the most specific object relating to the event, such as the object representing an HTML tag. If there is no handler, the event is passed up the document object tree until a handler that matches is found or until it is established without doubt that there is no handler.

Handlers are able to consume an event and terminate the event handling process for that event or they may choose to pass the event upwards to a parent object. This is very sub-class, super-class like behavior and is again borrowed from the HyperCard and Object Oriented prototypes.

Event bubbling has been selected as a candidate for standardization, since it is a fundamentally more useful and automated way to propagate events through the DOM. DOM level 2 documents describing an MSIE-like event model have been published and the relevant topics are included here because that event model is supported by Netscape version 6. The event model is expected to be enhanced a little at DOM level 3 when that standard matures.

Event handler (Definition)

A script function that is called in response to an event trigger.

Property/method value type:	`Boolean primitive`

Each event is associated with a handler. By default a `null` handler is assigned to the event so it appears that nothing happens when the event fires. It's likely that inside the interpreter the event is processed and simply calls a handler that returns straight away. You can replace that handler as the page content is processed.

Event handlers are associated with objects in the following ways:

- By placing JavaScript code in HTML tag attributes
- By setting the object property for the handler

An event handler should conform to the following pattern:

```
function checkValue(anObject){   \\ someCode...   return true;}
```

The object that is passed to the handler is an `Event` object that describes the event that has called the handler. This was not always supported and so may be null in some implementations. It was introduced with Netscape version 4.0.

When building a page, it is sensible to place the handler functions in the `<HEAD>` block. You can do script driven property assignments to attach the handler to the objects, but that cannot take place until the page is almost complete. It is far more sensible to use the HTML tag attribute to attach the handler function where it is needed. It also keeps everything to do with that tag and its attributes in one place. The other disadvantage to script assigning the handler to a property is that the document tree needs to be walked. This can sometimes take a while and can be problematical if the `</BODY>` tag closure has not yet been processed. Legally you cannot place anything after a `</BODY>` closure. The only way then to ensure something happens when the `<BODY>` block is closed is to execute it under the `<BODY ONLOAD="...">` handler. But then why do that if you won't use tag attributes for the `<INPUT>` handlers.

If you want to, you can include the entire script of the event handler code at the point where it is associated with the HTML tag. However, this then prevents reuse and becomes hard to manage. It is better to gather the event handling logic into a single named function, organized so that it has everything it needs to process that event. Then, simply reference the function in the tag attribute that is associated with the event.

Event handlers should be designed to execute quickly and return. This is because, by their nature, they are part of the User Interface feedback process and anything that slows down the interaction between the user and the web page tends to frustrate the user and makes the application hard to use. You can let the user know that an action may take a while to complete. Even better, maybe you can create a progress indicator to show them how it's doing.

Event handlers may be invoked sooner than you expect them to be. Certainly, it is possible for them to be triggered before the page is fully loaded into the browser. Be careful that a prematurely triggered event handler does not try to manipulate objects that do not yet exist.

Event handler functions should return Boolean `true` or `false` depending on what action you want the host environment to take following your event handler's processing of the event.

Warnings:

- Event handlers should always return `true` or `false`. However, this is not enforced and won't generate an error so it isn't always necessary and often won't cause anything to happen whichever value you return. However, this might change if the interpreter vendors tighten up their functional specifications, so it's good practice to always return a Boolean result.
- Some event handlers cannot be set from a tag attribute. Those will have to be set from a script by assigning the handler to the appropriate property.
- Event handling architectures differ somewhat between Netscape and MSIE. Netscape provides event routing management while the event hierarchy allows events to bubble up through the document object model. If you are doing anything other than simply handling the event through the default handler, you need to be aware of the difference.

Example code:

```
<HTML>
<HEAD>
<SCRIPT>
function errorHandler()
{
   alert("An error has occurred");
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT>
window.onerror = errorHandler;
ablert("an error");
</SCRIPT>
</BODY>
</HTML>
```

Wrox *Instant JavaScript* – page – 52

Event handler in <SCRIPT> (Definition)

You can associate an event handler using the `<SCRIPT>` tag's attributes.

HTML syntax:	`<SCRIPT FOR="aName" EVENT="anEvent">`	
Argument list:	*aName*	The name of an `<INPUT>` element
	anEvent	The name of an event to be handled

In MSIE, you can give each `<INPUT>` tag a `NAME` attribute.

This can then be used to map a `<SCRIPT>` block to that `<INPUT>` object. The `<SCRIPT>` block is further mapped to the event names that the `<INPUT>` block might generate trigger events for. You end up with one `<SCRIPT>` block per event per named `<INPUT>` object.

The upside of this is that you don't have complicated function name mappings, but the downside is that you can end up with a large number of discrete `<SCRIPT>` blocks.

Internally, MSIE has to be turning these into some kind of function object otherwise they would be interpreted as inline Global code.

Warnings:

- Beware of using functionality that is not portable to your entire target audience. This is useful, but only on MSIE browsers. This capability is born out of the VBScript support in MSIE and is better confined to that language.

Event handler properties (Definition)

Objects can have event handlers attached via property values.

From JavaScript version 1.1, you can attach event handlers by saving a reference to a function object in a property whose name is the same as the event.

If there is no handler defined then MSIE stores a reference to the `null` object in the `event` property of the `Element` object, while Netscape leaves the property undefined.

The property names must be all lower case even though the convention is to use mixed case when the event handlers are defined in HTML as tag attributes.

It is a useful thing to be able to define event handlers like this since mixing JavaScript and HTML in tag attributes is somewhat messy and can become more difficult to maintain.

A major benefit of this technique is that you can dynamically change the event handler associated with an object without changing the document's HTML. You might want to make the error handler more complex after repeated errors. Or you might want to reuse some objects and have form value checking change according to some user choices.

See also:	Calling event handlers, `Element.onevent`

Event handler scope (Definition)

The scope of an event handler is somewhat different to the normal scope.

Although event handlers are functions like any other, they are not called from global code and therefore are running in a different scope chain context to that which your functions normally execute.

The head of the scope chain is the `call` object. Arguments passed to the event handler are available here as they would be in other function calls.

In a normal context, the next object in the scope chain might be the `global` object. However for the event handler, it is the object to which the event was directed. This makes event handles somewhat easier to write.

For example, the `form` object yielded in the scope for an event handler attached to an `<INPUT>` tag is the `form` object that the `FormElement` object belongs to. This scope chain continues up the document hierarchy (the DOM), until it reaches the `global` object. You can share various parts of the form handling code by plugging it into objects at different points in the DOM.

The scope chain for an `<INPUT>` object is the reverse of its DOM location. Thus:

```
window.document.form.button.event
```

will seek to resolve its identifiers in this order:

- `call` object
- `button` object
- `form` object
- `document` object
- `window` (`global`) object

Warnings:

- You need to be explicit about how objects and event handlers are declared and called.
- Inside an event handler, you should call `window.open()` and not just `open()` because the `document` object is located sooner in the scope chain than the `window` object. This means that `open()` will call the `document.open()` method before it would have resolved to the `window.open()` method.
- You should also be careful not to add properties to your objects whose name is the same as other pre-defined objects in the DOM. If you do, you risk seriously compromising your script's ability to run correctly within its scope.
- Beware that only the code defined in the HTML tag attribute is executed in an event handler scope chain. Calls to other functions will execute them in the scope that they are defined in due to the static scope rules for functions. You can get round this by defining a JavaScript version 1.2 `Closure` object. However this technique is not supported by MSIE version 4 browsers.

Event management (Definition)

The Netscape 4 event management suite provides event routing facilities.

The Netscape browser provides event management capabilities in version 4.0 that are different to those provided by MSIE. There are four management functions provided to facilitate this:

- `captureEvents()`
- `releaseEvents()`
- `routeEvent()`
- `handleEvent()`

Without using these management functions, events simply fire at the default handler for the event. Now you can route the events to other handlers, invoking whichever ones you need. As such, this adds to the basic functionality.

Cross-references:

Wrox *Instant JavaScript* – page – 55

Event model (Definition)

A framework within which events are triggered and handled by the interpreter.

The HTML 4.0 standard refers to events relating to HTML as intrinsic events. That includes the following:

- Conditions that cause events
- Attributes in tags that support events
- Scripts in the page that handle events
- A JavaScript host object that an event operates on
- Control being passed temporarily to the interpreter during the event handling
- Data associated with and passed to the handler by the event

The DOM level 2 standard introduces an event model based on the MSIE event bubbling technique. It is embodied in the following object classes:

- `EventTarget`
- `EventListener`
- `Event`
- `EventException`
- `DocumentEvent`
- `UIEvent`
- `MouseEvent`

- `MutationEvent`

Events can be added using the `addEventListener()` method that is inherited by any Elements that can be treated as `EventTarget` objects. The `EventTarget` class is not a concrete class in its own right but is an extension of an existing object class to add event handling capabilities to it.

DOM level 3 is expected to enhance the event model further with the addition of the following classes:

- `KeyEvent`
- `EventGroup`
- `EventGrouped`
- `DocumentEventGroup`

See also:	DOM Events, Dynamic HTML, `Element.onevent`, `MutationEvent` object, `unwatch()`, `watch()`

Event names (Definition)

Rules for naming event handlers.

When you specify the name of an event as an HTML tag attribute, because tag attributes in HTML are case insensitive, you only have to spell the event name correctly. You can type it in any mixture of upper and lower case and the browser should still be able to associate it with the correct fragment of JavaScript. These are all equally valid:

- `<INPUT TYPE="text" ONCHANGE="handleEvent();">`
- `<INPUT TYPE="text" onchange="handleEvent();">`
- `<INPUT TYPE="text" onChange="handleEvent();">`
- `<INPUT TYPE="text" OnChAnGe="handleEvent();">`

It is conventional to do it like this:

- `<INPUT TYPE="text" onChange="handleEvent();">`

Inside the JavaScript interpreter, you can associate handlers using properties. However the event names must be correctly cased in that situation: they would be lower case. You don't need to put the `onChange` tag attribute in, because you are registering the error handler inside the script block, like this:

```
<HTML>
<BODY>
<FORM NAME="the_form"><INPUT TYPE="text" NAME="the_text"></FORM>
<SCRIPT>document.the_form.the_text.onchange=alert("Changed");</SCRIPT>
</BODY>
</HTML>
```

Here is a list of all event names although they don't all apply to every object in the document.

Event	Handler	Usage
Abort	`onabort`	When image loading is aborted.
AfterPrint	`onafterprint`	When printing has just finished.
AfterUpdate	`onafterupdate`	When an update is completed.

Table continued on following page

Event	Handler	Usage
Back	`onback`	The user has clicked on the [BACK] button in the toolbar.
BeforeCopy	`onbeforecopy`	Immediately before a copy to the clipboard.
BeforeCut	`onbeforecut`	Immediately before a cut to the clipboard.
BeforeEditFocus	`onbeforeeditfocus`	Immediately before the edit focus is directed to an element.
BeforePaste	`onbeforepaste`	Immediately before the clipboard is pasted.
BeforePrint	`onbeforeprint`	Immediately before printing begins.
BeforeUnload	`onbeforeunload`	Called immediately prior to the window being unloaded.
BeforeUpdate	`onbeforeupdate`	Called immediately before an update commences.
Blur	`onblur`	When an input element loses input focus.
Bounce	`onbounce`	Triggered when a marquee element hits the edge of its element area.
Change	`onchange`	When edit fields have new values entered or a popup has a new selection, this event's handler can check the new value.
Click	`onclick`	When the user clicks the mouse button on the `Element` object that represents the object on screen.
ContextMenu	`oncontextmenu`	Special handling for contextual menus.
Copy	`oncopy`	When a copy operation happens.
Cut	`oncut`	When a cut operation happens.
DataAvailable	`ondataavailable`	Some data has arrived asynchronously from an applet or data source.
DataSetChanged	`ondatasetchanged`	A data source has changed the content or some initial data is now ready for collection.
DataSetComplete	`ondatasetcomplete`	There is no more data to be transmitted from the data source.
DblClick	`ondblclick`	When the user double-clicks on an object.
Drag	`ondrag`	When a drag operation happens.
DragDrop	`ondragdrop`	Some data has been dropped onto a window.
DragEnd	`ondragend`	When a drag ends.
DragEnter	`ondragenter`	When a dragged item enters the element.
DragLeave	`ondragleave`	When a dragged item leaves the element.
DragOver	`ondragover`	While the dragged item is over the element.
DragStart	`ondragstart`	The user has commenced some data selection with a mouse drag.
Drop	`ondrop`	When a dragged item is dropped.
Error	`onerror`	Triggered if an error occurs when loading an image.
ErrorUpdate	`onerrorupdate`	An error has occurred in the transfer of some data from a data source.

Table continued on following page

Event	Handler	Usage
FilterChange	`onfilterchange`	A filter has changed the state of an element or a transition has just been completed.
Finish	`onfinish`	A marquee object has finished looping.
Focus	`onfocus`	When the form element is selected for entry.
Forward	`onforward`	The user has clicked on the [FORWARD] button in the toolbar.
Help	`onhelp`	The user has pressed the [F1] key or selected [help] from the toolbar or menu.
KeyDown	`onkeydown`	When a key is pressed.
KeyPress	`onkeypress`	Pressing the key down and releasing it again elicits this event.
KeyUp	`onkeyup`	When a key is released.
Load	`onload`	When an object has completed loading.
LoseCapture	`onlosecapture`	When an element loses event capturing permission.
MouseDown	`onmousedown`	When the mouse button is pressed.
MouseDrag	`onmousedrag`	An event handler for mouse drag operations.
MouseMove	`onmousemove`	When the mouse pointer is moved.
MouseOut	`onmouseout`	When the mouse pointer leaves the active area occupied by the `Element` object that represents the object on screen.
MouseOver	`onmouseover`	When the mouse pointer enters the active area owned by the object.
MouseUp	`onmouseup`	When the mouse button is released.
Move	`onmove`	The browser window has been moved.
Paste	`onpaste`	When a paste operation happens.
PropertyChange	`onpropertychange`	When an object property is modified (similar to the Netscape Navigator `watch()` method).
ReadyStateChange	`onreadystatechange`	An object in the window has changed its ready state.
Reset	`onreset`	The user has clicked a reset button in a form.
Resize	`onresize`	As the window is resized, this event is triggered.
RowEnter	`onrowenter`	The data in a field bound to a data source is about to be changed.
RowExit	`onrowexit`	The data in a field bound to a data source has been changed.
Scroll	`onscroll`	The window has been scrolled.
Select	`onselect`	Some textual content in the window has been selected.
SelectStart	`Onselectstart`	A select action is beginning.
Start	`Onstart`	A marquee element is beginning its loop.

Table continued on following page

Event	Handler	Usage
Stop	`Onstop`	When a stop action occurs.
Submit	`Onsubmit`	The user has clicked on the submit button in a form.
Unload	`onunload`	Triggered when the document is unloaded.

In the topics that describe the events, the intercap (capitalised word breaks) form is used so that the event name reads more easily.

Warnings:

- Netscape version 4.0 allows event name properties to have some uppercase characters. For example, a portable script would set the `onchange` property. A non-portable script that only worked in Netscape would set the `onChange` property. It is probably best to avoid using this if you want your scripts to run as widely as possible.
- Not all versions of the browsers support the assignment of handlers to object properties. This depends on the object type, browser version and probably the phase of the moon.

See also:	Event, Event handler, Event model, Keyboard events, `Window.releaseEvents()`

Event object (Object/DOM)

Early Netscape and MSIE browsers define different event object models. In MSIE, a single `Event` object is available globally and shared by all events.

Availability:	DOM level – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
JavaScript syntax:	-	*myEvent* = event
	-	*myEvent* = *myWindow*.event
	N	*myEvent* = *myDocumentEvent*.createEvent(*aType*)
Argument list:	*aType*	An event type
Object properties:	altKey, bubbles, button, cancelable, cancelBubble, charCode, clientX, clientY, ctrlKey, currentTarget, data, dataFld, dataTransfer, eventPhase, fromElement, height, keyCode, layerX, layerY, modifiers, offsetX, offsetY, pageX, pageY, propertyName, qualifier, reason, recordset, repeat, returnValue, screenX, screenY, shiftKey, srcElement, srcFilter, srcUrn, target, timeStamp, toElement, type, which, width, x, y	

Class constants:	ABORT, ALT_MASK, AT_TARGET, BACK, BLUR, BUBBLING_PHASE, CAPTURING_PHASE, CHANGE, CLICK, CONTROL_MASK, DBLCLICK, DRAGDROP, ERROR, FOCUS, FORWARD, HELP, KEYDOWN, KEYPRESS, KEYUP, LOAD, LOCATE, META_MASK, MOUSEDOWN, MOUSEDRAG, MOUSEMOVE, MOUSEOUT, MOUSEOVER, MOUSEUP, MOVE, RESET, RESIZE, SCROLL, SELECT, SHIFT_MASK, SUBMIT, UNLOAD, XFER_DONE
Object methods:	initEvent(),preventDefault(),stopPropagation()
Collections:	bookmarks[],boundElements[]

The event models in Netscape version 4 and MSIE version 4 support an `Event` object. However, both browsers support different properties for this object. It may be possible with some smart JavaScript code to normalize these to look like the same object model. You could either define your own or take one and emulate it in the other.

As well as being different, the `Event` object is passed to event handlers in a different way for each browser. Netscape version 4 passes the `Event` object as an argument. MSIE version 4 stores a reference to it in the global variable called `event`.

Netscape provides a set of static constants that can be used to manufacture modifier masks. These can then be tested against the `Event.modifiers` property. These constants have names that all end with the suffix "`_MASK`". There are other constants provided so masks for event types can be made. These can be tested against the `Event.type` property.

MSIE does not support these static constants in the same way and uses fully spelled-out event names as string primitive values for matching. This ultimately may be better because Netscape is constrained for space as regards bit values for new events. There are only 32 bits and most have already been allocated to event types.

As of version 6.0 of Netscape, the underlying event model is based on the DOM level 2 event module. This is fundamentally different to the support of events in earlier versions of the Netscape browser. DOM level 2 and Netscape 6.0 converge on the same basic model as MSIE. This adds some new properties, methods and static constants in accordance with the DOM specification. Some properties persist from earlier versions.

The DOM level 2 specification for events describes a category of HTMLEvents which it suggests is based on DOM level 0 capabilities. There is only a small amount of information about the event type strings and the event capabilities in the DOM level 2 context. No ECMAScript binding is described and because DOM level 0 has never been published as a standard, there is a little ambiguity about these events. The standardization is somewhat de-facto regarding them and in due course, as the DOM event model evolves, this should all become more consistent and more completely documented.

Warnings:

- Properties belonging to an `Event` object cannot be set in Netscape unless the script has the `UniversalBrowserWrite` privilege. You also cannot watch events in other windows if they are loaded from different sources unless the script also has the `UniversalBrowserWrite` privilege.

- The properties and methods supported by Netscape and MSIE differ greatly in name and function. You will need to be very careful when building sophisticated event management capabilities into your scripts.
- Netscape does not implement all of the events for which there are static constants defined.

Example code:

```
// List the event constants in Netscape Navigator.
// This does not work in MSIE.
d  = document;
e  = Event;
s1 = "<TR><TD>";
s2 = "</TD><TD>";
s3 = "</TD></TR>";
d.write("<TABLE BORDER=1>");
d.write(s1 + "MOUSEDOWN" + s2 + e.MOUSEDOWN + s3);
d.write(s1 + "MOUSEUP"   + s2 + e.MOUSEUP   + s3);
d.write(s1 + "MOUSEOVER" + s2 + e.MOUSEOVER + s3);
d.write(s1 + "MOUSEOUT"  + s2 + e.MOUSEOUT  + s3);
d.write(s1 + "MOUSEMOVE" + s2 + e.MOUSEMOVE + s3);
d.write(s1 + "CLICK"     + s2 + e.CLICK     + s3);
d.write(s1 + "DBLCLICK"  + s2 + e.DBLCLICK  + s3);
d.write(s1 + "KEYDOWN"   + s2 + e.KEYDOWN   + s3);
d.write(s1 + "KEYUP"     + s2 + e.KEYUP     + s3);
d.write(s1 + "KEYPRESS"  + s2 + e.KEYPRESS  + s3);
d.write(s1 + "DRAGDROP"  + s2 + e.DRAGDROP  + s3);
d.write(s1 + "FOCUS"     + s2 + e.FOCUS     + s3);
d.write(s1 + "BLUR"      + s2 + e.BLUR      + s3);
d.write(s1 + "SELECT"    + s2 + e.SELECT    + s3);
d.write(s1 + "CHANGE"    + s2 + e.CHANGE    + s3);
d.write(s1 + "RESET"     + s2 + e.RESET     + s3);
d.write(s1 + "SUBMIT"    + s2 + e.SUBMIT    + s3);
d.write(s1 + "LOAD"      + s2 + e.LOAD      + s3);
d.write(s1 + "UNLOAD"    + s2 + e.UNLOAD    + s3);
d.write(s1 + "ABORT"     + s2 + e.ABORT     + s3);
d.write(s1 + "ERROR"     + s2 + e.ERROR     + s3);
d.write(s1 + "MOVE"      + s2 + e.MOVE      + s3);
d.write(s1 + "RESIZE"    + s2 + e.RESIZE    + s3);
d.write("</TABLE>");
```

Event.altKey (Property)

A Boolean value in MSIE that represents the state of the [alt] key.

Availability:	JScript – 3.0 Internet Explorer version – 4.0 Opera – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myEvent*.altKey

When an event is being processed, you may want to know the state of the *[alt]* key on the keyboard.

This Boolean property returns true when the *[alt]* key is pressed and false when it is not.

This property reflects the state of the *[alt]* key at the instant when the event was triggered. The user may have released the *[alt]* key in the meantime, so you should not assume that if the *[alt]* key was pressed earlier on that it is still pressed when the event handler is being executed.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.modifiers`, `MouseEvent.altKey`, `onKeyDown`

Property attributes:

`ReadOnly`.

Event.bookmarks[] (Collection)

A collection of all the ADO bookmarks tied to the rows affected by the current event.

JavaScript syntax:	ASP	*myEvent*.bookmarks

This is part of the ADO server side support in the Microsoft ASP server.

See also:	Active Server Pages, ADO

Property attributes:

`ReadOnly`.

Event.boundElements[] (Collection)

A collection of all the elements on the page that are bound to a dataset.

JavaScript syntax:	ASP	*myEvent*.boundElements

This is part of the ADO server side support in the Microsoft ASP server.

See also:	Active Server Pages

Property attributes:

`ReadOnly`.

Event.bubbles (Property)

A Boolean value that indicates whether the event can bubble or not.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	N *myEvent*.bubbles

If this value is `true`, then the event can bubble. That means it can propagate upwards to its parent node and onwards towards the head of the document hierarchy.

Property attributes:

`ReadOnly`.

Event.button (Property)

The mouse button that was pressed to trigger the event in MSIE.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myEvent*`.button`

This property will contain a value to indicate the mouse button that was pressed to trigger the event.

Note that on a Macintosh, this value is meaningless as there is only one button on an Apple Macintosh mouse although you can retrofit a third party 2 or 3 button mouse.

Third party mice can be added to Apple Macintosh systems to provide multiple (2 or 3) button functionality, but they are by no means commonplace and it is probably safe to assume only a 1 button mouse on the Macintosh platform.

The values for the buttons are defined to cope with 1, 2 or 3 button mice.

The following values correspond with mouse buttons:

- 0 – No mouse button was pressed when the event was triggered
- 1 – The left button was pressed
- 2 – The right button was pressed
- 3 – The middle button was pressed

DOM level 2 event handling moves this property to the `MouseEvent` object.

Warnings:

- This is not supported by Netscape which returns mouse button values and key codes in the same property (`which`).

See also:	`Event.which`, `MouseEvent.button`, `onClick`, `onDblClick`, `onMouseDown`, `onMouseUp`

Property attributes:

`ReadOnly`.

Event.cancelable (Property)

If the event can be cancelled, then this flag will be set `true`.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myEvent`*`.cancelable`

Events can be cancelled and have their default action prevented. If the event can support this, then the `true` value will be present. This will affect the value returned to the dispatcher that triggered the event. Dispatchers should behave consistently whether they are `EventTarget` objects or the implementation that the scripts are executing in.

Property attributes:

`ReadOnly`.

Event.cancelBubble (Property)

A flag that halts event bubbling in MSIE browsers.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myEvent`*`.cancelBubble = `*`aBooleanValue`*
Argument list:	*`aBooleanValue`*	A `true` or `false` setting

Event propagation passes events up the DOM hierarchy, calling the handler for each event in turn. This propagation effect can be stopped at once by setting the `cancelBubble` property to `true`.

Setting this property `true` in an event handler may improve stability in dynamically generated HTML fragments that have mouse rollover code associated with them.

For example, you can implement a ticker in JavaScript instead of Java. However, on some MSIE implementations (Macintosh for example), the browser crashes as you rollover several objects that have been created dynamically. Using the `cancelBubble` technique may stop runaway events from propagating and causing contention in the browser core.

See also:	Event propagation

Event.charCode (Property)

The character code of a key that was pressed to trigger the event relating to this object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myEvent*`.charCode`

Events may be triggered by keystrokes. This property provides a means of determining which key was pressed.

Note that this is a character code property so it is a character value mapped to a keyboard key and therefore should take account of internalization.

Event.clientX (Property)

MSIE mouse position relative to the web page.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myEvent*`.clientX`

This is the horizontal position of the mouse when the event was triggered. The position is calculated relative to the visible document area within the window or frame the mouse was positioned in when the event triggered.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.clientY`, `Event.pageX`, `Event.pageY`, `Event.screenX`, `Event.screenY`, `MouseEvent.clientX`

Property attributes:

`ReadOnly`.

Event.clientY (Property)

MSIE mouse position relative to the web page.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myEvent`*`.clientY`

This is the vertical position of the mouse when the event was triggered. The position is calculated relative to the visible document area within the window or frame the mouse was positioned in when the event triggered.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.clientX`, `Event.pageX`, `Event.pageY`, `Event.screenX`, `Event.screenY`, `MouseEvent.clientY`

Property attributes:

`ReadOnly`.

Event.ctrlKey (Property)

A Boolean value in MSIE that represents the state of the [control] key.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myEvent`*`.ctrlKey`

When an event is being processed, you may want to know the state of the *[control]* key on the keyboard.

This Boolean property returns true when the *[control]* key is pressed and false when it is not.

This property reflects the state of the *[control]* key at the instant when the event was triggered. The user may have released the key in the meantime, so you should not assume that if the *[control]* key was pressed earlier on that it is still pressed when the event handler is being executed.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.modifiers`, `MouseEvent.ctrlKey`, `onKeyDown`

Property attributes:

`ReadOnly`.

Event.currentTarget (Property)

A reference to the object whose listener is being called with the receiving `Event` object.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`EventTarget` object	
JavaScript syntax:	N	*myEvent*`.currentTarget`

This is a useful property which provides a means of sharing listener scripts between several event handlers. You can then determine which one of several objects was the `EventTarget` that had the event dispatched to it.

Property attributes:

`ReadOnly`.

Event.data (Property)

The URL of the data dropped into a the window from an `onDragDrop` event.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myEvent*`.data`

This property contains information that describes what was just dropped onto the object that owns the `onDragDrop` handler. Normally, that would be a URL that refers to the entity that was dropped.

Warnings:

- When using this property in Netscape, you will need the `UniversalBrowserRead` privilege to see the value and `UniversalBrowserWrite` privilege to change it.

See also:	`UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `Window.ondragdrop`

Property attributes:

`ReadOnly`.

Event.dataTransfer (Property)

A means of transferring drag and drop data via the `Event` object. This refers to a `dataTransfer` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`dataTransfer` object	
JavaScript syntax:	IE	*`myEvent`*`.dataTransfer`

The browser loads the object as it handles the drag and drop operation. Refer to the `dataTransfer` object topic for further details.

See also:	`dataTransfer` object

Event.eventPhase (Property)

Describes what phase the event is currently being processed in.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myEvent`*`.eventPhase`

A new concept that has been introduced at DOM level 2 is that of event phases. This allows your handler to determine the current disposition of an event from the script interface. You can examine the `eventPhase` property and test it against one of the predefined constants.

DOM level 2 introduces these static constants to the `Event` class to describe the current state of an event that is encapsulated by the `Event` object:

Value	Symbolic Name
1	CAPTURING_PHASE
2	AT_TARGET
3	BUBBLING_PHASE

See also:	Event type constants

Property attributes:

`ReadOnly`.

Event.fromElement (Property)

The object that the mouse is moving from.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Object` object	
JavaScript syntax:	IE	*myEvent*.fromElement

This property is useful in `onMouseOver` event handlers. It is a reference to the object that mouse was previously over when it entered an object. That object receives a `onMouseOver` event. It also knows about the `onMouseOver` object via the `toElement` property of the `Event` object.

See also:	`Event.toElement`

Property attributes:

`ReadOnly`.

Event.height (Property)

The new height of a resized window or frame.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myEvent*.height

If a window or frame is resized by the user, the new height value is available in this property.

See also:	`Event.width`

Event.initEvent() (Method)

An `Event` object initializer that must be called before dispatching the `Event` object to an `EventTarget`.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEvent*.initEvent(*aType*, *aBubble*, *aCancel*)

Argument list:	*aType*	A string indicating the event type
	aBubble	A boolean flag indicating whether the event can bubble
	aCancel	A boolean flag indicating whether the event can be cancelled

This method is used to initialize `Event` objects that have been created with the `DocumentEvent` object. It is intended that this be called at the outset although the DOM level 2 specification allows for an implementation to call it several times later on if necessary.

The event type argument value must conform to the conventions discussed in the `Event.type` topic.

The first of the remaining arguments is a flag value to indicate whether the event is bubbling or capturing in its behavior. The last argument is a flag to indicate whether the event can be cancelled.

See also:	`Event.type`

Event.keyCode (Property)

The code point for the key that was pressed in MSIE.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myEvent*`.keyCode`

This is the Unicode code point value and not the character code. This means the value is numeric.

You can also use the mask values to determine if any of the modifier keys were held down. Here is a list of the modifier key mask values:

Bit	Constant	Event type
2^0	ALT_MASK	The [alt] key was held down while key was pressed
2^1	CONTROL_MASK	The [control] key was held down while key was pressed
2^2	SHIFT_MASK	The [shift] key was held down while key was pressed
2^3	META_MASK	The [meta] key was held down while key was pressed

Warnings:

- This is not supported by Netscape which returns choice values in the `which` property value.

See also:	`Event.which`, `onKeyDown`

Event.layerX (Property)

The X coordinate of the event within a layer.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myEvent*`.layerX`

In Netscape, mouse positions are available within a `layer` object. These may not be the same positions as the mouse coordinates within a window. This is because a layer may have been scrolled with respect to the window. Nevertheless if you are working on the layer, you need coordinates that are relative to your target to save having to compute them.

Warnings:

- Netscape 6.0 completely removes layer support. If you use layers, your pages will break.

See also:	`Event.layerY`

Property attributes:

`ReadOnly`.

Event.layerY (Property)

The Y coordinate of the event within a layer.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myEvent*`.layerY`

In Netscape, mouse positions are available within a `layer` object. These may not be the same positions as the mouse coordinates within a window. This is because a layer may have been scrolled with respect to the window. Nevertheless if you are working on the layer, you need coordinates that are relative to your target to save having to compute them.

Warnings:

- Netscape version 6.0 completely removes layer support. If you use layers, your pages will break.

See also:	`Event.layerX`

Property attributes:

`ReadOnly`.

Event.modifiers (Property)

A bitmask provided by Netscape, which contains a bit flag for each modifier key.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myEvent`*`.modifiers`

The modifiers are supplied as a mask which needs to be assembled using bitwise OR techniques from the component values.

The mask values are summarized in this table:

Bit	Constant	Event type
2^0	ALT_MASK	The [alt] key was held down while key was pressed
2^1	CONTROL_MASK	The [control] key was held down while key was pressed
2^2	SHIFT_MASK	The [shift] key was held down while key was pressed
2^3	META_MASK	The [meta] key was held down while key was pressed

See also:	`Document.releaseEvents()`, `Event` object, `Event.altKey`, `Event.ctrlKey`, `Event.shiftKey`, Keyboard events, `Layer.releaseEvents()`, `onKeyDown`, `Window.releaseEvents()`

Property attributes:

`ReadOnly`.

Event.offsetX (Property)

The X coordinate of the event relative to its containing object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myEvent`*`.offsetX`

As you would expect, coordinate positions of the mouse are provided in mutually exclusive ways in Netscape and MSIE. This is the MSIE equivalent to the layer coordinate scheme in Netscape. Of course, MSIE does not have layers but they can be simulated by using arbitrary objects.

Warnings:

- The value in this property is calculated relative the coordinate system of the container of the source element that generated the event. This may not be the same as the coordinate scheme for the receiving object.

Property attributes:

`ReadOnly`.

Event.offsetY (Property)

The Y coordinate of the event relative to its containing object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myEvent`*`.offsetY`

As you would expect, coordinate positions of the mouse are provided in mutually exclusive ways in Netscape and MSIE. This is the MSIE equivalent to the layer coordinate scheme in Netscape. Of course, MSIE does not have layers but they can be simulated by using arbitrary objects.

Warnings:

- The value in this property is calculated relative the coordinate system of the container of the source element that generated the event. This may not be the same as the coordinate scheme for the receiving object.

Property attributes:

`ReadOnly`.

Event.pageX (Property)

Netscape mouse position relative to the web page.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myEvent`*`.pageX`

This is the Netscape mechanism for locating the mouse with respect to the window or frame coordinate address space. Of course it's different to the MSIE property that provides the same functionality. This means you need to build completely different event handling scripts for each platform, as if you didn't already have reason enough.

See also:	`Event.clientX`, `Event.clientY`, `Event.pageY`, `Event.screenX`, `Event.screenY`

Property attributes:

`ReadOnly`.

Event.pageY (Property)

Netscape mouse position relative to the web page.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myEvent`*`.pageY`

This is the Netscape mechanism for locating the mouse with respect to the window or frame coordinate address space. Of course it's different to the MSIE property that provides the same functionality. This means you need to build completely different event handling scripts for each platform, as if you didn't already have reason enough.

See also:	`Event.clientX`, `Event.clientY`, `Event.pageX`, `Event.screenX`, `Event.screenY`

Property attributes:

`ReadOnly`.

Event.preventDefault() (Method)

A means of preventing the default behavior from being activated after the event returns to its dispatcher.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0 Opera – 5.0	
JavaScript syntax:	N	*`myEvent`*`.preventDefault()`

This method only applies if the event can be cancelled. That is, if the `Event` object's `cancelable` property contains a true value. This value is readable but not writable. It is defined when the `Event` object is instantiated or initialized and cannot be changed later.

Calling this method at any time during the handling of the event will cancel the event immediately, returning control to the dispatcher. Any default handling will also be cancelled. You should be aware that if you dispatch an event from a script, it is your responsibility to make sure you check the return status of your dispatch call to ensure you do this consistently with implementation dispatched events.

Calling this method should cancel any subsequent event processing regardless of the kind of propagation being used. Any subsequent bubbling up or capturing should see that the event has been cancelled and should honor that without any further processing of the event.

Calling this method on an event whose `cancelable` property does not contain a `true` value should have no effect at all.

Event.propertyName (Property)

The name of a property that was changed and which triggered an `onPropertyChange` event.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myEvent`*`.propertyName`

This property is useful in the event handler code for the `onPropertyChange` event. You can also inspect the `srcElement` property of the same `Event` object to establish the object owning the changed property.

See also:	`Event.srcElement,onPropertyChange`

Event.reason (Property)

An indication of the status of a data transfer.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myEvent`*`.reason`

This is part of the database driven event handling which is triggered by a `DataSetComplete` event.

You can check this property to determine if the data transfer worked. The following values are supported:

- 0 – The transfer was successful
- 1 – The transfer was aborted prematurely
- 2 – Some kind of error occurred during the transfer

See also:	`onDataSetComplete`

Property attributes:

`ReadOnly`.

Event.repeat (Property)

If a keyboard can generate auto-repeating keystrokes, then this is set `true` when a keystroke is an auto-repeat of a previous one.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myEvent`*`.repeat`

Refer to:

`Event.keyCode`

Event.returnValue (Property)

A return value for the event.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myEvent`*`.returnValue`

You may want to modify the return value for the event handler. By assigning a new value to this property, the `returnValue` property of the event handler will be modified.

Because event handlers can only return a Boolean value, you only need to consider the possibility of changing the default `true` value to `false`.

If you return a `true` value, the event is handed back into the browser and it is able to continue handling the user interaction. For example, if a Click handler is introduced, it would behave as if the Click handler were not present.

Returning a `false` value informs the browser that your handler has done everything that is necessary to manage the event and it can now dispose of the event without any further action being taken on its part.

Event.screenX (Property)

Mouse position relative to the screen display.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0
Property/method value type:	`Number primitive`

JavaScript syntax:	-	*myEvent*.screenX

You may need to know the position of the mouse relative to the screen display coordinates and not the browser window or objects within it. This property provides the horizontal coordinate of the mouse within the screen.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.clientX`, `Event.clientY`, `Event.pageX`, `Event.pageY`, `Event.screenY`, `MouseEvent.screenX`

Property attributes:

`ReadOnly`.

Event.screenY (Property)

Mouse position relative to the screen display.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myEvent*.screenY

You may need to know the position of the mouse relative to the screen display coordinates and not the browser window or objects within it. This property provides the vertical coordinate of the mouse within the screen.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	`Event.clientX`, `Event.clientY`, `Event.pageX`, `Event.pageY`, `Event.screenX`, `MouseEvent.screenY`

Property attributes:

`ReadOnly`.

Event.shiftKey (Property)

A Boolean value in MSIE that represents the state of the *[shift]* key.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0

Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myEvent*.shiftKey

When an event is being processed, you may want to know the state of the *[shift]* key on the keyboard.

This Boolean property returns `true` when the *[shift]* key is pressed and `false` when it is not.

This property reflects the state of the *[shift]* key at the instant when the event was triggered. The user may have released the key in the meantime, so you should not assume that if the *[shift]* key was pressed earlier on that it is still pressed when the event handler is being executed.

DOM level 2 event handling moves this property to the `MouseEvent` object.

See also:	Event.modifiers, MouseEvent.shiftKey, onKeyDown

Property attributes:

`ReadOnly`.

Event.srcElement (Property)

An MSIE supported property containing the event source.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	Object reference	
JavaScript syntax:	IE	*myEvent*.srcElement

You can construct an event handler that is shared amongst several objects. If that is the case, this property allows you to determine which one triggered the event so that you can modify the event handler behavior accordingly.

See also:	Event.propertyName, Event.target, onPropertyChange

Property attributes:

`ReadOnly`.

Event.srcFilter (Property)

A filter object representing the filter that changed.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Property/method value type:	`Filter object reference`	
JavaScript syntax:	IE	*myEvent*`.srcFilter`

You can construct an event handler that is shared amongst several filters in MSIE. If that is the case, this property allows you to determine which one triggered the event, so that you can modify the event handler behavior accordingly.

Property attributes:

`ReadOnly`.

Event.stopPropagation() (Method)

Prevents propagation of event handling via bubbling or capture techniques.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0 Opera – 5.0	
JavaScript syntax:	N	*myEvent*`.stopPropagation()`

This is similar to event cancelling, but defers that cancellation until the end of the current handler. Any pending dispatches to the current `EventTarget` will be honored however.

Propagation of events to any parent node when bubbling is used or child nodes when event capturing is used will be inhibited.

Event.target (Property)

A property containing a reference to the object that the event was directed at.

Availability:	DOM level – 2 JavaScript – 1.2 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`EventTarget` object	
JavaScript syntax:	N	*myEvent*`.target`

You can construct an event handler that is shared amongst several target objects in Netscape. If that is the case, this property allows you to determine which one the event was aimed at, so that you can modify the event handler behavior accordingly.

DOM level 2 introduces the `EventTarget` object as a standard property, so it should be expected to be available more widely in due course than in the Netscape browser.

See also:	`Event.srcElement`, `MutationEvent.initMutationEvent()`

Property attributes:

`ReadOnly`.

Event.timeStamp (Property)

A time value at which the event was triggered.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myEvent*`.timeStamp`

This indicates the exact time (in milliseconds) when the event occurred. This should be equivalent to having called `Date.getUTCMilliseconds()` to obtain a measurement of the number of milliseconds since midnight on the first of January 1970.

The example demonstrates how this might be used to display an `alert()` dialog that indicates the number of milliseconds that have elapsed since the page was loaded.

The time stamp value here is the time the event was triggered. This is important because if you measure the time during an event handler, that may be some time after the event occurred. It may be important to collect a series of events and arrange them into sequence. The trigger time allows you to do this.

Warnings:

- The standard expects that this may not always be available, and that in such cases a value of zero should be returned.
- This feature appears to manifest a bug and unfortunately, the `Event` object does not seem to work with this property in the initial release of Netscape 6.0. This event model is a completely new implementation based on the DOM level 2 standard and so we might expect some instabilities in the early days.

Example code:

```
<HTML>
<HEAD>
<SCRIPT>
myLoadTime = new Date().getTime();
</SCRIPT>
</HEAD>
<BODY>
```

```
<SCRIPT>
document.write(myLoadTime);
</SCRIPT>
<HR>
<INPUT TYPE="BUTTON" VALUE="TOM" ONCLICK="measureTime(event);">
<SCRIPT>
function measureTime(anEvent)
{
   alert(anEvent.timeStamp- myLoadTime);
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Date` object, `Date.getUTCMilliseconds()`

Property attributes:

`ReadOnly`.

Event.toElement (Property)

The object to which the mouse is moving.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Object` object	
JavaScript syntax:	IE	*`myEvent`*`.toElement`

This property is useful in `MouseOut` event handlers. It is a reference to the object that the mouse is just entering when it left an object. That object receives a `MouseOver` event. It also knows about the `MouseOut` object via the `fromElement` property of the `Event` object.

See also:	`Event.fromElement`

Property attributes:

`ReadOnly`.

Event.type (Property)

A string that contains the event type name.

Availability:	DOM level – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myEvent*.type

The event types in pre-version 6.0 examples of Netscape are determined by matching against a bitmask, which is then used internally for capturing and routing events. Eventually during an event handler, an event is passed to a handler and the `type` property is set to a string that describes the event type.

The DOM level 2 event handling that is supported by Netscape version 6 works more like it did for the MSIE browser, although the event bubbling and event capture techniques are both available. The event type property is still available although the DOM level 2 event specification does not list a set of values but does mention some possible values incidentally. It does indicate that the value should be an XML name value as defined in the XML specification which simply describes its 'well formedness' but does not enumerate any valid event type values.

Certain name values are reserved. For example, the XML standard reserves all names beginning with "XML". The value is case-insensitive and this rule should apply after conversion from international characters to locale specific characters.

Likewise, the DOM standard reserves all names beginning with the string "DOM". It is also likewise case- and internationalization-insensitive in its reservation of this name start string.

The specification suggests that third party event definitions that are implementation-specific should include some kind of prefix to avoid namespace collisions.

Here are some Event type names that can be observed by closely inspecting the DOM level 2 event specification:

Value	Event object type
HTMLEvents	`HTML Element` objects
MouseEvents	`MouseEvent` object
MutationEvents	`MutationEvent` object
UIEvents	`UIEvent` object

The standard notes that Key events are not yet supported and will be added in a later DOM level.

See also:	`DocumentEvent.createEvent()`, Event type constants, `Event.initEvent()`, XML name

Property attributes:

`ReadOnly`.

Web-references:

http://www.w3.org/TR/1998/Rec-xml-19980210

Event.which (Property)

The number of the mouse button or the code point value of a key that was pressed in Netscape.

Availability:	JavaScript – 1.2 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myEvent*`.which`

Netscape uses a completely different means of determining which mouse button or keyboard key was pressed. It also detects *[alt]*, *[control]* and *[shift]* modifier keys using a different technique to that used by MSIE.

The mouse buttons don't even correspond to the same mapping as MSIE. Here are the mouse button value passed in the `which` property:

- 1 – The left button
- 2 – The right button in a two button mouse
- 2 – The middle button in a three button mouse
- 3 – The right button in a three button mouse

If the event is a keyboard triggered event, the `which` property will contain the ASCII character value of the keyboard key that was pressed. Note that it is the ASCII value and not the Unicode value although the distinction is very subtle.

DOM level 2 event handling replaces this property of the `Event` object with the `MouseEvent.button` property.

Warnings:

- This is not supported by MSIE, which uses the `button` and `keyCode` properties to return mouse button values and key codes separately from one another.

See also:	`Event.button`, `Event.keyCode`, Keyboard events, `MouseEvent.button`, `onClick`, `onDblClick`, `onKeyDown`, `onMouseDown`, `onMouseUp`

Property attributes:

`ReadOnly`.

Event.width (Property)

The new width of a resized window or frame.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`MyEvent`*`.width`

If a window or frame is resized by the user, the new height value is available in this property.

See also:	`Event.height`

Event.x (Property)

The X coordinate of the event within a positioned object.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myEvent`*`.x`

When this event is passed with a resize event in Netscape, this property indicates the width of the object having been resized.

Otherwise, in Netscape, it indicates the horizontal position of the mouse pointer measured relative to the layer in which the event occurred.

In MSIE, it indicates the horizontal position of the mouse pointer, measured relative to the parent element.

Property attributes:

`ReadOnly`.

Event.y (Property)

The Y coordinate of the event within a positioned object.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myEvent`*`.y`

When this event is passed with a resize event in Netscape, this property indicates the height of the object having been resized.

Otherwise, in Netscape, it indicates the vertical position of the mouse pointer measured relative to the layer in which the event occurred.

In MSIE, it indicates the vertical position of the mouse pointer, measured relative to the parent element.

Property attributes:

`ReadOnly`.

Event propagation (Definition)

The means whereby events are passed up a hierarchy of objects.

Event propagation is important and handled slightly differently in Netscape versus MSIE.

Events are processed by handlers in objects that support the event and are then passed upwards, being handled as necessary as they traverse a tree. This is especially useful when a single `event` object represents the event, as properties can be added or modified at each stage.

Propagation also saves you proliferating event handlers all over your script. It may be that you can handle all the errors you need to by attaching a handler at a high level and then waiting for events to be propagated up to it.

This would be fine apart from the fact that Netscape and MSIE model this in quite different ways. The only common factor between them is that events ultimately end up at the `window` or `document`. They arrive there by quite different means, but at least you do get one centralized opportunity to handle them.

Netscape prior to version 6.0 does it like this. First it makes a list of events that it wishes to capture. This is done with the `captureEvents()` method. Once the event capture bitmask is set up, you need to register some event handlers by assigning a reference to a function object to the event handler properties. Events are then only propagated by the event handler if it chooses to do so. The `routeEvent()` function passes the event to the next event that has signified an interest with the `captureEvents()` bitmask. Alternatively, you can use the `handleEvent()` function to pass the event to an object which will then select an appropriate handler. Event propagation in Netscape is very flexible but needs to be set up manually very carefully. Basically, events are captured at the top and passed down the tree to the leaf nodes.

MSIE implements an event propagation technique that operates in completely the opposite direction. Instead of starting the processing of events at the top of the DOM hierarchy, events start at the bottom and work their way upwards. This is more of a traditional event propagation model. If an event handler wants to inhibit the passing upwards of an event, it can do so by setting the `cancelBubble` property of the `Event` object to true. The so called Input or Raw events exhibit this bubbling effect while the Semantic events do not.

At version 6.0 of Netscape, the DOM level 2 event model is supported. This a complete reorganization of event modelling in Netscape and fits more closely with the event model in MSIE. The DOM standard appears to reach a helpful compromise though and allows for both kinds of event propagation. This event model is still undergoing some change and there are additional features at DOM level 3 which have yet to be ratified and are not implemented in any browser yet.

Warnings:

- Not all kinds of events in MSIE bubble up through the DOM hierarchy. This is because there are two distinct types of events. These are sometimes called raw events and semantic events. Raw events bubble and semantic events do not.

See also:	`CaptureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event bubbling, `Event.cancelBubble`, `Layer.captureEvents()`, `Layer.releaseEvents()`, Semantic event, `Window.captureEvents()`, `Window.handleEvent()`, `Window.releaseEvents()`, `Window.routeEvent()`

Event type constants (Constant/static)

Netscape defines a set of constants that represent event types.

Netscape provides some static properties of the `Event` object class that define mask values for event types. These can then be combined with a bitwise OR operator to build a mask that can be applied with the `captureEvents()` and `releaseEvents()` methods that are supported by `Window`, `Document` and `Layer` objects.

Here is a list of the available Event type constants:

Bit	Constant	Event type
2^0	MOUSEDOWN	The mouse button was pressed while the pointer was over the element.
2^1	MOUSEUP	The mouse button was released while the pointer was within the extent region of the element.
2^2	MOUSEOVER	The mouse has just moved over the extent region of the element.
2^3	MOUSEOUT	The mouse has just moved out of the extent region of the element.
2^4	MOUSEMOVE	The mouse was moved within the extent region of the element.
2^5	undefined	Reserved for future use.
2^6	CLICK	The element has been clicked on.

Table continued on following page

Bit	Constant	Event type
2^7	DBLCLICK	The element has been double-clicked on.
2^8	KEYDOWN	A key was pressed while the element had focus.
2^9	KEYUP	A key was released while the element had focus.
2^10	KEYPRESS	A key was pressed and released again while the element had focus.
2^11	DRAGDROP	Some entity has been dragged over and dropped onto the element.
2^12	FOCUS	The element has had input focus restored to it.
2^13	BLUR	Window or input element has lost input focus.
2^14	SELECT	An item in a pop-up menu was selected.
2^15	CHANGE	The input element's value has changed.
2^16	RESET	The [RESET] button within a <FORM> was clicked.
2^17	SUBMIT	The [SUBMIT] button within a <FORM> was clicked.
2^18	undefined	Reserved for future use.
2^19	LOAD	An element (usually a <BODY> or <IMG>) has completed loading.
2^20	UNLOAD	The element (usually a <BODY>) is about to be unloaded.
2^21	undefined	Reserved for future use.
2^22	ABORT	Image loading was aborted.
2^23	ERROR	A script error has occurred.
2^24	undefined	Reserved for future use.
2^25	MOVE	The element (usually a Window) was moved.
2^26	RESIZE	The element (usually a Window) was resized.
2^27	undefined	Reserved for future use.
2^28	undefined	Reserved for future use.
2^29	undefined	Reserved for future use.
2^30	undefined	Reserved for future use.
2^31	undefined	Reserved for future use.

See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Event` object, `Event.eventPhase`, `Event.type`, Keyboard events, `Layer.captureEvents()`, `Layer.releaseEvents()`, `Window.captureEvents()`, `Window.releaseEvents()`

EventCapturer object (Object/Navigator)

A special object that Netscape uses to grab events.

Availability:	JavaScript – 1.2 Netscape – 4.0	
JavaScript syntax:	N	*myEventCapturer* = window.open()

An object of this class is created when a `window.open()` method is executed in Netscape. Within the window, the `window` object is visible to the scripts running inside it. From outside, the creating script is handed an `EventCapturer` object as a handle on the window. In MSIE, you get a genuine `window` object back.

The properties of the Netscape `EventCapturer` object are difficult to inspect because they cannot be enumerated directly. The object, like many internal objects in Netscape has a constructor which can be inspected but the object is opaque otherwise.

Because the event manager complex is so new (and somewhat fragile in Netscape 6.0) it is hard to determine whether this is still true in that version. Some work needs to be done and a revised version of Netscape will be required before this can be verified.

See also:	`Window` object, `Window.open()`

EventException object (Object/DOM)

An object that describes the kind of event based exception that has occurred.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEventException* = new EventException()
Object properties:	`code`	
Class constants:	`UNSPECIFIED_EVENT_TYPE_ERR`	

During the processing of an event with its handler, some unexpected circumstance may cause an exception to occur. This is not quite the same as a `try ... catch` exception as defined in ECMAScript.

DOM level 2 describes an `EventException` object, but it's not obvious how this would be associated with any JavaScript function that could be set up to catch it. The DOM level 2 event specification is founded on the principle that the implementation should be at least ECMAScript (third edition) compliant. This should ensure it has sophisticated enough error handling support to cope with an exception being thrown. Neither specification describes in detail exactly how this should happen and so it is likely that, whilst we may have browsers that support a standard and consistent object model, we still have portability problems because they implement the surrounding infrastructure differently.

Assuming that a function handler were called, it would be passed a reference to an `EventException` object from which it could obtain a code value that describes the cause of the exception. Perhaps, the `onError` handler may be used to trap this but an implementation might choose to provide an `onException` handler.

At DOM level 2, only the `UNSPECIFIED_EVENT_TYPE_ERR` is defined as a static constant. This has the value 0. Other event types may be defined in later versions of the DOM specification.

See also:	EventTarget.dispatchEvent()

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
code	1.5 +	-	6.0 +	-	-	2 +	-

EventException.code (Property)

A property containing a code value that indicates which one of the available set of exceptions has occurred.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myEventException*.code

At DOM level 2, the event model only supports a single UNSPECIFIED_EVENT_TYPE_ERR code value.

It is expected that other exception values will be defined in subsequent levels of the DOM standard as they are released.

EventListener object (Object/DOM)

A script function that is called when an event is triggered.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEventListener* = function Listener(*anEvent*) { ... }
Argument list:	*anEvent*	A placeholder argument

This is an event handler function which you can define in the script source text and can then register as the listener for an event by means of the addEventListener() and removeEventListener() methods belonging to the EventTarget object.

The script function takes a single argument which is an Event object that is instantiated as the event is triggered.

Warnings:

- If you copy a document node with the `cloneNode()` method, the copies will not inherit the same listeners and you will need to add new listeners to handle any events that are dispatched to the new copies of the nodes.
- HTML 4.0 describes a way to associate listeners with objects as they are instantiated by means of the HTML tag attributes. However, to support multiple listeners, the internal mechanisms no longer use the member attribute mechanism for associating listeners with targets. This means that code that assigns values to the `onEventHandler` property family may no longer work as expected if you mix old and new style event handling techniques. Newer versions of browsers may deprecate the old way and may in subsequent versions render it unsupported.
- The DOM level 2 event model is somewhat ambiguous about this part of the event handling complex. It describes an event listener as having a `handleEvent()` method which is called. It is not clear how you would add a `handleEvent()` method as a member of a function object which was itself the element that was registered to receive the event.
- There may be changes to this aspect of the event model in later DOM levels to better support HTML based event specification.

See also:	`EventTarget.addEventListener()`, `MutationEvent` object

EventTarget object (Object/DOM)

A set of properties and methods that extend the behavior of DOM nodes to support event handling.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEventTarget* = *myEvent*.currentTarget
	N	*myEventTarget* = *myEvent*.target
	N	*myEventTarget* = *myMouseEvent*.currentTarget
	N	*myEventTarget* = *myMouseEvent*.relatedTarget
	N	*myEventTarget* = *myMouseEvent*.target
	N	*myEventTarget* = *myMutationEvent*.currentTarget
	N	*myEventTarget* = *myMutationEvent*.target
	N	*myEventTarget* = *myUIEvent*.currentTarget
	N	*myEventTarget* = *myUIEvent*.target
Object methods:	`addEventListener()`, `dispatchEvent()`, `removeEventListener()`	

Netscape version 6 introduces this capability and adds the `EventTarget` methods and properties to its `Node` objects. This provides the necessary tools for registering and deregistering event listeners and for dispatching an event to a `Node`.

See also:	`MouseEvent.initMouseEvent()`, `MouseEvent.relatedTarget`, `MutationEvent.initMutationEvent()`, `Node` object

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
addEventListener()	1.5 +	-	6.0 +	-	-	2 +	-
dispatchEvent()	1.5 +	-	6.0 +	-	-	2 +	-
removeEventListener()	1.5 +	-	6.0 +	-	-	2 +	-

EventTarget.addEventListener() (Method)

Add a listener function to handle events dispatched to the owning `EventTarget` node.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEventTarget*.addEventListener(*aType*, *aListener*, *aFlag*)
Argument list:	*aType*	A string containing the event type
	aListener	A reference to an `EventListener` function object
	aFlag	A Boolean value containing the `useCapture` disposition

The `addEventListener()` method will attach a function object to an `EventTarget` node in such a way that the function is called when the event is triggered. An `Event` object is passed to the function as an argument so you need to specify this in its declaration. This is how handler functions are registered as listeners.

You can replace a listener with another by registering a new listener with the same parameters. The old one will be discarded. If you want to stop the listener from responding to the event, you can deregister it with the `removeEventListener()` method.

The three parameters to the `addEventListener()` method are:

- A string describing the event type being registered.
- A reference to a function object that has been declared elsewhere in the script source text.
- A Boolean flag value that indicates whether the event listener should use bubbling (bottom up) or capture (top down) event propagation. Both types can be registered separately but must also be removed separately.

Examining the DOM level 2 specification suggests that these event type strings may be used:

Event string	Event object type	DOM
abort	HTMLEvent	2
blur	HTMLEvent	2
change	HTMLEvent	2
click	MouseEvent	2
DOMActivate	UIEvent	2

Table continued on following page

Event string	Event object type	DOM
DOMAttrModified	MutationEvent	2
DOMCharacterDataModified	MutationEvent	2
DOMFocusIn	UIEvent	2
DOMFocusOut	UIEvent	2
DOMNodeInserted	MutationEvent	2
DOMNodeInsertedIntoDocument	MutationEvent	2
DOMNodeRemoved	MutationEvent	2
DOMNodeRemovedFromDocument	MutationEvent	2
DOMSubtreModified	MutationEvent	2
error	HTMLEvent	2
focus	HTMLEvent	2
load	HTMLEvent	2
mousedown	MouseEvent	2
mousemove	MouseEvent	2
mouseout	MouseEvent	2
mouseover	MouseEvent	2
mouseup	MouseEvent	2
reset	HTMLEvent	2
resize	HTMLEvent	2
scroll	HTMLEvent	2
select	HTMLEvent	2
submit	HTMLEvent	2
unload	HTMLEvent	2

Note that the DOM level 2 event module specification is somewhat ambiguous on the specifics of event type values and you may want to refer to the specification if you are intending to exercise these capabilities in the Netscape Navigator version 6.0 browser. This functionality is fairly new and still in a state of evolution but since it is defined in a standard, it will become more widespread and is therefore the best way to ensure portability even if it takes a while for the various browser manufacturers to catch up and make their products compliant.

See also:	`Element.onevent`, `EventListener` object, `EventTarget.removeEventListener()`, `MutationEvent` object

EventTarget.dispatchEvent() (Method)

Create and send an event trigger to a target node.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myEventTarget*`.dispatchEvent(`*anEvent*`)`
Argument list:	*anEvent*	A reference to an `Event` object

Events can be created by your script independently of any other kind of event triggering. Indeed, they can be triggered using this mechanism from within the event handling complex because the event mechanisms specified by DOM level 2 must be re-entrant. That means they may be called recursively without any cross coupling of the local storage between nested or concurrent handlers.

Events triggered by this mechanism are handled in the same way as implementation generated events.

You must first create an `Event` object to pass as an argument to this method when you call it. The resulting Boolean value tells you whether the `preventDefault` flag was set by any of the listeners that were invoked. If this value is true, then any default behavior should be suppressed. It is quite important to provide a consistent level of support for this so that it behaves in the same way as an implementation controlled event dispatcher.

During the handling of the event being dispatched by this method, an `EventException` may be raised.

At DOM level 2, only the unspecified event type is available as an exception. This will be raised by an `unspecified` or `null` event type value.

See also:	`EventException` object

EventTarget.removeEventListener() (Method)

Deregister an event listener that was established with the `addEventListener()` method.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myEventTarget*`.addEventListener(`*aType*`,` *aListener*`,` *aFlag*`)`
Argument list:	*aType*	A string containing the event type
	aListener	A reference to an `EventListener` function object
	aFlag	A Boolean value containing the `useCapture` disposition

The `removeEventListener()` method will detach a previously registered function object from an `EventTarget` node. This will stop the event being handled by that target.

The three parameters to the `removeEventListener()` method are:

- A string describing the event type being registered.
- A reference to a function object that has been declared elsewhere in the script source text.
- A Boolean flag value that indicates whether the event listener should use bubbling (bottom up) or capture (top down) event propagation. Both types can be registered separately but must also be removed separately.

See also:	`Element.onevent`, `EventTarget.addEventListener()`

Exactly equal to (===) (Operator/identity)

The two values must be identically equal in value and type.

Availability:	ECMAScript edition – 3

Refer to:

Identically equal to (`===`)

Cross-references:

ECMA 262 edition 3 – section – 11.9.4

Exception (Definition)

An unexpected result from an expression evaluation.

An exception occurs when an expression yields a result that was not expected when you evaluate it. In numerical expressions, the `NaN` value is provided for just such a circumstance. `NaN` represents a numeric quantity that cannot be resolved within the range of meaningful values. The interpreter knows it is numeric but the value is wrong. The `undefined` and `Infinity` values also help in the management of such exceptions.

In general, the exception handling in JavaScript is better than that in a compiled language and therefore it is more forgiving. Its best efforts will usually be good enough to yield a working script where a compiled program may fail with a fatal error.

The DOM level 1 specification describes an enumerated set of exception codes as follows:

Value	Name	DOM
1	INDEX_SIZE_ERR	1
2	DOMSTRING_SIZE_ERR	1
3	HIERARCHY_REQUEST_ERR	1
4	WRONG_DOCUMENT_ERR	1
5	INVALID_CHARACTER_ERR	1
6	NO_DATA_ALLOWED_ERR	1
7	NO_MODIFICATION_ALLOWED_ERR	1
8	NOT_FOUND_ERR	1
9	NOT_SUPPORTED_ERR	1
10	INUSE_ATTRIBUTE_ERR	1
11	INVALID_STATE_ERR	2
12	SYNTAX_ERR	2
13	INVALID_MODIFICATION_ERR	2
14	NAMESPACE_ERR	2
15	INVALID_ACCESS_ERR	2

See also:	Expression, Infinity, `NaN`, undefined

Exception handling (Definition)

The process of managing errors.

This is enhanced in JavaScript version 1.3 by the addition of the `try ... catch` and `throw` statements.

See also:	`catch( ... ),throw,try ... catch ... finally`

execScript() (Method)

Execute a script.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	`execScript(`*`aSourceText`*`)`
	IE	*`myWindow`*`.execScript(`*`aSourceText`*`)`
Argument list:	*`aSourceText`*	Some legal JavaScript source

Refer to:

`Window.execScript()`

Executable code (Definition)

Script code that can be parsed and run as a program or function.

Availability:	ECMAScript edition – 2

Executable code is from the programmer's point of view a block of script source text that is parsed and executed by the interpreter.

There are five distinct types of executable code:

- Global code
- Eval code
- Function code
- Anonymous code
- Implementation-supplied code

See also:	Anonymous code, Eval code, Execution context, Function code, Global code, Implementation-supplied code

Cross-references:

ECMA 262 edition 2 – section – 10.1.2

ECMA 262 edition 3 – section – 10.1.2

Execute a function (Definition)

The act of calling a function during script execution.

Refer to:

Function call

Execution context (Definition)

An environment in which the script source code is executed.

Availability:	ECMAScript edition – 2

An execution context is the environment within which a portion of script code executes. If subsequent fragments of code are called, they are assembled to form a stack of execution contexts such that when one exits, the stack is popped and control returns to the immediate parent or caller.

The first item to be placed on the stack is the initial code that is considered to be global and is executed in a web browser as the page is parsed. Other types of host implementation may execute this global code at a different time. The topmost item on the stack is the code fragment that is currently executing. This might be the code in a called function or some code that is triggered by an event and is running as the handler for it.

Every execution context has associated with it its own variable object in which functions, formal parameters and variables are maintained as properties.

Each execution context also has its own private scope chain, which is a logical list of objects which are searched when name binding an identifier.

As the flow of control enters each execution context, its scope chain is created and initialized, variable instantiation is performed creating the variable object which in turn causes the arguments object to be created as well. At this time the value is also determined The particular values for these items depend on the kind of code being entered.

See also:	`Activation` object, Anonymous code, `argc` parameter, `Arguments` object, `argv` parameter, Eval code, Executable code, Function code, `Function` object, `Function.arguments[]`, Global code, `Global` object, Identifier resolution, Implementation-supplied code, `main()` function, Primary expression, Scope chain, `this`, Variable instantiation

Cross-references:

ECMA 262 edition 2 – section – 10

ECMA 262 edition 3 – section – 10

Execution environment (Definition)

The environment in which a script is executed.

The execution environment is where the script is run. In compiled languages, the translation environment and the execution environment may not be the same. JavaScript is interpreted and therefore the translation and execution environments are one and the same.

However, JavaScript can be transported across a network and may be executed in a server and then transferred to a client and executed there.

This means that the execution environment may change from time to time. The script should be aware of the context and environment it is being executed in if it needs to be portable in this way.

Future developments suggest that JavaScript may be available in hosted environments that will require the script to be delivered in a compact form. Indeed, some JavaScript interpreters are written in Java and decompose the script to Java byte-codes before executing them in the Java Virtual Machine. If these tokenized JavaScripts were transmitted to a remote machine, then JavaScript could be considered to be a compiled (or semi-compiled) language. In that case the translation environment would be different to the execution environment.

See also:	`argc` parameter, `argv` parameter, Environment, Garbage collection, Host environment, `main()` function, Script termination

Cross-references:

Wrox *Instant JavaScript* – page – 5

Exponent-log function (Definition)

Functions that calculate exponents and logs.

The ECMAScript standard defines several functions that calculate exponents and logs and several other value properties that are useful in this context:

- `Math.E`
- `Math.exp()`
- `Math.LN2`
- `Math.LN10`
- `Math.log()`
- `Math.LOG2E`
- `Math.LOG10E`

See also:	Integer-value-remainder, `Math` object, `Math.E`, `Math.exp()`, `Math.LN10`, `Math.LN2`, `Math.log()`, `Math.LOG10E`, `Math.LOG2E`, Power function, Trigonometric function

export (Statement)

Exports some properties to allow them to be imported into another execution context.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 Netscape – 4.0 Netscape Enterprise Server – 3.0	
JavaScript syntax:	N	`export` *`aFunction`*`;`
	N	`export` *`aProperty`*`;`
Argument list:	*`aFunction`*	A function object to export
	`aProperty`	a named property

ECMAScript edition 2 suggests this is a future extension. As of the third edition of the ECMAScript standard it is still denoted as a reserved word.

Netscape 4 anticipates that a future standard will endorse this capability and provides it anyway.

This functionality allows layers to define handlers for themselves and then export them to allow other layers or windows to call them.

This facility is also useful to allow controlled access via the security policy. This can then allow an unsigned script to have access to content in a signed script's context.

This is good Object Oriented Programming technique on the grounds that hiding the private data and making a public interface available means code can be reused. This black-box approach is much used in languages such as Java, SmallTalk and Objective-C.

Warnings:

- This only works in Netscape version 4 when the `LANGUAGE` attribute is set to "JavaScript1.2". This will affect the behavior of the `==` and `!=` operators as well.
- This can affect the security policy regarding the "same-signer" trustworthiness of a page.
- Be careful that you do not export a secure method or property and allow it to be executed or seen by insecure and untrusted non-signed scripts running in other windows.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
var myLocalVariable;
function myLocalFunction()
{
   document.write("Test");
}
export myLocalVariable;
export myLocalFunction;
</SCRIPT>
</BODY>
</HTML>
```

See also:	`import`, Same origin, Signed scripts

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

Expression (Definition)

Combining one or more operands with an operator creates an expression.

Availability:	ECMAScript edition – 2

An expression consists of an operand on its own, or a combination of operators and operands. An operand may be a constant value, a functional value, or a variable. Evaluating expressions can easily cause side effects, especially when functions are invoked.

Expressions are the contexts within which JavaScript operates on entities in its object model. There are a variety of different kinds of expressions according to whether you are referring to the destination or source of an assignment or reference.

Expressions fall into one of several categories according to the operator used in the expression.

The following expression types are defined in the ECMAScript standard:

Type	Description
Primary	A Primary Expression is a specific object, identifier or literal and may also be the result of evaluating another nested expression when it is surrounded by the grouping operators (round brackets).
Left-Hand-Side	This kind of expression identified the destination of an assignment (even if that assignment operation is only implied).
Postfix	Postfix expressions operate on Left-Hand-Side (sometimes called LValue) expressions.
Unary	Unary expressions can also be considered to be prefix expressions and also operate on LValues.
Multiplicative	Multiplicative expressions use the multiplicative operators to yield a result by operating on two other values which may themselves be nested.
Additive	Additive expressions use the additive operators to yield a result by operating on two other values which may be nested expressions.
Shift	Shifts the left value by an amount specified by the right value.
Relational	Relational expressions yield a Boolean result according to the relational test of the values either size of the operator.
Bitwise	Bitwise expressions perform a bit by bit operation across the entire integer width of the values.
Logical	Logical operators perform a test of the Boolean value of the two operands either side of the operator.
Conditional	Conditional expressions test a logical expression and perform one of two possible alternative code blocks.
Assignment	Assignment expressions can be broken down into a two-operand expression with the result being assigned to the value on the left.
Comma	Comma expressions occur rarely and are used to evaluate several expressions at once.

The operators are discussed in detail in individual topics. Refer to those topics for more details.

Expressions resolve eventually to a primary expression, which has a distinct value.

In a compound expression, the precedence (or "Who's on first") is governed by the operator selected for that sub-expression. However that operator-driven precedence model can be overridden by use of the grouping operators.

ECMA 262 edition 3 – section – 11

Expression statement (Definition)

Expressions do not necessarily have to be placed on the right of an assignment operator.

Availability:	ECMAScript edition – 2

An expression statement is an expression that is evaluated on a line by itself.

Expression statements consist of a stand-alone expression followed by a semi-colon (;).

An example of the main use of expressions in this context would be a function call. Since a function is a named block of code that can be called by putting its identifier into an expression, a function that does not return a value or where the value has been voided is being called like a procedure or sub-routine in other languages.

external (Property)

Reference to external objects outside of the interpreter.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`External` object	
JavaScript syntax:	IE	`external`
	IE	*`myWindow`*`.external`

See also:	`Window.external`

external object (Object/JScript)

Since MSIE can be embedded as a component into other applications, this object represents the object model of such a containing application.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*`myExternal`* `= external`
	IE	*`myExternal`* `=` *`myWindow`*`.external`
Object properties:	`menuArguments`	
Object methods:	`AddChannel(),AddDesktopComponent(),AddFavorite(), AddFavourite(),AutoCompleteSaveForm(),AutoScan(), ImportExportFavorites(),ImportExportFavourites(), IsSubscribed(),NavigateAndFind(),ShowBrowserUI()`	

Part of the MSIE on Windows environment object space. You should avoid using this facility if you want your scripts to be usable outside of the Windows environment.

To use this effectively, you need to know quite a bit about the application whose components you are calling in using this functionality. Each application has its own object model and unless you know how it works, making use of it will be a bit 'Hit and Miss'.

Warnings:

- Several methods for this object have arguments that are mandatory but may take empty strings or `null` values. This is somewhat diametrically opposed to the normal JavaScript behavior which dictates that unnecessary arguments are optional and can be assumed to be a default value when they are not present.

- By implementing methods with mandatory `null` or empty string values, Microsoft puts the script developer off balance and can cause unnecessary difficulty when developing scripts. Novices and even expert scripters may be caught out by this kind of implementation.
- You should always check the reference material if you are in any doubt as to how an API interface to a method is designed to work.

Property	JavaScript	JScript	N	IE	Opera	Notes
`menuArguments`	-	5.0 +	-	5.0 +	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
`AddChannel()`	-	5.0 +	-	5.0 +	-	-
`AddDesktopComponent()`	-	5.0 +	-	5.0 +	-	-
`AddFavorite()`	-	5.0 +	-	5.0 +	-	-
`AddFavourite()`	-	3.0 +	-	4.0 +	-	Warning
`AutoCompleteSaveForm()`	-	5.0 +	-	5.0 +	-	-
`AutoScan()`	-	5.0 +	-	5.0 +	-	-
`ImportExportFavorites()`	-	5.0 +	-	5.0 +	-	Warning
`ImportExportFavourites()`	-	3.0 +	-	4.0 +	-	Warning
`IsSubscribed()`	-	5.0 +	-	5.0 +	-	-
`NavigateAndFind()`	-	5.0 +	-	5.0 +	-	-
`ShowBrowserUI()`	-	5.0 +	-	5.0 +	-	Warning

external.AddChannel() (Method)

A means of adding a channel to an `external` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myExternal*.AddChannel(*aURL*)
Argument list:	*aURL*	The URL for a CDF file

With this method, you can use the Microsoft Active Channel system to share content delivered via channels.

This presents a dialog box allowing you to select a channel to add the channel defined in the argument or to specify a new one.

The argument value passed is a URL that points at a valid CDF file.

If the operation fails, an error event is generated and unless you are trapping the `onError` event with your own handler, the MSIE browser will present an error alert box.

See also:	`external.IsSubscribed()`, File extensions

external.AddDesktopComponent() (Method)

A means of adding an image or web site link to the desktop workspace.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myExternal*.AddDesktopComponent(*aURL*, *aType*)
	IE	*myExternal*.AddDesktopComponent(*aURL*, *aType*, *aLeft*)
	IE	*myExternal*.AddDesktopComponent(*aURL*, *aType*, *aLeft*, *aTop*)
	IE	*myExternal*.AddDesktopComponent(*aURL*, *aType*, *aLeft*, *aTop*, *aWidth*)
	IE	*myExternal*.AddDesktopComponent(*aURL*, *aType*, *aLeft*, *aTop*, *aWidth*, *aHeight*)
Argument list:	*aURL*	The URL where the resource can be located
	aType	What kind of item is added to the desktop
	aLeft	Left edge position
	aTop	Top edge position
	aWidth	Size width
	aHeight	Size height

This provides a way of customizing the underlying desktop with shortcuts and images.

You must always specify the URL value and the type indicator. The remaining option arguments describe the position and size of the item being placed on the desktop.

The type value must be one of:

- image
- website

This only works if you have the Active Desktop support installed. If it is not installed, this method does nothing.

Example code:

```
//Add the Wrox web site as a desktop item
window.external.AddDesktopComponent("http://www.wrox.com", "website", 100, 100,
200, 200);
```

external.AddFavorite() (Method)

Support for external applications and objects when using MSIE in the Windows environment. This adds an item to the favorites collection.

Availability:	JScript – 5.0 Internet Explorer – 5.0

JavaScript syntax:	IE	*myExternal*.AddFavourite(*aURL*)
	IE	*myExternal*.AddFavourite(*aURL*, *aName*)
Argument list:	*aURL*	A Url for a link in the bookmarks list
	aName	The name that goes in the menu list

With this method, you can add your own bookmarks to the favorites menu.

You must specify a URL value (otherwise there is no point in adding the bookmark). However, you need not specify the second argument which is the text displayed in the menu.

Typically you might provide a button on the page called "bookmark me" which might call some script to work out what the real URL should be. This gets round one of the major problems with framed sites in that a bookmark usually yields unpredictable results since you are accessing the site at a sub-framed level.

Example code:

```
// Bookmark a page from its current location
// using its document title string as an
// identifying text.
window.external.AddFavorite(location.href, document.title);
```

external.AutoCompleteSaveForm() (Method)

Support for external applications and objects when using MSIE in the Windows environment. This accesses the auto-complete mechanisms.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myExternal*.AutoCompleteSaveForm(*aForm*)
Argument list:	*aForm*	A reference to a `form` object

This method provides a way to save the contents of the text and password fields in the auto-complete storage area of your computer. Normally this would happen when the form is submitted but you can call this method to save the values without submitting the form.

If necessary, you can override the auto-complete capabilities for individual fields by means of the `AUTOCOMPLETE` HTML tag attribute being applied to the appropriate form input elements.

This method takes one argument that is mandatory. This argument is an object reference to the form whose fields are to be stored in the auto-complete registers.

external.AutoScan() (Method)

Connects to a web server using a template and registry scanning process to work out the target web server address from a partial domain name.

Availability:	JScript – 5.0 Internet Explorer – 5.0

JavaScript syntax:	IE	`myExternal.AutoScan(aDomain, anErrURL)`
	IE	`myExternal.AutoScan(aDomain, anErrURL, aTarget)`
Argument list:	`aDomain`	The domain address of a web site
	`anErrURL`	A URL to display if `aDomain` is inaccessible
	`aTarget`	The target window or frame to put the content into

This mechanism is used to find a web site when you are not certain of the URL.

The Registry in the client system contains a list of top level domains such as .com, .net, .org and .edu which will be tried one at a time until a valid connection is completed.

If none of these turns out to yield a working site address, then the error URL is accessed and displayed instead.

The browser will add the leading "www." to the domain address so you might only need to specify a domain value of "wrox" for the browser to eventually connect to "www.wrox.com".

external.ImportExportFavorites() (Method)

A mechanism for storing favorites lists on a server and getting them back later.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	`myExternal.ImportExportFavourites(aFlag, aURL)`
Argument list:	`aFlag`	A direction indicator
	`aURL`	A storage URL location

This is useful in a corporate environment where you may want to define a set of standard favorites and download them to the user's browser when they access the corporate Intranet.

Both arguments are mandatory so you must specify the direction and server location. This also requires that you have a server set up correctly to handle these requests.

The flag value should be `false` to save the favorites list and `true` to restore from the server.

When the method is called, the browser will ask you to confirm that you want to upload or download the favorites collection. The server needs to be carefully set up to erase any favorites that were previously stored unless you want to gradually accumulate a larger and larger collection of stored favorites. This deletion on the server does not propagate into the browser and any favorites retrieved from the server are merged with the existing set in the client browser.

It is not clear from the documentation whether duplicates are eliminated and if they are not, then it is likely that a later version of the browser would provide this capability.

If you do not specify a location value, then the browser will open a file dialog so you can import and export to the local file system. You must still provide an argument, but it can be an empty string to trigger this behavior.

Warnings:

- Oddly, this method can both save and retrieve the favorites using a flag value to determine the direction. This is slightly unusual and many similar actions in JavaScript provide one method to save and another to restore. You need to be constantly on the lookout for these kinds of inconsistent behaviors when developing JavaScript applications.

external.IsSubscribed() (Method)

Channel handling support is provided by this enquiry that determines whether the channel is registered.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myExternal`*`.IsSubscribed(`*`aURL`*`)`
Argument list:	*`aURL`*	The URL for a CDF file

You might want to enhance the script that adds channels by checking first to see if the user has already subscribed to a channel. That way you can avoid asking them the same question every time they enter the page that gives them access to the channel.

This query method returns a Boolean value `true` if the client is already subscribed and `false` if not.

The argument would be the same URL value that is used in the `addChannel()` method.

See also:	`external.AddChannel()`

external.menuArguments (Property)

The `window` object where a context menu was executed.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Window` object	
JavaScript syntax:	IE	*`myExternal`*`.menuArguments`

Once you have this window, you can inspect its `event` object to determine various properties that tell you about the user interaction.

external.NavigateAndFind() (Method)

This augments the anchor linking behavior and adds a highlighting capability.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myExternal*.NavigateAndFind(*aURL*, *aString*, *aTarget*)
Argument list:	*aURL*	The URL to link to
	aString	A string to be selected and highlighted
	aTarget	The frame or window to load the content into

You can use this method to link to a page and then highlight some fragment of text when it is loaded.

Although the target frame argument is mandatory, it can be an empty string.

external.ShowBrowserUI() (Method)

Accesses dialog panels that are built into the browser.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myExternal*.ShowBrowserUI(*aName*, null)
Argument list:	*aName*	The name of a UI dialog

This method takes two arguments although one is obviously a place holder. Both arguments are mandatory. The first indicates the dialog to be displayed while the second is a `null` value.

The values for selecting browser UI dialogs are:

- `LanguageDialog`
- `OrganizeFavorites`

Warnings:

- The API for this method breaks a rule of requiring a place holder argument to be set to `null` and yet mandating that it must be present. This is poor API design. It is possible that the argument may take undocumented values other than `null` which may alter its behavior but it should still be optional.

Fade() (Filter/transition)

A transition effect with the appearance of a dissolve between two images.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

filter – `Fade()`

false (Primitive value)

The Boolean false value.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

This is a Boolean primitive value representing the logically false state.

Conditional code execution depends on this value to signify the execution of a block of script code.

Warnings:

- Beware of a rather insidious effect when converting Boolean primitive values into objects. All objects yield the value `true` when converted back to a Boolean primitive. This also applies to a Boolean object having the value `false`.
- This `if()` test yields a `true` condition and selects the opposite branch to that which you would expect:

```
var myBoolean = new Boolean(false);

if(myBoolean)

{

 // This branch is called

}

else

{

 // You would have expected this one to be called

}
```

fdlibm (Product)

A publicly available library of math functions.

Availability:	ECMAScript edition –2

A freely distributable mathematical library available from Sun Microsystems. It supports the algorithms specified in IEEE 754. It is available by contacting fdlibm-comment@sunpro.eng.sun.com.

This library is commonly used to implement the mathematical functions belonging to the built-in native `Math` object.

Cross-references:

ECMA 262 edition 2 section 15.8.2

ECMA 262 edition 3 section 15.8.2

FIELDSET object (Object/HTML)

A field set within a form.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myFIELDSET* = *myDocument*.all.*anElementID*
	IE	*myFIELDSET* = *myDocument*.all.tags("FIELDSET")[*anIndex*]
	IE	*myFIELDSET* = *myDocument*.all[*aName*]
	-	*myFIELDSET* = *myDocument*.getElementById(*anElementID*)
	-	*myFIELDSET* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myFIELDSET* = *myDocument*.getElementsByTagName("FIELDSET")[*anIndex*]
HTML syntax:	`<FIELDSET> ... </FIELDSET>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey, align, form, margin, tabIndex`	
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDblClick, onDragStart, onErrorUpdate, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onScroll, onSelect, onSelectStart`	

A `FIELDSET` object represents a structured group of `Input` objects within a form. You can operate on them collectively. Grouping `Input` items might be useful for activating or hiding `Input` items without needing to access each one individually, which can be very useful if a form is undergoing rapid and continuous changes during its development. Controlling this with a `FIELDSET` allows the member elements to change without needing to modify your script.

See also:	`Element` object, `Input` object, `Input.accessKey`, `Legend` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
accessKey	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
align	-	3.0 +	-	4.0 +	-	-	-	-

onSelect	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	-
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

FIELDSET.align (Property)

The alignment of the field set within its surrounding objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFIELDSET*.align

The alignment of the `FIELDSET` object with respect to its containing parent object is defined in this property. The following alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

FIELDSET.margin (Property)

The margin around a fieldset to separate it from its surrounding objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myFIELDSET*.margin

You may want to place a margin round the fieldset of `Input` objects on screen. This property contains the current width settings for that margin.

File extensions (Definition)

A means of determining file content by a part of its file name.

JavaScript can be contained in a variety of file types. The one that you use, depends on what you plan to do with the script and the kind of environment it is being used in. Here is a summary of the file types you are likely to encounter:

Extension	Description
.123	Lotus 123 Document
.3dmf	QuickDraw 3D File
.509	Certificates
.669	669 MOD Music

Warnings:

- Beware of the `.pac` file extension. It is a `proxy.pac` auto-config file but it also represents an obscure image format supported by some plugins.

See also:	`.jar`, `.java`, `.js`, `<SCRIPT ARCHIVE="...">`, `<SCRIPT SRC="...">`, `external.AddChannel()`, Host environment, HTML file, Platform, `proxy.pac`

File object (Object/JScript)

A special JScript object representing a file on a locally mounted drive.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`myFile = File`
	IE	*`myFile`* `= new File(`*`aName`*`)`
	IE	*`myFile`* `= `*`myFileSystem`*`.GetFile(`*`aName`*`)`
	IE	*`myFile`* `= `*`myFileSystem`*`.CreateTextFile(`*`aName`*`, `*`aFlag`*`)`
	IE	*`myFile`* `= `*`myFileSystem`*`.OpenTextFile(`*`aName`*`, `*`aMode`*`, `*`aFlag`*`, `*`aFormat`*`)`
Argument list:	*`aName`*	The name of a file
	`aFlag`	A flag indicating whether the file can be overwritten
	`aMode`	An I/O mode for the file
	`aFormat`	A format code indicating ASCII or Unicode content

Object properties:	`Attributes, constructor, dataFld, dataSrc, DateCreated, DateLastAccessed, DateLastModified, defaultValue, Drive, Name, ParentFolder, Path, prototype, recordNumber, ShortName, ShortPath, Size, Type, value`
Object methods:	`blur(), byteToString(), clearError(), click(), close(), Copy(), Delete(), eof(), error(), exists(), flush(), focus(), getLength(), getPosition(), Move(), open(), OpenAsTextStream(), read(), readByte(), readln(), select(), setPosition(), stringToByte(), write(), writeByte(), writeln()`
Event handlers:	`onBlur, onClick, onDblClick, onFocus`

This object is available in many contexts. On the server-side, it allows access to the server file system. In that context it is available as part of the Netscape Enterprise Server product (see the separate `File` object entries for the NES version).

`File` objects may also exist client-side. Similar file system access may be possible there as well, although you should not expect this to work from within your browser. It may be available as part of a desktop scripting environment.

Although they aren't instantiated as `File` objects, it is sometimes convenient to refer to a `File` object when we really mean to refer to an `Input` object whose `type` property is set to the "`FILE`" value.

Warnings:

- Be aware that `File` objects are not standardized and may offer different methods, properties and functions in each context. Furthermore, the same named methods, properties and functions may not yield the same results across all implementations.
- The JScript `File` object and the identically named Netscape Enterprise Server `File` object do not share any properties or methods. They are completely different implementations.
- The JScript `File` object is somewhat odd in that its properties and methods are spelled with a capital letter at the start of their name. This is not typical JavaScript or JScript usage so you should beware of capitalization when scripting `File` objects with JScript.

File.Attributes (Property)

The file-system attributes of a file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	IE	*myFile*.Attributes

The `File` object is available for client-side use with the MSIE browser. This property contains its file system attributes.

This property manages the attributes as a bit-mask with individual bits controlling different attributes. The bits can be accessed individually using the integer value corresponding to a power of 2. The table lists the integers that represent each different attribute:

Value	Attribute
0	No special attributes –normal file.
1	Read only access.
2	Hidden file.
4	Indicates a system file.
8	Refers to drive volume label and cannot be altered.
16	Refers to a folder and cannot be changed.
32	File has changed and needs to be backed up again.
64	File object represents a shortcut and not a real file.
128	File is compressed.

You can use Bitwise OR expressions to merge them or accomplish the same with integer additions.

You cannot alter the settings of bits 8, 16, 64 and 128 as these affect the structure of a file. That is to say, you cannot change a file into a folder or disk volume.

You should read the current attributes setting and then modify it to write it back. The example illustrates some simple functions that encapsulate this conveniently.

Where the bit needs to be set, a simple bitwise OR with a single bit value is accomplished in a single line. To clear a bit, we could use a bitwise AND having the corresponding bit clear. In these examples a different technique is used for illustration where the bit is set regardless of its previous state and is then cleared using a subtraction. That saves the computation of a complex bit-mask. An intermediate temporary variable is used to avoid signalling the operating system with unnecessarily modification requests.

There are other alternative ways to accomplish this and you could write some generic functions to examine, set or clear a bit in a bit-mask and then call them from each of these wrappers indicating the bit you want to operate on.

Example code:

```
// Examine the read/write flag
function isReadOnly(aFile)
{
   return Boolean(aFile.Attributes & 1);
}
// Set the file read only
function setReadOnly(aFile)
{
   aFile.Attributes |= 1;
}
```

```
// Set the file read/write
function setWriteOnly(aFile)
{
   var myAttributes = aFile.Attributes |= 1;
   aFile.Attributes = myAttributes - 1;
}
// ----------------------------------------------------
// Examine the hidden flag
function isHidden(aFile)
{
   return Boolean(aFile.Attributes & 2);
}
// Hide the file
function setHidden(aFile)
{
   aFile.Attributes |= 2;
}
// Reveal the file
function setVisible(aFile)
{
   var myAttributes = aFile.Attributes |= 2;
   aFile.Attributes = myAttributes - 2;
}
// ----------------------------------------------------
// Examine the system flag
function isSystemFile(aFile)
{
   return Boolean(aFile.Attributes & 4);
}
// Set file to be a system file
function setSystem(aFile)
{
   aFile.Attributes |= 4;
}
// Set file to be a non system file
function setPublic(aFile)
{
   var myAttributes = aFile.Attributes |= 4;
   aFile.Attributes = myAttributes - 4;
}
// ----------------------------------------------------
// Examine the drive volume flag
function isDriveVolume(aFile)
{
   return Boolean(aFile.Attributes & 8);
}
// ----------------------------------------------------
// Examine the folder flag
function isFolder(aFile)
{
   return Boolean(aFile.Attributes & 16);
}
// ----------------------------------------------------
// Examine the backup flag
function needsBackup(aFile)
{
```

```
   return Boolean(aFile.Attributes & 32);
}
// Set backup required
function setBackup(aFile)
{
   aFile.Attributes |= 32;
}
// Clear backup
function clearBackup(aFile)
{
   var myAttributes = aFile.Attributes |= 32;
   aFile.Attributes = myAttributes - 32;
}
// ------------------------------------------------
// Examine the shortcut flag
function isShortCut(aFile)
{
   return Boolean(aFile.Attributes & 64);
}
// ------------------------------------------------
// Examine the compressed flag
function isCompressed(aFile)
{
   return Boolean(aFile.Attributes & 128);
}
```

See also:	`Folder.Attributes`

File.Copy() (Method)

A method that copies files.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFile*.Copy(*newFileName*, *aFlag*)
Argument list:	*newFileName*	The new file name to copy the file to
	aFlag	An indication of whether to overwrite or not

When operating on files on the client platform with MSIE, this method provides a means of copying files within the file system.

The destination argument needs to be a valid location within the file system the `File` object belongs to. Given that computers allow for the mounting of foreign file systems through a variety of different techniques, the target file system path may be constructed quite differently to that of the source path.

See also:	`FileSystem.CopyFile()`,`Folder.Copy()`

File.DateCreated (Property)

The creation date of the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.DateCreated`

The date the file was first created. This is obtained by inspecting the file system and directory information for the file.

See also:	`Folder.DateCreated`

File.DateLastAccessed (Property)

The date that a file was last accessed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.DateLastAccessed`

The date that the file was last accessed by an application. This is obtained by inspecting the file system and directory information for the file.

See also:	`Folder.DateLastAccessed`

File.DateLastModified (Property)

The last modified data for a file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.DateLastModified`

The date that the file was last modified by being written to. This is obtained by inspecting the file system and directory information for the file.

See also:	`Folder.DateLastModified`

File.Delete() (Method)

A method that deletes files.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFile*.Delete()

If need be, you can delete a file from the file system in the client environment. This may not be possible from a web browser due to the security protections surrounding the browser.

However, JScript is available as a general purpose scripting tool as part of the WSH facility on Windows. In that context it may well need to be able to delete a file.

File.Drive (Property)

The drive name that the file is stored on.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myFile*.Drive

This returns the drive name describing the drive that the file is currently stored on.

See also:	Folder.Drive

File.Move() (Method)

A file move method.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFile*.Move(*aPath*)
Argument list:	*aPath*	The new target part for the file

You may use this method in the Windows environment to move a file to a different folder within the file system. This follows the Unix tradition of calling the Rename command a Move command.

The destination path should be valid for the file system which the file is being moved. Given that computers allow for the mounting of foreign file systems through a variety of different techniques, the target file system path may be constructed quite differently to that of the source path.

See also:	FileSystem.MoveFile(),Folder.Move()

File.Name (Property)

The name of the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.Name`

The name portion of the file's full path and name is returned by this property.

You can also change the contents of this property to rename the file without moving it from the folder it is currently kept in.

See also:	`Folder.Name`

File.OpenAsTextStream() (Method)

A means of opening the file as if it were a text stream so JScript can do I/O on it.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`TextStream object`	
JavaScript syntax:	IE	`myFile.OpenAsTextStream(aMode, aFormat)`
Argument list:	*`aMode`*	An access mode for the file
	`aFormat`	A format control for the file

This method opens the file for JScript so that it can access or modify its contents when the JScript interpreter is in the Windows environment.

The mode parameter should be one of:

- `ForReading`
- `ForWriting`
- `ForAppending`

The format parameter can be set to open the file with a Unicode or ASCII character set. The default is ASCII if you request the system default value. These values are indicated with a numeric value as follows:

Value	Format
`-2`	Use system default
`-1`	Unicode text format
`0`	ASCII text format

See also:	`FileSystem.OpenTextFile()`, `TextStream` object

File.ParentFolder (Property)

The parent folder that contains the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*`myFile`*`.ParentFolder`

The `File` object represents a file living within a folder in the file system. This property returns an object that represents the folder containing the file.

See also:	`Folder` object, `Folder.ParentFolder`, `Folder.SubFolders[]`

File.Path (Property)

The path within the file system that locates the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.Path`

The full path to reach the file within the file system is yielded by this property.

See also:	`Folder.Path`

File.ShortName (Property)

The DOS 8.3 filename for the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myFile.ShortName`

In the Windows environment, even though long file names are used from the user's point of view, at the lowest level within the file system some files will still be stored under their old style DOS 8.3 format file names. This property yields the DOS equivalent short file name for a `File` object.

See also:	`Folder.ShortName`

File.ShortPath (Property)

The DOS 8.3 compatible path to the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.ShortPath`

In the Windows environment, even though long file and folder names are used from the user's point of view, at the lowest level within the file system some folders and files will still be stored under their old style DOS 8.3 format file names. This property yields the DOS equivalent path name for a `File` object.

See also:	`Folder.ShortPath`

File.Size (Property)

The size of the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myFile`*`.Size`

The size of the file measured in bytes is yielded by this property. This is effectively the same as the value returned by the `getLength()` method in the NES server environment.

See also:	`Folder.Size`

File.Type (Property)

The type of the file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFile`*`.type`

The file type extension of the file is yielded by this property. In the past, extensions conformed to a three character standard. With the cross mounting of foreign file systems which did not conform to the DOS 8.3 standard, file extensions can be of any length although they are usually less than five characters long.

It is normal to hide the file extensions from the users of desktop systems. In that case you may want to hold the filename and extension separately, so that you can hide the file extension to be consistent with what your users see on the desktop.

See also:	`Folder.Type`, `Input.type`

Property attributes:

`ReadOnly`.

File object (Object/NES)

An object that encapsulates a file on the local file system within the server.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
JavaScript syntax:	NES	*myFile* = File
	NES	*myFile* = new File(*aName*)
Argument list:	*aName*	A valid file name
Object methods:	byteToString(), clearError(), close(), eof(), error(), exists(), flush(), getLength(), getPosition(), open(), read(), readByte(), readln(), setPosition(), stringToByte(), write(), writeByte(), writeln()	

You can create a new instance of this class with the `File()` constructor.

Files tend to behave in a somewhat similar way in all languages and implementations. This generally means that they will read and write in 8 bit character sized elements. Beware of this as JavaScript is Unicode based so file contents may not exactly mirror the in-memory representation of a string.

Warnings:

- Be careful not to confuse this with the JScript `File` object. The JScript object may be supported in a Microsoft server but the Netscape Enterprise Server supports an object with a mutually exclusive set of properties and methods and neither kind of `File` object has any chance of being portable between a Netscape Enterprise Server and a Microsoft server. There are so many other differences between their object models that it is a waste of time trying to write a portable server-side script.

See also:	Netscape Enterprise Server, `unwatch()`, `watch()`

Method	JavaScript	JScript	NES	Notes
byteToString()	1.1 +	-	2.0 +	-
clearError()	1.1 +	-	2.0 +	-
close()	1.1 +	-	2.0 +	-
eof()	1.1 +	-	2.0 +	-

Method	JavaScript	JScript	NES	Notes
error()	1.1 +	-	2.0 +	-
exists()	1.1 +	-	2.0 +	-
flush()	1.1 +	-	2.0 +	-
getLength()	1.1 +	-	2.0 +	-
getPosition()	1.1 +	-	2.0 +	-
open()	1.1 +	-	2.0 +	-
read()	1.1 +	-	2.0 +	-
readByte()	1.1 +	-	2.0 +	-
readln()	1.1 +	-	2.0 +	-
setPosition()	1.1 +	-	2.0 +	-
stringToByte()	1.1 +	-	2.0 +	-
write()	1.1 +	-	2.0 +	-
writeByte()	1.1 +	-	2.0 +	-
writeln()	1.1 +	-	2.0 +	-

File() (Constructor)

A constructor for creating new instances of the `file` object in an NES server.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`File object`	
JavaScript syntax:	NES	`new File(`*`aFileName`*`);`
Argument list:	*`aFileName`*	A file path and name that is valid within the local file system

This constructor is used for creating new `File` objects, like this:

```
myFileObject = new File("/some/path/to/a/folder/filename.txt");
```

File.byteToString() (Method)

Convert a byte value into a string.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`String object`	
JavaScript syntax:	NES	*`myFile`*`.byteToString(`*`aNumber`*`)`
Argument list:	*`aNumber`*	A byte value to be converted to a string

This method provides a way of converting a single numeric value that represents a code point in the native character set to a character than can be written to a file from a string variable.

There is other similar functionality supported as a static method of the `String` object.

See also:	`File.stringToByte()`,`String.fromCharCode()`

File.clearError() (Method)

Reset the error property value.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
JavaScript syntax:	NES	*myFile*`.clearError()`

If the file access caused an error, you can clear that error status value by calling this method.

See also:	`File.error()`

File.close() (Method)

Close the file that was opened with the `File.open()` method.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	*myFile*`.close()`

This method closes a file that was opened for reading, writing or appending. It returns a Boolean value to indicate the success or failure of the closure.

See also:	`File.open()`

File.constructor (Property)

A reference to the constructor function for this object.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Function object`	
JavaScript syntax:	NES	*myFile*`.constructor`

The constructor is that of the built-in `File` prototype object.

You can use this as one way of creating file objects although it is more popular to use the new `File()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

File.eof() (Method)

This method returns a flag indicating whether we are at the end of the file or not.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	*`myFile`*`.eof()`

If we are currently positioned at the end of the file (the `getLength()` and `getPosition()` method calls return an equivalent value), then this method returns the Boolean `true` value. Any other position within the file will return `false`.

A zero length file can only ever have a file pointer positioned at its end of file so it will always return `true` if the `getLength`() method returns zero.

File.error() (Method)

An accessor function for the error property.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myFile`*`.error()`

If an error occurs during an operation on a `File` object, this property will yield the value of that error. You will need some additional source of reference to make sense of the possible error codes that might be presented by this method, as they will be operating system specific.

See also:	`File.clearError()`

File.exists() (Method)

A method that returns a flag to indicate whether the file exists or not.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	`myFile.exists()`

This method returns the Boolean `true` value if the file already exists within the file system and a Boolean `false` value if it does not.

File.flush() (Method)

Purges the output buffer to the file after some writing.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
JavaScript syntax:	NES	*`myFile`*`.flush()`

File writing tends to involve a certain amount of buffering by the file manager in the environment in which you are accessing the files. This is necessary to improve performance and throughput. The data is only physically transferred to the file when a buffer full of data is ready or when the file buffer is closed. This can mean that a JavaScript error can leave the file incomplete if it fails in a way that prevents the file from being closed properly. A run-time error would normally not write any pending data out to a file.

The `flush()` method allows you to force the file contents to be updated so that the file is complete and there are no pending contents yet to be written. You might force a `flush()` at the end of a record for example.

A `flush()` method may be called for much more frequently if you are using fixed length records and manually maintaining an index structure at the front of the file.

See also:	`File.write(),File.writeByte(),File.writeln(), response.flush()`

File.getLength() (Method)

Returns the length of the file measured in 8 bit characters.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*`myFile`*`.getLength()`

The length of the file is returned. You may want to compute a position within the file based on this value and use it with the `setPosition()` method later on.

See also:	`File.setPosition()`

File.getPosition() (Method)

Returns the current position in the file where the next read or write is to take place.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myFile*`.getPosition()`

The position of the file pointer within the file is returned relative to the beginning of the file. You can then use this value with the `setPosition()` method.

See also:	`File.setPosition()`

File.open() (Method)

Opens a file for reading, writing or appending.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
JavaScript syntax:	NES	*myFile*`.open(`*aMode*`);`
Argument list:	*aMode*	A mode of opening the file (read, write, append)

This method opens the file that is encapsulated by the `File` object.

C language programmers will be immediately familiar with this method. It behaves very similarly to the `fopen()` call in the ANSI C language libraries. The difference is that this method lacks a filename argument which is moved to the constructor function which is called separately.

The following flag values can be used with this method:

Flag	Description
r	Opens the file for reading
r+	Opens the file for reading and writing
w	Opens the file for writing
w+	Opens the file for writing and reading

Table continued on following page

Flag	Description
A	Opens the file for appending
a+	Opens the file for reading and appending
br	Opens a Windows binary file for reading
br+	Opens a Windows binary file for reading and writing
bw	Opens a Windows binary file for writing
bw+	Opens a Windows binary file for writing and reading
ba	Opens a Windows binary file for appending
ba+	Opens a Windows binary file for reading and appending

If you are using this in a server-side application (within NES), you should make sure the project locking is activated to avoid file corruption happening if there are multiple simultaneous accesses to the file.

Example code:

```
<SERVER>
// Example file create, open and write taken from
// Wrox Professional JavaScript
myFile = new File("file.txt");
myFile.open("a");
myFile.writeln("Append this line to the file.");
myFile.close();
</SERVER>
```

See also:	`File.close()`,`FileSystem.CreateTextFile()`, `FileSystem.OpenTextFile()`,`project.lock()`

File.prototype (Property)

The prototype for the `File` object which can be used to extend the interface for all `File` objects.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`File object`	
JavaScript syntax:	NES	`File.prototype`
	NES	*`myFile`*`.constructor.prototype`

Refer to:

`prototype` property

File.read() (Method)

Reads a string of characters from the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myFile*`.read(`*aByteCount*`)`
Argument list:	*aByteCount*	Read this many bytes from the file

When you call this method, you need to indicate the length of the string you want to retrieve.

You might use this in a record structured file where the records are all of a fixed length.

See also:	`File.readByte(),File.readln(),File.write()`

File.readByte() (Method)

Reads a single byte or character from the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myFile*`.readByte()`

When this reads a byte, the position register for the `File` object is indexed onwards by one item.

This would be used to read a file as a stream of characters where the individual records will need to be determined by the script as it reads and buffers the file.

See also:	`File.read(),File.readln(),File.writeByte()`

File.readln() (Method)

Reads from the current position up to the next newline character in the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*myFile*`.readln()`

After this method returns the string read from the file, the position pointer is then located at the beginning of the next line.

You would use this to read records that are variable length and terminated by a newline character.

See also:	`File.read()`,`File.readByte()`

File.setPosition() (Method)

Sometimes you may need to reposition the file pointer. This method allows you to position it at exactly the right place.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	*`myFile`*`.setPosition(`*`aPosition`*`)`
	NES	*`myFile`*`.setPosition(`*`aPosition`*`, `*`aControl`*`)`
Argument list:	*`aControl`*	A means of indicating what kind of offset to use
	`aPosition`	A valid position within the file

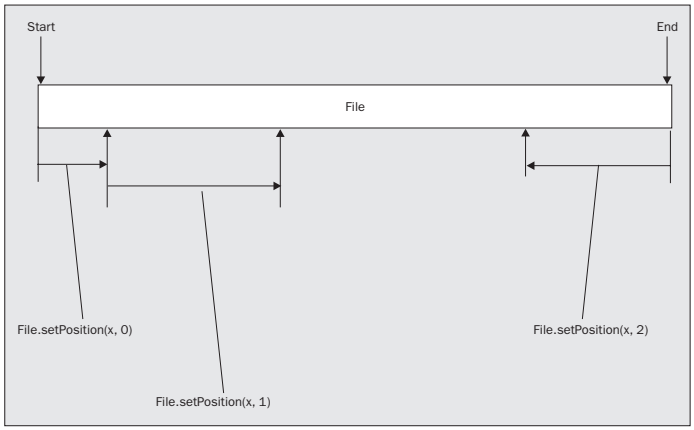
File positioning mechanisms are a fundamental part of building indexed record oriented files and managing fixed length records and fields in a sequential and variable length file structure.

The position control takes an integer value that selects a reference technique for setting the new position value.

A position control value of `0` (zero) indicates the new position should be measured from the start of the file.

A position control value of `1` adds the offset to the current position. This should allow forwards or backwards movement relative to the current position.

A position control value of `2` is measured relative to the end of the file.



See also:	`File.getLength()`,`File.getPosition()`

File.stringToByte() (Method)

Converts the first character of the string argument into a byte value.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*myFile*`.stringToByte(`*aString*`)`
Argument list:	*aString*	A string containing at least one character

This converts a single character to a numeric value. It is equivalent to the character to number conversions supported by the `String` object.

See also:	`File.byteToString()`,`String.charAt()`, `String.charCodeAt()`

File.write() (Method)

Writes a string of data out to the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	*myFile*`.write(`*aString*`)`
Argument list:	*aString*	Some text to be written to the file

As the string is written to the file, the method will return a Boolean value that indicates success or failure of the write access.

The length of the content is the controlling factor here. This might be used to write individual fields of a variable length record structure or, if you have loaded the string value you intend to write with a fixed length value, you can use this to write fixed length data to a file.

See also:	`File.flush()`,`File.read()`,`File.writeByte()`, `File.writeln()`

File.writeByte() (Method)

Writes a single byte to the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server–2.0	
JavaScript syntax:	NES	*myFile*.writeByte(*aNumber*)
Argument list:	*aNumber*	The value of a byte to be written to the file

This is the complement of the `readByte()` method which is used to write a continuous stream of character bytes to a file. This imposes no structure on the file other than that which you contrive with your JavaScript code.

See also:	`File.flush()`,`File.readByte()`,`File.write()`, `File.writeln()`

File.writeln() (Method)

Writes a string and automatically place a newline character after it in the file.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
JavaScript syntax:	NES	*myFile*.writeln(*aString*)
Argument list:	*aString*	Some text to be written to the file

This method is functionally very similar to the `write()` method. In this case however, an additional trailing newline character is added automatically by the method. You could append the newlines yourself and use the `write()` method instead.

Use this technique to write variable length records to a file.

See also:	`File.flush()`,`File.write()`,`File.writeByte()`

file: URL (Request method)

Loads a local file into a window.

This request method is useful for retrieving files from the local file systems or can be used to display a window containing the HTML version of a directory in the client machine.

The file path values are platform dependent although web browsers tend to understand Unix path rules and convert them to the local platform specific conventions, although MSIE doesn't do this quite as well when navigating local file systems.

On MSIE for Windows, you must at least specify a disk drive letter because the Unix root directory is not mapped. This presents network mapped drives and removable media all at the same peer level. So start with this:

```
file:c:\
```

MSIE is so well integrated into the Windows environment that it immediately recognizes that you are browsing the file system and goes into desktop explorer mode. This adds a folder icon to the toolbar and you can then navigate exactly as you would from the desktop.

The web browsers attempt to take this functionality across to other platforms and so on the Macintosh, with MSIE, try this:

```
file:/
```

MSIE version 5.0 does a much better job and is aware of local network zones and can see other machines connected via the AppleTalk protocol. Given that you can satisfy the security requirements, you can browse a network of machines and keep shared documents on a workgroup server. On the Macintosh MSIE does a better job if the Finder has already mounted a shared volume on the desktop.

Using this technique you can also run applications provided the URL resolves to the name of an executable file. On Windows 98, this URL fires up the desktop calculator:

```
file:C:\Windows\Calc.exe
```

This means you can build a link on your page that activates local applications really easily. This works across platforms too. On the Macintosh, a functionally equivalent URL would be:

```
file://G3/APPS/Desk%20tools/Calculator%207.5
```

You may need to explore your hard disk to work out the paths to your installed applications. Don't forget that you need to use escaped URL values.

The same automated activation works for documents too. For example, locate an Excel spreadsheet and link to it from a document. When you click on the link, this will open Excel and load the document into it.

Older versions of Netscape Navigator are less capable of navigating the whole file system and initially start at the folder the browser application lives in. Netscape 6.0 exhibits a bug and this whole area of the browser needs more work before it is useful.

Accessing these capabilities from script is a little more tricky. `window.location.href` assignment effectively does the same thing on a Macintosh. On Windows, there are already capabilities for activating applications via the ActiveXObject and you need to use that technique because `window.location.href` does not like having applications loaded into browser frames.

Warnings:

- Be very careful what you browse on your system and how. You may corrupt your system although read-only access is unlikely to cause any harm.

See also:	javascript: URL, URL, view-source: URL

Files object (Object/JScript)

A collection of files belonging together in a folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFiles* = *myFolder*.Files
Object properties:	Count	
Object methods:	Item()	

This object is obtained by inspecting the `Files` property of a `Folder` object. The `Files` object is a collection containing objects that encapsulate the files in that folder. Each file is represented by a separate `File` object. You can then examine each of those objects to operate on them as you need to.

The `Files` object provides a method for searching and extracting a named `File` object within the collection and a property that yields the number of `File` objects in the collection.

You should be able to traverse the `Files` object using array indexing techniques or by means of an `Enumerator` object.

See also:	`Enumerator` object

Property	JavaScript	JScript	N	IE	Opera	Notes
Count	-	3.0 +	-	4.0 +	-	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	Notes
Item()	-	3.0 +	-	4.0 +	-	-

Files.Count (Property)

A count of the number of file items in the `Files` collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	IE	*myFiles*.Count

The number of `File` objects belonging to the `Files` collection is yielded by this property. You can build enumeration loops if you know the extent of a collection. You cannot change this value.

Property attributes:

`ReadOnly`.

Files.Item() (Method)

An accessor for retrieving individual `File` objects by name from a `Files` collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`File object`	
JavaScript syntax:	IE	*`myFiles`*`.Item(`*`aName`*`)`
Argument list:	*`aName`*	The name of a file within its folder

With this method, you can locate a named `File` object within the `Files` collection if it is present. The file name is used as a key to locate the required object.

FileSystem object (Object/JScript)

An object that represents an entire file system for a specific disk drive.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myFileSystem`* `= ` *`myDrive`*`.FileSystem`
	IE	*`myFileSystem`* `= new ActiveXObject ("Scripting.FileSystemObject")`
Object methods:	`BuildPath(), CopyFile(), CopyFolder(), CreateFolder(), CreateTextFile(), DeleteFile(), DeleteFolder(), DriveExists(), FileExists(), FolderExists(), GetAbsolutePathName(), GetBaseName(), GetDrive(), GetDriveName(), GetExtensionName(), GetFile(), GetFileName(), GetFolder(), GetParentFolderName(), GetSpecialFolder(), GetTempName(), MoveFile(), MoveFolder(), OpenTextFile()`	
Collections:	`Drives[]`	

When building scripts to run in the Windows environment, possibly for use with WSH, you may need to operate on files and folders within the file system hierarchy of the computer. This object encapsulates the file system so that you can operate on its methods and properties.

File systems may have been shared across from other computers but the network manager should make them appear identical to local drives. Foreign file systems should also be mapped to local drives and appear to have a structure that is familiar. However, there may be file name differences. Certain characters may be valid on one operating system and invalid on another or there may be different limitations on file name length and capitalization rules.

See also:	`Drive.FileSystem`, `File` object

Method	JavaScript	JScript	N	IE	Opera	Notes
`BuildPath()`	-	3.0 +	-	4.0 +	-	-
`CopyFile()`	-	3.0 +	-	4.0 +	-	-
`CopyFolder()`	-	3.0 +	-	4.0 +	-	-
`CreateFolder()`	-	3.0 +	-	4.0 +	-	-
`CreateTextFile()`	-	3.0 +	-	4.0 +	-	-
`DeleteFile()`	-	3.0 +	-	4.0 +	-	-
`DeleteFolder()`	-	3.0 +	-	4.0 +	-	-
`DriveExists()`	-	3.0 +	-	4.0 +	-	-
`FileExists()`	-	3.0 +	-	4.0 +	-	-
`FolderExists()`	-	3.0 +	-	4.0 +	-	-
`GetAbsolutePath Name()`	-	3.0 +	-	4.0 +	-	-
`GetBaseName()`	-	3.0 +	-	4.0 +	-	-
`GetDrive()`	-	3.0 +	-	4.0 +	-	-
`GetDriveName()`	-	3.0 +	-	4.0 +	-	-
`GetExtensionName()`	-	3.0 +	-	4.0 +	-	-
`GetFile()`	-	3.0 +	-	4.0 +	-	-
`GetFileName()`	-	3.0 +	-	4.0 +	-	-
`GetFolder()`	-	3.0 +	-	4.0 +	-	-
`GetParentFolderName()`	-	3.0 +	-	4.0 +	-	-
`GetSpecialFolder()`	-	3.0 +	-	4.0 +	-	-
`GetTempName()`	-	3.0 +	-	4.0 +	-	-
`MoveFile()`	-	3.0 +	-	4.0 +	-	-
`MoveFolder()`	-	3.0 +	-	4.0 +	-	-
`OpenTextFile()`	-	3.0 +	-	4.0 +	-	-

FileSystem.BuildPath() (Method)

A method for manufacturing paths within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFileSystem*`.BuildPath(`*aPath*`, `*aName*`)`
Argument list:	*aPath*	A previously existing path
	aName	A name to be added to extend the path

This yields a path value for use within the file system.

FileSystem.CopyFile() (Method)

A method for copying files within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*`.CopyFile(`*aSource*`, `*aTarget*`, `*aFlag*`)`
Argument list:	*aSource*	The file to copy from
	aTarget	The file to copy to
	aFlag	A flag to indicate whether to overwrite

Although you can copy files by using the `Copy()` method that belongs to a `File` object, the `FileSystem` object also supports file copying from a point of view that is external to a file.

See also:	`File.Copy()`

FileSystem.CopyFolder() (Method)

A method for copying folders within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*`.CopyFolder(`*aSource*`, `*aTarget*`, `*aFlag*`)`
Argument list:	*aSource*	The folder to copy from
	aTarget	The folder to copy to
	aFlag	A flag to indicate whether to overwrite

From the `FileSystem`, you can copy a whole folder hierarchy in a single operation. As is the case with the `File` object, the `Folder` object also provides a `Copy()` method too.

See also:	`Folder.Copy()`

FileSystem.CreateFolder() (Method)

A method for creating new folders within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*myFileSystem*`.CreateFolder(`*aName*`)`
Argument list:	*aName*	The name of a folder to be created

You may need to create a new folder as a destination to copy files to or to use as a location to create them in.

See also:	`Folder` object

FileSystem.CreateTextFile() (Method)

A method for creating new empty text files within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`File object`	
JavaScript syntax:	IE	*myFileSystem*`.CreateTextFile(`*aName*`,` *aFlag*`)`
Argument list:	*aName*	The name of a text file to be created
	aFlag	A flag to indicate whether to overwrite

This is a means of creating a new text file. As is often the case with the Windows environment, it has become bloated by having several alternative methods for achieving the same result. If you are not careful, this can lead to sloppy coding and some very difficult to maintain systems.

It is highly recommended that you choose only one of the several available techniques where there are alternatives and apply that wherever you can. It is likely you'll find one of the other ways of creating new files more appropriate and you should be able to ignore this method most of the time.

See also:	`File` object, `File.open()`

FileSystem.DeleteFile() (Method)

A method for deleting files from the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*.DeleteFile(*aName*, *aFlag*)
Argument list:	*aName*	The name of a file to be deleted
	aFlag	A flag that indicates whether to force the deletion or not

Files can be deleted by using the `File` object's own `Delete()` method or by deleting them at the file system level.

See also:	`File.Delete()`

FileSystem.DeleteFolder() (Method)

A method for deleting folders from the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*.DeleteFolder(*aName*, *aFlag*)
Argument list:	*aName*	The name of a folder to be deleted
	aFlag	A flag that indicates whether to force the deletion or not

As is the case with files, there is an alternative way to delete folders too. You can either use this method or the `Delete()` method that belongs to the `Folder` object itself.

See also:	`Folder.Delete()`

FileSystem.DriveExists() (Method)

A method for testing the existence of a drive.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myFileSystem*.DriveExists(*aName*)
Argument list:	*aName*	The name of a disk drive to be tested

You can test for the existence of a drive within the file system using this method.

FileSystem.Drives[] (Collection)

A list of all `Drive` objects within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Drives object`	
JavaScript syntax:	IE	*`myFileSystem`*`.Drives`

This property yields a collection of `Drive` objects, each one representing a different drive unit.

See also:	`Drives` object

FileSystem.FileExists() (Method)

A means of testing for the existence of a file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.FileExists(`*`aName`*`)`
Argument list:	*`aName`*	The name of a file to be tested for existence

You can test for the existence of a file in the file system with this method.

FileSystem.FolderExists() (Method)

A means of testing for the existence of a folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.FolderExists(`*`aName`*`)`
Argument list:	*`aName`*	The name of a folder to be tested for existence

You can test for the existence of a folder within the file system with this method.

FileSystem.GetAbsolutePathName() (Method)

A method that returns the complete path name of a file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetAbsolutePathName(`*`aPath`*`)`
Argument list:	*`aPath`*	A relative or absolute path to be examined

Given that you have a partial reference to a file by name, this method will return a fully qualified path that describes that file's unique location within the file system.

FileSystem.GetBaseName() (Method)

A method that returns the base name of a file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetBaseName(`*`aPath`*`)`
Argument list:	*`aPath`*	A path to be examined

This method yields the base portion of a path.

FileSystem.GetDrive() (Method)

A method that returns a drive object from the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Drive object`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetDrive(`*`aName`*`)`
Argument list:	*`aName`*	The name of a drive in the file system

Given a path within the file system, this method returns an object representing the drive containing that path.

See also:	`Drive` object

FileSystem.GetDriveName() (Method)

A method to obtain the drive name of a drive within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetDriveName(`*`aLetter`*`)`
Argument list:	*`aLetter`*	The letter of a drive to examine for its name

Given a file path, the drive name within it is extracted and returned.

FileSystem.GetExtensionName() (Method)

A method to yield the file extension from the path name.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetExtensionName(`*`aPath`*`)`
Argument list:	*`aPath`*	A full path to the file to be examined

Given a path name, the file extension portion of it is extracted and returned.

FileSystem.GetFile() (Method)

A method to obtain a `File` object from a File system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`File object`	
JavaScript syntax:	IE	`myFileSystem.GetFile(aName)`
Argument list:	*`aName`*	The name of a file to construct a `File` object for

Given a file path within the file system, this method returns an object that represents the file.

See also:	`File` object

FileSystem.GetFileName() (Method)

A method to extract a file name from a path.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetFileName(`*`aPath`*`)`
Argument list:	*`aPath`*	A full or relative path to examine

Given a file path, this method extracts and returns the file name portion of it.

FileSystem.GetFolder() (Method)

A method to extract the folder from a path.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetFolder(`*`aPath`*`)`
Argument list:	*`aPath`*	A path to examine for a deepest folder object

Given a path name, this method extracts and returns an object representing the innermost folder within it.

See also:	`Folder` object

FileSystem.GetParentFolderName() (Method)

A method to extract the parent folder from a path.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileSystem`*`.GetParentFolderName(`*`aPath`*`)`
Argument list:	*`aPath`*	The path to a file or folder whose parent is required

Given a path, this method returns the name of a parent folder within that path.

FileSystem.GetSpecialFolder() (Method)

A method to yield a special folder within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*myFileSystem*`.GetSpecialFolder(`*aNumber*`)`
Argument list:	*aNumber*	An identifier for the special folder required

There are many special locations within the file system where objects are stored. Given a keyword, this method maps the keywords to physical locations within the file system.

The following special folders are supported in the Windows environment:

Number	Description
0	Windows files folder
1	System files folder
2	Temporary items folder

See also:	`Folder` object

FileSystem.GetTempName() (Method)

A method to generate a unique temporary file name.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFileSystem*`.GetTempName()`

There are often times when you need a temporary file name. If you want to generate a unique name yourself you can. It is generally better to let the operating system do this because it can generate and test for uniqueness far more reliably than you can.

FileSystem.MoveFile() (Method)

A method to move a file within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*.MoveFile(*aSource*, *aTarget*)
Argument list:	*aSource*	The file to move from
	aTarget	The file to move to

As well as being able to move files with their own `Move()` method, you can move them from within the file system as well.

See also:	`File.Move()`

FileSystem.MoveFolder() (Method)

A method to move a folder within the file system.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFileSystem*.MoveFolder(*aSource*, *aTarget*)
Argument list:	*aSource*	The folder to move from
	aTarget	The folder to move to

Folder objects can be moved from within the file system or by invoking the `Move()` method that belongs to the `Folder` object itself.

See also:	`Folder.Move()`

FileSystem.OpenTextFile() (Method)

A method for opening text files for I/O.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`File object`	
JavaScript syntax:	IE	*myFileSystem*.OpenTextFile(*aName*, *aMode*, *aFlag*, *aFormat*)

Argument list:	*aName*	The name of the file to be created
	aFlag	A flag indicating whether the file can be created if necessary
	aMode	An access mode for the file
	aFormat	A format control for the file

Yet another way to open files that is named inconsistently with every other way that files can be operated on. In this case, we are opening files from the file system's point of view.

It is recommended that you select only one preferred technique for opening text files for I/O and sticking to it. If you mix and match and use several alternatives, you will become confused and so will everyone else who has to maintain your scripts in the future.

This is the equivalent of a `File.Open()` when the JScript interpreter in the Windows environment needs to read the contents of the text in the file.

The mode parameter should be one of:

- `ForReading`
- `ForWriting`
- `ForAppending`

The format parameter can be set to open the file with a Unicode or ASCII character set. The default is ASCII if you request the system default value. This parameter is indicated with a numeric value as follows:

Value	Format
`-2`	Use system default
`-1`	Unicode text format
`0`	ASCII text format

See also:	`File` object, `File.open()`, `File.OpenAsTextStream()`, `TextStream` object

FileUpload object (Object/DOM)

A text field in a form for entering the name of a file to be uploaded to the server.

Availability:	DOM level –1 JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera –3.0
Inherits from:	`Input object`

JavaScript syntax:	-	*myFileUpload* = *myDocument*.aFormName.anElement Name
	-	*myFileUpload* = *myDocument.aFormName*.elements[*anItemIndex*]
	IE	*myFileUpload* = *myDocument*.all.*anElementID*
	IE	*myFileUpload* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myFileUpload* = *myDocument*.all[*aName*]
	-	*myFileUpload* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myFileUpload* = *myDocument*.forms[*aFormIndex*] .elements [*anItemIndex*]
	-	*myFileUpload* = *myDocument*.getElementById(*anElementID*)
	-	*myFileUpload* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myFileUpload* = *myDocument*.getElementsByTagName ("INPUT") [*anIndex*]
HTML syntax:	<INPUT TYPE="file">	
Argument list:	*anItemIndex*	A reference to an element in a collection
	anIndex	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
	aFormIndex	A reference to one specific form in the collection
Object properties:	accept, size, type, value	
Object methods:	handleEvent(), select()	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onChange, onDragStart, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onSelect, onSelectStart	

Many properties, methods and event handlers are inherited from the Input object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all subclasses of the Input object superclass.

There isn't really a FileUpload object class, but it is helpful when trying to understand the wide variety of input element types, if we can reduce the complexity by discussing only the properties and methods of a file upload. In actual fact, the object is represented as an item of the Input object class.

Unlike MSIE, Netscape Navigator does not support the defaultValue property or the select() method for this subclass of the Input object.

Warnings:

- To be able to upload a file under script control, you must have the UniversalFileRead privilege granted to the script.

Inheritance chain:

`Element` object, `Input` object, `Node` object

FileUpload.accept (Property)

A list of acceptable MIME types for a file upload in a form.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFileUpload`*`.accept`

Refer to:

MIME types

FileUpload.handleEvent() (Method)

Passes an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myFileUpload`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape Navigator prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`FileUpload` object, `handleEvent()`

FileUpload.select() (Method)

Triggers a `Select` event on a `FileUpload` object.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*`myFileUpload`*`.select()`

This selects all the text in the `FileUpload` object so that it can be cut or copied by the user if necessary, or used as `TextRange` and have a command executed on it. It also triggers a `Select` event.

See also:	`Document.execCommand()`, `Input.select()`, `TextRange.execCommand()`

FileUpload.size (Property)

Returns the size of the file to be uploaded.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myFileUpload`*`.size`

It may be important to limit the size of files being uploaded to the server.

It is very possible that vindictive users may use file uploading to try and crash your server or deny its availability to other users by uploading massive files to it.

On the other hand, there may be limits you want to impose as a courtesy to the network managers who run the LANs and WANs where your users will be browsing. Allowing the user to upload unnecessarily large files will saturate their network as well as your server.

By testing this property, you can impose limits of acceptability on file uploads.

See also:	`Input.size`

FileUpload.type (Property)

The type of a form input element.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myFileUpload`*`.type`

The type value for a `FileUpload` is always "`file`". This value is necessary to determine the type of form element because this object is really an instance of the `Input` class.

See also:	Input.type

Property attributes:

ReadOnly.

FileUpload.value (Property)

The file name entered by the user for the file to be uploaded.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myFileUpload*.value

This property yields the name of the file that is to be uploaded. You may want to check this for its suitability. Perhaps you need a text file and the user chose an executable. Careful checking at the client can save serious problems at the server when your data processing code receives the uploaded file. Sending an image file to a server back-end that was expecting a small text file containing short lines can cause a server crash.

See also:	Input.value, UniversalFileRead

Filter (Definition)

A mechanism for providing display effects in MSIE.

The filters fall into three broad groups.

Static filters can be used (and stacked) to enhance the visual display effect of an object as it is rendered on screen. By using time-out loops you can also use them as animated effects by altering one property continuously.

The transitional filters control the change from one display to another, but can be used as static filters by freezing them at a fixed point in the transition.

The procedural filters calculate a surface according to a shading algorithm.

There are examples in the filter topics of how to use the latest variants of these filters. The older versions are now deprecated in favor of a new set and the examples have been omitted for the deprecated filters. In any case, they can all be implemented in terms of the new versions of the filters.

The major change took place at version 5.5 of MSIE and it is recommended that you use the latest filter set for any new projects.

Warnings:

- This is not the same as the event filtering provided by Netscape Navigator

See also:	`Element.filters[]`

filter – Alpha() (Filter/visual)

A visual filter for controlling transparency.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	`Enabled, Opacity, FinishOpacity, StartX, StartY, FinishX, FinishY, Style`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This filter is used to define a transparency level with an optional gradient effect.

The `Enabled` property can be set `true` to switch on the effect of this filter or `false` to deactivate it.

The `Opacity` property describes the initial opacity value. The values `0` and `100` represent the full range of alpha levels with `0` being fully transparent to `100` being fully opaque.

When using a gradient, the `FinishOpacity` describes the opacity required on completion.

The `StartX` and `StartY` properties are the starting coordinates of the gradient.

The `FinishX` and `FinishY` properties are the ending coordinates of the gradient.

The `Style` property defines the kind of gradient to use for the alpha channel filter. The following kinds of gradient are supported:

Index	Description
`0`	Uniform alpha level defined by the opacity name=value pair. The entire element is rendered at the same opacity level.
`1`	A linear gradient is specified. The two opacity levels define the start and end gradient points while the start and finish coordinates define the gradient normal vector.
`2`	Radial gradient starting at the `StartX`, `StartY` position and using the two opacity values for range.
`3`	Rectangular gradient spanning the rectangle defined by the start and end coordinates and using the start and end opacity values.

There are two examples. One shows the creation of the filter from script, the other implements the same effect but shows the modification of an existing object defined by `<STYLE>` tags.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as name=value pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="pulsateButton()">
<INPUT ID="MYBUTTON" TYPE="button" VALUE="Button">
<BR>
<SCRIPT>
var theOpacity = 0;
var theIncrement = 1;
function pulsateButton()
{
   theOpacity += theIncrement;

   myFilter = "Alpha(opacity="+theOpacity+")";
   document.all.MYBUTTON.style.filter = myFilter;
   if((theOpacity % 100) == 0)
   {
      theIncrement *= -1;
   }

   setTimeout("pulsateButton()", 5);
}
</SCRIPT>
</BODY>
</HTML>
-----------------------------------------------------------------
<HEAD>
<STYLE>
INPUT.aFilter {filter:Alpha(Opacity=50);}
</STYLE>
</HEAD>
<BODY onLoad="pulsateButton()">
<INPUT ID="MYBUTTON" TYPE="button" VALUE="Button" CLASS="aFilter">
<BR>
<SCRIPT>
var theOpacity = 0;
var theIncrement = 1;
var theFilter = document.all.MYBUTTON.filters[0];
function pulsateButton()
{
   theOpacity += theIncrement;

   theFilter.opacity = theOpacity;
   if((theOpacity % 100) == 0)
   {
      theIncrement *= -1;
   }

   setTimeout("pulsateButton()", 5);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – AlphaImageLoader() (Filter/procedural)

An image is displayed in the object with some additional control over how it is displayed.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, SizingMethod, Src`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

If you consider the content of the object and its background as two layers that are composited together, this filter interposes an additional image layer between them.

This layer can have its transparency adjusted as well as scaling and clipping to position the image where you want it.

The `Enabled` property can be set `true` to switch on the effect of this filter or `false` to deactivate it.

The `SizingMethod` property can be set to one of the following values:

- The `crop` value forces the image to be cropped to fit the HTML Element content's extent rectangle.
- The `image` value forces the HTML Element to be resized to accommodate the extent rectangle of the image file.
- The `scale` value forces the image to be scaled to fit the current extent rectangle for the HTML Element.

The `Src` property is mandatory and needs to point at a valid and absolute image URL value that can be loaded.

The example demonstrates these capabilities by cycling round all three settings using a `switch` case selector.

Example code:

```
<HTML><HEAD></HEAD>
<BODY>
<SCRIPT>
var theState = 0;
// Cycle the sizingMethod property to size the image.
function changeState(oObj)
{
   switch(theState)
   {
      case 0:
      theState = 1;
      CONTAINER.filters(0).sizingMethod = "image";
      oObj.innerText = 'Scale to fit';
      break;
      case 1:
      theState = 2;
      CONTAINER.filters(0).sizingMethod = "scale";
      oObj.innerText = 'Crop to fit';
      break;
      case 2:
      theState = 0;
      CONTAINER.filters(0).sizingMethod = "crop";
      oObj.innerText = 'Normal';
      break;
   }
}
</SCRIPT>
<DIV ID="CONTAINER" STYLE="position:absolute; left:140px; height:50; width:50;
filter:progid:DXImageTransform.Microsoft.AlphaImageLoader(src='C:\FilterTests\Logo
150.gif', sizingMethod='scale');" >
</DIV>
<BUTTON onclick="changeState(this);">Scale to fit</BUTTON>
</BODY>
</HTML>
```

See also:	`Filter` object, Procedural surfaces, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	5.5 +	-	4.0 +	-	-
`SizingMethod`	-	5.5 +	-	5.5 +	-	-
`Src`	-	5.5 +	-	5.5 +	-	-

filter – Barn() (Filter/transition)

A transition effect with the appearance of barn doors opening or closing.

Availability:	JScript –5.5 Internet Explorer –5.5

Object properties:	Duration, Enabled, Motion, Orientation, Percent, status
Object methods:	apply(), play(), stop()

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `Motion` property can use the values in or out to determine the direction that the transition moves in.

The `Orientation` property indicates whether the effect is applied horizontally or vertically with the values `horizontal` or `vertical`.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between `0` and `100`.

The `status` value can be read to determine the current disposition of the transition filter. It will return one of three values. The `0` value indicates the transition has stopped, `1` indicates that it is completed and `2` that it is still in progress.

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example shows the filter being applied in a continuous time-out loop.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Barn(orientation=vertical,
motion=out) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
```

```
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC=".\Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility = "visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility = "hidden";
      DIV2.style.visibility = "visible";
   }
   else
   {
      DIV1.style.visibility = "visible";
      DIV2.style.visibility = "hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 2000);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – BasicImage() (Filter/visual)

Controls over the basic image display attributes of the containing HTML Element object.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, GrayScale, Invert, Mask, MaskColor, Mirror, Opacity, Rotation, XRay`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This filter was added for version 5.5 of MSIE and consolidates the image handling capabilities of the filters in earlier versions of the MSIE browser.

The `Enabled` property turns the filter on and off by assigning the `true` or `false` value to it.

The `GrayScale` property replaces the functionality of the `GrayScale()` filter. Setting it to `1` discards the color information while zero makes it inactive.

The `Invert` property replaces the functionality of the `Invert()` filter. However, note that it inverts the value in the RGB color space and not the HSV color space that the deprecated `Invert()` filter used to use.

The `Mask` property replaces the functionality of the now deprecated `Mask()` filter. Any pixels set to transparent will be replaced by the color defined in the `MaskColor` operator. This means that `MaskColor` must be specified when the `Mask` operator is used.

The `Mirror` property replaces the deprecated `FlipH()` filter. The value `0` and `1` control whether the mirror effect is applied. To reproduce the effect of the `FlipV()` filter, use the `Rotation` operator first to rotate the element by 90 degrees.

The `Opacity` property can accept a floating point value between `0.0` and `1.0`. `0.0` is completely transparent while `1.0` is completely opaque.

The `Rotation` property takes a set of values to specify which of of the four cardinal directions to rotate the object. The value `0` corresponds to no rotation. Angles of 90, 180 and 270 degrees are indicated by the values `1`,`2` and `3` respectively. This does not provide a free rotate facility. You can use it in combination with the mirroring to perform `Mirror` flips other than a straightforward left to right mirror.

The `XRay` property displays the image taking the average of the red and green values of each pixel and then inverting it. This is not quite the same as an invert on the GrayScale value. It is also different to what the earlier `XRay()` filter provided according to the documentation. Earlier `XRay()` filters were documented as proving just an edge detected outline.

The example shows an image in its normal and XRay modes.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
X-Ray--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.BasicImage(xray=1)";

document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

filter – BlendTrans() (Filter/blend)

A blend filter for controlling transitions.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This blend transition filter is used to control the fading in and out of the filtered element. This would be used to create a dissolve effect.

The duration name=value pair specifies a floating point value in seconds which controls how quickly the effect should take place.

The use of this feature is deprecated in favor of the named transitions introduced in later versions of MSIE and which can be used as static or transitional effects.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as name=value pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `RevealTrans()`, `Filter` object, `style.filter`, Transition

filter – Blinds() (Filter/transition)

A transition effect with the appearance of venetian blinds opening or closing.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`bands, Direction, Duration, Enabled, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `bands` property defines the number of strips that the blinds filter will use for its transition effect. The value should be in the range 1 to 100.
- The `Direction` property determines which direction the transition should proceed. It accepts the values: left, right, up or down.
- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example runs continuously in a timeout loop.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Blinds(orientation=vertical,
motion=out) ">

filter – Blur() (Filter/visual)

A visual filter for blurring objects.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	Enabled, MakeShadow, PixelRadius, ShadowOpacity
Supported by objects:	A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMEST, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP

This visual filter provides a way of adding motion blur to elements as they are drawn into the display. Versions of the MSIE browser prior to version 5.5 implement the `MotionBlur()` filter as a `Blur()` filter.

As of the IE 5.5 browser, the `Blur` effect provides a simple Gaussian blur which is non directional. The Previous motion blurring artifacts is now available with a specialized `MotionBlur()` filter.

From version 5.5 of MSIE, the properties supported by this filter have changed to this set:

- The `Enabled` property turns the blurring effect on and off when set to `true` or `false`, respectively.
- The `MakeShadow` property allows you to select between displaying the object as a shadow, or as its normal RGB values. Set to `true` to get a blurred shadow effect.
- The `PixelRadius` property takes a floating point value to indicate the radius of the blurring effect. The value ranges from 1.0 to 100.0 in pixels.
- The `ShadowOpacity` property takes a floating point value in the range 0.0 to 1.0 to indicate the opacity of the blurred image. The value 0.0 is completely transparent while 1.0 is completely opaque.

The example shows how to make a blurred shadow effect.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Blur(makeshadow=true,
pixelradius=5.0, shadowopacity=0.5)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	filter – `MotionBlur()`, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	3.0 +	-	4.0 +	-	-
`MakeShadow`	-	3.0 +	-	4.0 +	-	Warning
`PixelRadius`	-	3.0 +	-	4.0 +	-	Warning
`ShadowOpacity`	-	3.0 +	-	4.0 +	-	Warning

filter – CheckerBoard() (Filter/transition)

A transition effect with the appearance of chequer board blinds opening or closing.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Direction, Duration, Enabled, SquaresX, SquaresY`

This transition effect supports the following properties:

- The `Direction` property determines which direction the transition should proceed. It accepts the values: left, right, up or down.
- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

- The `SquaresX` and `SquaresY` properties describe how many squares the effect should use across the content being transitioned.

The example runs in a continuous loop.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.CheckerBoard(direction=left,
squaresx=10, squaresy=10) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 2000);
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	filter – Blinds(), Filter object, style.filter

Property	JavaScript	JScript	N	IE	Opera	Notes
Direction	-	5.5 +	-	5.5 +	-	-
Duration	-	5.5 +	-	5.5 +	-	-
Enabled	-	5.5+	-	5.5 +	-	-
SquaresX	-	5.5 +	-	5.5 +	-	-
SquaresY	-	5.5 +	-	5.5 +	-	-

filter – Chroma() (Filter/visual)

A visual filter for chroma key effects.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	Enabled, Color
Supported by objects:	A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP

This visual filter provides a way to define a particular color as being transparent. This is sometimes called chroma keying (a technique much used in the television industry).

The Color property defines a hex triplet value which is deemed to be transparent for this element.

Version 5.5 of the MSIE browser adds the Enabled property which controls whether the effect is applied by means of the true and false value.

The example makes black the transparent color for the image.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as name=value pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.
- This can display some unattractive visual artifacts with images that have been compressed or dithered to reduce the number of colors available. It also does not work very well round the edges of anti-aliased images.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Chroma(color=#000000)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Filter` object, `style.filter`

Property	JavaScript	JScript	Nav	IE	Opera	Notes
`Enabled`	-	3.0 +	-	4.0 +	-	-
`Color`	-	3.0 +	-	4.0 +	-	Warning

filter – Compositor() (Filter/visual)

As content is added to an object, it can be colored to indicate that it is changed content.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, Function`
Object methods:	`apply(), play()`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

Although this is implemented as a transitional effect, it actually only affects the display of an HTML Element in a static manner.

The Function property provides a way to select a rule for displaying a pixel color based on the two corresponding pixels in the previous and new image content of the HTML element being filtered.

The actual function is selected by a numeric value as follows (as described by the MSDN scripting reference information):

Code	Operation	Description
0	CLEAR	Neither pixel value displayed.
1	MIN(A, B)	Show the less bright of the two pixels.
2	MAX(A, B)	Show the brighter of the two pixels.
3	A	*Input A* shown, *Input B* ignored.
4	A OVER B	*Input A* displayed over *Input B*. All of *Input A* is visible, and *Input B* shows through translucent regions of *Input A*.
5	A IN B	Display all parts of *Input A* that are contained in *Input B*. Only regions with nonzero alpha values for both images are visible, and no part of *Input B* shows through.
6	A OUT B	Display all parts of *Input A* that are not contained in *Input B*. No part of *Input B* is displayed.
7	A ATOP B	Display *Input A* covering *Input B*, with each sample scaled by the alpha channel of *Input B*.
8	A SUBTRACT B	Display *Input A* with the sample color values of *Input B* subtracted from the corresponding sample color values of *Input A*. The resulting color is scaled by the alpha values of *Input A*.
9	A ADD B	Display *Input A* with the sample color values of *Input B* added to the corresponding sample color values of *Input A*. The resulting color value is scaled by the alpha value of *Input A*.
10	A XOR B	Display pixels of each set of input where the two images do not overlap. Pixels that overlap are scaled by their inverse alpha value.
19	B	*Input B* shown, *Input A* ignored.
20	B OVER A	*Input B* displayed over *Input A*. All of *Input B* is visible, and *Input A* shows through translucent regions of *Input B*.
21	B IN A	Display all parts of *Input B* that are contained in *Input A*. Only regions with nonzero alpha values for both images are visible, and no part of *Input A* shows through.
22	B OUT A	Display all parts of *Input B* that are not contained in *Input A*. No part of *Input A* is displayed.
23	B ATOP A	Display *Input B* over *Input A*, with each sample scaled by the alpha channel of *Input A*.
24	B SUBTRACT A	Display *Input B* with the sample color values of *Input A* subtracted from the corresponding sample color values of *Input B*. The resulting color is scaled by the alpha values of *Input B*.
25	B ADD A	Display *Input B* with the sample color values of *Input A* added to the corresponding sample color values of *Input B*. The resulting color value is scaled by the alpha value of *Input B*.

The `apply()` method should be executed on the `filter` object to capture the initial (*state A*) image pixel map. Then the `play()` method can be applied after some changes have taken place. At this point the *state B* image can be determined and compared with the *state A* image.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY bgcolor=gray onload="loader()">
<BUTTON onClick="filterThing()">Click me</BUTTON>
<BR>
<DIV ID="CONTAINER"
STYLE="filter:progid:DXImageTransform.Microsoft.Compositor(function=20);
position:absolute; height:300; width:300">
<IMG SRC="./Logo150.gif" STYLE="position:absolute; left:50; top:50;">
</DIV>
<SCRIPT>
function loader()
{
   CONTAINER.filters.item(0).Apply();
   CONTAINER.innerHTML = HIDDEN.innerHTML;
   CONTAINER.filters.item(0).Play();
}
function filterThing()
{
   CONTAINER.filters.item('DXImageTransform.Microsoft.Compositor').Function = 2;
}
</SCRIPT>
<DIV ID="HIDDEN" STYLE="display:none">
<IMG SRC="./Logo150.gif" STYLE="position:absolute; left:50; top:50;">
<IMG SRC="./Logo150.gif" STYLE="position:absolute; left:70; top:70;">
</DIV>
</BODY>
</HTML>
```

filter – DropShadow() (Filter/visual)

A visual filter for creating drop shadows.

Availability:	JScript –3.0 Internet Explorer –4.0

Object properties:	Enabled, OffX, OffY, Positive , Color
Supported by objects:	A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP

This visual filter creates drop shadow effects. These are quite useful for lifting control elements out of the page to make them more readily visible.

The following properties are supported:

- The `Enabled` property was added at version 5.5 of MSIE to implement a consistent way of enabling/disabling filters by means of its `true` or `false` setting.
- The `offx` and `offy` properties define the magnitude and direction of the dropshadow.
- The `positive` property specifies whether all pixels or only visible pixels generate a drop shadow. Setting this value to 0 applies a shadow based on every pixel in the element. A value of 1 only shadows non-transparent pixels.
- The `Color` property provides a way to determine the drop shadow color. This is not available on earlier versions of the MSIE browser.

The example shows the effect of adding a drop shadow to an image. In this example, you will see that the shadow has a hard edge created by a point source of light –you may want to use the `Blur` filter to provide a more natural effect with soft edges.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.DropShadow(offx=10, offy=10,
positive=1, color=gray)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	color value, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	3.0 +	-	4.0 +	-	-
`OffX`	-	3.0 +	-	4.0 +	-	Warning
`OffY`	-	3.0 +	-	4.0 +	-	Warning
`Positive`	-	3.0 +	-	4.0 +	-	Warning
`Color`	-	3.0 +	-	4.0 +	-	Warning

filter – Emboss() (Filter/visual)

Displays the image content of the HTML element as if it were an embossed effect.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, Bias`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

The grayscale values of the image are used as a height map, and an image is generated by using this height map with a light source to cast a shadow. The result is a grayscale image.

The following properties are supported:

- The `Enabled` property can be set to `true` or `false` to switch the filter on or off.
- The `Bias` property controls an intensity level that is added to the brightness of the embossed filter output. The value can range from -1.0 to 1.0 with brighter images as the value becomes more positive.

The example shows the application of an Emboss filter to an image. However when running tests, the `Bias` value did not seem to have any visible effect on MSIE 5.5 running on Windows 98.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
```

```
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Emboss()";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	filter – `Engrave()`, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	5.5 +	-	5.5 +	-	-
`Bias`	-	5.5 +	-	5.5 +	-	-

filter – Engrave() (Filter/visual)

An effect that is the opposite of the embossed image appearance.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, Bias`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESST, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This filter operates in a similar way to the `Emboss()` filter. In this case, the height information is inverted giving the effect of an engraved image.

The following properties are supported:

- The `Enabled` property can be set to `true` or `false` to switch the filter on or off.
- The `Bias` property controls an intensity level that is added to the brightness of the engraved filter output. The value can range from -1.0 to 1.0 with brighter images as the value becomes more positive.

The example shows the application of an `Engrave` filter to an image. However when running tests, the Bias value did not seem to have any visible effect on MSIE 5.5 running on Windows 98.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Engrave()";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	filter – `Emboss()`, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	5.5 +	-	5.5 +	-	-
`Bias`	-	5.5 +	-	5.5 +	-	-

filter – Fade() (Filter/transition)

A transition effect with the appearance of a dissolve between two images.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, Overlap, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `Overlap` property is a floating point value from 0.0 to 1.0 that determines what proportion of the duration time both images should be partially visible.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example runs in a continuous loop.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Fade(duration=5, overlap=2)
">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
```

```
    }
    CONTAINER.filters[0].Play();
    setTimeout("switchState()", 2000);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – FlipH() (Filter/visual)

A visual filter for horizontal mirror effects.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This visual filter is used for creating symmetrically mirrored copies of an element flipped on the horizontal axis. There are no properties to use with it.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the IE 5.5 browser. You can also use the `Matrix()` filter in place of this.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `BasicImage()`, filter – `Matrix()`, `Filter` object, `style.filter`

filter – FlipV() (Filter/visual)

A visual filter for vertical mirror effects.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This visual filter is used for creating symmetrically mirrored copies of an element flipped on the vertical axis. There are no properties to use with it.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the IE 5.5 browser. You can also use the `Matrix()` filter in place of this.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `BasicImage()`, filter – `Matrix()`, `Filter` object, `style.filter`

filter – Glow() (Filter/visual)

A visual filter for adding a glow effect.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	`Enabled, Color, Strength`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This visual filter adds a glow effect surrounding the filtered element.

The following properties are supported:

- The `Enabled` property was added for version 5.5 of MSIE to provide a consistent interface for controlling whether a filter is active. It takes the values `true` or `false` to enable or disable the filter.
- The color property defines the color value for the glow.
- The strength property sets the intensity of the glow with a value from 1 to 255.

The glow effect is demonstrated in the example.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Glow(color=lightgreen,
strength=20)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	3.0 +	-	4.0 +	-	-
`Color`	-	3.0 +	-	4.0 +	-	Warning
`Strength`	-	3.0 +	-	4.0 +	-	Warning

filter – Gradient() (Filter/procedural)

A procedural definition of a gradient effect.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, StartColor, StartColorStr, EndColor, EndColorStr, GradientType`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

The following properties can be used with this filter:

- The `Enabled` property can be set to `true` or `false` to control whether the `Gradient()` is used or not.
- The `StartColor` and `EndColor` properties can be specified as a 32 bit integer in decimal or hexadecimal notation. The extra 8 bits of information specify an alpha channel blending effect.

The `StartColorStr` and `EndColorStr` properties can be specified as a hexadecimal color value string including the alpha channel value. Color names may not work properly.

You should use `StartColor` or `StartColorStr` and `EndColor` or `EndColorStr` according how you want to specify the start and end colors. This is another example of where the MSIE browser syntax breaks with the traditional color naming conventions and goes off in another direction. This lack of consistency even within a browser makes it more difficult for beginners to learn how use these features.

- The `GradientType` property selects the kind of gradient to apply. It simply controls the orientation of the gradient. A zero value specifies a vertical gradient while the 1 value specifies a horizontal gradient.

The example shows how to enable the gradient and select its direction interactively.

Example code:

```
<HTML><HEAD></HEAD>
<BODY>
<SCRIPT>
var theState = 0;
var theGradientType = 0;
function selectGradientType()
{
   theGradientType = (theGradientType + 1) % 2;
   CONTAINER.filters(0).GradientType = theGradientType;
}

function switchState(anObject)
{
   switch(theState)
   {
      case 0:
         theState = 1;
         CONTAINER.filters(0).enabled = "true";
         anObject.innerText = 'Remove effect';
         break;
      case 1:
         theState = 0;
         CONTAINER.filters(0).enabled = "false";
         anObject.innerText = 'Apply effect';
         break;
   }
}
</SCRIPT>
<BUTTON onclick="switchState(this);">Apply effect</BUTTON>
<BR>
<BUTTON onclick="selectGradientType();">Next style</BUTTON>
<BR>
<DIV ID="CONTAINER" STYLE="position:absolute; left:140px; height:250; width:250;
filter:progid:DXImageTransform.Microsoft.Gradient(enabled='false',
startColorStr='#FF0000FF', endColorStr='#00FFFF00', GradientType=0);">
<CENTER><BR><BR><BR>
```

```
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</BODY>
</HTML>
```

filter – GradientWipe() (Filter/transition)

A transition effect with the appearance of a wipe with a soft edge.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, GradientSize, Motion, Percent, status, WipeStyle`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `GradientSize` property indicates what proportion of the object is covered by the gradient band. The value is in the range 0.0 to 1.0 and is a floating point value.
- The `Motion` property can be defined as forward or reverse to indicate the direction of the transition.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.
- The `WipeStyle` property is an integer value to determine which direction the gradient wipe travels. The value 0 selects a horizontal wipe while the value 1 selects a vertical wipe.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The play() method executes the transition effect using the control values and taking the time specified in the duration value. You can override the duration property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example runs in a continuous loop. Note that you should ensure the loop is at least long enough to cope with the effect duration otherwise a jerky transition will result.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.GradientWipe(duration=5,
gradientsize=0.4, motion=forward, wipestyle=0) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; "><CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
```

```
    }
    CONTAINER.filters[0].Play();
    setTimeout("switchState()", 7000);
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Filter` object, `style.filter`

filter – Grayscale() (Filter/visual)

A visual filter for converting to a grayscale appearance.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This visual filter removes all color information from the filtered element and display it in grayscale mode only. There are no properties associated with it.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the IE 5.5 browser.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `BasicImage()`, `Filter` object, `style.filter`

filter – Inset() (Filter/transition)

A diagonal wipe across the image revealing the new image.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

There do not appear to be any values that control the direction of the inset which wipes diagonally rightwards and downwards. The example shows how to apply this in a cyclic manner.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Inset(duration=2) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
```

```
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 7000);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – Invert() (Filter/visual)

A visual filter for inverting image colors.

Availability:	JScript –3.0 Internet Explorer –4.0

This visual filter inverts the color value of every pixel in the filtered element.

There are several color models that could be used for this. The display is based around the RGB model and a printout would use the CMY or CMYK model. Inverting either of these would yield a different effect.

So, the browser will invert the colors using the HSV model. This should work consistently across all display mediums.

HSV stands for Hue, Saturation and Value (which means brightness or luminosity in most cases).

The Hue value is represented by a color wheel where the colors are specified on an angular basis from 0 to 360 degrees. Opposite sides of the wheel yield complementary colors.

The Saturation value defines the amount of color. No color at all yields a purely grayscale appearance.

The Value or lightness axis defines how bright the pixel is.

So inverting a pixel using HSV will perform these operations on discrete components of the color value:-

- Switch the color to one that is 180 degrees round the color wheel.
- Complement the saturation value. Unsaturated pixels become saturated and vice versa.
- Lightness is complemented making dark pixels light and vice versa.

Using this model to invert the pixels in an element should make it stand out clearly against a background.

There are no properties defined for this filter at present.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the IE 5.5 browser.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `BasicImage()`, `Filter` object, `style.filter`

filter – Iris() (Filter/transition)

A transition effect with the appearance of an iris opening or closing.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, IrisStyle, Motion, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `IrisStyle` property is used to define the shape of the iris that is opened or closed. It can be one of DIAMOND, CIRCLE, CROSS, PLUS, SQUARE or STAR.
- The `Motion` property can use the values in or out to determine the direction that the transition moves in.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example shows how to call this effect using a continuous loop.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Iris(duration=2, motion=out,
irisstyle=cross) ">

filter – Light() (Filter/visual)

A visual filter for simulating a lighting model.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	`Enabled`
Object methods:	`clear(), addAmbient(), addCone(), addPoint(), changeColor(), changeStrength(), moveLight()`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This visual filter simulates the effect of a light source being played on the element.

The `Enabled` property is supported –it was added for version 5.5 of MSIE to provided a consistent way of controlling whether a filter was active or not.

There are also methods for defining the type of light source, the location of it, and its intensity. The light source color can also be specified. These methods are supported:

- The `clear()` method removes all currently defined light sources. It has no parameters. You should stack your light sources with this being the first one unless you want to accumulate the lighting effects during any dynamic updating.
- The `addAmbient()` method is used to add another ambient light source. The red, green, blue and strength parameter values describe its lighting properties. The parameters are presented in this order:
  - Red intensity
  - Green intensity
  - Blue intensity
  - Strength

- The `addCone()` method is used to to describe a directional light source. Its parameters include a description of the beam direction and spread. The parameters are presented in this order:
  - Left coordinate of the light source.
  - Top coordinate of the light source.
  - Z-axis level of the light source.
  - Left coordinate of the target light focus.
  - Top coordinate of the target light focus.
  - Red intensity
  - Green intensity
  - Blue intensity
  - Strength
  - Spread
- The `addPoint()` method is used to describe a point light source. The parameters are presented in this order:
  - Left coordinate of the light source.
  - Top coordinate of the light source.
  - Z-axis level of the light source.
  - Red intensity
  - Green intensity
  - Blue intensity
  - Strength
- The color of a light source can be changed by calling the `changeColor()` method. The parameters are presented in this order:
  - Light number
  - Red intensity
  - Green intensity
  - Blue intensity
  - Replace or accumulate color flag
- The intensity of the light impinging on the object can be modified for each light source with the `changeStrength()` method. The parameters are presented in this order:
  - Light number
  - Strength value
  - Replace or accumulate strength flag

- The location of a light source can be modified with the `moveLight()` method. The parameters are presented in this order:
  - Light number
  - Left coordinate of the light source.
  - Top coordinate of the light source.
  - Z-axis level of the light source.
  - Relative or absolute move flag

The example demonstrates how several light sources can be combined and then moved in a `mouseMove` event loop to simulate the effect of a torchlight in a darkened room. The `clear()` function is necessary to avoid the light sources simply accumulating a lighting effect with each mouse move. The ambient light source raises the background illumination to a dull grey.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
<STYLE>
.aFilter
{
   background-color:#FFFFFF;
   filter:light();
   position:absolute;
   top: 100;
   left: 100;
   color: cyan;
   height: 250;
   width: 250;
}
</STYLE>
</HEAD>
<BODY onMouseMove="myHandler()">
<DIV ID="EXAMPLE" CLASS="aFilter">
<BR><BR><BR>
<CENTER>
This text is highlighted<BR>
with a light source.
</CENTER>
</DIV>
<SCRIPT>
function myHandler()
{
   myLightX = 125;
   myLightY = 125;
   myLightZ = 1;
```

```
    myTargetX = event.x;
    myTargetY = event.y;
    myRed = 200;
    myGreen = 64;
    myBlue  = 32;
    myStrength = 100;
    mySpread = 220;
    EXAMPLE.filters[0].clear();
    EXAMPLE.filters[0].addAmbient(64, 100, 10, 100);
    EXAMPLE.filters[0].addCone(myLightX, myLightY, myLightZ, myTargetX, myTargetY,
myRed, myGreen, myBlue, myStrength, mySpread);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – Mask() (Filter/visual)

A visual filter for creating a transparent mask.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated
Object properties:	`Color`

This visual filter is used for creating transparent masks. The transparent regions are defined by pixels set to the color value specified by the `Color` property.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the IE 5.5 browser.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.
- According to the latest MSDN documentation, this filter appears to have been renamed as `MaskFilter()`.

See also:	filter – `BasicImage()`, filter – `MaskFilter()`, `Filter object`, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Color`	-	3.0 +	-	4.0 +	-	Warning, Deprecated

filter – MaskFilter() (Filter/visual)

Uses the transparent color pixels of an object into a mask.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled , Color`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This filter behaves differently according to whether a pixel in the HTML `Element` object being filtered is transparent or not.

Transparent pixels are added to the mask image. Non-transparent pixels are set to be transparent in the mask image.

The following properties are available to control this filter:

- The `Enabled` property provides a consistent means of controlling whether the filter is active or not. It can accept a value of `true` or `false`.
- The `Color` property defines the color value selected for the mask.

The example shows how a transparent GIF file can be used to cut out a shape with this filter.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.MaskFilter(color=lightgreen,
strength=20)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

`Enabled`	-	5.5 +	-	5.5 +	-	-
`Color`	-	5.5 +	-	5.5 +	-	-

filter – Matrix() (Filter/visual)

A means of applying sophisticated rotation, translate, and scaling effects to an image using matrix transformation.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, M11, M12, M21, M22, Dx, Dy, SizingMethod, FilterType`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET< Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

Matrix transformation of images provides the ability to do free rotation to any angle if you are prepared to do the trigonometrical maths.

This matrix transformation provides the following possibilities:

- Scaling
- Rotation
- Flipping

The matrix transformations are based on a 2x2 matrix with an additional linear vector.

The following properties are supported:

- The `Enabled` property can be set to `true` or `false` to control whether the `Matrix()` filter is active or not.
- The `M11`, `M12`, `M21` and `M22` properties contain the four values that comprise the matrix. You can define values in each one of them on its own or you can perform more complex transforms by defining several at once.
- The `Dx` and `Dy` properties take floating point values and are used to move the resulting filtered output along a linear vector. This helps to simplify the transformation matrix and allows it to be implanted as a 2x2 matrix instead of a 2x3 or 3x3 matrix.
- The `FilterType` property is used to select a method for deriving the resulting filter output. This is necessary because when transforming objects with a matrix, you need to interpolate pixel values to fill in gaps. This operator can be defined as a bilinear or nearest neighbor interpolation function. The bilinear interpolation is better at the expense of needing more compute power. The nearest neighbor interpolation technique may be more useful for animated effects.
- The `sizingMethod` property determines how the results are displayed. They can either be clipped to fit the container or the container can be resized to accommodate the new size of the transformed output. The values are "clip to original" or "auto expand".

The following simple operations can be applied:

- Flip horizontal
- Flip vertical
- Resize
- Rotate

A horizontal flip can be accomplished with this code fragment:

```
myFilter.M11 -= myFilter.M11;

myFilter.M12 -= myFilter.M12;
```

A vertical flip can be accomplished with this code fragment:

```
myFilter.M21 -= myFilter.M21;

myFilter.M22 -= myFilter.M22;
```

A resize of the whole image can be accomplished like this:

```
myFilter.M11 *= aScaleFactor;

myFilter.M12 *= aScaleFactor;

myFilter.M21 *= aScaleFactor;

myFilter.M22 *= aScaleFactor;
```

A horizontal stretch can be done like this:

```
myFilter.M11 *= aScaleFactor;

myFilter.M12 *= aScaleFactor;
```

And a vertical stretch like this:

```
myFilter.M21 *= aScaleFactor;

myFilter.M22 *= aScaleFactor;
```

A rotation is a little more complex:

```
deg2radians = Math.PI * 2 / 360;

rad = deg * deg2radians;

costheta = Math.cos(rad);

sintheta = Math.sin(rad);

myFilter.M11 = costheta;

myFilter.M12 = -sintheta;

myFilter.M21 = sintheta;

myFilter.M22 = costheta;
```

The example demonstrates these transformations individually. Strange shearing effects can be achieved by modifying the coefficients of the rotation matrix. These introduce scaling artifacts which might be useful when fitting an image into a space, perhaps for designing some VRML like projected surfaces without using VRML itself.

Example code:

```
<HTML>
<HEAD>
<STYLE>
.aFilter
{
   filter:progid:DXImageTransform.Microsoft.Matrix(sizingMethod='auto expand');
   position:absolute;
}
```

```
</STYLE>
</HEAD>

filter – MotionBlur() (Filter/visual)

An enhanced motion blur artifact that replaces the older `Blur()` filter functionality.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, Add, Direction, Strength`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This visual filter provides a way of adding motion blur to elements as they are drawn into the display.

The `Blur()` filter supplied with the version 4.0 of the MSIE browser was really a motion blur. At version 5.5 of MSIE, the filters have been enhanced and rationalized. The result is that the old `Blur()` filter has been renamed to `MotionBlur()` and a new `Blur()` filter has been introduced to provide a simpler gaussian blur effect without motion artifacts.

The following properties are supported by this filter:

- The `Enabled` property turns the motion blurring effect on and off by setting it to `true` or `false`.
- The `add` property can have two values. If it is set to 1, it includes the original image as well as the blurred image. If the value 0 is defined, just the blurred effect is displayed.
- The `direction` property defines the angle of the motion blur with respect to the original object. The value is specified in degrees from 0 to 359 moving clockwise as the values increase.
- The `strength` property defines how many pixels distance to apply the blur effect.

The example shows an image with motion blur applied.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.MotionBlur(direction=60,
strength=50, add=0)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	filter – `Blur()`, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	5.5 +	-	5.5 +	-	-
`Add`	-	5.5 +	-	5.5 +	-	-
`Direction`	-	5.5 +	-	5.5 +	-	-
`Strength`	-	5.5 +	-	5.5 +	-	-

filter – Pixelate() (Filter/transition)

A transition effect with the appearance of a coarse pixelated dissolve.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, MaxSquare, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `MaxSquare` property indicates the largest possible size of a pixelated square. This can be in the range 2 to 50.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example demonstrates a gross pixelation transition effect.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Pixelate(duration=2,
maxsquare=50) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
```

```
    else
    {
       DIV1.style.visibility="visible";
       DIV2.style.visibility="hidden";
    }
    CONTAINER.filters[0].Play();
    setTimeout("switchState()", 5000);
}
</SCRIPT>
</BODY>
</HTML>
```

`play()`	-	5.5 +	-	5.5 +	-	-
`stop()`	-	5.5 +	-	5.5 +	-	-

filter – Pixelate() (Filter/visual)

An effect that simulates the pixellation achieved when lowering the display resolution of an image.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Enabled, Duration, MaxSquare, Percent, status`
Object methods:	`apply(), play(), stop()`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, FRAMESET, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

Although this may be used as a static filter, it can also be used with the `duration value`, `Apply()`, `Stop()` and `Play()` methods to control a transition effect.

The effect retains the current image size but takes groups of pixels and averages them and replaces the group with the average value. The effect is similar to that achieved by reducing the image and expanding it again without applying interpolation.

This can be useful for greeking out some content that you don't want to display. For example, you can obscure facial features or car number plates in this way.

The following properties can be applied to this filter when it is used as a static visual effect (Other transition control properties are not useful in this context):

- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `MaxSquare` property defines the maximum width in pixels of a pixelated square. This is effectively the amount of pixelation that occurs.
- The `Percent` property sets the point in the overall transition effect at which to capture the transition and use it as a static filter effect.

The example demonstrates the pixelation filter applied as a static effect.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Pixelate(maxsquare=10)";
document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

filter – RadialWipe() (Filter/transition)

A transition effect with the appearance of a radar display wiping round.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, Percent, status, WipeStyle`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.
- The `WipeStyle` property is one of clock, wedge or radial which indicates the shape of the transition effect.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example demonstrates the use of the clock version of the radial wipe.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.RadialWipe(duration=2,
wipestyle=clock) ">

filter – RandomBars() (Filter/transition)

A transition effect with the appearance of random bars sliding down.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	Duration, Enabled, Orientation, Percent, status
Object methods:	apply(), play(), stop()

This transition effect supports the following properties:

- The `Duration` property controls the time it takes to play-back the transition effect.
- The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.
- The `Orientation` property indicates whether the effect is applied horizontally or vertically with the values `horizontal` or `vertical`.
- The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The `status` property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The `apply()` method sets the transition effect to its initial condition.
- The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.
- The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example demonstrates the vertical orientation of this effect.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.RandomBars(duration=2,

filter – RandomDissolve() (Filter/transition)

A transition effect with the appearance of a fine pixelated dissolve.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	Duration, Enabled, Percent, status
Object methods:	apply(), play(), stop()

This transition effect supports the following properties:

- The Duration property controls the time it takes to play-back the transition effect.
- The Enabled property provides a way to activate or inhibit the filter from working by assigning the true or false value to it.
- The Percent property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.
- The status property value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- The apply() method sets the transition effect to its initial condition.
- The play() method executes the transition effect using the control values and taking the time specified in the duration value. You can override the duration property by passing an optional duration argument to this method when it is called.
- The stop() method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an onFilterChange event handler if there is one defined.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.RandomDissolve(duration=2)
">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 5000);
}
</SCRIPT>
</BODY>
</HTML>
```

Method	JavaScript	JScript	N	IE	Opera	Notes
apply()	-	5.5 +	-	5.5 +	-	-
play()	-	5.5 +	-	5.5 +	-	-
stop()	-	5.5 +	-	5.5 +	-	-

filter – RevealTrans() (Filter/reveal)

A reveal filter for controlling transitions.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This reveal filter controls a transition effect that specifies the kind of wipe to use between the hiding and showing of a filtered element.

The duration `name=value` pair is specified in the same way as for the `blendTrans()` filter. It specifies a floating point value in seconds which controls how quickly the effect should take place.

The transition-shape `name=value` pair specifies the kind of wipe effect to use. It is an integer value which defines the following wipe patterns:

index	Description
00	Box in
01	Box out
02	Circle in
03	Circle out
04	Wipe up
05	Wipe down
06	Wipe right
07	Wipe left
08	Vertical blinds
09	Horizontal blinds
10	Checkerboard across
11	Checkerboard down
12	Random dissolve
13	Split vertical in

Table continued on following page

index	Description
14	Split vertical out
15	Split horizontal in
16	Split horizontal out
17	Strips left down
18	Strips left up
19	Strips right down
20	Strips right up
21	Random bars horizontal
22	Random bars vertical
23	Random

These are loosely modelled on some of the standard SMPTE wipes and dissolves although the full complement is not available.

This is deprecated in favor of using named filters that provide the visual transition effect.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter –BlendTrans(), Filter object, style.filter, Transition

filter – Shadow() (Filter/visual)

A visual filter for creating a shadow.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	`Enabled , Color, Direction`
Supported by objects:	`A, ACRONYM, ADDRESS, B, BDO, BIG BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP`

This visual filter is used to define a shadow effect. The filtered element is displayed as a silhouette.

The following properties are available for use with this filter:

- The `Enabled` property was added at version 5.5 of the MSIE browser to provide a consistent way of enabling and disabling filters by assigning a `true` or `false` value to it.
- The color of the cast shadow is defined by the color property and the direction property specifies the angle of the shadow with respect to the original filtered element's location. This value is specified in degrees, measured in a clockwise direction from 0 to 359 as the values increase.

You may want more control over the shadow appearance and so other filters might be closer to the desired effect. This one is good for a simple shadow effect. The example shows it being applied to an image.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Shadow(direction=120,
color=yellowgreen)";

document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Filter` object, `style.filter`, `style.textShadow`

Property	JavaScript	JScript	N	IE	Opera	Notes
`Enabled`	-	3.0 +	-	4.0 +	-	Warning
`Color`	-	3.0 +	-	4.0 +	-	Warning
`Direction`	-	3.0 +	-	4.0 +	-	Warning

filter – Slide() (Filter/transition)

A transition effect with the appearance of one image sliding over another.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`bands, Duration, Enabled, Percent, SlideStyle, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- `bands`
- `Duration`
- `Enabled`
- `Percent`
- `SlideStyle`
- `Status`

The `bands` property defines the number of strips that the sliding filter will use for its transition effect.

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The `SlideStyle` property indicates what sort of sliding effect is used. It can be one of `HIDE`, `PUSH` or `SWAP`.

The `status` value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- `apply()`
- `play()`
- `stop()`

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example shows one of the available variants of this filter.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Slide(duration=2, bands=5,
slidestyle=swap) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 5000);
}
</SCRIPT>
</BODY>
</HTML>
```

filter – Spiral() (Filter/transition)

Reveals the new image with a spiral effect.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, GridSizeX, GridSizeY, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- `Duration`
- `Enabled`
- `GridSizeX`
- `GridSizeY`
- `Percent`
- `Status`

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `GridSizeX` and `GridSizeY` properties indicate the granularity of the effect.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The `status` value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- `apply()`
- `play()`
- `stop()`

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example shows how to apply this transition.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Spiral(duration=2,
gridsizex=10, gridsizey=10) ">

filter – Stretch() (Filter/transition)

A variation on a wipe effect except that the new image appears to stretch over the old one. The old one is squashed until it disappears.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, Percent, status, StretchStyle`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- `Duration`
- `Enabled`
- `Percent`
- `status`
- `StretchStyle`

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The status value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The `StretchStyle` property describes the kind of effect that the transition uses. It can be one of `HIDE`, `PUSH` or `SPIN`.

The following methods are supported by this transition filter:

- `apply()`
- `play()`
- `stop()`

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

The example shows the spin variant of this effect.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Stretch(duration=2,
stretchstyle=spin) ">
```

<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function switchState()
{
   CONTAINER.filters[0].Apply();
   if (DIV1.style.visibility == "visible")
   {
      DIV1.style.visibility="hidden";
      DIV2.style.visibility="visible";
   }
   else
   {
      DIV1.style.visibility="visible";
      DIV2.style.visibility="hidden";
   }
   CONTAINER.filters[0].Play();
   setTimeout("switchState()", 5000);
}
</SCRIPT>
</BODY>
</HTML>
```

Method	JavaScript	JScript	N	IE	Opera	Notes
apply()	-	5.5 +	-	5.5 +	-	-
play()	-	5.5 +	-	5.5 +	-	-
stop()	-	5.5 +	-	5.5 +	-	-

filter – Strips() (Filter/transition)

Reveals new image by sliding diagonal strips across the image.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	Duration, Enabled, Motion, Percent, status
Object methods:	apply(), play(), stop()

This transition effect supports the following properties:

- Duration
- Enabled
- Motion
- Percent
- Status

The Duration property controls the time it takes to play-back the transition effect.

The Enabled property provides a way to activate or inhibit the filter from working by assigning the true or false value to it.

The Motion property indicates which order and direction the transition moves in. The value can be one of leftdown, leftup, rightdown or rightup.

The Percent property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The status value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- apply()
- play()
- stop()

The apply() method sets the transition effect to its initial condition.

The play() method executes the transition effect using the control values and taking the time specified in the duration value. You can override the duration property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

One variant of this filter is demonstrated in the example.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Strips(duration=2,
motion=leftdown) ">

filter – Wave() (Filter/visual)

A visual filter for creating ripple effects.

Availability:	JScript –3.0 Internet Explorer –4.0
Object properties:	Enabled, Add, Freq, LightStrength, Phase, Strength
Supported by objects:	A, ACRONYM, ADDRESS, B, BDO, BIG, BLOCKQUOTE, body, BUTTON, CAPTION, CENTER, CITE, CODE, custom, DD, DEL, DFN, DIR, DIV, DL, DT, EM, FIELDSET, FONT, FORM, FRAME, Hn, I, IFRAME, IMG, INPUT, INS, KBD, LABEL, LEGEND, LI, MARQUEE, MENU, NOBR, OL, P, PLAINTEXT, PRE, Q, RT, RUBY, runtimeStyle, S, SAMP, SMALL, SPAN, STRIKE, STRONG, style, SUB, SUP, TABLE, TD, TEXTAREA, TH, TT, U, UL, VAR, XMP

This visual filter applies a rippled distortion effect to the filtered element. The effect is applied only along the vertical axis.

The following properties can be applied to this filter:

- Enabled
- Add
- Freq
- LightStrength
- Phase
- Strength

The Enabled property was introduced at version 5.5 of the MSIE browser to provide a consistent interface for activating and disabling filters by assigning the true or false value to it.

Like the MotionBlur() filter, the Add property specifies whether the original unmodified image should be placed over the rippled copy. A value of 1 adds the original while a value of 0 displayed only the rippled copy.

The `Freq` property specifies the number of waves to be applied as the distorting effect is rendered.

The `LightStrength` property indicates the intensity of the light playing on the rippled surface with a value in the range 0 to 100.

The `Phase` property defines the percentage offset for the sine wave curve in the range 0 to 100 which corresponds to an angular phase offset of 0 to 359 degrees.

The `Strength` property defines the wave rendering effect's intensity. This value must be between 0 and 255 with 0 providing no distortion and 255 causing a gross ripple effect.

The example shows this ripple effect being applied to an image.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
Normal--&gt;
<IMG ID="NORMAL" SRC="./Logo150.gif">
Filtered--&gt;
<IMG ID="MYIMAGE" SRC="./Logo150.gif">
<BR>
<SCRIPT>
myFilter = "progid:DXImageTransform.Microsoft.Wave(freq=6, lightstrength=90,
phase=60, add=1, strength=10)";

document.all.MYIMAGE.style.filter = myFilter;
</SCRIPT>
</BODY>
</HTML>
```

filter – Wheel() (Filter/transition)

Reveals the new image with a rotating spoked wheel effect.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, Percent, spokes, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- `Duration`
- `Enabled`
- `Percent`
- `spokes`
- `status`

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The `spokes` property indicates how many spokes there are in the cartwheel that is used for the transition effect. The value can range from 2 to 20 with 8 being a typical value.

The `status` value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- `apply()`
- `play()`
- `stop()`

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

This filter is demonstrated in the example.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="swiitchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.Wheel(duration=2, spokes=10)
">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
<BR>
<BR>
<BR>
<HR>
<CENTER>
This is a DIV block containing text.
</CENTER>
<HR>
</DIV>
<DIV ID="DIV2" STYLE="visibility:hidden; position:absolute; top:50; left:10;
width:240; height:180; background:antiquewhite; ">
<CENTER>
<BR>
<IMG SRC="./Logo150.gif">
</CENTER>
</DIV>
</DIV>
<SCRIPT>
DIV1.style.visibility="visible";
function swiitchState()
{
CONTAINER.filters[0].Apply();
if (DIV1.style.visibility == "visible")
{
DIV1.style.visibility="hidden";
DIV2.style.visibility="visible";
}
else
{
DIV1.style.visibility="visible";
DIV2.style.visibility="hidden";
}
CONTAINER.filters[0].Play();
setTimeout("swiitchState()", 5000);
}
</SCRIPT>
</BODY>
</HTML>
```

`stop()`	-	5.5 +	-	5.5 +	-	-

filter – XRay() (Filter/visual)

A visual filter that displays only the element edges.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated

This visual filter detects the visible edges of the filter element and only draws them. This might be useful for greeking a graphical object as it is dragged around with the cursor.

There are no properties for this filter.

The use of this filter is now deprecated in favor of the `BasicImage()` filter that was implemented with the version 5.5 MSIE browser.

Warnings:

- Filters are defined in style sheets as if they were a function call with its arguments expressed as `name=value` pairs. This is not the typical way to define arguments so you should be aware of this anomaly when working with filters.

See also:	filter – `BasicImage()`, `Filter` object, `style.filter`

filter – Zigzag() (Filter/transition)

Reveals the new image with a zigzag effect.

Availability:	JScript –5.5 Internet Explorer –5.5
Object properties:	`Duration, Enabled, GridSizeX, GridSizeY, Percent, status`
Object methods:	`apply(), play(), stop()`

This transition effect supports the following properties:

- `Duration`
- `Enabled`
- `GridSizeX`
- `GridSizeY`
- `Percent`
- `Status`

The `Duration` property controls the time it takes to play-back the transition effect.

The `Enabled` property provides a way to activate or inhibit the filter from working by assigning the `true` or `false` value to it.

The `GridSizeX` and `GridSizeY` properties indicate the granularity of the effect.

The `Percent` property controls the point at which the effect can be halted to provide a static effect. The value can be between 0 and 100.

The status value can be read to determine the current disposition of the transition filter. It will return one of three values. The 0 value indicates the transition has stopped, 1 indicates that it is completed and 2 that it is still in progress.

The following methods are supported by this transition filter:

- `apply()`
- `play()`
- `stop()`

The `apply()` method sets the transition effect to its initial condition.

The `play()` method executes the transition effect using the control values and taking the time specified in the duration value. You can override the `duration` property by passing an optional duration argument to this method when it is called.

The `stop()` method can be called at any time during the time the transition is running to halt the transition play-back. This will also trigger the execution of an `onFilterChange` event handler if there is one defined.

This filter is demonstrated in the example.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY onLoad="switchState()">
<DIV ID="CONTAINER" STYLE="position:absolute; top: 0; left: 0; width: 300;
height:300;  filter:progid:DXImageTransform.Microsoft.ZigZag(duration=2,
gridsizex=15, gridsizey=15) ">
<DIV ID="DIV1" STYLE="position:absolute; top:50; left:10; width:240;
height:180;background:ivory">
```

```
<BR>
<BR>
<BR>

Filter object (Object/JScript)

A single `filter` object obtained from an element's filters array.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFilter* = *myElement*.filters(*anIndex*)
	IE	*myFilter* = *myElement*.filters[*anIndex*]
	IE	*myFilter* = *myFilters*[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
Object properties:	`enabled`	

This object defines a visual effect that is used when the display is updated as the result of a change to the content of an element. The `Filter` object has properties that relate to the individual filters. There are some common properties (and methods) that are available to all filters and in some cases the same property name can mean different things depending on the filter being applied.

You should access the `filter` objects via the *`Filters`* collection because you may have the same filter type repeated for a cascading effect and so you need to be sure that you are addressing the right one.

There are three kinds of filters that can be applied to an object.

- `Visual`
- `Reveal`
- `Blend`

A `visual` filter is used to enhance the visual appearance of objects; maybe to flip them over, add a glow effect or a drop shadow.

A `reveal` filter is used to apply a transition effect as the appearance changes.

A `blend` filter controls the speed at which a `reveal` filter is applied.

You can define more than one filter, they just need to be space separated from one another.

Here is a list of the procedural filter function names:

- `AlphaImageLoader()`
- `Gradient()`

Here is a list of the static filters supported at version 5.5 of the MSIE browser:

- `Alpha()`
- `BasicImage()`
- `Blur()`
- `Chroma()`
- `Compositor()`
- `DropShadow()`
- `Emboss()`
- `Engrave()`
- `Glow()`
- `Light()`
- `MaskFilter()`
- `Matrix()`
- `MotionBlur()`
- `Pixelate()`
- `Shadow()`
- `Wave()`

The old `blendTrans()` and `revealTrans()` filters are now replaced by these transition filters:

- `Barn()`
- `Blinds()`
- `CheckerBoard()`
- `Fade()`
- `GradientWipe()`
- `Inset()`
- `Iris()`
- `Pixelate()`
- `RadialWipe()`
- `RandomBars()`
- `RandomDissolve()`
- `Slide()`
- `Spiral()`
- `Stretch()`
- `Strips()`
- `Wheel()`
- `Zigzag()`

Filters are defined as if they were a sequence of space delimited function calls. they aren't really functions because their argument passing mechanism is not truly JavaScript based. Arguments to each filter function are defined as `name=value` pairs.

Refer to the specific topics on each filter function for details of what it does and how you can control it.

When using the filters in the context of the `style` object, the function name for each filter must be preceded by this string (although some less sophisticated filters seem to work without this):

`"progid:DXImageTransform.Microsoft."`

You can apply the filters directly as properties of the filter object that belongs to HTML `element` objects themselves.

Thus:

```
myFilter.Shadow(someAttributes)
```

Warnings:

- Filters are not supported in all versions of MSIE on the Macintosh. In fact they are not really well supported outside of the MSIE browser or the Win32 platform.
- There are various sources of documentation about these filters. There is some difference between them regarding the spelling of the filters names and the availability of the filters. The naming conventions are sometimes all lower case and at others a mixed upper and lower case. This suggests that the filter name parser may be case-insensitive. This also applies to the `name=value` pairs that are passed as arguments to the filter functions.
- Certain filter functions are no longer included in the MSDN reference material and so they may be considered to be deprecated.
- We have conformed to the case style of the MSDN reference and have included all the filters that were covered in earlier references as well as those that have been added recently. Those that appear not to be in the MSDN reference anymore are marked as deprecated as follows:
  - `FlipH()`
  - `FlipV()`
  - `Grayscale()`
  - `Invert()`
  - `Mask()`
  - `XRay()`

These are deprecated filters that used to provide blends and reveals:

- `BlendTrans()`
- `RevealTrans()`

Note that the functionality and availability of the filters has changed significantly from version 4.0 to version 5.5 of the MSIE browser and the older deprecated filters have been assimilated into the functionality of the new filter set. No previously existing filter appearance has been lost but they do need to be operated differently.

Property	JavaScript	JScript	N	IE	Opera	Notes
`enabled`	-	3.0 +	-	4.0 +	-	-

Filter.enabled (Property)

A flag indicating whether a filter is enabled.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myFilter`*`.enabled`

This value can be set `true` or `false` to switch a filter in and out of the display.

Example code:

```
// Alternative ways of referring to a filter
// and controlling its enabled state.  This assumes
// the filter was instantiated with a <STYLE> tag previously.
myFilters = myElement.filters;
myFilter1 = myFilters.item(1);
myFilter2 = myFilters.item("DXImageTransform.Microsoft.Alpha");
myFilter1.enabled = true;
myFilter2.enabled = false;
```

Filters object (Object/JScript)

The `filters` object is part of the MSIE filter mechanisms and is a special case of the `collection` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myFilters`* `=` *`myElement`*`.filters`
Object properties:	`length`	
Object methods:	`item()`	

See also:	`Element.filters[]`, `Filter` object, `style.filter`

Property	JavaScript	JScript	N	IE	Opera	Notes
`length`	-	3.0 +	-	4.0 +	-	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	Notes
`item()`	-	3.0 +	-	4.0 +	-	-

Refer to:

`Collection` object

Filters.item() (Method)

An item selector for accessing a single filter within the collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Filter object`	
JavaScript syntax:	IE	*myFilters*`.item(`*anIndex*`)`
	IE	*myFilters*`.item(`*aSelector*`)`
	IE	*myFilters*`.item(`*aSelector*`, `*anIndex*`)`
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

Filters.length (Property)

The length of the filter collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myFilters*`.length`

Property attributes:

`ReadOnly.`

Refer to:

`Collection.length`

final (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

finally ... (Statement)

Part of the `try ... catch ... finally` error-handling mechanism.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0

The ECMAScript standard (edition 2) defined the `finally` keyword and reserves it for future use. At edition 3, it was made a required keyword.

In anticipation of that, it is available in JavaScript version 1.4. This is also now supported in JScript version 5.0 as well.

Refer to the `try ... catch ... finally` topic for more details.

Warnings:

- This is not available for use server-side with Netscape Enterprise Server 3.

See also:	`catch( ... )`, throw, `try ... catch ... finally`

Cross-references:

ECMA 262 edition 2 section –7.4.3

ECMA 262 edition 3 section –7.5.2

find() (Method)

A means of performing a text search on the document content.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`find()`
	-	`find(`*`aSearchKey`*`)`
	-	`find(`*`aSearchKey`*`, `*`aCaseSense`*`)`
	-	`find(`*`aSearchKey`*`, `*`aCaseSense`*`, `*`aDirection`*`)`
	-	`myWindow.find()`
	-	*`myWindow`*`.find(`*`aSearchKey`*`)`
	-	*`myWindow`*`.find(`*`aSearchKey`*`, `*`aCaseSense`*`)`
	-	*`myWindow`*`.find(`*`aSearchKey`*`, `*`aCaseSense`*`, `*`aDirection`*`)`
Argument list:	*`aCaseSense`*	A switch for case sensitivity
	`aDirection`	A direction to search
	`aSearchKey`	The text to search for

Refer to:

`Window.find()`

FindProxyForURL() (Function/proxy.pac)

The main function in a `proxy.pac` file.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	`FindProxyForURL(`*`aFullURL`*`, `*`aHostname`*`)`
Argument list:	*`aFullURL`*	The complete URL to be checked for proxy access.
	`aHostname`	The hostname component of a URL for convenience

This function is called at request time for every URL. Therefore any lengthy and complex coding in here is going to be detrimental to the performance of your browser.

The `String` and `Math` object methods/functions are available in this context.

The return value from this function tells the browser how to reach the target URL.

For directly connected sites, the value "DIRECT" should be returned. This is usually appropriate for hosts within the same domain or on the same sub-net. The functions `isPlainHostName()` and `isInNet()` both return `true` for machines that should use `DIRECT` connection. However only one of them needs to return `true` for this to be the desired outcome. If both are `false`, then either a SOCKS gateway or PROXY server is needed.

For secure access using the HTTPS: protocol, the function might return "SOCKS" plus some details of the SOCKS host and port to use. You may choose to perform secure access by some other means.

For the remaining cases, your script should probably return "PROXY" with details of the PROXY server (or servers) to use. If more than one proxy server is returned, they are consulted in the order they are listed. This gives you an opportunity to add some load balancing logic if you care to. That is quite important if you have more than one proxy server, since you might return the proxies in the same order every time. That would more-or-less guarantee that the first one was loaded until it simply couldn't respond any more and the second would only kick in as a last resort. Randomizing the order in which they are presented ensures the work is fairly divided between them.

This function must return a very specific result. The following values are examples:

```
"DIRECT"

"SOCKS sockshost:1081"

"PROXY proxy1:1080 ; proxy2:1080"
```

Here we provide an example based on the one provided in the Wrox Instant JavaScript book (by Nigel MacFarlane) that illustrates all of these capabilities. The logic is unraveled to illustrate the selection technique at the expense of a minor performance hit.

Example code:

```
// Example proxy.pac file
function FindProxyForURL(aFullURL, aHostname)
{
   // Check for hosts in the same domain as the client
   if(isPlainHostName(aHostname))
   {
      return "DIRECT";
   }
   // Check for hosts in the same IP sub-net
   if(isInNet(aHostname, "192.168.1.0"))
   {
      return "DIRECT";
   }
   // Check for secure http: protocol
   if(aFullURL.substring(0, 6) == "https:")
   {
      return "SOCKS sockshost:1081";
   }
   // Check for secure news protocol
   if(aFullURL.substring(0, 6) == "snews:")
   {
      return "SOCKS sockshost:1081";
```

```
    }
    // Return a randomly selected proxy list
    if(Math.random() < 0.5)
    {
       return "PROXY proxy1:1080 ; proxy2:1080";
    }
    else
    {
       return "PROXY proxy2:1080 ; proxy1:1080";
    }
 }
```

FlipH() (Filter/visual)

A visual filter for horizontal mirror effects.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

filter – `FlipH()`

FlipV() (Filter/visual)

A visual filter for vertical mirror effects.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

filter – `FlipV()`

float (Reserved word)

Reserved for future language enhancements.

The inclusion of this reserved keyword in the ECMAScript standard suggests that future versions of ECMAScript may be more strongly typed.

This keyword also represents a Java data type and the `float` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	`double`, Integer, `java.lang.Float`, LiveConnect, `long`, Reserved word, `short`

ECMA 262 edition 2 section –7.4.3

ECMA 262 edition 3 section –7.5.3

Floating constant (Definition)

A floating constant is a literal floating point value.

A floating constant is a literal numeric value representing a floating-point number. Generally these would appear in comparison expressions, assignments or arithmetic expressions.

There may be some loss of precision with extremely long numbers or floating point values that are very small. In addition, some interpreters may perform rounding slightly differently. Fully ECMA compliant implementations should conform to the IEEE 754 specifications and therefore should be consistent with one another.

See also:	Constant, Constant expression, Floating point, IEEE 754, Number, Numeric literal

Floating point (Definition)

A type of number value.

Availability:	ECMAScript edition –2

Although a floating-point value may be equal in magnitude to an integer, logically they are different due to the typing of the value. However, typing in JavaScript is weak and a floating point value and an integer value may well compare equal where they might not have in other languages.

If ever the JavaScript language acquires a stronger typing facility, some scripts may fail on this point.

See also:	Decimal point (.), Floating constant, Floating point constant, Number

Cross-references:

ECMA 262 edition 2 section –7.7.3

O'Reilly *JavaScript Definitive Guide* –page –36

Floating point arithmetic (Definition)

Arithmetic operations performed on floating point values.

See also:	`Math` object, Floating point

Floating point constant (Definition)

A floating point value.

This is a special case of the arithmetic constant that provides non-integer values.

See also:	Arithmetic constant, Constant expression, Floating point, `Math.E`, `Math.LN10`, `Math.LN2`, `Math.LOG10E`, `Math.LOG2E`, `Math.PI`, `Math.SQRT1_2`, `Math.SQRT2`, `Number.MAX_VALUE`, `Number.MIN_VALUE`

Flow control (Definition)

Redirecting the program execution away from the linear flow.

Normal execution of the script proceeds from the top to the bottom, one statement at a time. This makes for a not very flexible or capable program.

Conditional execution of one section of code or another allows the execution flow to be controlled according to the result of a computation that yields a Boolean result. These either conditionally execute a piece of code, or not as is the case with the `if()` construct, or conditionally execute either one fragment of code or another as is the case with the `if()else` construct. The ternary operator `?:` provides an alternative way to construct an `if()else` mechanism at the expense of readability and potential obfuscation of your script.

Iterators are used to cycle round a section of code repeatedly until some condition is met.

A `for()` iterator will normally be used to index a counter to enumerate through a set of items, possibly in an array.

A `while`() iterator will execute the same code over and over until something in that code block changes the value of the condition at the head of the `while()` block.

Reserved words (as of ECMA edition 2) suggest that `do()` iterators and `switch()case` trees will be introduced later, or may be implemented now by forward-looking JavaScript interpreter builders. Edition 3 of the standard introduces these and a mandatory requirement.

See also:	Conditionally execute (?:), `do ... while( ... )`, `else ...`, `for( ... ) ...`, `for( ... in ... ) ...`, `if( ... ) ...`, `if( ... ) ... else ...`, Obfuscation, `switch( ... ) ... case: ... default: ...`, `while( ... ) ...`

Wrox *Instant JavaScript* –page –22

focus() (Method)

Direct the keyboard and mouse focus onto the window.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`focus()`
	-	*`myWindow`*`.focus()`

See also:	`Input.blur(),Window.blur(),Window.focus()`

Folder object (Object/JScript)

A special JScript `folder` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myFolder`* `=` *`myFile`*`.ParentFolder`
	IE	*`myFolder`* `=` *`myFolder`*`.ParentFolder`
	IE	*`myFolder`* `=` *`myFileSystem`*`.CreateFolder(`*`aPath`*`)`
	IE	*`myFolder`* `=` *`myFileSystem`*`.GetFolder(`*`aPath`*`)`
	IE	*`myFolder`* `=` *`myFileSystem`*`.GetSpecialFolder(`*`aNumber`*`)`
	IE	*`myFolder`* `=` *`myFolders`*`.Item(`*`aPath`*`)`
Argument list:	*`aPath`*	The pathname of the folder to be created
	`aNumber`	A code referring to a special folder
Object properties:	`Attributes, DateCreated, DateLastAccessed, DateLastModified, Drive, IsRootFolder, Name, ParentFolder, Path, ShortName, ShortPath, Size, SubFolders, Type`	
Object methods:	`Copy(), Delete(), Move()`	
Collections:	`Files[], SubFolders[]`	

This is an object used in the Windows environment, probably as part of the WSH implementation to encapsulate a single folder within the file-system.

See also:	`File` object, `File.ParentFolder`, `FileSystem.CreateFolder()`, `FileSystem.GetFolder()`, `FileSystem.GetSpecialFolder()`, `Folder.ParentFolder`, `Folders.Add()`, `Folders.Item()`

Folder.Attributes (Property)

The file system attributes of a folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myFolder`*`.Attributes`

Folders have attributes that control how they can be used and accessed. This property contains the attributes for the folder encapsulated by this object.

The attributes can be manipulated in a similar way to those belonging to the `File` object.

This property manages the attributes as a bit-mask with individual bits controlling different attributes. The bits can be accessed individually using the integer value corresponding to a power of 2. The table lists the integers that represent each different attribute:

You can use Bitwise `OR` expressions to merge them or accomplish the same with integer additions.

Value	Attribute
0	No special attributes –normal folder.
1	Read-only access.
2	Hidden folder.
4	Indicates a system folder.
8	Refers to drive volume label and cannot be altered.
16	Refers to a directory and cannot be changed.
32	Folder has changed and needs to be backed up again.
64	Folder object represents a shortcut and not a real folder.
128	Folder is compressed.

You cannot alter the settings of bits 8, 16, 64 and 128 as these affect the structure of a file. That is to say, you cannot change a folder into a file or disk volume.

You should read the current attributes setting and then modify it to write it back. The example illustrates some simple functions that encapsulate this conveniently.

Where the bit needs to be set, a simple bitwise `OR` with a single bit value is accomplished in a single line. To clear a bit, we could use a bitwise `AND` having the corresponding bit clear. In these examples a different technique is used for illustration where the bit is set regardless of its previous state and is then cleared using a subtraction. That saves the computation of a complex bit mask. An intermediate temporary variable is used to avoid signalling the operating system with modification unnecessarily requests.

There are other alternative ways to accomplish this and you could write some generic functions to examine, set or clear a bit in a bit-mask and then call them from each of these wrappers indicating the bit you want to operate on.

Example code:

```
// Examine the read/write flag
function isReadOnly(aFolder)
{
   return Boolean(aFolder.Attributes & 1);
}
// Set the folder read only
function setReadOnly(aFolder)
{
   aFolder.Attributes |= 1;
}
// Set the folder read/write
function setWriteOnly(aFolder)
{
```

```
   var myAttributes = aFolder.Attributes |= 1;
   aFolder.Attributes = myAttributes - 1;
}
// ------------------------------------------------
// Examine the hidden flag
function isHidden(aFolder)
{
   return Boolean(aFolder.Attributes & 2);
}
// Hide the folder
function setHidden(aFolder)
{
   aFolder.Attributes |= 2;
}
// Reveal the folder
function setVisible(aFolder)
{
   var myAttributes = aFolder.Attributes |= 2;
   aFolder.Attributes = myAttributes - 2;
}
// ------------------------------------------------
// Examine the system flag
function isSystemFolder(aFolder)
{
   return Boolean(aFolder.Attributes & 4);
}
// Set file to be a system folder
function setSystem(aFolder)
{
   aFolder.Attributes |= 4;
}
// Set file to be a non system folder
function setPublic(aFolder)
{
   var myAttributes = aFolder.Attributes |= 4;
   aFolder.Attributes = myAttributes - 4;
}
// ------------------------------------------------
// Examine the drive volume flag
function isDriveVolume(aFolder)
{
   return Boolean(aFolder.Attributes & 8);
}
// ------------------------------------------------
// Examine the folder flag
function isFolder(aFolder)
{
   return Boolean(aFolder.Attributes & 16);
}
// ------------------------------------------------
// Examine the backup flag
function needsBackup(aFolder)
{
   return Boolean(aFolder.Attributes & 32);
}
```

```
// Set backup required
function setBackup(aFolder)
{
   aFolder.Attributes |= 32;
}
// Clear backup
function clearBackup(aFolder)
{
   var myAttributes = aFolder.Attributes |= 32;
   aFolder.Attributes = myAttributes - 32;
}
// ------------------------------------------------
// Examine the shortcut flag
function isShortCut(aFolder)
{
   return Boolean(aFolder.Attributes & 64);
}
// ------------------------------------------------
// Examine the compressed flag
function isCompressed(aFolder)
{
   return Boolean(aFolder.Attributes & 128);
}
```

See also:	`File.Attributes`

Folder.Copy() (Method)

A method to copy folders.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFolder*.Copy(*aTarget*)
	IE	*myFolder*.Copy(*aTarget*, *aFlag*)
Argument list:	*aTarget*	A valid path within the destination file system
	aFlag	A flag to indicate whether to overwrite an existing folder

Although you can copy whole folders from the file system via the `FileSystem` object's `CopyFolder()` method, this is a more fine-grain means of copying folders.

It is highly recommended that you choose one of the several alternative techniques for copying folders and stick to it. It is far less confusing that way.

This copy method is better than using the `FileSystem.CopyFolder()` method because it's clearer in the script that we are operating on a `Folder`. The other method appears ambiguous because we are operating on something contained in the file system and not the object directly. It feels instinctively better to be operating on objects directly rather than by proxy.

See also:	`File.Copy(),FileSystem.CopyFolder()`

Folder.DateCreated (Property)

The date that the folder was created.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFolder`*`.DateCreated`

The file-system maintains a whole range of properties for its folders and files. This property exposes the date and time that the folder was first created.

See also:	`File.DateCreated`

Folder.DateLastAccessed (Property)

The date that the folder was last accessed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFolder`*`.DateLastAccessed`

The file-system maintains a whole range of properties for its folders and files. This property exposes the date and time that the folder was last accessed by an application.

See also:	`File.DateLastAccessed`

Folder.DateLastModified (Property)

The date that the folder was last modified.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFolder`*`.DateLastModified`

The file-system maintains a whole range of properties for its folders and files. This property exposes the date and time that the folder was last modified by adding files to it or removing them from it. It isn't clear whether modifying a file will affect the modification date and time of a folder that contains it. It may depend on the file-system the folder exists within and how the application modifies the file. It may rewrite the file and delete the old one. In that case, modifying a file will alter the modification date and time of the folder it lives in.

See also:	`File.DateLastModified`

Folder.Delete() (Method)

A method to delete a folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFolder*`.Delete(`*aFlag*`)`
Argument list:	*aFlag*	A flag to indicate whether to force the deletion

You may remove folders via the `FileSystem.DeleteFolder()` method or with this method. Choose one and stick to it if you can.

See also:	`File.Delete(),FileSystem.DeleteFolder()`

Folder.Drive (Property)

The `drive` name that folder belongs to.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFolder*`.Drive`

This returns a `Drive` name that describes the drive that the folder is currently stored on.

See also:	`Drive` object, `File.Drive`

Folder.Files[] (Collection)

Availability:	JScript –3.0 Internet Explorer –4.0
Property/method value type:	`Files object`

Folder.IsRootFolder (Property)

A flag indicating whether the folder is the root folder for the drive it lives in.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myFolder`*`.IsRootFolder`

It may be useful to detect whether a folder is a root folder. If you have built a tree-walking script to navigate round a file system hierarchy folder by folder, this property tells you when you have reached the top.

See also:	`Folder.ParentFolder`

Folder.Move() (Method)

A means of moving folders.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myFolder`*`.Move(`*`aTarget`*`)`
Argument list:	*`aTarget`*	A valid path within the destination file system

Moving or renaming folders is accomplished with this method or with the `FileSystem.MoveFolder()` method, whichever you prefer.

See also:	`File.Move(),FileSystem.MoveFolder()`

Folder.Name (Property)

The name of a folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myFolder.Name`

This property yields the name of the folder itself within the file-system's pathing syntax.

See also:	`File.Name`

Folder.ParentFolder (Property)

The folder containing the `folder` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*myFolder*`.ParentFolder`

You can use this as a means of walking up the folder hierarchy until you reach the root folder.

See also:	`File.ParentFolder`, `Folder` object, `Folder.IsRootFolder`

Folder.Path (Property)

The file-system path to the folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFolder*`.Path`

This property yields the complete and fully qualified path to the folder within the context of its parent file-system.

See also:	`File.Path`

Folder.ShortName (Property)

The DOS 8.3 name for the folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFolder*`.ShortName`

In the Windows environment, even though long file names are used from the user's point of view, at the lowest level within the file system some folders will still be stored under their old style DOS 8.3 format folder names. This property yields the DOS equivalent short folder name for a `Folder` object.

See also:	`File.ShortName`

Folder.ShortPath (Property)

The DOS 8.3 path to the folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFolder`*`.ShortPath`

In the Windows environment, even though long file and folder names are used from the user's point of view, at the lowest level within the file system, some folders and files will still be stored under their old style DOS 8.3 format file names. This property yields the DOS equivalent path name for a `Folder` object.

See also:	`File.ShortPath`

Folder.Size (Property)

The size of the folder contents.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myFolder`*`.Size`

The total size of all the files in the folder measured in bytes, is yielded by this property. At least this is consistent with the size property belonging to the `File` objects. It remains to be seen whether this actually yields the same value as you would get if you obtained the size properties from every file in the folder and summed them yourself. There may be invisible files and this property should include their sizes too.

See also:	`File.Size`

Folder.SubFolders[] (Collection)

A list of sub-folders within the receiving `folder` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folders object`	
JavaScript syntax:	IE	*`myFolder`*`.SubFolders`

If you are walking up the folder hierarchy, you can use the `parentFolder` property.

This collection of `Folder` objects provides a way of traversing down the folder hierarchy to the leaf nodes at the deepest level.

See also:	`File.ParentFolder`

Folder.Type (Property)

The folder object type.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFolder`*`.type`

This is used as a way to determine the type of an object when `Folder` objects are mixed with `File` objects in a collection obtained from a `Folder` or `FileSystem`.

`Folder` objects should return a type value of "`File Folder`".

See also:	`File.Type`

Property attributes:

`ReadOnly`.

Folders object (Object/JScript)

A special JScript object that contains a collection of `Folder` objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myFileSystem`*`.Folders`
Object properties:	`Count`	
Object methods:	`Add(), Item()`	

You can access items in this array with the methods provided or you can create an `Enumerator` object to index through the collection one object at a time.

Property	Java Script	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
Count	-	3.0 +	-	4.0 +	-	-	-	-	-	-	ReadOnly

Method	Java Script	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
Add()	-	3.0 +	-	4.0 +	-	-	-	-	-	-	-
Item()	-	3.0 +	-	4.0 +	-	-	-	-	-	-	-

Folders.Add() (Method)

Add a folder to the collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myFolders*.Add(*aName*)
Argument list:	*aName*	The name of the new Folder object to be created

If you refer to an existing folder within the file system, an object is created to encapsulate it and that Folder object is then added to the Folders collection.

You can also create new folders by using a name that does not yet already exist within the folder that this collection is a child object of. The new folder will be created and then encapsulated as before.

See also:	Folder object

Folders.Count (Property)

Return a count of the number of Folder objects in the collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	IE	*myFolders*.Count

You cannot modify this property to change the extent of the collection. It should however be modified as folders are created or destroyed within the file system.

Property attributes:

ReadOnly.

Folders.Item() (Method)

Locate and return a reference to a specifically named Folder.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Folder object`	
JavaScript syntax:	IE	*myFolders*`.Item(`*aName*`)`
Argument list:	*aName*	The name of the `Folder` object to be located

You can use this to retrieve a `Folder` object that encapsulates an existing folder. Like the `Add()` method, this can also be used to create new folders and to instantiate an encapsulating object before returning it.

See also:	`Folder` object

FONT object (Object/HTML)

An object that represents a `<FONT>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myFONT* `=` *myDocument*`.all.`*anElementID*
	IE	*myFONT* `=` `myDocument.all.tags("FONT")[anIndex]`
	IE	`myFONT =` *myDocument*`.all[`*aName*`]`
	-	*myFONT* `=` *myDocument*`.getElementById(`*anElementID*`)`
	-	*myFONT* `=` *myDocument*`.getElementsByName (`*aName*`)[`*anIndex*`]`
	-	*myFONT* `=` *myDocument* `.getElementsByTagName("FONT") [`*anIndex*`]`
HTML syntax:	`<FONT> ... </FONT>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`color, face, size`	

Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`

With this object, you can manipulate the appearance of text enclosed within the `<FONT>` tag and its corresponding `</FONT>` closure tag.

However, although this may be possible now, a more future-proof technique would be to modify the attributes of the `style` object associated with the block of text that is contained by this `FONT` object. Indeed, you may wish to replace the `<FONT>` tag with a `<DIV>` or `<SPAN>` tag and employ a `CLASS="..."` HTML tag attribute to attach `style` object to it.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`color`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

FONT.color (Property)

The color of text contained within a `<FONT>` block.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFONT*`.color`

The color of text affected by this `FONT` object will be defined in this property.

The color can be specified in the normal way according to the HTML color specifiers.

See also:	`BASEFONT.color`, Color names, Color value, `String.fontcolor()`

FONT.face (Property)

The font face for text contained within the `<FONT>` block.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFONT*`.face`

The font face to be used for text controlled by the `<FONT>` tag is defined by this property. It is appropriate to define a list of font faces in priority order in the normal way. The browser will use the first one it encounters that it has available.

FONT.size (Property)

The size of text contained within the `<FONT>` block.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myFONT*.size

The size of text rendered by the browser under control of this FONT object is controlled by this property. Absolute and relative sizes are supported in the normal way.

See also:	String.fontsize()

for(...) ... (Iterator)

An iterator mechanism –a loop construct.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
JavaScript syntax:	-	*aLabel*: for(*anInitializer*; *aCondition*; *aModifier*)
Argument list:	*aCondition*	An expression that yields a Boolean value
	aLabel	An optional label to name the iterator
	aModifier	Modifies the value being enumerated
	anInitializer	Assigns the starting value

A for loop is established by setting up the control construct in the header and associating a statement block to be evaluated each time the loop is iterated.

The control construct in a for loop has three semi-colon-separated expressions. They are all optional.

The first one initializes the enumerator. It can also declare and initialize a variable to be used for this purpose if one has not already been created.

The second is the condition to test for exit when the required number of loops has been iterated. The for() loop exits when this value becomes false. While it is true, the loop will continue to cycle.

The third is the incrementor (or decrementor if you prefer).

The code in the statement block can be completed early with the break, continue or return statements.

A break will cause the for() loop to drop out and execution to continue at the line following its statement block.

A continue statement will cycle to the next iteration and begin executing the statement block without executing the remaining lines in the block.

A return will exit the loop and its enclosing function and can only be used if the loop is executing inside a function block otherwise the return is meaningless.

You can understand how the `for()` loop works by considering how it can be restated as a `while()` loop.

```
for(anInitializer; aCondition; aModifier)
```

Can be recast as:

```
anInitializer;

while(aCondition)

{

someCode;

aModifier;

}
```

Although the items in the head of a `for()` iterator heading are optional, the semicolons must all be present to indicate the placement of any expressions in the heading.

There is an alternative construction called the `for ... in ...` statement which is especially useful for operating on objects. Refer to the `for ... in ...` topic for details.

At version 1.2 of JavaScript, a named continue can be used with this iterator. If the named continue is executed, control passes to the top of the named for loop. The increment expression is evaluated, then the test expression. If necessary the loop iterates once more.

Example code:

```
// Reccomended form
for(ii=0; ii<100; ii++)
{
   document.write("-");
}
// Possibly dangerous during maintenance
for(ii=0; ii<100; ii++)
document.write("-");
// Loop within a loop
for(ii=0; ii<100; ii++)
{
   for(jj=0; jj<ii; jj++)
   {
      document.write("-");
   }
   document.write("<BR>");
}
// Loop forever doing some task
for(;;)
{
   animateSpinningGraphic();
}
```

See also:	break, `continue`, `do ... while( ... )`, Flow control, `for( ... in ... ) ...`, Iteration statement, Label, Off by one errors, `while( ... ) ...`

Wrox *Instant JavaScript* –page –24

for(... in ...) ... (Iterator)

An iterator mechanism –a loop construct.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –5.0 Internet Explorer –5.0 Netscape –2.0 Netscape Enterprise Server–2.0 Opera–3.0	
JavaScript syntax:	-	*aLabel*: for(*anLValue* in anObject) { *someCode* };
Argument list:	*aLabel*	An optional label to identify the loop
	anLValue	A value that can be assigned to
	anObject	An object whose properties will be cycled
	someCode	Some code that executed each time round the loop

A `for ... in` iteration statement is used to enumerate through the properties of an object.

The first item in the control construct is a container that a value can be assigned to. An `LValue` or Left-Hand Side expression in other words. The item following the in keyword, is the object whose properties are to be enumerated.

Each time round the loop, the name of an object property will be assigned to the `LValue` and it can then be used as an index to the property value in that object.

Properties that have the `DontEnum` attribute set will not be enumerated in this iteration statement.

During each iteration, the property name can be used as an array index key to extract the property value.

At version 1.2 of JavaScript, a named continue can be used with this iterator. If the named continue is executed, control passes to the top of the named for loop. The loop starts over with the next property name being assigned to the specified variable.

Warnings:

- It is often the case that some properties will not be enumerated with this mechanism. In particular, properties of host objects seem particularly prone to this problem.

Example code:

```
// Loop through the properties of an object only printing properties
// that have the string data type.
for(myProperty in myObject)
{
   if(typeof(myObject[myProperty]) == "string")
   {
      document.write(myProperty, myObject[myProperty]);
   }
}
```

Form (Definition)

A browser page that can be filled in and submitted with user specified values.

See also: `Document` object, `Form` object

Form element (Definition)

Those components that are used to construct a form document.

Refer to:

`Form.elements[]`

Form object (Object/HTML)

An object representing an HTML `<FORM>` tag.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0
Inherits from:	`Element object`
JavaScript syntax:	- *myForm* = *myDocument*.*aFormName* IE *myForm* = *myDocument*.all.*anElementID* IE *myForm* = *myDocument*.all.tags("FORM")[*anIndex*] IE *myForm* = *myDocument*.all[*aName*] - *myForm* = *myDocument*.forms.*aFormName* - *myForm* = *myDocument*.forms[*aFormName*] - *myForm* = *myDocument*.forms[*anIndex*] - *myForm* = *myDocument*.getElementById(*anElementID*) - *myForm* = *myDocument*.getElementsByName(*aName*)[*anIndex*] - *myForm* = *myDocument*.getElementsByTagName ("FORM")[*anIndex*] - *myForm* = *myFormArray*[*aFormName*] - *myForm* = *myFormArray*[*anIndex*] - *myForm* = *myInputObject*.form
HTML syntax:	`<FORM> ... </FORM>`
Argument list:	*aFormName* — The name of a form in the document *anIndex* — A reference to an element in a collection *aName* — An associative array reference *anElementID* — The `ID` value of an `Element` object
Object properties:	`acceptCharset, accessKey, action, elements, encoding, enctype, length, method, name, tabIndex, target`
Object methods:	`handleEvent(), reset(), submit()`
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReset, onSelectStart, onSubmit`
Collections:	`elements[]`

Each `<FORM>` tag creates an object in the `document.forms[]` array. However even if the forms are given names, those names become properties within the document object and are not assigned as element names in the `forms[]` array, because the associative naming is lacking. Access to form objects at level 0 of the DOM may need some attention when the DOM becomes level 1.

In MSIE, the form details are collected in a FORM object rather than a `Form` object. It is these object naming differences that can cause some problems with scripts, and it is possible that some implementations will actually make object class references case insensitive to avoid this problem.

Warnings:

- You can normally enumerate the properties in a `Form` object to access the Form input elements. However, if you place a `<TEXTAREA>` into a `<FORM>` then Netscape 4.7 on Macintosh will not enumerate the `Form` properties. The script halts but no error message is generated. MSIE has no problem enumerating a `<FORM>` containing a `<TEXTAREA>` tag.

See also:	`Collection` object, `Document.<form_name>`, `Document.forms[]`, `Element` object, `Element.all[]`, `Form.elements[]`, `Form.handleEvent()`, `Input.accessKey`, `Input.form`, `Legend` object

Inheritance chain:

`Element` object, `Node` object

Form.acceptCharset (Property)

The character set that the form will be prepared to accept input from.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myForm*.acceptCharset

This becomes important if you are serving forms to different international language communities. You need to define the character set that your form is able to accept.

This property may return a single character set or a list of character sets that can be supported.

Form.action (Property)

A property that contains the submit action method for the <FORM>.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myForm*.action
HTML syntax:	<FORM ACTION="...">	

This value corresponds to the ACTION="..." tag attribute in the <FORM> tag that represents this Form object. This indicates the server side form handler method.

Warnings:

- The value you might store in this property is ignored by MSIE version 3 because it has read-only access to the property.

Form.elements.length (Property)

The number of input elements there are in the form. This is a reflection of the Form.length property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myForm*.elements.length

Form.elements.length is not really a property of the Form object but it is convenient to discuss it here since it is related to the Form.length property.

The structural model of the form and its length property is somewhat confusing because there is an elements[] collection which is really what is being measured. Somehow, the elements all being members of the Form object, means that the Form object's length value is really the length value of the elements[] collection.

The elements collection is really a reference to the Form object and this means the elements collection is polluted with a lot of associatively named member items that are not actually form elements at all.

It is possible that future browser versions will correct this and that a proper FormElementArray class is created. For legacy reasons, the Form.length parameter may need to persist.

See also:	Collection.length, Form.length, FormElement object, length

Property attributes:

ReadOnly.

Form.elements[] (Collection)

An array containing a list of elements belonging to a form.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	-	*myForm*.elements
HTML syntax:	`<INPUT>`	

This property actually refers to the parent `Form` object which contains the elements array content superimposed on its existing properties.

Each item in this array represents an input control element within the form. Each input element is created with a separate `<INPUT>` tag. Any of the following element types can be present in a form object's `elements[]` array although it's unlikely you'll see them all there together:

- `Button`
- `Checkbox`
- `FileUpload`
- `Hidden`
- `Option`
- `Password`
- `Radio`
- `Reset`
- `Select`
- `Select (multiple)`
- `Submit`
- `Text`
- `Textarea`

See also:	`Button` object, `BUTTON` object, `Checkbox` object, `Collection` object, `FileUpload` object, `Form` object, `FormElement` object, `Hidden` object, `Option` object, `Password` object, `RadioButton` object, `ResetButton` object, `Select` object, `SubmitButton` object, `TEXTAREA` object, `TextCell` object

Property attributes:

`ReadOnly`.

Form.encoding (Property)

The type of encoding that the form needs to undergo during submission.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myForm*`.encoding`
HTML syntax:	`<FORM ENCTYPE="...">`

This value corresponds to the `ENCTYPE="..."` tag attribute in the `<FORM>` tag that represents this form object.

This specifies a MIME type for the form when it is submitted to a server.

Warnings:

- The value you might store in this property is ignored by MSIE version 3 because it can only read-access the property.
- This property is not supported on the WebTV platform.
- The DOM specification at level 1 specifies that this property should be called `enctype` and not `encoding`. In MSIE, the `enctype` property has a control attribute while the `encoding` property does not. This suggests that the `encoding` property is simply mapped to the `enctype` property internally.

See also:	JellyScript, MIME types

Form.enctype (Property)

An alias for the `Form.ecoding` property as specified by DOM level 1.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myForm*`.enctype`

Refer to:

`Form.encoding`

Form.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myFileUpload`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`Document` object, `Form` object, `handleEvent()`

Form.length (Property)

The number of elements in a form.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myForm`*`.length`

This may be the same as the `form.elements.length` value. Because of this, the `Form.elements` property may return a reference to the `Form` object itself in some implementations.

See also:	`Collection.length`, `Form.elements.length`, length

Property attributes:

`ReadOnly`.

Form.method (Property)

The method of submission for the `form` object.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myForm*.method
HTML syntax:	`<FORM METHOD="...">`	

This value corresponds to the `METHOD="..."` tag attribute in the `<FORM>` tag that represents this form object.

Warnings:

- The value you might store in this property is ignored by MSIE version 3 because it can only read-access the property.

Form.name (Property)

This corresponds to the `NAME` attribute of the `<FORM>` tag.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myForm*.name
HTML syntax:	`<FORM NAME="...">`	

Forms may be accessed by the `NAME` or `ID` attribute in some browsers. It is recommended practice to always use the `NAME` value.

Form.reset() (Method)

Invoke a form reset on the field content.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera–3.0	
JavaScript syntax:	-	*myForm*.reset()

Refer to:

onReset

Form.submit() (Method)

Invoke a form submit to the server.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
JavaScript syntax:	-	*myForm*.submit()

If your verification script is happy that the form data is correct, you can call this method to force the form data to be submitted.

Form.tabIndex (Property)

A control of where the form appears in the tabbing order of the page.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myForm*.tabIndex

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms. Pressing the [tab] key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

Form.target (Property)

A target window or frame for the form response to be displayed in.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera–3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myForm*.target
HTML syntax:	`<FORM TARGET="...">`	

This value corresponds to the `TARGET="..."` tag attribute in the `<FORM>` tag that represents this form object.

Here are some example target values:

- `_parent`
- `_self`
- `_top`
- `_blank`
- Window name
- Frame name

Warnings:

- The value you might store in this property is ignored by MSIE version 3 because it can only read-access the property.

See also:	`<MAP TARGET="...">,Anchor.target,BASE.target, Location.target,Map.target`

Form verification (Definition)

A process of checking user entered form values.

You can attach a script to the `Submit` button in a form to verify the entire contents of the form as it is submitted.

You may prefer to add event handlers to the individual form elements to check them whenever they change.

This is very like the traditional data entry approach to building database loading systems.

Historically, a data entry system would carry out checks at the end of entering each field of data. It would then carry out checks on the whole record before loading it into the database. At that point some integrity checks may also come into play.

In the context of form data verification, our field end checks correspond to the scripts that run when a `Form` element changes. They can only logically check the internal integrity of that individual form element. They should be concerned with correct formatting of the value and range checking it for validity and size.

Our record end checks in the context of Form verification are done when the `Submit` button is pressed. This can check the integrity of data from field to field. That is best done at this point because if it's done at the field editing level, it needs to take account of default values which need to be considered as valid entry data. That complicates the field integrity checks. Cross-checking fields with one another should logically be done at a higher administrative level.

If all the fields correlate, the form can be submitted. If one or more needs to be corrected, a message can be presented and the offending item marked, selected or focussed for correction.

Formal Parameter List (Definition)

The arguments that are passed to a function when it is called.

Availability:	ECMAScript edition –2

The list of parameters in the function declaration. This defines the calling interface to the function.

As the formal parameter list is parsed, each item is represented by a property added to the variable object belonging to the owner of the evaluation. The attributes of the property being added depend on the type of code being evaluated. The values to be stored in each parameter's property attribute are determined by the caller.

If fewer values are provided than there are formal parameters, the remaining parameters will have the value undefined assigned to their properties in the variable object.

If more than one formal parameter shares the same name, then earlier values are overwritten by later ones in order of appearance in the Script Source Text. If an overwrite like this occurs and there are insufficient values passed by the caller, a previously defined value could be replaced by the undefined value.

See also:	`function( ... ) ...`, Script Source Text, Variable Declaration, Variable instantiation

FormArray object (Object/browser)

The `FormArray` object is a collection of objects referring to the `Form` objects for the current document.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0	
JavaScript syntax:	-	*myFormArray* = *myDocument*.forms
Object properties:	`length`	
Object methods:	`item()`	

The array is constructed by taking the `<FORM>` tags in the document and building a unique `Form` object for each.

In MSIE, the `FormArray` is constructed by adding an element to the array for each `Form` object and setting its key to be the value of the `NAME="..."` HTML tag attribute. For two named `<FORM>` tags, there will be only two entries in the array.

In Netscape, the array is constructed a little differently. First, the `Form` objects are created as was the case with MSIE. Then they are added to the array and can be accessed numerically. The `FormArray.length` property is then set according to the number of `Form` objects in the array. Then, additional elements are added to the `FormArray` to correspond to the `NAME="..."` HTML tag attribute. If you have this in your document:

```
<FORM NAME="ONE">

...

<FORM NAME="TWO">

...
```

Then your `FormArray` will contain these entries:

- `0 -> Form ONE`
- `1 -> Form TWO`
- `ONE -> Form ONE`
- `TWO -> Form TWO`

However the length property will still only return the value 2.

If you make both <FORM> tags identical, with the same NAME value, like this:

```
<FORM NAME="ONE">
...

<FORM NAME="ONE">

...
```

Then, you will get this array:

- 0 -> First form
- 1 -> Second form
- ONE -> Form ONE

The length value still reports 2 but if you enumerate the array contents in a for(... in ...) loop, you get three entries now instead of four.

Regardless of how you define the forms in MSIE, it will always have the correct number of elements in the FormArray but they might have the same name. You can still access them numerically though.

Warnings:

- Although the FormArray is a collection, the MSIE 5.0 browser on the Macintosh will crash if you try to use the item() method on it.
- Be careful to avoid naming forms identically if you have more than one in a document. You still get the correct number of Form objects but accessing them via the FormArray may become problematic if you use the name attributes to locate them associatively.

See also:	Collection object, Document.forms[]

Property	Java Script	JScript	N	IE	Opera	HTML	Notes
length	1.0 +	3.0 +	2.0 +	4.0 +	-	-	Warning, ReadOnly

Method	Java Script	JScript	N	IE	Opera	HTML	Notes
item()	-	3.0 +	-	4.0 +	-	-	-

FormArray.item() (Method)

An item selector for picking items out of a collection of forms.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Form` object	
JavaScript syntax:	IE	*myFormArray*`.item(`*anIndex*`)`
	IE	*myFormArray*`.item(`*aSelector*`)`
	IE	*myFormArray*`.item(`*aSelector*`, `*anIndex*`)`
Argument list:	*AnIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

FormArray.length (Property)

The number of forms in the form array.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myFormArray*`.length`

This property yields the number of forms in the document. Each form is represented by its own individual `Form` object.

The `length` property is consistent across Netscape and MSIE in that it reports the number of unique `Form` objects that are available. However, this is not the length of the array in Netscape because additional elements are placed into the array to access the `Form` objects associatively by name.

Warnings:

- The `length` value is only correct in Netscape if you are accessing the array with numeric index values. You will get more than *myFormArray*`.length` objects if you enumerate the array with a `for( ... in ... )` loop. In that case you will visit each `Form` object more than once.

See also:	`Collection.length`

Property attributes:

ReadOnly.

FormElement object (Object/browser)

An object representing an HTML `<INPUT>` tag in a `<FORM>`.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Inherits from:	Input object	
JavaScript syntax:	IE	*myFormElement* = *myDocument*.all.anElementID
	IE	*myFormElement* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myFormElement* = *myDocument*.all[*aName*]
	-	*myFormElement* = *myDocument*.getElementById(*anElementID*)
	-	*myFormElement* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myFormElement* = *myForm*.*anElementName*
	-	*myFormElement* = *myForm*.elements[*anItemIndex*]
	-	*myFormElement* = myForm[*anIndex*]
	-	*myFormElement* = *myFormElements*Array[*anItemIndex*]
	-	*myFormElement* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
	anItemIndex	A reference to a single item within the form elements array
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDblClick, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit, onSelect`	

This is a generic description of a `form element` object. The object will really be a concrete manifestation of a particular class but is available generally as an item in the elements array that belongs to the form.

Refer to the `Input` object topics for a more detailed description of `FormElement` functionality.

See also:	`Button` object, `BUTTON` object, `Checkbox` object, `Element` object, `Element.all[]`, `Form.elements.length`, `Form.elements[]`, `Input` object, `Password` object, `RadioButton` object, `ResetButton` object, `Select` object, `SubmitButton` object, `TextCell` object

Event name	JavaScript	JScript	N	IE	Opera	HTML	Notes
onAfterUpdate	-	3.0 +	-	4.0 +	-	-	-
onBeforeUpdate	-	3.0 +	-	4.0 +	-	-	-

onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	4.0 +	Warning
onRowEnter	-	3.0 +	-	4.0 +	-	-	-
onRowExit	-	3.0 +	-	4.0 +	-	-	-
onSelect	1.0 +	3.0 +	2.0 +	4.0 +	3.0 +	-	-

Inheritance chain:

`Element` object, `Input` object, `Node` object

FormElementsArray object (Object/browser)

A collection containing the input elements of a form. This is provided by adding properties to the `FORM` object the elements belong to.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
JavaScript syntax:	-	*myFormElementsArray* = *myForm*.elements
Object properties:	length	

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
length	-	3.0 +	-	4.0 +	-	-	ReadOnly

Refer to:

`Collection` object

FormElementsArray.length (Property)

The number of input elements within a form.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myFormElementsArray`*`.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

forward() (Method)

Equivalent to the user clicking on the `[FORWARD]` button.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`forward()`
	-	*`myWindow`*`.forward()`
See also:	`History.forward()`	

Refer to:

`Window.forward()`

frame (Property)

This is another name for self and window.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`Window object`	
JavaScript syntax:	IE	`frame`
	IE	*`myWindow`*`.frame`

Property attributes:

`ReadOnly`.

Refer to:

`Window.frame`

Frame object (Object/DOM)

An object representing an HTML `<FRAME>` tag.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Inherits from:	`Window` object	
JavaScript syntax:	-	*myFrame* = frame
	-	*myFrame* = frames[*anIndex*]
	IE	*myFrame* = *myDocument*.all.*aFrameID*
	IE	*myFrame* = *myDocument*.all.tags("FRAME")[*anIndex*]
	IE	*myFrame* = *myDocument*.all[*aName*]
	-	*myFrame* = *myDocument*.getElementById(*anElementID*)
	-	*myFrame* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myFrame* = *myDocument*.getElementsByTagName("FRAME")[*anIndex*]
	IE	*myFrame* = *myDocument*.parentWindow
	-	*myFrame* = *myFrame*Array[*anIndex*]
	-	*myFrame* = parent
	-	*myFrame* = self
	-	*myFrame* = top
	-	*myFrame* = window
HTML syntax:	`<FRAME>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	borderColor, className, dataFld, dataSrc, defaultStatus, frameBorder, height, isTextEdit, lang, language, longDesc, marginHeight, marginWidth, name, noResize, parent, parentElement, parentTextEdit, scrolling, sourceIndex, src, style, tagName, title, top	
Object methods:	close(), contains(), getAttribute(), removeAttribute(), setAttribute()	

Event handlers:	onAfterPrint, onBeforePrint, onBeforeUnload, onBlur, onDragDrop, onError, onFocus, onHelp, onLoad, onMouseMove, onMove, onResize, onScroll, onUnload
Collections:	all[], attributes[], children[]

The methods and properties of a frame are the same as those for a window object.

Note that MSIE supports a FRAME object as opposed to a Frame object for the management of frames within a frame-set.

DOM level 2 adds the following properties:

- contentDocument

Warnings:

- Be aware that if you store a reference to a frame object and the frame is closed, if you don't dispose of the reference to the frame object then it cannot be garbage collected. A frame object with no associated frame is not much use unless you need to keep the object persistent due to having added some properties to it. If this is the case, then arguably the frame object was the wrong place to put such things.

See also:	BODY object, captureEvents(), Collection object, Document object, Document.activeElement, Document.captureEvents(), Document.frames[], Document.parentWindow, Document.releaseEvents(), Frames object, Global object, IFRAME object, Layer.captureEvents(), Layer.releaseEvents(), Layer.window, self

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
borderColor	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

Window object

Frame.borderColor (Property)

The color of a border around a frame.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myFrame*.borderColor

You can use this property to determine the color of a border surrounding a frame.

See also:	color names, color value

Frame.close() (Method)

A redundant method that should be ignored.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myFrame*.close()

This method is inherited from the `Window` object class but is of no use in the context of a `Frame` object.

Warnings:

- Attempting to close a frame in a frame-set serves no purpose whatsoever.

See also:	`Window.close()`

Frame.defaultStatus (Property)

A default status value that only applies when the mouse is in the frame.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*.defaultStatus

Refer to:

`Window.defaultStatus`

Frame.frameBorder (Property)

A control attribute for borders around frames.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive.`	
JavaScript syntax:	-	*myFrame*`.frameBorder`

this property provides a way to switch frame borders on and off. Although it is a switching property and behaves as if it were a Boolean value it really is implemented as a String value.

This is because it accepts a yes/no value or a 0/1 value depending on which browser you are using. The following values may be used:

- yes –Supported by all browsers to turn frame borders on
- no –Supported by all browsers to turn frame borders off
- 0 –Supported by MSIE to turn frame borders off
- 1 –Supported by MSIE to turn frame borders on

See also:	`IFRAME.frameBorder, IFRAME.frameSpacing`

Frame.height (Property)

The height of a frame.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myFrame*`.height`

Frames can vary in size from browser to browser. Although you can measure the height of a frame, setting it accurately to a desired and exact size is virtually impossible. MSIE is marginally better at this than Netscape.

Warnings:

- Height and width control of frames in Netscape is nothing less than a lottery. There are all kinds of platform dependant weirdness that crop up and you may find yourself doing a browser sniff and building in corrective `document.writes()` that fix up the Frame sizes on the fly.
- Note that there is no width property to be able to measure the frame width value.

See also:	`IFRAME.height`

Frame.longDesc (Property)

This is a URL which points at a document containing a long description of the contents of this frame.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myFrame*`.longDesc`

See also:	`IFRAME.longDesc`

Frame.marginHeight (Property)

The vertical height of a top and bottom margin round a frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*`.marginHeight`

Margins flow round the entire frame. You cannot operate on them individually, but you can operate on the vertical and horizontal margins separately.

This property is the size of the margins at the top and bottom of the frame.

See also:	`IFRAME.frameSpacing`, `IFRAME.marginHeight`

Frame.marginWidth (Property)

The horizontal width of a margin round a frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*.marginWidth

Margins flow round the entire frame. You cannot operate on them individually but you can operate on the vertical and horizontal margins separately.

This property is the size of the margins to the left and right of the frame.

See also:	`IFRAME.frameSpacing`, `IFRAME.marginWidth`

Frame.name (Property)

This corresponds to the `NAME` attribute of the `<FRAME>` tag.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*.name
HTML syntax:	`<FRAME NAME="...">`	

See also:	IFRAME.name

Refer to:

`Window.name`

Frame.noResize (Property)

A switch to control the resize box on a frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myFrame*.noResize

This is a Boolean value to turn the frame resizing control on and off. Unlike the border control, this is a truly Boolean value accepting either `true` or `false` as its setting.

See also:	`IFRAME.noResize`

Frame.parent (Property)

A reference to the window (frame) that contains the frame.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myFrame*.parent

See also:	`Dialog` object, `Window.parent`

Frame.scrolling (Property)

A switch to control the appearance of scrollbars on a frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*.scrolling

Yet another deviant property in the browser mess! Having just discussed the `noResize` property which is a switching mechanism having a Boolean setting, here we are with another switching property. However, as is the case with border controls, this one is not Boolean. Instead it accepts the values:

- `yes`
- `no`
- `auto`

Warnings:

- Be aware that if you allow the scrollbars to be invisible by setting this property to "no" or "auto" when they are not present, Netscape will ignore the `scroll()` method that you apply to the `Window` object. This means that to scroll the content of a window, you must have visible scrollbars. MSIE is far more forgiving and lets you scroll as much as you like regardless of whether the scrollbars are present or not.
- You can work around this in Netscape by creating Layers that can be scrolled independently of the presence of window scrollbars.

See also:	`IFRAME.scrolling`

Frame.src (Property)

The URL for a document contained within the frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrame*`.src`

Frames have their content loaded in much the same way as for a window. This property describes the source URL of the document that controls the content of a frame. You can reload the frame by redefining this value but it is probably better to use the `location.href` value for that.

See also:	`IFRAME.src`

Frame.top (Property)

The top-level window that owns the hierarchy the current frame lives in.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Property/method value type:	`Window object`
JavaScript syntax:	- *myFrame*`.top`

Property attributes:

`ReadOnly`.

Refer to:

`Window.top`

FrameArray object (Object/browser)

A collection of frames within a window. Actually there is no `FrameArray` object type because it is implemented as a `Frames` object.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0
JavaScript syntax:	- *myFrame*`Array = frames` - *myFrame*`Array = `*myDocument*`.frames` - *myFrame*`Array = `*myWindow*`.frames`
Object properties:	`length`
Object methods:	`item()`
See also:	`Collection` object, `Frame` object, `Window.frames[]`, `Frames` object

Property	JavaScript	JScript	N	IE	Opera	Notes
`length`	1.0 +	1.0 +	2.0 +	3.02 +	-	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	Notes
`item()`	-	3.0 +	-	4.0 +	-	-

FrameArray.item() (Method)

An item picker for accessing individual frames within a collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Frame object`	
JavaScript syntax:	IE	*myFrame*`Array.item(`*anIndex*`)`
	IE	*myFrame*`Array.item(`*aSelector*`)`
	IE	*myFrame*`Array.item(`*aSelector*`, `*anIndex*`)`
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

FrameArray.length (Property)

The number of frame objects in a frame collection.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`frames.length`
	-	*myDocument*`.frames.length`
	-	*myFrame*`Array.length`
	-	*myWindow*`.frames.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

frameRate (Property)

An indication of the frame rate for the current display.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	`frameRate`
	N	*`myWindow`*`.frameRate`

Property attributes:

`ReadOnly`.

Refer to:

`Window.frameRate`

Frames object (Object/browser)

A collection of frames belonging to a document or window.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*`myFrames`* `= frames`
	-	*`myFrames`* `=` *`myDocument`*`.frames`
	-	*`myFrames`* `=` *`myWindow`*`.frames`
Object properties:	`length`	
Object methods:	`item()`	

An array of `Frame` objects contained within the document or window.

If the `Frames` object were named consistently with the rest of MSIE, it might be called a `FrameArray` object.

Note that `Frame` objects is really another name for `Window` objects.

Each entry in the `Frames` object is a reference to a `Window` object for the specified frame.

Giving the individual frames a name with the `NAME=". . ."` HTML tag attribute does not feed through into the `Frames` array. The entries are simply numbered with their index value.

The `frames` property in Netscape points at a `Window` object rather than a `Frames` object. Although there is no `Frames` array in Netscape, the `Window` object acquires a length value which is the number of `Frame` objects. However, the frames are not enumerable by index number. We can simulate the functionality of the `Frames` array but to do this, we will need to enumerate all the properties of the `Window` object and eliminate the ones we don't want.

The example below illustrates how to enumerate through the properties of a `Window` object and extract only those which are valid `Frame` objects. The `toString` function forces the new array to pose as a new object class. This actually works in MSIE and Netscape and yields an array that is consistent in both browsers.

Warnings:

- The `frames` property in MSIE points at a `Frames` array object that is easy to enumerate and operate on by itself. In Netscape, the properties that would have been stored in the `Frames` array in MSIE are simply dumped into the global property space, and stored in a `Window` object. This not only makes them harder to find but much harder to operate on in a logical way. Yet again it illustrates the need for script developers to be aware of the finer points regarding the differences between MSIE and Netscape.

Example code:

```
// Build a FrameArray in Netscape
var myIndex = 0;
var myFramesArray = new Array();
myFramesArray.toString = function () { return "[object FrameArray]"; }

for(var myProp in frames)
{
   if(isDesiredFrameObject(myProp, frames[myProp]))
   {
      myFramesArray[myIndex] = frames[myProp];
      myIndex++;
   }
}

// Select genuine frame objects
function isDesiredFrameObject(aProperty, anObject)
{
   if(toString(anObject) == "[object Window]")
   {
      switch(aProperty)
      {
         case "frames" :
         case "parent" :
         case "top"    :
         case "self"   :
            return false;
         default       :
            return true;
      }
   }
   return false;
}
```

See also:	`Collection` object, `Document.frames[]`, `Frame` object, `Window` object, `Window.frames[]`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`item()`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	Warning

Frames.length (Property)

The number of frames in the window to which the frames array belongs. The number of inline frames in the current document.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`frames.length`
	-	*`myDocument`*`.frames.length`
	-	*`myWindow`*`.frames.length`
HTML syntax:	`<IFRAME>`	

See also:	`Frames` object, `Collection.length`

Property attributes:

`ReadOnly`.

Cross-references:

Wrox *Instant JavaScript* –page –81

frames[] (Collection)

The frames array belongs to the `window` object.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Frames object`	
JavaScript syntax:	-	`frames`
	-	*`myWindow`*`.frames`
HTML syntax:	`<FRAME>`	

See also:	`Document.frames[]`, `Frames` object, `Window.frames[]`

Property attributes:

`ReadOnly`.

Cross-references:

Wrox *Instant JavaScript* –page –81

FRAMESET object (Object/HTML)

An object that represents a `<FRAMESET>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*`myFrameSET`* `= ` *`myDocument`*`.all.`*`aFramesetID`*
	IE	*`myFrameSET`* `= ` *`myDocument`*`.all.`*`anElementID`*
	IE	*`myFrameSET`* `= ` *`myDocument`*`.all.tags("FRAMESET")[`*`anIndex`*`]`
	IE	*`myFrameSET`* `= ` *`myDocument`*`.all[`*`aName`*`]`
	-	*`myFrameSET`* `= ` *`myDocument`*`.getElementById(`*`anElementID`*`)`
	-	*`myFrameSET`* `= ` *`myDocument`*`.getElementsByName(`*`aName`*`)[`*`anIndex`*`]`
	-	*`myFrameSET`* `= ` *`myDocument`*`.getElementsByTagName` `("FRAMESET") [`*`anIndex`*`]`

HTML syntax:	`<FRAMESET> ... </FRAMESET>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey, border, borderColor, cols, frameBorder, frameSpacing, rows, tabIndex`	
Event handlers:	`onBeforeUnload, onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onUnload`	

This object encapsulates the top level frame-set in a multi-paned window. You need to be a little bit cunning to access the object for the `FRAMESET` because normally you are running a script that lives inside one of its frames.

Logically, you might assume that a `FRAMESET` object has a property with a list of frames contained within it. Actually, you can navigate the hierarchy but it's via the usual DOM properties such as `childNodes` and `firstChild` etc.

The `FRAMESET` object can be a useful way of maintaining session state. Although it is only present in the MSIE browser, the Netscape browser can accomplish the same session store techniques with the `global` object that belongs to the document containing the frame-set.

See also:	`Element` object

Property	Java Script	JScript	N	IE	Opera	DOM	HTML	Notes
`accessKey`	-	3.0 +	-	4.0 +	-	-	-	-

onMouseDown	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.2 +	3.0 +	4.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onResize	1.2 +	3.0 +	4.0 +	4.0 +	-	-	-	Warning
onUnload	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	-	Warning

Inheritance chain:

`Element` object, `Node` object

FRAMESET.accessKey (Property)

A key that needs to be pressed before the input object will respond to data entry.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFrameSET`*`.accessKey`

The key defined in this property needs to be held down for any input events to be triggered on this object or its children.

FRAMESET.border (Property)

A switching attribute that controls the border around the frames in a frame-set.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFrameSET`*`.border`

This property indicates the thickness of frame borders around all the frames. The borders are turned on and off with the `frameBorder` property.

Even if the borders are turned off, the value of this property controls the spacing between frames. Setting the border color forces the borders to appear regardless of the `frameBorder` setting.

See also:	`FRAMESET.frameBorder`, `FRAMESET.frameSpacing`

FRAMESET.borderColor (Property)

An attribute controlling the color of a border around the frames in a frame-set.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myFrameSET`*`.borderColor`

You can use this property to determine the color of a border surrounding a frame. The borders are turned on and off with the `frameBorder` property.

Even if the borders are turned off, the value of the border property controls the spacing between frames. Setting the border color forces the borders to appear regardless of the `frameBorder` setting.

FRAMESET.cols (Property)

The column arrangement of frames within a frame-set.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myFrameSET`*`.cols`

The value defined in the `COLS` HTML tag attribute is reflected into this property. It appears exactly as it does in the HTML document source.

FRAMESET.frameBorder (Property)

A switching attribute for the border around individual frames within the frame-set.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myFrameSET`*`.frameBorder`

This property controls whether the frame borders are visible or not.

Even if the borders are turned off, the value of the border property controls the spacing between frames. Setting the border color forces the borders to appear regardless of the `frameBorder` setting.

See also:	`FRAMESET.border`

FRAMESET.frameSpacing (Property)

A property indicating the amount of space between frames within the frame-set.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myFrameSET*`.frameSpacing`

The spacing distance between frames is specified in this property. Actually, from a functional point of view, it behaves exactly the same as the border property.

See also:	`FRAMESET.border`

FRAMESET.rows (Property)

The row control attribute for the frame-set.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFrameSET*`.rows`

The value defined in the `ROWS` HTML tag attribute is reflected into this property. It appears exactly as it does in the HTML document source.

FRAMESET.tabIndex (Property)

A numeric ordering of the `<FRAMESET>` within the parent document's tabbing sequence.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myFrameSET*`.tabIndex`

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms. Pressing the `[tab]` key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

Free-format language (Definition)

A somewhat relaxed layout strategy for source code.

JavaScript is a free-format language. That means it has a very relaxed attitude to the organization and layout of the script source text. You can place multiple statements on one line and separate them with semi-colons. It is also forgiving enough to allow you to omit semi-colons, which it will put in for you as the script is executed. There are some cases where this cannot apply because for JavaScript to do this, the programmer's original intent must be quite unambiguous. This is called automatic semi-colon insertion and is covered in a topic of its own.

See also:	Automatic semi-colon insertion, JavaScript language

Wrox *Instant JavaScript* –page –17

ftp: URL (Request method)

A request from a web browser to an ftp server to send a file.

This will download a file using the FTP protocol. In most respects it is very like accessing with HTTP. However, you may need to specify a user name and password.

See also:	javascript: URL, URL

Function (Definition)

The action of executing a function object's script source text.

Availability:	ECMAScript edition –2

Functions and methods are similar but not the same thing.

Methods provide a function like behavior because they can be called and sometimes return a value. They operate on the content of the receiving object to which they are attached and yield information about the internals of the object.

Functions perform some transformation on the input arguments and return a result that is dependent on them. This computation is complete independent of the contents of any object.

Accessor methods to set and get internal values of an object are presented externally as properties.

In JavaScript, functions are first class data items. That means they are implemented as objects and can be manipulated in expressions and assigned to `LValues`. You could create an array that contains a collection of function objects. You can pass a function as a parameter to another function or store a reference to it in a variable. To do this in a compiled language would require you to do some pointer manipulation. In Objective C, this kind of functionality is called dynamic late binding and allows methods to be attached to event triggers at run-time.

A function is a construct that performs a task. It is derived from the procedural language model rather than the Object Oriented Language model. Procedural language functions are analogous to Object Oriented language methods but they are not quite the same. Functions are called and carry out some procedural task, while methods are invoked by sending a message to a receiving object – they may however belong to a class or an object instance of a class. Class methods are most likely to be factory methods for creating instance objects of that class.

Function calls can only be received by function objects otherwise a runtime error results – however, those `Function` objects generally belong to other objects and are stored as properties of the owner object.

A method is a specially written function that operates on the receiving object and can be shared between several objects using the `'this'` variable to refer to the receiving object.

Associating a function with an object renders that function the active code to be called when a method is invoked on that object. Invoking a method sends a message to the object, the receiving object looks for a property with the message name which contains a reference to callable function object. If it doesn't have one, it calls its parent and delegates the message upwards.

In JavaScript version 1.2, function definitions can be nested within one another. You can end up with local scope chains being nested within one another. Be sure to scope any variables to exist within the level of function nesting that you need. You can accomplish this with the `var` keyword.

Example code:

```
// Example of JavaScript version  1.2 function nesting
// Create a globally scoped value
var scope = "Global"

// Define a function object and store a global reference to it
myFunc1 = function outer()
{
   var scope = "Outer"
   // Define an inner anonymous function and store a global reference to it
   myFunc2 = function ()
   {
      var scope = "Inner"
      return scope;
   }
   return scope;
}

// Call the various functions to establish the scope of the variables
document.write("<TABLE BORDER=1>");
document.write("<TR><TH>Scope</TH>");
document.write("<TH>Value</TH></TR>");
document.write("<TR><TD>Global</TD>");
document.write("<TD>");
document.write(scope);
document.write("</TD></TR>");
document.write("<TR><TD>myFunc1</TD>");
document.write("<TD>");
document.write(myFunc1());
document.write("</TD></TR>");
```

```
document.write("<TR><TD>myFunc2</TD>");
document.write("<TD>");
document.write(myFunc2());
document.write("</TD></TR>");
document.write("</TABLE>");
```

Function arguments (Definition)

The parameters that are passed to a function as it is called.

When values are passed to a function as it is called, primitive values are passed by value. This means that from inside the function you see a copy of the value and cannot damage the one outside.

Objects are passed by reference. If you modify the properties of an object that is passed into a function by way of an argument, you will be modifying the master instance of that object because there is only one.

This means that calling a function can have side effects that you may not expect unless you realize that this is happening.

Wrox *Instant JavaScript* –page –27

Wrox *Instant JavaScript* –page –29

Function call (Definition)

A means of invoking a function definition.

A function may be invoked at any time. Typically in a web browser, functions are attached to event handlers belonging to document objects.

A function call consists of the identifier that names the function and a set of parentheses enclosing the optional parameters. The declaration of the function specifies the identifier and the formal parameter list.

The identifier must match letter for letter in the same case.

When a function is called either as a procedure or as part of an expression, there is the possibility of somewhat massive side effects to take place before the function returns. Indeed, it is possible to build a function that actually never returns.

Functions can be called in other documents, other frames and other windows. However, there are some security implications regarding whether those functions are accessible –the calling and called functions must exist in pages that were loaded from the same server or domain unless the security controls can be relaxed.

It is generally easier to call functions in parent windows and frames and then call downwards to their children. This allows some session state to be maintained in the parent's global scope. The parent can be a frameset and need not be a visible window or frame.

If you are using the parent as a means of maintaining state information, you might want to implement accessor functions to store and retrieve state information. This allows the validation of the values to be range checked in one place and for the physical storage implementation to be hidden. This is indicative of a good Object Oriented Programming style.

The result returned by a function call depends on the function script source text.

Cross-references:

Wrox *Instant JavaScript* –page –27

Function call operator ( ) (Definition)

The parentheses change a property into a function/method.

- A property invoked as an `LValue` is used as an assignment target.
- A property invoked as an `RValue` returns its value, which for a function or method is the function declaration.
- A property invoked as an `RValue` with the parentheses and some optional arguments is called as a function or method.

The distinction between a function and method is whether the script source text in the function body makes use of the `'this'` keyword to operate on the receiving objects properties.

See also:	Arguments object, Function, Function code, Function literal, Function property, function(...) ..., `Function.arguments[]`, Grouping operator ( )

Function code (Definition)

Script source in a declared function.

Availability:	ECMAScript edition –2

Function code is the script source text that appears between the braces in a function declaration.

This could also fall under the heading of `eval` code if the function is being declared as a component within some script source text that has been passed to the `eval()` function for processing.

Function code initializes the scope chain to include its activation object followed by the `global` object.

Variable instantiation is performed using the activation object as the variable object and any initial variables are flagged with a `DontDelete` attribute.

The caller provides `this` value but in some situations the value `null` may be passed. In that case, the `global` object will be used in its place.

See also:	Compound statement, `eval()`, Executable code, Execution context, Function call, Function call operator ( ), function(...) ..., Script

Function definition (Definition)

The description of a function in the script source text.

See also:	Declaration, Function call, Function call operator ( ), Parameter, `function( ... ) ...`

Function literal (Definition)

A way of creating functions on the fly within your script.

JavaScript version 1.2 introduces a genuine literal syntax for creating anonymous functions.

Previously we might have used a function constructor and assigned the result to an object. This is more simple and straightforward. It looks just like a normal function declaration, except that there is no name defined for the function.

Example code:

```
// An example function literal
var cube_value = function(a) { return a*a*a; };
```

See also:	Anonymous function, Function call operator ( ), function(...) ...

Function object (Object/core)

An object of the class "Function".

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server–2.0 Opera –3.0	
JavaScript syntax:	-	*myFunction* = Function
	-	*myFunction* = new Function()
Object properties:	arity, caller, constructor, length, prototype	
Object methods:	apply(), call(), toSource(), toString(), valueOf()	
Collections:	arguments[]	

An instance of the class "`Function`" is created by using the new operator on the `Function()` constructor. The new object adopts the behavior of the built-in prototype object through the prototype-inheritance mechanisms.

All properties and functions of the prototype are available as if they were part of the instance.

Many built-in objects are functions. They can be invoked with arguments. Some of these are constructors. They are functions that are intended to be used with the new operator.

Function objects come in four varieties according to how they are implemented. They may be built-in to the interpreter or may be provided as extensions in the script itself. The four types of functions are:

- Declared functions in script source text
- Anonymous functions build with the `Function` object constructor
- Implementation-supplied functions built into the host environment
- Internal functions built into the language

JavaScript has such relaxed syntax rules that it forgives the programmer if the arguments to a function are omitted. Instead, the interpreter will automatically pass the undefined value in place of the missing argument.

Every built-in function has the `Function` prototype object as the value returned by its internal `Prototype` property with the exception of the `Function` prototype object itself, which would return the `Object` prototype object.

The prototype for the `Function` prototype object is the `Object` prototype object.

If you want to create a function with no name, you can create your own `Function` object with the new operator. That function would have some script source associated with it and you can then call your function directly. Although it won't have a name, it would appear as if it did in the script source when you call it. However the name it would appear to have is actually the name of the variable containing the reference to it. Since it is an object, two variables can refer to the same object and you could call the same function under two different names. That might happen if you pass the function as an argument in the calling interface to another function. This is a way of implementing call-backs. You might build a comparator like this and pass it to a `sort()` function.

Creating function objects and referring to them in variables is somewhat like using an `eval()` function to execute script source that you have built in a string.

Example code:

```
// Create a function object
var myFunction = new Function("arg1, arg2", "return(arg1 * arg2);");

// And call it
document.write(myFunction(5, 10));
```

O'Reilly *JavaScript Definitive Guide* –page –42

Function() (Constructor)

A Function object constructor.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
JavaScript syntax:	-	`new Function()`
	-	`new Function(`*`someArguments`*`)`
Argument list:	*`someArguments`*	Some formal parameters and a block of script source

The function constructor can be called with the new operator or as a function.

The initial value of `Function.prototype.constructor` is the built-in `Function` constructor.

The arguments supplied to the `Function()` constructor are all assumed to be parameters apart from the last one which is taken to be the body Source Script Text. If there is only one argument, then that is taken to be the body of the function.

If there are no arguments, an empty function is created.

Note that it is permissible but not necessary to have a separate argument for each formal parameter. All three of these examples produce exactly the same result:

- new Function("a", "b", "c", "return a+b+c")
- new Function("a, b, c", "return a+b+c")
- new Function("a, b", "c", "return a+b+c")

A prototype property is automatically created in case the function object is used as a constructor at some future time.

The function constructor will always create top level functions without static scoping. This is a little different to the behavior of a function literal, available in JavaScript version 1.2 onwards.

Function() (Function)

A Function object constructor.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	`Function()`
	-	`Function(`*`someArguments`*`)`
Argument list:	*`someArguments`*	Some formal parameters and a block of script source

When the `Function` constructor is called as a function, it creates and initializes a new function object. The function call `Function()` is equivalent to the expression new `Function()` with the same arguments.

The arguments supplied to the `Function()` constructor are all assumed to be parameters apart from the last one which is taken to be the body Source Script Text. If there is only one argument, then that is taken to be the body of the function.

See also:	Cast operator, Constructor function, constructor property, Function call, `Function.prototype`, Implicit conversion

ECMA 262 edition 3 section –15.3.1

Function.apply() (Method)

Use a function object as if it belonged to another target object.

Availability:	ECMAScript edition –3 JavaScript –1.3 JScript –5.5 Internet Explorer –5.5 Netscape –4.06	
Property/method value type:	`Function result`	
JavaScript syntax:	-	`myFunction.apply(`*`anObject`*`, `*`anArray`*`)`
Argument list:	*`anArray`*	A set of arguments presented as an array
	`anObject`	An object to apply the function to

If you want to force a particular function implementation to be used on an object, you can locate the one you want and pass it an object on which to operate. The function then executes as if it were a property of the passed object instead of the receiving object.

This can be useful to restore some functionality that may have been overridden or to share a function definition between several objects.

This is effectively like adding the function as a property to the target object, executing it, passing the arguments to it and then deleting the function property afterwards. Applying a function is a lot easier.

This is similar to the `call()` method that passed the arguments as a comma separated list. This passes them as an array.

Example code:

```
// Use the fundamental valueOf method on an object that has overridden
// its own valueOf method
Object.prototype.valueOf.apply(myTargetObject);
```

See also:	`Element.applyElement()`

Cross-references:

ECMA 262 edition 3 section –15.3.4.3

Function.arguments[] (Collection)

The values passed to the function when it is called.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server–2.0 Opera –3.0 Deprecated	
JavaScript syntax:	-	*myFunction*.arguments

This property is only defined within a function body in a web browser. However some implementations may provide external arguments via this property.

Refer to the `Arguments` object topic for more details on how to access the caller and callee properties.

Warnings:

- This is an alternative way to access the arguments of a function. It is left over from earlier versions of JavaScript and although it still works, as of JavaScript version 1.2 it is deprecated. You should use the `arguments` object without there being any `function` object prefix to access it as a property.

See also:	Argument, Argument list, Arguments object, `Arguments.length`, `arguments[]`, Execution context, Function arguments, Function call, Function call operator ( ), function(...) ..., `Object.prototype`, Parameter

Property attributes:

`ReadOnly`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 section –10.1.6

ECMA 262 edition 2 section –10.1.8

ECMA 262 edition 3 section –10.1.8

Wrox *Instant JavaScript* –page –27

Function.arity (Property)

The number of arguments expected by a function call.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server–3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myFunction*.arity

This property yields a numeric value representing the maximum number of arguments the function expects to be called with and can support.

The `arity` property of the `Function` constructor returns 1 but it accepts a variable number of arguments.

Otherwise, the `arity` property returns a value that is typical for the function. Because the number of arguments can often be variable, this typical value should be used with caution.

This value is not necessarily the same as the length of the arguments array that is available inside the function when it is called. This indicates the actual number of arguments that were passed.

You can compare the two values to verify that the function was called with the correct arguments.

Warnings:

- There is a bug in the Netscape implementation of this property unless the `LANGUAGE` attribute is defined as "Javascript1.2" for the `<SCRIPT>` tag.

See also:	`Arguments.length`, Function call, Function object, `Function.length`, `Function.prototype`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 section –15.3.3.2

ECMA 262 edition 2 section –15.3.5.1

Function.call() (Method)

Uses a function object as if it belonged to another target object.

Availability:	ECMAScript edition –3 JavaScript –1.3 JScript –5.5 Internet Explorer –5.5 Netscape –4.06	
Property/method value type:	`Function result`	
JavaScript syntax:	-	*myFunction*`.call(`*anObject*`,` *anArgumentList*`)`
Argument list:	*anArgumentList*	A list of arguments
	anObject	An object to apply the function to

If you want to force a particular function implementation to be used on an object, you can locate the one you want and pass it an object on which to operate. The function then executes as if it were a property of the passed object instead of the receiving object.

This can be useful to restore some functionality that may have been overridden or to share a function definition between several objects.

This is effectively like adding the function as a property to the target object, executing it, passing the arguments to it and then deleting the function property afterwards. Applying a function is a lot easier.

This is similar to the `apply()` method which passed the arguments as an array. This passes them as a comma separated list.

Example code:

```
// Call this function against another object
myFunctionObject.call(myTargetObject, 100, "aaa");
```

See also:	Event handler scope

Cross-references:

ECMA 262 edition 3 section –15.3.4.4

Function.caller (Property)

A reference to the caller of the function.

Availability:	JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server–2.0 Opera –3.0 Deprecated
Property/method value type:	`Object object`
JavaScript syntax:	- *myFunction*`.caller`

Warnings:

- This is an alternative way to access the caller of a function. It is left over from earlier versions of JavaScript and although it still works, as of JavaScript version 1.2 it is deprecated. You should use the `arguments` object without there being any `function` object prefix to access it as a property and reference the caller from there.

See also:	`Arguments.caller`

Property attributes:

`ReadOnly`, `DontEnum`.

Function.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition –2

This is an internal property that describes the class that a `Function` object instance is a member of. The reserved words suggest that in the future, this property may be externalised.

See also:	Class, Function call, `Function` object

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 section –8.6.2

ECMA 262 edition 2 section –15.3.2.1

ECMA 262 edition 3 section –8.6.2

Function.constructor (Property)

A reference to a constructor object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myFunction*`.constructor`

The initial value of `Function.prototype.constructor` is the built-in `Function` constructor.

You can use this as one way of creating function objects although it is more popular to use the new `Function()` technique or to simply create them in the script source text.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	Function call, `Function.prototype`

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 2 section –15.3.4.1

ECMA 262 edition 3 section –15.3.2

Function.length (Property)

The number of arguments expected by a function call.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myFunction*`.length`

This property yields a numeric value representing the number of arguments the function expects to be called with and can support.

The `length` property of the `Function` constructor returns 1 but it accepts a variable number of arguments.

Otherwise the `length` property returns a value that is typical for the function. Because the number of arguments can often be variable, this typical value should be used with caution.

This value is not necessarily the same as the length of the arguments array that is available inside the function when it is called. This indicates the actual number of arguments that were passed.

Warnings:

- There is a bug in the Netscape implementation of this property unless the `LANGUAGE` attribute is defined as "JavaScript1.2" for the `<SCRIPT>` tag.
- In any case the `function.length` property is deprecated in favor of the `arity` property. This is to avoid confusion between functions and arrays.

See also:	`Arguments.length`, Function call, Function object, `Function.arity`, `Function.prototype`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 section –15.3.3.2

ECMA 262 edition 2 section –15.3.5.1

ECMA 262 edition 3 section –15.3.5.1

Function.prototype (Property)

The prototype for the `Function` object that can be used to extend the interface for all `Function` objects.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server–2.0 Opera –3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	`Function.prototype`
	-	*`myFunction`*`.constructor.prototype`

This is the prototype function object belonging to the `global` object and from which all `Function` objects are descended.

The initial value of `Function.prototype` is the built-in `Function` prototype object.

The value of the prototype property of a function is used to initialize child objects when that function is used as a constructor.

The following properties are inherited from the `Function.prototype`:

- `Function.prototype`
- `Function.constructor`

The following methods are inherited from the `Function.prototype`:

- `Function.toString()`

The following properties are provided by the instances of the `Function` object:

- `Function.length`

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the output capabilities of Function objects
function sourceDump()
{
   myString = this.toString();
   myArray  = myString.split("{");
   myString = myArray.join("<BR>{<BR>");
   myArray  = myString.split("}");
   myString = myArray.join("<BR>}<BR>");
   return myString;
}

// Register the new function
Function.prototype.sourceDump = sourceDump;

// Create a function and test the Function.sourceDump() method
var myFunction = new Function("arg1, arg2", "return(arg1 * arg2);");
document.write(myFunction.sourceDump());
</SCRIPT>
</BODY>
</HTML>
```

See also:	Function call, Function object, `Function()`, `Function()`, `Function.arity`, `Function.constructor`, `Function.length`, `Function.toString()`, prototype property

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

ECMA 262 edition 3 section –15.3

Function.toSource() (Method)

Returns a string primitive version of the function.

Availability:	JavaScript –1.3 JScript –3.0 Internet Explorer –4.0 Netscape –4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFunction*`.toSource()`

This value is identical to the `toString()` method (exclusive to Netscape). In MSIE, it is not supported but since `toString()` is available in MSIE the recommended approach is to use `toString()` instead of `toSource()` for portability reasons.

Function.toString() (Method)

Returns a string primitive version of an object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –3.0 Netscape –4.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myFunction*`.toString()`

The result of calling this method is to obtain the source text of the function definition unless it is a host implemented function. In that case, an implementation dependent value will be returned by this method.

See also:	Cast operator, Function call, `Function.prototype`, `Function.valueOf()`,`toString()`

Cross-references:

ECMA 262 edition 2 section –15.3.4.2

ECMA 262 edition 3 section –15.3.4.2

Function.valueOf() (Method)

Returns a string primitive version of the function.

Availability:	ECMAScript edition –2 JavaScript –1.1 Netscape –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myFunction`*`.valueOf()`

This value is identical to the `toString()` method (exclusive to Netscape). The recommended approach is to use `toString()` instead of `valueOf()` for reasons of consistency.

The result of calling this method is to obtain the source text of the function definition unless it is a host implemented function.

See also:	`Function.toString()`

Cross-references:

ECMA 262 edition 2 section –15.3.4

Function object properties (Definition)

User defined properties added to a function object.

You can add your own properties to a function object. These can then be used as static variables inside the function. Since the function object persists, so do its properties. Variables declared inside the function with a `var` statement only persist while the function context is called and present in the scope chain.

See also:	Static method, Static variable

Function property (Definition)

A property belonging to an object which can be called as a function.

Availability:	ECMAScript edition –2

`Function` properties are implemented as `function` objects stored as the value of a named property within an object.

See also:	Call, `escape()`, `eval()`, Function call, Function call operator ( ), `isFinite()`, `isNaN()`, `parseInt()`, `unescape()`

Cross-references:

ECMA 262 edition 2 section –15.1.2

ECMA 262 edition 3 section –15.1.2

Function prototype (Definition)

A description of the calling interface to a function.

Warnings:

- In C language, the declaration of a function may also include a function prototype. This defines the calling interface to the function so that the compiler can give warning about any function calls that do not conform to the prototype.
- JavaScript does not support this function prototyping because it is not a strongly typed language and the scripts are not compiled before execution. Do not confuse function prototype calling interface specifications with the JavaScript `Function.prototype` object, which is part of the inheritance mechanism.

See also:	const, Function call, function(...) ...

Function scope (Definition)

The context within which the body script runs is the function scope.

JavaScript uses static scoping. This means that the functions are executed in the scope in which they are defined. This is important because any global values they refer to belong to the page in which they live. That is not necessarily the page that they were called from. This is only likely to cause any confusion when a multiple framed document is being rendered.

The function scope is the state of the scope chain as it was when the function was called, plus the `call` object added onto the end of the scope chain. The `call` object is the function being executed.

Because the `call` object is added to the scope chain, you don't need to refer to it explicitly and the current context inherits all its properties and methods.

Warnings:

- The static properties of a regular expression object do not conform to the same static scoping rules. Their static or class-based properties are dynamically scoped and available in the scope chain from which they are executed.

See also:	Event handler scope, `RegExp` object

function(...) ... (Declaration)

The description of a function in the script source text.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server–2.0 Opera –3.0	
JavaScript syntax:	-	`function` *`anIdentifier`* `(`*`aParameter`*`, ...) { scriptSource }`
Argument list:	*`anIdentifier`*	The name of the function being declared
	`aParameter`	One of the formal parameters to be passed to the function when it is called
	`scriptSource`	The source text for the script code that is executed when the function is called

A function declaration is a description of a function in the script source text. It provides the function name and a list of its arguments. It also provides a block of script code to be executed when the function is called.

Functions can be declared in the script source to add to the functions your script can make use of. When they are called, the prototype inheritance mechanism matches most local instances of the function having the name that the caller requests. This provides a way to override methods in parent prototypes or the `global` object.

When functions are declared in `global` and `eval` code, the new function object that is instantiated is added to the `variable` object for the owner of the script source text. It uses the function identifier as a name for the dictionary entry in the `variable` object. The functions are added in the order in which they appear in the Script Source Text and will replace any previously existing entry. Attributes are set according to the type of code being evaluated.

New functions can be added to the scripting environment as needed. They are described in the source script text with function declarators.

A function is declared with the function keyword, a set of parentheses enclosing its passed arguments and a block of executable code enclosed in curly braces.

Functions will always return a result but a function call can be cast to a void type to discard the resulting value. If you don't indicate a result to return yourself, the function mechanism would return the value undefined.

The internal mechanics of function declaration is to add a function property to the `global` object whose name is the function's identifier. The value of that property is a function object with the given parameter list and statement block.

If the function definition is part of the source text supplied to an `eval` function, then the function may be added to an internal activation object rather than the `global` object.

The act of executing or invoking a function is to call it.

Calling a function is accomplished by using the function property of an object as an `RValue` and appending the parentheses grouping operators with option arguments grouped within them.

Functions can be created and their script can refer to objects that don't yet exist. However, you may not run them until the objects they refer to have been created. This is often the case with event handlers that are defined speculatively on the basis that they may be needed but in fact they may never be called at all.

As of JavaScript version 1.2, you can declare new functions anywhere in a script source text. Prior to this, you could only define them in `global` code but not inside any `if()` blocks, `loop` blocks or `with` blocks. In JavaScript version 1.2, functions can be declared inside these contexts and inside functions themselves. This means that function availability can be localized to only be usable within a function's context scope.

Warnings:

- Debugging namespace collisions between function and variable names can be difficult to debug. For very large projects with many people working on shared code, you may want to establish some strict naming conventions to partition the namespace.
- This is an issue because function declarations occur before variable declarations. If you declare a variable with the same name as a function and assign a value to it the function will be inaccessible since you will have replaced the reference to its object with the value you just assigned to the variable.
- This will still happen even if the `var` declaration is placed sequentially earlier in the script block than the function declaration. The first pass declares and sets up the function. The second pass instantiates the variable.
- Remember that functions are created at compile (parse) time, and variables at run-time.

Example code:

```
// Here is an example function declaration:
function circularArea (aRadius)
{
   someGlobalValue = aRadius;
   return(Math.pow(aRadius,2)*Math.PI);
}
```

```
// We are using functions belonging to the Math object to
// raise the passed in radius value to the power of 2
// and multiply the result by the constant value of PI.
// We can call this and assign its value like this:
myArea = circularArea(12);
alert(myArea);

// If we simply wanted to execute the function and discard its
// result we might use this form:
void circularArea(10000);

// The conseqence is just to set the global value but we don't
// do anything with the returned value.
```

Wrox *Instant JavaScript* –page –26

Fundamental data type (Definition)

The basic simple native data types.

The fundamental data types in JavaScript are:

- Number
- String
- Boolean

All other data types are expressed in terms of these kinds of value.

See also:	Boolean, Number, Regular expression, String

Furniture (Definition)

A name for the various items that form the window border.

Refer to:

`Window furniture`

Garbage collection (Definition)

The mechanism by which deallocated strings and objects are cleared from memory.

Garbage collection happens in JavaScript, but you have very little control over when and how. Since you don't have pointers, you cannot identify items that need to be released and nor do you need to.

Garbage collection happens in a web browser implementation when the page is reloaded. Any objects, strings, functions and variables you were using are discarded and no longer available. If you want to keep them around, you need to put them somewhere else, possibly in a parent `FRAMESET` object or as member properties of the `Navigator` object although that's not very portable.

The old JavaScript context is completely destroyed and a new one is made from scratch. This means that each page owns a pool of memory from which its scripts allocate storage. The pool is flushed on a page by page basis. This may get a little more complicated when you have scripts running across frames, since some pools will get flushed and others won't –be careful that the top-most frame does not become a memory hog, as this is the only one you cannot purge without losing all the session state. You could store the state data in cookies or in a transitory page in a separate window and then fetch it back again after the frame-set is regenerated. However, this "solution" is a bit of a hack, and it's better to solve the problem at source rather than try to hide the consequences.

There are many garbage collection algorithms, some better than others, but since you have no control over garbage collection, there is little point in investigating it, other than to influence the strategy you might use for creating and destroying objects. Some techniques may yield better performance in certain browsers due to the garbage collection algorithm the browser uses. Since the browser implementers tend to change this from time to time, there is no guarantee that a technique you deploy now will be optimal for the next version of the same browser.

However, you should try to avoid creating and destroying large numbers of strings and objects, since this seems to lead to memory leakage on most platforms. MSIE version 4 on Windows is particularly prone to this and it's not hard to develop animation loops that consume 50K of memory on each cycle. Virtually any elimination of String construction/destruction is worthwhile in cyclic situations. Indeed, you might find that `innerText` properties are a better place to store textual content than strings if things become extreme.

Get() (Function/internal)

Internal private function that is used to access public properties.

Availability:	ECMAScript edition –2

This internal function is used to retrieve internal properties from objects.

If the property exists in the receiving object, its value will be returned.

If the property is not a member of the receiving object, then if the `Prototype` property for this object returns null, we have reached the top of the prototype chain so the property is undefined. The result will be the undefined value.

If the property does not exist, and there is a parent `Prototype` object, then the message is passed to that object for evaluation.

The `Get` internal function may indeed return a value when received by a host object, even if that host object would respond to the `HasProperty` function with a false result indicating that the property does not exist.

See also:	Accessor method, `GetValue()`, Internal Method

Cross-references:

ECMA 262 edition 2 –section –8.6.2.1

ECMA 262 edition 3 –section –8.6.2.1

GetBase() (Function/internal)

Internal private function.

Availability:	ECMAScript edition –2

This internal function returns the base object component pointed at by the reference item passed as its argument.

A runtime error will be generated if the passed in object is not a reference item.

See also:	Reference

Cross-references:

ECMA 262 edition 2 –section –8.7.1

ECMA 262 edition 3 –section –8.7.1

getClass() (Function)

Returns the `JavaClass` of a `JavaObject`.

Availability:	JavaScript –1.1 Netscape version –3.0	
JavaScript syntax:	N	*myJavaObject*.getClass()

Refer to:

`JavaObject.getClass()`

GetObject() (Function)

A JScript function that returns a reference to an object representing a file belonging to an application on your system.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Automation object	
JavaScript syntax:	IE	GetObject(*aLocation*)
	IE	GetObject(*aLocation*, *anObjectType*)
	IE	GetObject(*aLocation*!*aSubObject*)
	IE	GetObject(*aLocation*!*aSubObject*, *anObjectType*)
Argument list:	*anObjectType*	What sort of application and object class type to be created
	aLocation	A path to the file for the object to be instantiated
	aSubObject	A fragment identifier for a sub-object within the file

When this function is called, the application may be activated to provide a remote interface to the file. You can also specify fragments within the file.

The path argument points at the file within the file system where the object you want reposes.

This is related to the `ActiveXObject()` constructor which creates an object that points at an application or document without loading a file to instantiate it.

The objects created by this function are called `Automation` objects.

The location value can have a fragment identifier delimited by an exclamation mark. With this, for example, you can refer to one worksheet within an Excel document.

Example code:

```
// Locate an Excel spreadsheet
myWorkbook = GetObject("F:\\DOCUMENTS\\ACCOUNTS.XLS");
// Locate one worksheet within an Excel spreadsheet
myWorkSheet = GetObject("F:\\DOCUMENTS\\ACCOUNTS.XLS!sheet4");
```

See also:	ActiveXObject()

GetPropertyName() (Function/internal)

Internal private function.

Availability:	ECMAScript edition –2

This internal function returns the property name component of the reference item passed in its argument.

A run time error is generated if the argument passed is not a reference item.

See also:	Reference

Cross-references:

ECMA 262 edition 2 –section –8.7.2

ECMA 262 edition 3 –section –8.7.2

GetValue() (Function/internal)

Internal private function.

Availability:	ECMAScript edition –2

This internal function returns the value contained in the property belonging to the object pointed at by the reference item passed in its argument.

If the passed-in argument is not a reference item, it is returned as the result.

If the object being referred to does not exist, a run-time error is generated.

Otherwise the usual `Get()` function behavior is invoked for the property named in the reference.

See also:	`Get()`, Reference

ECMA 262 edition 2 –section –8.7.3

ECMA 262 edition 3 –section –8.7.1

Global code (Definition)

Script source that is outside of any function code blocks.

Availability:	ECMAScript edition –2

Global code is that source text that is outside of all function declarations.

On initialization of some global code into an execution context, the scope chain is initialized to only contain the global object and nothing else.

Variable instantiation is performed using the global object as the variable object and with empty property attributes.

This value is set to point at the global object.

See also:	Executable code, Execution context, `function(…)… `, Script

Global object (Object/core)

A special type of object that is always available in the prototype chain.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.0 Netscape –2.0	
JavaScript syntax:	-	*myGlobal* = document.parentWindow
	-	*myGlobal* = frame
	-	*myGlobal* = self
	-	*myGlobal* = window
	-	*myGlobal* = window.frames[*anIndex*]
Argument list:	*anIndex*	A reference to a window object which is also a global object for that window
Object properties:	clientInformation, clipboardData, closed, crypto, defaultStatus, dialogArguments, dialogHeight, dialogLeft, dialogTop, dialogWidth, document, event, external, frame, frameRate, history, innerHeight, innerWidth, java, length, location, locationbar, Math, menubar, name, navigator, netscape, offScreenBuffering, opener, outerHeight, outerWidth, Packages, pageXOffset, pageYOffset, parent, personalbar, pkcs11, returnValue, screen, screenLeft, screenTop, screenX, screenY, scrollbars, secure, self, status, statusbar, sun, toolbar, top, window	
Class constants:	Infinity, NaN, undefined	
Object methods:	addClient(), addResponseHeader(), alert(), Array(), attachEvent(), back(), blob(), blur(), Boolean(), callC(), clearInterval(), clearTimeout(), close(), confirm(), Date(), debug(), deleteResponseHeader(), detachEvent(), disableExternalCapture(), enableExternalCapture(), escape(), eval(), execScript(), find(), flush, focus(), forward(), Function(), getOptionValue(), getOptionValueCount(), home(), isFinite(), isNaN(), moveBy(), moveTo(), navigate(), Number(), Object(), open(), parseFloat(), parseInt(), print(), prompt(), redirect, registerCFunction(), resizeBy(), resizeTo(), scroll(), scrollBy(), scrollTo(), setHotkeys(), setInterval(), setResizable(), setTimeout(), setZOptions(), showHelp(), showModalDialog(), showModelessDialog(), ssjs_generateClientID(), ssjs_getCGIVariable(), ssjs_getClientID(), stop(), String(), typeof(), unescape(), write()	
Functions:	atob(), btoa(), captureEvents(), handleEvent(), releaseEvents(), routeEvent()	
Event handlers:	onAfterPrint, onBeforePrint, onBeforeUnload, onBlur, onDragDrop, onError, onFocus, onHelp, onLoad, onMove, onResize, onUnload	
Collections:	frames[]	

The `Global` object is unique and is created before any code is executed. In an ECMAScript compliant implementation it is where variables, methods, functions and properties are stored if you don't explicitly attach them to another object yourself. The member properties, methods, functions and variables are globally available because the `Global` object is placed into the scope chain of every execution context.

In a web browser, the `Global` object is also the `Window` object. In a server-side implementation, the `Global` object is probably the `Response` object but this is not mandatory. Other implementations will use one of the host objects as the `Global` object but there is no defined and standard choice.

Since you don't ever use the keyword `Global` and can avoid using the keyword `Window`, the properties and methods look as if they are part of the core language rather than members of an object. Web browsers are becoming more ECMAScript compliant as new versions are released.

The `Global` object is added to the scope chain of a program when it commences execution. Other built-in objects are accessible as initial properties of the `Global` object. Some of these are added as core functionality and are available in all implementations. Others are added as host objects defined differently for each implementation.

When the `Global` object is created, it always has at least the following properties:

- `Object` object
- `Function` object
- `Array` object
- `String` object
- `Boolean` object
- `Number` object
- `Date` object
- `Math` object
- Value properties
- Utility function properties
- Additional host defined properties

Most of the properties initially provided by the `Global` object cannot be enumerated as their `DontEnum` attribute is set (at least in ECMA-compliant implementations).

The initial properties soon change and are added to when the flow of control enters execution contexts and begins to process scripts.

The value properties that are initially set up in the `Global` object are listed in this table:

Name
`Infinity`
`NaN`

Refer to the discussion on each of value properties for more details.

Some host implementations create aliases for the `Global` object and store those self-referring aliases in the `Global` object when it is initialized. An example of this behavior is the `window` object created in some web browser host implementations of JavaScript.

There is one `Global` object for each window in a web browser. There is also one for each frame in a frame-set. This means that you can have `Global` objects that have global variables that are not shared with one another.

However, you can access them by referring to the parent object. This goes to an object context that contains the current frame. You can also access the top or outer window of a frame-set hierarchy directly.

Whether you can truly access objects in other windows or frames comes down to some basic security issues. Generally the security policy prevents access to code that arrives from different servers. You can legally get at values in pages served from the same host as your page was served from. It is unreasonable to be able to access variables in a page served from another host. This can lead to difficulties if you serve your site from multiple hosts. It isn't as limiting as all that though and there are ways to grant permission via the security policy in the browser.

`Global` objects support different sub-sets of the complete range of properties according to the context in which they are used. Server-side JavaScript won't support anything to do with window display and client-side (browser) JavaScript does not need to know about request-response handling.

If you want to access a `Global` object in another context, perhaps in a different window, you need to assign it to a variable. In the syntax listing this is illustrated by assigning references to `Global` objects to the *`myGlobal`* variable.

Warnings:

- You cannot use the `Global` object with the new operator to make a copy.
- You cannot call the `Global` object as a function.
- The value of the internal Prototype property of the `Global` object is implementation dependent. Since it contains the `Object` object as one of its children, it could not inherit its Prototype from there since that could set up an endlessly recurring loop of Prototype inheritors. It is likely that the Prototype of the `Global` object is `Null`. If it is important that you know the value of this, then you should test it with a debugging script first. However, you may be writing non-portable code if you depend on the value that it indicates.
- In a web browser, the Window object serves as the `Global` object. It owns all the properties that you would expect the `Global` object to have in a core implementation. The hosting environment adds the other window-based properties.

Global special variable (Definition)

Special variables that are globally available.

Availability:	ECMAScript edition –2

Some special variables are created in the interpreter to assist with program execution and to define certain special values. You must avoid using these as identifiers.

Here is a list of the special variable names:

Name
`Infinity`
`NaN`

Some implementations may allow you to redefine the value of these special variables. This can cause unpredictable side effects later on.

See also:	`Global` object, `Infinity`, `NaN`

Glow() (Filter/visual)

A visual filter for adding a glow effect

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

Filter – `Glow()`

Glue code (Definition)

Supporting code to integrate JavaScript with the environment.

This so called glue code is that which provides a conduit for signals to be sent between different parts of the hosting environment. Most likely as far as JavaScript is concerned, this would be a mechanism for transmitting events to the interpreter so that a particular handler function can be activated.

There are many proprietary names for these mechanisms, but fundamentally they all do the same job, which is to connect the script to the environment. Here are some examples of enabling technologies that may be involved to a greater or lesser extent in some platforms:

- ActiveX
- LiveConnect
- AppleEvents
- Signals
- BSD Sockets
- Call-backs from plugins

See also:	ActiveX, ECMAScript, Host environment, LiveConnect, Plugin object

Wrox *Instant JavaScript* –page –12

Gotcha (Definition)

A pitfall or catch-out for the unwary and the experienced script developer.

Refer to:

Pitfalls

goto (Reserved word)

Reserved for future language enhancements.

This keyword suggests that future versions of JavaScript may support the `goto` statement which will unconditionally go to a labelled portion of script source text. This also suggests that labels will need to be supported as well.

ECMA edition 3 already mandates that case and default labels are supported for the benefit of the `switch()` statement.

The ECMA standard notes that although it is reserved future use, an implementation is still compliant if it provides the appropriate functionality of these reserved keywords.

Gradient() (Filter/visual)

A procedural definition of a gradient effect.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `Gradient()`

GradientWipe() (Filter/transition)

A transition effect with the appearance of a wipe with a soft edge.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `GradientWipe()`

Grayscale() (Filter/visual)

A visual filter for converting to a grayscale appearance.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

Filter – `Grayscale()`

Greater than (>) (Operator/relational)

Compares two operands to determine which is nearer to +Infinity.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`anOperand1 > anOperand2`*
Argument list:	*`anOperand1`*	A value that can be compared numerically or lexically
	`anOperand2`	A compatible value

Returns `true` if the left operand is numerically greater than the right operand or is sorted later in the Unicode collating sequence when two string values are compared.

In numeric comparisons, the presence of `NaN` in either or both operands will yield undefined instead of `true` or `false`.

When comparing two strings, a prefixing plus sign is present, then a numeric coercion of a string takes place before the comparison. Numeric coercion takes place when either of the operands is numeric.

In ECMA compliant JavaScript implementations, string values are simply compared according to the Unicode character code point values, with no attempt to provide the more complex semantically oriented definitions of character and string equality defined in the Unicode version 2.0 specification.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

The result is the Boolean value `true` if *`anOperand1`* is numerically or lexically greater than *`anOperand2`*; otherwise `false` is returned.

Greater than or equal to (>=) (Operator/relational)

Compare two operands to determine which is nearer to +Infinity or whether they are equal.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`anOperand1 >= anOperand2`*
Argument list:	*`anOperand1`*	A value that can be compared numerically or lexically
	`anOperand2`	A compatible value

Returns true if the left operand is numerically greater than or equal to the right operand or is sorted later or identically in the Unicode collating sequence when two string values are compared.

In numeric comparisons, the presence of `NaN` in either or both operands will yield undefined instead of `true` or `false`.

When comparing two strings, a prefixing plus sign is present, then a numeric coercion of a string takes place before the comparison. Numeric coercion takes place when either of the operands is numeric.

In ECMA compliant JavaScript implementations, string values are simply compared according to the Unicode character code point values, with no attempt to provide the more complex semantically oriented definitions of character and string equality defined in the Unicode version 2.0 specification.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

The result is the Boolean value `true` if *`anOperand1`* is numerically or lexically greater than or equal to *`anOperand2`*; otherwise `false` is returned.

Grouping operator ( ) (Delimiter)

A means of controlling precedence of evaluation in expressions.

Availability:	ECMAScript edition –2

The grouping operator is a pair of parentheses placed around an expression or expressions to control the precedence of evaluation in expressions so that the sub-expressions are evaluated in the correct order. It is also used to enclose the arguments to a function or method.

Placing parentheses around expressions controls the order in which they are evaluated and can override the normal precedence that operators assume. This allows `delete` and `typeof` operations to be applied to expressions in parentheses for example.

Controlling the precedence of expressions allows operators with lower precedence to be evaluated ahead of the higher priority expression operators. For example:

```
A + B * C
```

by implication is executed like this:

```
A + (B * C)
```

A and B can be added before the multiplication like this:

```
(A + B) * C
```

This forces the addition to occur before the multiplication and is functionally equivalent to:

```
A*C + B*C
```

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

See also:	Associativity, delete, Function call operator ( ), Operator, Operator Precedence, Parentheses ( ), Primary expression, typeof

ECMA 262 edition 3 –section –11.1.6

handleEvent() (Function)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`handleEvent(`*`anEvent`*`)`
	N	*`myWindow`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An `Event` object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

This method is supported by all objects that respond to events. It is part of the event management suite which allow events to be routed to handlers other than just the one that defaults to being associated with an event.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`Button.handleEvent()`, `captureEvents()`, `Checkbox.handleEvent()`, `Document.handleEvent()`, Event handler, Event management, `FileUpload.handleEvent()`, `Form.handleEvent()`, `Input.handleEvent()`, `Layer.handleEvent()`, `Password.handleEvent()`, `RadioButton.handleEvent()`, `ResetButton.handleEvent()`, `Window.handleEvent()`, `Window.routeEvent()`

Wrox *Instant JavaScript* - page 55

Handler (Definition)

An event handler can be attached to an HTML tag as an attribute.

The event handlers can be attached to a particular object within the HTML document or within JavaScript. Some event handlers can only be attached with HTML tag attributes. Others only by setting the event handler property of an object to point at an event handling function.

The names of the handlers in HTML are case-insensitive, although there are some conventions.

The value associated with the event handling tag attribute is a fragment of JavaScript code. The script source text forms the body of an anonymous function object. This may simply contain a call to the name of an event handling function or it may be several lines of JavaScript code. It is probably a good idea to encapsulate the handler into a function and refer to it by name.

HasInstance() (Function/internal)

Internal private function to test for the existence of an instance.

Availability:	ECMAScript edition - 3

This internal function returns a Boolean value indicating whether the `function` object is the prototype of an instance object that is passed as an argument. If it is, then the function returns `true`.

This is an internal function very similar to the `Object.isPrototypeOf()` method.

See also:	`Object.isPrototypeOf()`

Cross-references:

ECMA 262 edition 3 section - 15.3.5.3

HasProperty() (Function/internal)

Internal private function to test for the existence of a property.

Availability:	ECMAScript edition - 2

This internal function returns a Boolean value indicating whether the object contains the named property.

If the receiving object has the property, then the result is `true`.

If the receiving object does not, then the prototype chain is walked until the property is found or the chain is exhausted.

If a `null` prototype is found, the `false` value is returned.

Host objects may or may not strictly honor the intent of this internal function. The ECMA standard allows for the possibility that a host object may still properly manage `Get` and `Put` internal functions, even if the `HasProperty` function returns `false` for the properties being accessed.

To cope with that eventuality, ECMAScript edition 3 provides a way to test whether an object has a property of its own, but this test ignores the prototype inheritance. You might simulate that by walking up the prototype chain, testing objects as you go.

ECMA 262 edition 3 section - 8.6.2.4

HEAD object (Object/HTML)

A special MSIE object that represents the head block of an HTML document.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myHEAD* = *myDocument*.all.*anElementID*
	IE	*myHEAD* = *myDocument*.all.tags("HEAD")[*anIndex*]
	IE	*myHEAD* = *myDocument*.all[*aName*]
	-	*myHEAD* = *myDocument*.getElementById(*anElementID*)
	-	*myHEAD* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myHEAD* = *myDocument*.getElementsByTagName("HEAD")[*anIndex*]
HTML syntax:	`<HEAD> ... </HEAD>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`profile`, `vAlign`	
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`	

This object inherits from HTML. It has a `TITLE` object as one of its children and its sibling is the `BODY` object that represents the contents of the `<BODY>` tag.

The `CLASS` tag attribute is supported by MSIE but serves no purpose other than maintaining consistency. You should avoid its use even though the reference is maintained within the corresponding `HEAD` object.

See also:	`BODY` object, `Element` object, `HEAD.profile`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`profile`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`vAlign`	-	3.0 +	-	4.0 +	-	-	-	Warning

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseOver`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

HEAD.profile (Property)

The `profile` property of the current document's `<HEAD>` block.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 5.0 Internet Explorer - 5.0 Netscape - 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myHEAD*`.profile`
HTML syntax:	`<HEAD PROFILE="...">`	

This value should contain the value of the PROFILE attribute of the document's <HEAD> block. The PROFILE value is a means of sharing meta-data profiles between many documents. It's very like an include file for meta information, but does not get used very much. This property should contain a URL value for a shared meta-data profile.

It might be useful to be able to access the internals of this file, but the property only yields the URL that reaches the file on the server or local file system.

See also:	HEAD object

HEAD.vAlign (Property)

The vertical alignment associated with the <HEAD>.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myHEAD*.vAlign

Although this property is present and accessible, it should not affect the display of the page at all.

Warnings:

- This property is probably an implementation mistake. Although it is visible when the properties of the HEAD object are enumerated, it has no use in that context.

Hexadecimal value (Definition)

A numeric value based on a radix of 16.

A hexadecimal value is an integer composed of only the following characters:

```
0 1 2 3 4 5 6 7 8 9

A B C D E F

a b c d e f
```

Note the use of the alphabetic characters to extend the decimal number digit set.

Hexadecimal values are always prefixed by a zero and X character.

The sequence carries over for the next increment when each column reaches the value F. Thus:

```
0x00 0x01 0x02 0x03 0x04 0x05 0x06 0x07

0x08 0x09 0x0A 0x0B 0x0C 0x0D 0x0E 0x0F

0x10 0x11 0x12 0x13 0x14 0x15 0x16 0x17
```

Hexadecimal values have a historical significance, having been used in the earliest computer systems. However, these days they are particularly useful since they map quite conveniently to the binary system. Each hexadecimal digit corresponds to four binary digits. Two hex digits map to a byte and four to a word. This is particularly useful and is evidenced by hexadecimal values being used to generate Unicode escape sequences.

There are several hexadecimal values that are useful. These are summarized in the following table:

Value	Description
0x0	All bits clear
0x20	The single bit to toggle between upper and lower case letters
0x7F	A seven bit character mask
0x8000	The sign bit of a 16 bit integer value
0x80000000	The sign bit of a 32 bit integer value
0xDF	A mask that excludes the upper/lower case bit
0xFF	All bits set in a byte
0xFFFF	All bits set in a 16 bit word
0xFFFFFFFF	All bits set in a 32 bit word

Hidden object (Object/DOM)

A field of data submitted with the form but not visible to the user.

Availability:	DOM level - 1 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Inherits from:	`Input object`	
JavaScript syntax:	-	*myHidden* = *myDocument*.*aFormName*.*anElementName*
	-	*myHidden* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*myHidden* = *myDocument*.all.*anElementID*
	IE	*myHidden* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myHidden* = *myDocument*.all[*aName*]
	-	*myHidden* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myHidden* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*myHidden* = *myDocument*.getElementById(*anElementID*)
	-	*myHidden* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myHidden* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	`<INPUT TYPE="hidden">`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `NAME` attribute of an element
	anElementID	The `ID` attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the `forms` collection
Object properties:	`type`, `value`	
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onHelp`, `onRowEnter`, `onRowExit`	

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

There isn't really a `Hidden` object class but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a hidden field. In actual fact, the object is represented as an item of the `Input` object class.

`Hidden` objects don't respond to any events. They can't since they are not visible and therefore the user cannot interact with them to trigger one.

They may be accessed by event handling functions associated with the `Form` object but very little else.

Unlike MSIE, Netscape does not support the `defaultValue` property for this sub-class of the `Input` object. It also does not support the `onFocus` event, although why MSIE should support focus control onto a `Hidden` object is not clear.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT">?</DIV>
<FORM>
   <INPUT TYPE="hidden" VALUE="A" NAME="BOX_A">
   <INPUT TYPE="hidden" VALUE="B" NAME="BOX_B">
   <INPUT TYPE="hidden" VALUE="C" NAME="BOX_C">
   <INPUT TYPE="hidden" VALUE="D" NAME="BOX_D">
   <INPUT TYPE="button" VALUE="Reveal" onClick="handleClick()">
</FORM>
<SCRIPT>
function handleClick()
{
   myString  = "[";
   myString += document.forms[0].BOX_A.value;
   myString += "] [";
   myString += document.forms[0].BOX_B.value;
   myString += "] [";
   myString += document.forms[0].BOX_C.value;
   myString += "] [";
   myString += document.forms[0].BOX_D.value;
   myString += "]";
   document.all.RESULT.innerText = myString;
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Element` object, `Form.elements[]`, `Input` object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`type`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	1 +	ReadOnly
`value`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	1 +	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	Notes
`onAfterUpdate`	-	3.0 +	-	4.0 +	-	-	-
`onBeforeUpdate`	-	3.0 +	-	4.0 +	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	Warning
`onRowEnter`	-	3.0 +	-	4.0 +	-	-	-
`onRowExit`	-	3.0 +	-	4.0 +	-	-	-

Inheritance chain:

`Element` object, `Input` object, `Node` object

Hidden.type (Property)

The `type` value for the `<INPUT>` object that describes the hidden field.

Availability:	DOM level - 1 JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myHidden`*`.type`

The `type` value for a hidden field is always "`hidden`". This value is necessary to determine the type of form element because this object is really an instance of the `Input` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

Hidden.value (Property)

The `value` of a hidden field in a form.

Availability:	DOM level - 1 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera browser - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myHidden`*`.value`

The value of a hidden form is probably its main purpose for existence. The idea is that you can pass values into a form by means of hidden fields and when the form is submitted, those values are passed back to the server with the form data that the user has entered. It is often used as a means of maintaining state across a user session.

See also:	`Input.value`

Hiding scripts from old browsers (Pitfall)

Old browsers need to have script content disguised.

If you are presenting your HTML on the web to an audience that may use browsers that cannot cope with the `<SCRIPT>` tag, then you will need to hide the script inside the `<SCRIPT>` block. This is done by placing HTML comment tags around the script code.

This depends on the JavaScript interpreter providing some non-standardized behavior. That is, it needs to recognize the HTML comment opening tag as being some valid syntax, even though it is not really legal.

Beware that the closing HTML comment tag is placed on a line that itself is a JavaScript comment. However, you must also make sure that the closing `</SCRIPT>` tag is placed on a line of its own or the interpreter cannot see it and the `<SCRIPT>` block then becomes unterminated.

Example code:

```
<SCRIPT>
<!-- // Hide from older browsersalert("some script here");// end hiding -->
</SCRIPT>
```

See also:	`COMMENT` object, Pitfalls

Wrox *Instant JavaScript* - page 46

Hierarchy of objects (Definition)

To fully understand JavaScript and in particular its use in the browser, it is helpful to know how objects relate to one another.

In the core JavaScript language, objects are related to one another by means of the prototype chain. This is a hierarchy that determines the inheritance of functionality from a super-class, although it's an object-based inheritance and not really a class-based inheritance. You can only walk up this hierarchy. There is no convenient way to determine what objects are sub-classed from an object.

From version 5.0 of MSIE and version 6.0 of Netscape, there are several hierarchy models available for traversing the document. The HTML view of the document is not quite the same as the DOM view. In general, each one is based on a property to traverse up the tree to a parent and collections for traversing down the tree to the leaf nodes. Here are some examples of the different hierarchical arrangements.

- The `parentElement` and `children[]` collection operate on the HTML tag-based hierarchy.
- The `parentNode` property and `childNodes[]` collection can be used to traverse the DOM hierarchy which exposes the interstitial text objects between the HTML tags. These are not visible to the HTML view.
- The spatial layout and positioning of objects relative to one another can be walked upwards by means of the `offsetParent` property. You can't traverse this tree from top to bottom without inspecting the contents of the `children[]` collection and looking at each child's `offsetX` and `offsetY` properties.

- The `all[]` collection flattens the whole tree from the receiving object downwards. The `document.all[]` collection is the complete tree. This can slow things down if you are searching it to find a single object.
- An editing hierarchy is constructed with the `parentTextEdit` property which describes the relationship between items that can have a text range created for them, and hence have some selectable content that can be cut or copied to the clipboard (usually as text).
- Function calls construct a hierarchy by means of the `Argument` objects which link upwards to the calling function's `Arguments` object. This provides a way to walk through a stack trace to diagnose a calling sequence.
- You can create custom hierarchies by using nested `<DIV>` tags and navigating them by means of the corresponding `DIV` objects they instantiate.
- A spatial hierarchy is created in Netscape version 4 with the `<LAYER>` tags. Layers sharing a common parent are siblings and can be ordered relative to one another.
- A CSS style hierarchy is implemented in MSIE to describe the relationship between CSS style rule objects and their owning parent style sheet.
- Another hierarchy can be built by importing style sheets into one another to allow styles to be managed in a more modular fashion. This is also supported at the rule level by means of the `styleSheet.addRule()` method.

The DOM level 2 standard adds a suite of traversal methods for walking through a document object model. It is embodied in the following classes:

- `NodeIterator`
- `NodeFilter`
- `TreeWalker`
- `DocumentTraversal`

Related to the traversal suite, the DOM level 2 standard also introduces the Range suite. This is embodied in these classes:

- `Range`
- `DocumentRange`
- `RangeException`

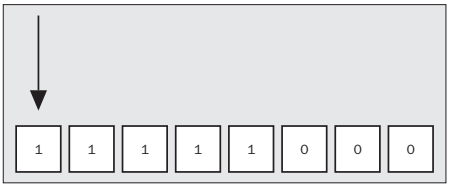
High order bit (Definition)

The most significant bit in an integer value.



See also:	Bit, Bit-field, Bitwise operator, byte

History (Background)

Scripting language history.

Availability:	ECMAScript edition - 2

The JavaScript language was invented by Brendan Eich at Netscape. In the early days, it was known as LiveScript.

The ECMA 262 standard is based on the earlier work at Netscape where they embedded the JavaScript interpreter into the Netscape version 2.0 web browser. Microsoft also embedded script-driven capabilities into their version 3.0 of the MSIE browser. The Microsoft interpreter implements a language called JScript as opposed to JavaScript.

Microsoft clearly chose not to use the word JavaScript. It might be because any product name containing the word 'Java' needs to be licensed from Sun Microsystems or that it was a Netscape originated name. Given the very public antagonism between Microsoft and the other two, this is understandable. Perhaps it also gives Microsoft a little extra leeway to extend the language in non-standard ways.

Both Microsoft and Netscape have continued to enhance their implementations in subsequent versions of their web browsers, taking them sometimes in completely opposing directions.

In November 1996, the language started to become standardized by a working group under the ECMA organization. At this stage it was also commonly referred to as ECMAScript and became a published standard in June 1997. By April 1998, the ECMA 262 standard had been adopted as an international standard as ISO/IEC 16262 which prompted a second edition of the ECMA standard to keep the two fully aligned.

A third edition of the ECMA 262 standard was published in October 1999.

On the horizon are upgraded interpreters from Netscape and Microsoft, and the availability of JavaScript in a variety of other products such as TV set-top boxes, mobile phones and embeddings into legacy applications.

Wrox *Instant JavaScript* - page 3

history (Property)

An alias to the `window.history` property.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`History object`	
JavaScript syntax:	-	`history`
	-	*`myWindow`*`.history`

Property attributes:

`ReadOnly`.

Refer to:

`Window.history`

History object (Object/browser)

A `history` object owned by the `window`. This exposes information about URLs that have been visited previously.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
JavaScript syntax:	-	*`myHistory`* `= history`
	-	*`myHistory`* `=` *`myWindow`*`.history`
Object properties:	`current, length, next, previous`	
Object methods:	`back(), forward(), go()`	

Netscape version 4 provides access to the `history` array by signed scripts. Earlier versions of Netscape and MSIE do not provide this level of access and therefore the `history` object is limited in what you can do with it.

Some properties can be accessed by non-privileged scripts.

In Netscape, each element in the `History` object array is a String containing the URL for that item in the history. In MSIE, the objects are not accessible directly.

Warnings:

- The array elements and properties of this object cannot be accessed by JavaScript unless the script has the `UniversalBrowserRead` privilege granted to it.
- On Netscape, the `toString()` method is not correctly implemented and returns the value "[`object`]" instead of "[`object History`]".

See also:	`Collection` object, `UniversalBrowserAccess`, `UniversalBrowserRead`, `Window.history`

Property	**JavaScript**	**JScript**	**N**	**IE**	**Opera**	**HTML**	**Notes**
`current`	1.1 +	-	3.0 +	-	3.0 +	-	Warning, ReadOnly.
`length`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	ReadOnly.
`next`	1.1 +	-	3.0 +	-	3.0 +	-	Warning, ReadOnly.
`previous`	1.1 +	-	3.0 +	-	3.0 +	-	Warning, ReadOnly.

Method	**JavaScript**	**JScript**	**N**	**IE**	**Opera**	**HTML**	**Notes**
`back()`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	-
`forward()`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	-
`go()`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	Warning

History.back() (Method)

Go to the previous page.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
JavaScript syntax:	-	*`myHistory`*`.back()`

This is accessible to unsigned scripts.

See also:	`Window.back()`

History.current (Property)

The URL of the current window content.

Availability:	JavaScript - 1.1 Netscape Navigator - 3.0 Opera browser - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myHistory*.current

If you are accessing the URL of the current page, it is probably better to use the `location` object and access its `href` property.

Warnings:

- The `UniversalBrowserRead` privilege is required to access this property value.

See also:	`UniversalBrowserRead`

Property attributes:

`ReadOnly`.

History.forward() (Method)

Go to the next page.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
JavaScript syntax:	-	*myHistory*.forward()

This is accessible to unsigned scripts.

See also:	`Window.forward()`

History.go() (Method)

Return to a URL from the `history` array.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera browser - 3.0	
JavaScript syntax:	-	*myHistory*.go(*anIndex*)
	-	*myHistory*.go(*aURL*)
	-	*myHistory*.go(*aDocTitle*)
Argument list:	*anIndex*	Denotes which history item to go to
	aURL	A URL value to go to
	aDocTitle	The name of a document (in Netscape)

You can perform a soft reload of a page, retaining its current settings by means of the `History.go(0)` method call.

The following values are meaningful as an argument:

- -4 indicates you want to go back 4 pages.
- -1 indicates you want to go back one page.
- 0 requests a reload of the current page
- 2 indicates you want to go forward two pages
- A URL indicates a specific page to load
- A Document title references the history list associatively

Warnings:

- There are some bugs in this method in versions of Netscape prior to version 4. MSIE version 3 also exhibits unruly behavior.

Example code:

```
// Recall a page from the history keeping form settings intact
history.go(-1);
```

See also:	`Location.reload()`

History.length (Property)

The number of history entries available.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myHistory`*`.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

History.next (Property)

The next document in the `history` array.

Availability:	JavaScript - 1.1 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myHistory`*`.next`

The value you get back from this property will depend very much on what navigation the user has recently performed. Most of the time this would yield a `null` or undefined value unless the user has used the [BACK] button.

Warnings:

- The `UniversalBrowserRead` privilege is required to access this property value.
- This property is not supported on the WebTV platform.

See also:	JellyScript, `UniversalPreferencesRead`

Property attributes:

`ReadOnly`.

History.previous (Property)

The previous document in the `history` array.

Availability:	JavaScript - 1.1 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myHistory*.previous

You may find it more useful to build a stack of pages visited in a persistent array. This can be tricky within a single window, but if you are prepared to use a frameset, you can create a global session store for such things. That way you'd be able to traverse a logical history rather than the possibly random page ordering that the user navigated.

Warnings:

- The `UniversalBrowserRead` privilege is required to access this property value.

See also:	`UniversalPreferencesRead`

Property attributes:

`ReadOnly`.

H<n> object (Object/HTML)

An object that represents the `<H1>` to `<H6>` tags.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myH1* = *myDocument*.all.*anElementID*
	IE	*myH1* = *myDocument*.all.tags("H1")[*anIndex*]
	IE	*myH1* = *myDocument*.all[*aName*]
	-	*myH1* = *myDocument*.getElementById(*anElementID*)
	-	*myH1* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myH1* = *myDocument*.getElementsByTagName("H1")[*anIndex*]

HTML syntax:	`<H1> ... </H1>,<H2> ... </H2>,<H3> ... </H3>,<H4> ... </H4>,<H5> ... </H5>,<H6> ... </H6>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`	
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

The properties, methods, collections and event handling support for the `<H1>` tag object are also provided for `<H2>` through `<H6>` tag objects as well. It is only necessary to document one of these object classes, although the other header types are each instantiated as objects of an appropriately named class in MSIE. The syntax examples illustrate the use of an `<H1>` tag object.

The `<H1>` through `<H6>` tags are block-level tags. That means that they force a line break before and after themselves.

The DOM level 1 specification refers to this and its sibling object types as a `HeadingElement` object.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`align`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseOver`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

H<n>.align (Property)

The alignment of an <H1> to <H6> tag.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myH1*.align

The alignment of the H1 (to H6) object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- absbottom
- absmiddle
- baseline
- bottom
- center
- left
- middle
- right
- texttop
- top

home() (Method)

Go to the home page according to the user preferences.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`home()`
	N	*myWindow*.home()

Refer to:

Window.home()

Host environment (Definition)

The environment in which a JavaScript interpreter has been embedded.

The host environment is where the JavaScript interpreter lives.

Typically this might be a web browser, a web server back end, or an embedded implementation. There are other possibilities as well, limited only by the imagination of the software developers and their ingenuity in finding new ways to apply JavaScript.

JavaScript is usually interpreted. However, recent digital TV systems are deploying byte code compiled JavaScript and it is also being used in that way for mobile devices.

Cross-references:

Wrox *Instant JavaScript* - page 5

Wrox *Instant JavaScript* - page 42

Host features (Definition)

That which is added to the language due to the hosting environment it runs in.

Host features are those which the implementation adds around the native feature set. Host features would include new object types. There are entire groups of objects which collected together provide a host environment capability.

For example, the HTML Document Object Model describes a page as it lives inside a web browser.

The PDF file format can contain a collection of objects and the PDF reader adds others to construct a different kind of object model.

A process control system might contain an object model representation of a brewery or a nuclear reactor, although it is unlikely you would control either with just a JavaScript interpreter. You could build a monitoring system with a mimic display that was a fairly good illustration of the processes though.

The browser, server or operating system is said to host the interpreter. That is where the terminology of host environments, host features and so on is derived.

See also:	ECMAScript, Host environment

Cross-references:

Wrox *Instant JavaScript* - page 12

Wrox *Instant JavaScript* - page 42

Host object (Definition)

An object that is built-in, but is provided by the hosting environment.

Availability:	ECMAScript edition - 2

A host object is any additional non-native object provided by the interpreter at the outset of script execution.

Host objects may or may not strictly honor the intent of the `Get` and `Put` internal function. The ECMA standard allows for the possibility that a host object may still properly manage `Get` and `Put` internal functions, even if the `HasProperty` function returns `false` for the properties being accessed.

See also:	`argv` parameter, `for( ... in ... ) ...`, `HasProperty()`, Implementation-defined behavior, `main()` function

Cross-references:

ECMA 262 edition 2 - section 4.3.8

ECMA 262 edition 3 - section 4.3.8

HR object (Object/HTML)

An object that represents an `<HR>` tag.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myHR* = *myDocument*.all.*anElementID*
	IE	*myHR* = *myDocument*.all.tags("HR")[*anIndex*]
	IE	*myHR* = *myDocument*.all[*aName*]
	-	*myHR* = *myDocument*.getElementById(*anElementID*)
	-	*myHR* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myHR* = *myDocument*.getElementsByTagName("HR")[*anIndex*]
HTML syntax:	`<HR>`	

Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`, `color`, `noShade`, `size`, `width`	
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

The `<HR>` tag is a block-level tag. That means that it forces a line break before and after itself.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`align`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

HR.align (Property)

An attribute to control the alignment of the <HR> object on screen.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myHR*.align

The alignment of the HR object with respect to its containing parent object is defined in this property. The following expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

HR.color (Property)

The color of the <HR> object.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myHR*.color

The color of the horizontal rule defined by this HR object will be defined in this property.

The color can be specified in the normal way according to the HTML color specifiers.

Warnings:

- In JavaScript the `noShade` and `color` properties operate independently of one another, even though setting the `COLOR="..."` HTML tag attribute implies a `NOSHADE` attribute as well when defined in the document HTML source.

See also:	Color names, Color value

HR.noShade (Property)

A switch attribute, used to control whether there is a shadow around the`<HR>` object.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myHR*`.noShade`

This Boolean value can be set to `true` which will change the horizontalrule style from the 3D appearance to a flat non-shaded look. Setting the property to `false` restores the 3D-shaded appearance again.

Warnings:

- In JavaScript the `noShade` and `color` properties operate independently of one another even though setting the `COLOR="..."` HTML tag attribute implies a `NOSHADE` attribute as well when defined in the document HTML source.

HR.size (Property)

A measure of the thickness of the `<HR>` object, expressed in pixels.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myHR*`.size`

The thickness of the horizontal rule, measured in pixels.

HR.width (Property)

A width measurement of the <HR> object.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myHR*.width

The width of the rule can be defined in pixels as an absolute measure or by specifying the value as a percentage of its containing element's width.

Although the value is noted as being a String primitive, a numeric value is specified for the width measured in pixels. It is a string value simply sot hat it can accommodate the percentage value.

HTC (Definition)

This is an abbreviation for the MSIE based HTML components (which used to be called scriptlets).

See also:	Scriptlet, HTML Component

.htc (File extension)

A file containing a behavior handler script for use in MSIE browsers.

This file contains an HTML Component (HTC). These used to be called scriptlets but have been evolved and renamed when used in an MSIE web browser.The Windows Script Host environment continues to use scriptlets but these have also evolved into something quite different to an HTC.

Refer to the `Element.addBehavior()` topic for a more detailed explanation of how these files are used.

See also:	`<STYLE>, Element.addBehavior(), Scriptlet`

.htm (File extension)

An HTML page.

Refer to:

File extensions

HTML (Standard)

The standard notation for creating web pages.

HTML is short for HyperText Markup Language. It is a markup language belonging to the SGML (Standard Generalized Markup Language) family.

Currently, the HTML state of the art is framed in the HTML version 4.0 standard as defined by the World Wide Web Consortium (W3C). However, much web content is still presented in an HTML 3.2 conformant manner.

TV set-top boxes that employ HTML are generally built around an HTML 3.2 core which means that web content that needs to be deployed to the PC based browser and the TV viewer needs to be downgraded to be compatible with that standard version.

Browser manufacturers are still yet to release fully HTML 4.0 compliant browsers.

The strategic importance of HTML version 4.0 is to separate document content from presentation style. This means that certain techniques are deprecated in favor of the use of style sheets.

This adds much complexity to the JavaScript support since its API to those style controls is not as well standardized as the underlying Document Object Model (DOM). However, there is also significant flexibility in the new styling model, and to date, the MSIE browser has made great strides in implementing a robust styling model that provides many Dynamic HTML capabilities.

It is hoped that the forthcoming Netscape 6.0 might offer similar capabilities.

See also:	Web browser

.html (File extension)

An HTML page.

Refer to:

File extensions

HTML Character entity (Definition)

Character value escapes for use in HTML.

HTML Character entities are escape sequences that work in the HTML source domain. The character entities have a defined format that begins with an ampersand as a control sequence introducer and terminates with a semi-colon. The value between them is the character description.

Many of these have symbolic names which browsers honor to a greater or lesser extent depending on the browser and its vintage. HTML 4.0 defines a large number of these escaped entities. If the character you wish to represent does not have a symbolic name, you can use the decimal value of the character and then place a hash symbol in-front. You can also use the hexadecimal notation by placing an x in front of the value. Thus:

`<` defines the less-than or < symbol.

`'` defines a single quote or apostrophe character.

`'` also defines a single quote character.

Here is a table of useful character entity values:

Warnings:

- Inside `<SCRIPT>` tags, you are inside the JavaScript source domain and you use a different set of escape mechanisms. If you use the HTML escape mechanisms inside JavaScript source, your script is likely to break unless you are intentionally outputting them to the HTML source space via a `document.write()` method.
- The character set you are using inside the `<SCRIPT>` tags is completely different to that used in HTML. The script source is written using Unicode characters (ISO 10646). If you are generating HTML, a great manyof the character codes are mapped differently. This is because the HTML character entities are defined according to an ISO standard (ISO 8859). Even then, national language variants of the browser should map the character entity values to the correct character glyph which should ensure that what the designer intended is what you actually see, regardless of the actual character code transformations that take place.
- Most of the character entities are supported by both MSIE and Netscape. A few characters are supported inconsistently. All of the character entities with values less than 32 are control codes anyway, so although the browsers treat them differently, it shouldn't prove to be significant. Those character entities that are undefined in the HTML specification aren't supported in the same way either, and should probably be avoided. Recent updates to the HTML standard allow for Unicode character values to be used above character entity 255, and some of these have symbolic names defined. Refer tothe HTML specification available from the W3C at http://www.w3.org/TR/html4/ for further details.
- Of the rest:
- The general currency symbol (¤) is unsupported.

- There is currently no Euro symbol implemented although its character entity •and Unicode value 20AC are defined but not in the version of the Unicode standard that is currently mandated (version 2.0). Unicode is about to undergo a revision and at that time, browser manufacturers will then need to accommodate the changes to remain compliant.
- The broken vertical bar ( ) does not work on Netscape, nor does the soft hyphen (), and neither do the superscripted numbers and fractional values.
- ETH and THORN are broken in both browsers in both upper and lower case variants.
- Netscape also lacks support for Y acute in both upper and lower case.
- Most of these are fairly obscure and not likely to cause much difficulty aside from some very specialized national language support. TheEuro character, however, is likely to become more important whether the currency thrives or not.

HTML Comment tag (<!– ... –>) (HTML Tag)

HTML comments can be used to hide scripts.

See also:	COMMENT object, Hiding scripts from old browsers

HTML Component (Definition)

An HTML Component is a small modular fragment of script contained in an `.htc` file and can be shared across several pages.

These used to be called scriptlets but have evolved into HTML Components. Do not confuse them with Windows Script Host scriptlets: these are something different altogether.

See also:	Scriptlet

http://msdn.microsoft.com/workshop

HTML entity escape (Pitfall)

It looks like HTML but it isn't intended to be.

You can sometimes innocently include some text into your script that when presented with a`document.write()`, gets completely misunderstood by the HTML parser. This will almost certainly be due to the presence of "<" and">" characters in the output. It is likely that the browser will see what it thinks is a tag, but then ignore it according to the "I don't know what it is - so I won't display it" rule, as it won't be a recognized tag.

Use HTML escapes to output the character as intended.

This is important for the following characters if not for others:

```
< becomes &lt;

> becomes &gt;

& becomes &amp;
```

Cross-references:

Wrox *Instant JavaScript* –page 3

HTML object (Object/HTML)

An object in MSIE that represents an `<HTML>` tag.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 3.0 Internet Explorer - 4.0 Netscape - 6.0

Inherits from:	`Element` object	
JavaScript syntax:	IE	*myHTML* = *myDocument*.all.*anElementID*
	IE	*myHTML* = *myDocument*.all.tags("HTML")[0]
	IE	*myHTML* = *myDocument*.all.tags("HTML")[*anIndex*]
	IE	*myHTML* = *myDocument*.all[*aName*]
	IE	*myHTML* = *myDocument*.all[*anIndex*]
	-	*myHTML* = *myDocument*.documentElement
	-	*myHTML* =*myDocument*.getElementById(*anElementID*)
	-	*myHTML* =*myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myHTML* =*myDocument*.getElementsByTagName ("HTML")[*anIndex*]
HTML syntax:	`<HTML> ... </HTML>`	
Argument list:	*anIndex*	A selector for one particular HTML element
	aName	An associative array reference
	anElementID	The ID value of an `Element` object
Object properties:	`title,version`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

This object is otherwise known as the HTML object.

The `<HTML>` tag is a block-level tag, although it cannot be placed inside any other tag. Like the body tag, it is considered to be a block-level tag on grounds of its behavior in a framed context.

Warnings:

- Be careful how you operate on this object. Traversing its properties in a `for( ... in ... )` loop can recursively lock up your browser.
- The index value that points at this object in the `all[]` array for the document will be 0 if there is no DTD statement and 1 if there is. A correctly formed document should have a DTD statement. Use a dynamic mechanism for locating the object of type HTML instead of hardwiring the index value.

onKeyUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.2 +	3.0 +	4.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

HTML.title (Property)

The document title.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myHTML*`.title`
HTML syntax:	`<TITLE>`*aTitle*`</TITLE>`	
Argument list:	*aTitle*	A title text

The DOM standard at level 1 requires that the title property of an HTML object should contain the text from the `<TITLE>` HTML tag in the`<HEAD>` block of the document. At least, this is the implication, because it refers the reader to the HTML specification, which defines that `<TITLE>`is only legal inside `<HEAD>` blocks. We can't really say this is part of the DOM specification, which unfortunately makes it ambiguous.

Netscape makes this available as the `document.title` property, as does MSIE. However, MSIE does support this property as a member of the HTML object even though it is not mentioned in the Microsoft documentation.

In Netscape, the title property of an HTML object exists but is empty, hence it cannot be guaranteed to be available in Netscape 6.0.

See also:	`Document.title`

HTML.version (Property)

The version string of an HTML document.

Availability:	DOM level - 1 JavaScript - 1.5 JScript - 5.0 Internet Explorer - 5.0 Netscape - 6.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myHTML*.version
HTML syntax:	<HTML VERSION="*aVersion*">	
Argument list:	*aVersion*	A version text

This property is intended to hold the value of the VERSION="..." HTML tag attribute which is used in conjunction with the <HTML> tag. It has now been superseded by the <!DOCTYPE> DTD tag and is now deprecated.

The MSIE browser does reflect this HTML tag into the version property, although it is not mentioned in the documentation.

Warnings:

- This feature is deprecated in favor of placing aproperty DTD statement at the start of the document.

HTML tag attribute (Definition)

HTML tags have attributes, some of which can be accessed fromscripts.

Earlier versions of the browsers required that HTML tag attributes were enclosed in double quotes. More recent browsers also allow the use of single quotes or even no quotes in some cases. This may be useful when enclosing fragments of JavaScript that contain quoted text strings.

See also:	Attribute object, Attributes object

HTTP-EQUIV="..." (HTML Tag Attribute)

The name attribute for a pseudo header item.

Refer to:

<META>

http: URL (Request method)

A request from a web browser to a web server to send a document.

This requests a document from a web server. Most web traffic isrequested this way.

See also:	javascript: URL, URL

https: URL (Request method)

A request from a web browser to a secure web server to send a document with an encrypted and secure protocol.

Requests a document from a secure web server. Your encryption code needs to be compatible and this may involve an exchange of security certificates.

See also:	javascript: URL, Security policy, URL

HyperLink (Definition)

HyperLinks are references to documents served elsewhere. They may be pages, assets or includable files.

See also:	`Anchor.href, BASE.href,IMG.href, Location.href, StyleSheet.href,` HTML

HyperLink object (Object/HTML)

Another name for the `Url` object.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0	
Inherits from:	`Element` object	
JavaScript syntax:	-	*myHyperLink* = *myDocument*.links[*anIndex*]
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

In Netscape, links are stored in `Url` objects. These are distinctly different to `Anchor` objects.

MSIE does not distinguish between the two but since there is no constructor, it is hard to know what object type they are. Generally they are assumed to be `Url` objects.

Because the class name is `Url` in Netscape, the link objects are discussed in detail under that lexical topic location.

MSIE supports a `LINK` object class but this is a special object that stems from a `styleSheet` item. It doesn't support all the properties that a `Url` object does and is probably more concerned with managing the appearance of a `Url` object on the screen.

See also:	`Area` object, `Element`.all[], `LinkArrayobject`, URL, `Urlobject`

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.2 +	3.0 +	4.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseOver`	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
`onMouseUp`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

I object (Object/HTML)

An object that represents the font style controlled by the <I> HTML tag.

Availability:	DOM level –1 JScript –3.0 Internet Explorer –4.0 Deprecated	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myI* = *myDocument*.all.*anElementID*
	IE	*myI* = *myDocument*.all.tags("I")*[anIndex]*
	IE	*myI* = *myDocument*.all[*aName*]
	-	*myI* = *myDocument*.getElementById(*anElementID*)
	-	*myI* = *myDocument*.getElementsByName(*aName*)[anIndex]
	-	*myI* = *myDocument*.getElementsByTagName("I")[anIndex]
HTML syntax:	<I> ... </I>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

<I> tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

See also:	`Element` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.0 +	3.0 +	2.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.2 +	3.0 +	4.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	3.0 +	2.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

iCab (Web browser)

A web browser alternative to MSIE and Netscape Navigator.

The iCab web browser is only available on the Macintosh but has some interesting features not found in other products. It is developed by a small German company run by Alexander Clauss and Oliver Joppich. The browser was originally developed for use on the Atari platform.

The browser is compact, fast and standards-based and can be downloaded free from the iCab web site (http://www.iCab.de). The current version is 2.1 and is available at the moment as a preview or Beta product (see web-references).

Earlier versions do not fully support JavaScript although implementation of a completely standards based version of the interpreter is expected in the final release. It also supports some of the browser specific tags that Netscape and Microsoft have added to their browsers. This is necessary to avoid the browser not being able to properly render the pages currently deployed on the web. However, iCab also has an HTML validator built in and this triggers an indicator on the screen when the page is non-HTML 4.0 compliant. This shows up as a smiley face when the HTML is good and a frowning face when it's not. Clicking on the frowning face yields a report of the non-compliant HTML. This is a good browser for developers to use.

iCab supports some interesting features such as image and cookie filtering. This allows much finer control over image display than simply switching images on and off. By default, iCab is set up to not filter out banner ads, but by virtue of its awareness of standard banner ad image sizes it can prevent the display of banners leaving other graphics intact. It can also filter based on URL contents. Cookie filtering is also flexible and sophisticated.

The `<LINK REL="...">` and `<LINK REV="...">` tags are actively supported and provide some structural navigation when sites implement these tags properly.

Access the iCab web site for more details of special features.

ID="..." (HTML Tag Attribute)

MSIE document objects can be referenced conveniently with an ID name if it is added with this tag attribute.

Many objects are identified in the DOM hierarchy of the web browser by means of their id property. This value is defined as an HTML tag attribute.

Some objects can be accessed using a `<NAME="...">` HTML tag attribute instead of or as well as the `ID="..."` HTML tag attribute.

Netscape 4.0 supports ID access but only apparently for visible elements. Version 6.0 is much more consistent now that it supports the DOM standard properly.

See also:	`Document.ids[],Document.layers[], Document.scripts[],Element.id,NAME="..."`

Identically equal to (===) (Operator/identity)

Compares two values for equality and identical type.

Availability:	ECMAScript edition –3 JavaScript –1.3 JScript –1.0 Internet Explorer –3.02 Netscape –4.06	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*anOperand1 === anOperand2*
Argument list:	*anOperand1*	A value of a comparable type
	anOperand2	A value of the same type as operand 1

The two operands are compared and the Boolean `true` value is returned if they are equal and of the same type.

The equality operator is not always transitive. For example, two string objects may represent the same string value. Comparing the objects for equality will yield `false` because the references to the objects are being compared and not the object values themselves. However forcing a string comparison may in fact yield a `true` value when testing for equality. Do this by converting the objects as part of the comparison process by type conversion or `valueOf()` methods.

Numeric values may require rounding to take place, and testing for equality may be accurate down to a precision finer than your script cares about. You can set a precision value in a variable, then subtract the value you are comparing with from the absolute value of the comparee. If the difference is smaller than your precision value, then the two values are close enough to yield a match.

The associativity is from left to right.

Refer to the operator precedence topic for details of execution order.

The result is the Boolean value `true` if *`anOperand1`* is numerically or lexically equal to *`anOperand2`* and both operands are of the same type otherwise `false` is returned.

Warnings:

- Be careful not to confuse the single and double equals operators with the triple equals operator.
- Placing a single equals in place of a test for equality will assign the right-hand value to the left-hand operand and clobber the value accidentally. Placing a single equals sign in-stead of the identity operator has the same effect.
- Using the equality operator in place of the identity operator is more subtle. Sometimes the test will appear to work correctly because the values in the two objects could be the same. That would have failed the identity test because they may be equal but are not identical.
- The interpreter may be forgiving enough that a run-time error isn't generated, but the side effects could be subtle and make it hard to diagnose the cause.
- This is not available for use server-side with Netscape Enterprise Server 3.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myObject1 = 100;
myObject2 = "100";
if(myObject1 == myObject2)
{
   document.write("Objects are equal<BR>");
}
else
{
   document.write("Objects are NOT equal<BR>");
}
```

```
if(myObject1 === myObject2)
{
   document.write("Objects are identical<BR>");
}
else
{
   document.write("Objects are NOT identical<BR>");
}
</SCRIPT>
</BODY>
</HTML>
```

Identifier (Definition)

A means of referring uniquely to a variable, property or method.

Variables and functions have unique names. These names are called identifiers.

An identifier is a string of characters, composed of letters, digits or two other special characters ($ and _). An identifier name must begin with a non-digit (that is a letter or underscore). JavaScript is case-sensitive and an identifier spelled with uppercase letters is distinct from one having the same name spelled with lowercase letters.

You should not use any of the reserved keywords as identifier names.

An identifier refers to a variable, property or function and is the user-defined way to distinguish one item from another.

Identifiers can be of unlimited length, although for practical purposes they should be kept to a reasonable length, say 30 to 40 characters at most. The following characters are valid for use in identifiers:

a b c d e f g h i j k l m

n o p q r s t u v w x y z

A B C D E F G H I J K L M

N O P Q R S T U V W X Y Z

0 1 2 3 4 5 6 7 8 9

$ _ (Underscore)

Identifiers are case-sensitive. The following all denote different identifiers:

```
exampleidentifier

exampleIdentifier

ExampleIdentifier

EXAMPLEidentifier

EXAMPLEIDENTIFIER
```

The dollar sign should be used sparingly and according to the ECMA standard is reserved for use by mechanically generated code.

Warnings:

- You cannot use reserved words as identifier names.
- Avoid using the dollar sign. MSIE version 3.0 and Netscape 2.02 cannot cope with dollar signs in variable names. MSIE version 3.02 cannot tell the difference between one identifier and another when the names only differ in the case of the letters that spell the identifier name.

Wrox *Instant JavaScript* –page –14

Identifier resolution (Definition)

The process of resolving and locating an identifier.

Availability:	ECMAScript edition –2

Identifiers are resolved by binding the name to the value container through the scope chain.

A hierarchical access mechanism adds items to the front of the scope chain as code is nested. The most local variable object belonging to the current execution context is searched first. If the name is not resolved, then the scope chain is walked until a matching name is located or the global code's execution context is reached. If there is still no match, then the undefined value is returned.

An identifier is considered to be a primary expression when it is being evaluated.

Identity operator (Definition)

A close cousin of the equality operator family.

Equality operators are generally used for comparing primitive values.

If they are used for comparing objects, the objects are converted to primitives and then tested. This may not be the test you are trying to accomplish.

Imagine two objects, each distinct from one another but containing the same value in the properties that are yielded by the `toString()` or `valueOf()` methods. They are different objects but they will test `true` for equality.

The identity operators provide a way to test whether they are the same object or not.

There are two identity operators:

- === Identically equal to
- !=== Not identically equal to

You can use these in relational expressions in much the same way as you would the equality operators but remember that you are testing references to objects not values.

See also:	Identically equal to (===), NOT Identically equal to (!==)

ids (Property)

An alternative reference to the `document.ids` property in JSS.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Collection object`	
JavaScript syntax:	N	`ids`
	N	*`myDocument`*`.ids`

Warnings:

- This functionality is removed from Netscape 6.0.

See also:	JavaScript Style Sheets, Document.ids[]

IEEE 754 (Standard)

An international standard for floating point number handling and storage in 8 bytes.

Availability:	ECMAScript edition –2

The IEEE 754 standard defines the behavior of a numeric environment in such a way that the computation should generate the same result across any compliant platforms.

It specifies the exact format for the storage and manipulation of the values. It also specifies bounding ranges for exponents and mantissas.

The standards describes how and when rounding should occur and the direction in which rounding takes place. Exceptions are also described and this determines how the `NaN` value is generated and propagated through expressions.

ECMA 262 edition 2 –section –3

ECMA 262 edition 3 –section –3

if(...) ... (Selector)

A conditional execution mechanism.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
JavaScript syntax:	-	*aLabel*: if(*aCondition*) { *someCode*}
Argument list:	*aCondition*	An expression that yields a Boolean value
	aLabel	An optional identifier to name the if block
	someCode	Some script source text that is executed if the condition tests `true`

The `if()` statement is used to conditionally execute a code block depending on the result of a conditional expression. This mechanism is called branching.

The expression in the parentheses is evaluated and cast to a Boolean value. If it yields a `true` value as a result, then the code in the associated block is executed. Otherwise, the code is ignored and execution continues at the line following the closing brace of the code block.

JavaScript allows you to omit the braces around the code block if the code is a single line. You must place the trailing semi-colon on the line to delimit the script source text that is associated with the `if()` statement.

At version 1.2 of JavaScript, you can name the `if` statement and use the labelled form of the break keyword to exit the conditional code block prematurely.

Warnings:

- Beware of leaving the braces off the associated script source text as it is possible for this to be ambiguous to the reader and can lead to difficulties when adding more code to be executed conditionally. It can become easy to add a second line of code but still omit the braces. In that case, only the first line will be conditional but the second will always be executed regardless of the result of the `if()` condition. This can lead to completely unexpected behavior and is quite difficult to diagnose.

Example code:

```
// Reccomended form
if(a == b)
{
   z = 100;
   alert("z set to 100");
}

// Possibly dangerous during maintenance
if(a !== b)
   z = 100;
```

ECMA 262 edition 3 –section –12.5

Wrox *Instant JavaScript* –page –22

if(...) ... else ... (Selector)

A conditional execution mechanism.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
JavaScript syntax:	-	*aLabel*: if(*aCondition*) { *someCode*} else { *someOtherCode*)
Argument list:	*aCondition*	An expression that yields a Boolean value
	aLabel	An optional identifier to name the if block
	someCode	Some script source text that is executed `if` the condition tests `true`
	someOtherCode	Some script source text that is executed if the condition tests `false`

The `if() ... else` statement is used to conditionally execute one or other code block depending on the result of a conditional expression.

The expression in the parentheses is evaluated and cast to a Boolean value. If it yields a `true` value as a result, then the code in the first associated block is executed. Otherwise, the code in the first block is ignored and the code in the block following the `else` keyword is executed.

Each `else` keyword for which the associated `if()` is ambiguous will be associated with the nearest possible `if()` that would otherwise have no corresponding `else`.

At version 1.2 of JavaScript, you can name the `if` statement and use the labelled form of the break keyword to exit the conditional code block prematurely.

Example code:

```
// Reccomended form
if(a == b)
{
   z = 100;
}
else
{
   z = 200;
}

// Possibly dangerous during maintenance
if(a == b)
z = 100;
else
z = 200;
```

IFRAME object (Object/HTML)

An object that represents an <IFRAME> tag.

Availability:	DOM level –1 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myIFRAME* = *myDocument*.all.*anElementID*
	IE	*myIFRAME* = *myDocument*.all.tags("IFRAME")[*anIndex*]
	IE	*myIFRAME* = *myDocument*.all[*aName*]
	-	*myIFRAME* = *myDocument*.*aName*
	-	*myIFRAME* = *myDocument*.getElementById(*anElementID*)
	-	*myIFRAME* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myIFRAME* = *myDocument*.getElementsByTagName("IFRAME")[anIndex]
HTML syntax:	`<IFRAME> ... </IFRAME>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align, dataFld, dataSrc, frameBorder, frameSpacing, height, hspace, longDesc, marginHeight, marginWidth, name, noResize, scrolling, src, tabIndex, vspace, width`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

An `<IFRAME>` is a special MSIE supported tag that introduces an inline frame into a document that appears like a block structured element within the document text flow, accessible as a named frame object that belongs to the document.

Its properties appear to be all read-only in the MSIE browser. Changing them seems to have no visible effect at all. The properties belonging to the object retain the values that you assign and return them when requested but the display does not change.

The DOM level 1 specification refers to `IFRAME` objects as `IFrameElement` objects and this makes them available in Netscape by virtue of its support for DOM level 1.

DOM level 2 adds the following properties:

- `contentDocument`

Warnings:

- Netscape does not support the `<IFRAME>` tag prior to version 6.0, but it does support an `<ILAYER>` tag which describes an inline laye,r which is not the same thing but may provide a way to emulate the `<IFRAME>` functionality in some cases.
- MSIE seems to have trouble locating an `IFRAME` object in the document hierarchy, and you cannot refer to the object directly in the same way that you can with other objects.
- With an `IFRAME` object whose ID is "MYFRAME" this accessor works:
  - `document.all.MYFRAME`
- But these accessors don't:
  - `document.MYFRAME`
  - `MYFRAME`
- Even worse, the IFRAME appears to float in some separate plane to its containing object. Placing an `<IFRAME>` inside a `<DIV>` block exhibits some very strange behavior. Its position seems locked to the top left of the `<DIV>` but its right edge seems to be able to flow outside the `<DIV>` area.
- Netscape 6.0, which implements `IFRAME` objects, does not appear to fare any better, exhibiting similarly strange behavior.

onMouseUp	1.5+	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

IFRAME.align (Property)

A controlling attribute that affects the alignment of the `<IFRAME>` with respect to its parent object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*.align

The alignment of the `IFRAME` object with respect to its containing parent object is defined in this property. An expected and widely available set of alignment specifiers are available, as follows (the default is bottom):

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Warnings:

- None of the alignment values seem to affect the appearance of the `IFRAME` object in MSIE or Netscape 6.0.

IFRAME.frameBorder (Property)

Describes a 3D border effect to be drawn round the inline frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.frameBorder`

The `frameBorder` property should allow you to turn the engraved frame border effect on and off. Its should accept the following values (the default is yes):

- 0
- 1
- yes
- no

Warnings:

- This seems to have no effect on the appearance of the `IFRAME` object in the MSIE or Netscape browsers.

See also:	`Frame.frameBorder`

IFRAME.frameSpacing (Property)

A frame spacing margin around the `<IFRAME>` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myIFRAME*`.frameSpacing`

A spacing distance between multiple frames that is measured in pixels on the screen.

Warnings:

- The spacing controls for an IFRAME are provided in differently named properties and HTML tag attributes to those supported by the normal `<FRAME>` in `<FRAMESET>` objects.
- They don't seem to work on the MSIE or Netscape browsers at all.

See also:	`Frame.frameBorder`, `Frame.marginHeight`, `Frame.marginWidth`

IFRAME.height (Property)

Contains the height of the inline frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.height`

The current height of the IFRAME can be measured from this property. You ought to be able to modify it but it seems not to work.

Warnings:

- This appears to be a read-only property in MSIE and Netscape.

See also:	`Frame.height`, `IFRAME.width`

IFRAME.hspace (Property)

A measure of the horizontal spacing either side of the `<IFRAME>` to separate it from any adjacent objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myIFRAME*`.hspace`

This works the same as the `hspace` you apply to an `image` object. It introduces some space between objects that run together on the same line. It appears as if the margin has been altered but it is a different spacing control.

The space is applied equally on both sides of the `IFRAME` object.

Warnings:

- This has no visible effect on the `IFRAME` object in MSIE and Netscape.

See also:	`IFRAME.vspace`

IFRAME.longDesc (Property)

This is a URL which points at a document containing a long description of the contents of this frame.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myIFRAME*`.longDesc`

It needs to be defined as the `IFRAME` is created to have any meaningful purpose.

Warnings:

- This yields nothing in MSIE and Netscape.

See also:	`Frame.longDesc`

IFRAME.marginHeight (Property)

A measure of the vertical margin above and below the `<IFRAME>` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.marginHeight`

Margins flow round the entire frame. You cannot operate on all four individually but you can operate on the vertical and horizontal margin pairs independently.

That means the top and bottom margin must be the same, as must the left and right.

This property is the size of the margins at the top and bottom of the frame.

This is a bit like the `vspace` property but since neither seems to have any effect it is difficult to prove they operate independently.

Warnings:

- This seems to have no visible effect in MSIE and Netscape.

See also:	`Frame.marginHeight`

IFRAME.marginWidth (Property)

A measure of the horizontal margin to the left and right of the `<IFRAME>` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.marginWidth`

Margins flow round the entire frame. You cannot operate on them individually but you can operate on the vertical and horizontal margins separately.

That means the top and bottom margin must be the same, as must the left and right.

This property is the size of the margins to the left and right of the frame.

This is a bit like the `hspace` property but since neither seems to have any effect it is difficult to prove that they operate independently.

Warnings:

- This seems to have no visible effect in MSIE and Netscape.

See also:	`Frame.marginWidth`

IFRAME.name (Property)

The value of the `NAME="..."` HTML tag attribute.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myI*`FRAME.name`

This reflects the value defined in the HTML tag attribute. It's not likely that you would want to change it.

See also:	`Window.name`

IFRAME.noResize (Property)

A switch value that controls whether the `<IFRAME>` can be resized or not.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myI*`FRAME.noResize`

This is a Boolean value to turn the frame resizing control on and off. Unlike the border control, this is a truly Boolean value accepting either `true` or `false` as its setting.

However, it has no effect whatsoever –this is because inline frames can't be resized in Internet Explorer 4.0 anyway.

See also:	`Frame.noResize`

IFRAME.scrolling (Property)

A switching attribute that controls the appearance of scrollbars on the `<IFRAME>` when its content exceeds the available space.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.scrolling`

Yet another deviant property in the browser mess! Having just discussed the `noResize` property which is a switching mechanism having a Boolean setting, here we are with another switching property. However, as is the case with border controls, this one is not Boolean. Instead it accepts the values:

- `yes`
- `no`
- `auto`

See also:	`Frame.scrolling`

IFRAME.src (Property)

The URL of the document content inside the `<IFRAME>` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.src`

Inline frames have their content loaded in much the same way as for a window. This property describes the source URL of the document that controls the content of an inline frame. You can reload the inline frame by redefining this value, but it is probably better to use the `location.href` value for that.

See also:	`Frame.src`

IFRAME.tabIndex (Property)

A numeric ordering of the <IFRAME> within the parent document's tabbing sequence.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myI*FRAME.tabIndex

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms. Pressing the [tab] key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

IFRAME.vspace (Property)

A spacing in the vertical axis between the <IFRAME> and its adjacent objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	IE	*myI*FRAME.vspace

This works the same as the vspace you apply to an image object. It introduces some space between objects that run together on adjacent lines. It appears as if the margin has been altered but it is a different spacing control.

The space is applied equally above and below the IFRAME object.

Warnings:

- Changing this seems to have no visible effect on the IFRAME object in MSIE and Netscape.

See also:	IFRAME.hspace

IFRAME.width (Property)

Contains the width of the inline frame.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIFRAME*`.width`

The current width of the IFRAME can be measured from this property. You ought to be able to modify it, but it doesn't seem to work.

Warnings:

- This appears to be a read-only property in MSIE and Netscape.

See also:	`IFRAME.height`

IIS (Product)

Internet Information Server. A Microsoft server product.

Refer to:

Internet Information Server

Image animation (Useful tip)

Using cached images to animate an image.

If you cache some images in local memory, you can perform some very slick animations.

You can effect animation with the `lowsrc` property in the same way as you can with the `src` property but the `src` property must remain empty while you do that. If you specify both and the browser is running in a low resolution device, the `lowsrc` image will be used instead of the `src` image.

The example shows you how to do animation with `src` properties.

Example code:

```
<HTML>
<BODY>
<!-- Image cache technique -->
<SCRIPT>
// First create an image buffer array
var myImages = new Array(10);

// Now load the array with image objects getting them from the server
for(var myIndex = 0; myIndex<10; myIndex++)
{
   myImages[myIndex] = new Image();
   myImages[myIndex].src = "assets/image_" + myIndex + ".jpg";
}

var mySequence = 0;
function animate()
{
   mySequence = (mySequence + 1)%10;
   document.images[0].src = myImages[mySequence].src;
}

setInterval("animate()", 100);
</SCRIPT>

<IMG SRC="assets/image_0.jpg" NAME="targetimage">

</BODY>
</HTML>
```

See also:	`Image.lowsrc`, `Image.src`

Image object (Object/HTML)

An object representing an HTML `<IMG>` tag in Netscape.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myImage* = *myDocument*.all.*anElementID*
	IE	*myImage* = *myDocument*.all.tags("IMG")[*anIndex*]
	IE	*myImage* = *myDocument*.all[*aName*]
	-	*myImage* = *myDocument*.*anImageName*
	-	*myImage* = *myDocument*.getElementById(*anElementID*)
	-	*myImage* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myImage* = *myDocument*.images[*anIndex*]
	-	*myImage* = *myI*mageArray[*anIndex*]
	-	*myImage* = *myDocument*.getElementsByTagName("IMG")[*anIndex*]

HTML syntax:	`<IMG>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`border, complete, constructor, defaultValue, height, hspace, lowsrc, name, size, src, vspace, width, x, y`	
Object methods:	`select()`	
Event handlers:	`onAbort, onBlur, onClick, onDblClick, onError, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

The `image` object added at version 1.1 of JavaScript introduced the possibility of dynamically replacing images under script control.

Event handling support via properties containing function objects was added to `Image` objects at version 1.1 of JavaScript.

The `image` object supported by Netscape and the `IMG` object supported by MSIE are so different to each other that they are covered as separate objects. They share a few similarities but not many. By inspection, they are instances of different classes.

Warnings:

- In the MSIE browser, the images are instantiated inside `IMG` objects because they correspond to the `IMG` tag. There is an `Image` object created as another name for the same `IMG` tag and if you instantiate a new copy of it you get an `IMG` object. This means you should be careful when examining the constructors and class names of `image` objects, as their object type is not portable across platforms.

Example code:

```
<HTML>
<HEAD>
<SCRIPT>
function moved()
{
   document.all.ONE.width = event.x;
}
</SCRIPT>

</HEAD>

<BODY onMouseMove="moved()">
Move mouse horizontally to scale image<BR>

<IMG HEIGHT=40 ID="ONE" SRC="assets/image_9.jpg">

</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Node` object

Image() (Constructor)

A constructor for new browser images.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	`new Image()`

When the Image constructor is used in a new expression it creates a new object based on the `Image` prototype.

You can then assign values to the properties of that new `Image` object as needed.

`Image` objects are generally constructed so that image assets can be requested from the server and retained in the browser cache. This can happen in the background without the image needing to appear on the display.

Then, when you need to perform an image replacement, the browser knows that the image is stored locally and can be located more quickly than if it had to request it from the server at the time it is required.

This can significantly speed up the animation effects you choose to reproduce.

See also:	Web browser

Image() (Function)

A function for constructing new browser images.

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	`Image()`

You can either use the function to create new images or another `image` object which can be cloned instead.

See also:	`Image()`, Web browser

Image.border (Property)

The thickness of the border round an image.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myImage.border`*

The border will be highlighted if the image is embedded inside an anchor tag.

Image.Class (Property/internal)

Internal property that returns an object class.

This is an internal property that describes the class that an `Image` object instance is a member of. The reserved words suggest that in the future, this property may be externalized.

See also:	Web browser

Property attributes:

`DontEnum`, `Internal`.

Image.complete (Property)

The current state of an image loading operation.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myImage.complete`*

This is a Boolean property that reflects the current loading status of an `image` object. It should yield the value `false` until the image has completely transferred from the server to the client browser.

Warnings:

- Netscape 4 will incorrectly yield a `true` value when the image has not yet completely loaded.

Property attributes:

`ReadOnly`.

Image.constructor (Property)

An `Image` object constructor.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Image object`	
JavaScript syntax:	N	*`myImage.constructor`*

The constructor is that of the built-in `Image` prototype object.

You can use this as one way of creating arrays, although it is more popular to use the new `Image()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

Image.height (Property)

The height of an image.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage.height`*

The image space is defined by an extent rectangle that surrounds the space occupied by it on the screen. The extent rectangle is the smallest rectangle that can completely enclose the item. This property specifies the height of that extent rectangle.

Including height and width information on images is optional, but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the image has been fetched before reserving sufficient space for it in the display.

See also:	`Image.width`, `IMG.height`, `IMG.width`

Property attributes:

`ReadOnly`.

Image.hspace (Property)

The horizontal spacing attribute value.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage.hspace`*

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `hspace` property controls the margin to the left and right of the object.

See also:	IMG.hspace

Property attributes:

`ReadOnly.`

Image.lowsrc (Property)

The low-resolution version of the image can be supplied from this URL.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myImage.lowsrc`*

This is a useful technique to make the site appear to be faster than it really is. You specify a low resolution version of the image that can be contained in a much smaller file. This is then loaded first by the browser while it downloads the larger image.

Although this property is read/write, changing it does not force the image to be reloaded again.

DOM level 1 describes this as a `lowSrc` property. Note the capitalization.

For this to work as intended, you must specify the `lowsrc` (`lowSrc`) property value prior to the `src` property value otherwise the high quality image will be fetched first.

See also:	Image animation, IMG.lowsrc

Image.name (Property)

This corresponds to the NAME attribute of the <IMG> tag.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myImage.name*
HTML syntax:	<IMG NAME="...">	

Objects are identified either by the NAME="..." HTML tag attribute or by the ID="..." HTML tag attribute.

Netscape shows a marginal preference for the name property, while MSIE seems slightly better disposed towards the ID property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

This property cannot be used with Image objects that are manufactured at run-time from the Image() constructor. They can be collected in an array and accessed associatively as named array elements, but images you create in script aren't part of the document and therefore can't be addressed as if they are.

See also:	IMG.name

Image.src (Property)

The URL where the image is located.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myImage.src*

If you change the src property of an image it will be replaced on the browser's display screen. The only limitation is that the images that are replaced are exactly the same shape and size as the previous image.

Some browsers may forgive you if you display differently sized images, and some may scale the images to fit.

This can lead to all manner of creative effects such as rollover highlights, clocks, animations, progress bars etc. You can also simulate checkboxes graphically as well as all manner of other useful and 'pretty' user interface widgets.

For animations to work smoothly, you should ensure that the images have been cached locally first otherwise the animation will appear somewhat jerky while they are fetched from a server.

See also:	Image animation, Image preloading, `IMG.src`

Image.vspace (Property)

The vertical spacing attribute value.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage.vspace`*

Margins placed around objects are either modified separately, with all four margin sides having a different property, or by adjusting the horizontal margins and vertical margins using just two values.

The `vspace` property controls the margin at the top and bottom of the object.

See also:	`IMG.vspace`

Property attributes:

`ReadOnly`.

Image.width (Property)

The width of an image.

Availability:	DOM level –1 JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage.width`*

The image space is defined by an extent rectangle that surrounds the space occupied by it on the screen. The extent rectangle is the smallest rectangle that can completely enclose the item. This property specifies the width of that extent rectangle.

Including height and width information on images is optional, but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the image has been fetched before reserving sufficient space for it in the display.

See also:	`Image.height`, `IMG.height`, `IMG.width`

Property attributes:

`ReadOnly`.

Image.x (Property)

The X coordinate of the image within the client display area.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage`*`.x`

The horizontal position of the object in the display, measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Property attributes:

`ReadOnly`.

Image.y (Property)

The Y coordinate of the image within the client display area.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myImage`*`.y`

The vertical position of the object in the display, measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Property attributes:

`ReadOnly`.

Image preloading (Useful tip)

A technique for caching images locally in readiness for an animation.

If you want to animate some images, you will need to cache them locally to make sure the animation moves smoothly. If you don't, the animation will be very jerky while the images are fetched from the server.

The action of setting the `src` attribute of the `image` object in the buffer array is simply to recall the images and store them in the cache. The `image` objects then act as a repository to store the `src` value so it can be assigned to the target image in an animation loop.

Warnings:

- Note that this technique is a waste of time if you set your browser cache to zero bytes capacity and force a document to be requested from the server every time, at least that is what happens in MSIE (and is what you would expect).
- Netscape adds a trick to this by caching objects that you are holding in memory and referencing via script variables –it's a little smarter, and knows that you are intentionally caching images even though you have set your cache size to zero.
- Some versions of MSIE fetch the image from the server every time you reference it, regardless of your cache settings or the fact that you have preloaded it and stored a reference to it in a variable.

Example code:

```
<!-- Image cache technique -->
<SCRIPT>
// First create an image buffer array

var myImages = new Array(10);

// Now load the array with image objects getting them from the server
for(var myIndex = 0; myIndex<10; myIndex++)
{
   myImages[myIndex] = new Image();
   myImages[myIndex].src = "assets/image_" + myIndex + ".jpg";
}

var anIndex=Math.ceil(Math.random()*10);

document.write("<IMG SRC=" + myImages[anIndex].src + " >");
</SCRIPT>
```

See also:	`Image.src`

ImageArray object (Object/browser)

A collection of `image` objects.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	*myImageArray* = *myDocument*.images
Object properties:	length	
Object methods:	item()	

The MSIE and Netscape browsers each maintain an `ImageArray` object, which is just a special case of the `Array` object. However, although they both store objects that represent images in that array, those image objects are quite different. For a start, in Netscape they are of the class "`Image`" while in MSIE they are of the class "`IMG`" (named after the HTML tag). This is fortunate in a way, because you can use this difference to detect what kind of object you are operating on if you need to perform complex image management activities.

For MSIE image objects refer to the `IMG` object topic and its properties.

For Netscape Navigator `image` objects refer to the `Image` object topic and its properties.

Warnings:

- Beware of the differences between the properties that MSIE and Netscape Navigator provide to support image management.

See also:	`Collection` object, `Document.images[]`, `Image` object, `IMG` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
length	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
item()	-	3.0 +	-	4.0 +	-	-	-

ImageArray.item() (Method)

An item selector for accessing a single image within the collection.

Availability:	JScript –3.0 Internet Explorer –4.0
Property/method value type:	`Image` object

JavaScript syntax:	IE	*myImageArray*.item(*anIndex*)
	IE	*myImageArray*.item(*aSelector*)
	IE	*myImageArray*.item(*aSelector*, *anIndex*)
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

ImageArray.length (Property)

A collection of image objects in the current document.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myImageArray*.length

See also:	`Image` object, `Collection.length`

Property attributes:

`ReadOnly`.

IMG object (Object/HTML)

The MSIE object wrapper for images.

Availability:	DOM level –1 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –3.0
Inherits from:	`Element` object

JavaScript syntax:	IE	*myIMG* = *myDocument*.all.*anElementID*
	IE	*myIMG* = *myDocument*.all.tags("IMG")[*anIndex*]
	IE	*myIMG* = *myDocument*.all[*aName*]
	-	*myIMG* = *myDocument*.anImageName
	-	*myIMG* = *myDocument*.getElementById(*anElementID*)
	-	*myIMG* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myIMG* = *myDocument*.images[*anIndex*]
	-	*myIMG* = *myImageArray*[*anIndex*]
	-	*myIMG* = *myDocument*.getElementsByTagName("IMG") [*anIndex*]
HTML syntax:	<IMG><INPUT TYPE="IMAGE">	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, align, alt, border, complete, dataFld, dataFormatAs, dataSrc, defaultValue, dynsrc, fileCreatedDate, fileModifiedDate, fileSize, fileUpdatedDate, height, href, hspace, iccProfile, isMap, longDesc, loop, lowsrc, name, protocol, prototype, readyState, size, src, start, tabIndex, useMap, vspace, width	
Object methods:	select()	
Event handlers:	onAbort, onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDataAvailable, onDataSetChanged, onDataSetComplete, onDblClick, onDragStart, onError, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onScroll, onSelectStart	

<IMG> tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

Event handling support via properties containing function objects was added to IMG objects at version 1.1 of JavaScript.

The DOM level 1 specification refers to this as an ImageElement object. Netscape implements an Image class with somewhat different properties. By inspecting their DOM attributes, you can see that they are instances of different classes.

See also:	Element object, Image object, ImageArray object, Input.accessKey

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

IMG.align (Property)

The alignment of an image within its surrounding objects.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.align

The alignment of the `IMG` object with respect to its containing parent object is defined in this property. The following expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `none`
- `right`
- `texttop`
- `top`

IMG.alt (Property)

An alternative text used when the `Image` is defined as an input item.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.alt

Objects can have an alternative text string associated with them. This is useful for browsers that cannot cope with the tag and hence may display the alternate text. If spoken styles are supported, the text may be read out to the user. Some browsers will also display the `alt` text as a tool-tip if the mouse pointer is positioned over the object and remains static for a few seconds.

IMG.border (Property)

Controls the border around an `image` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.border

The border will be highlighted if the image is embedded inside an anchor tag.

See also:	`Image.border`

IMG.complete (Property)

Returns a value indicating whether the image has completely loaded or not.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myIMG*.complete

The constructor is that of the built-in `Image` prototype object.

You can use this as one way of creating arrays, although it is more popular to use the new `Image()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`Image.constructor`

Property attributes:

`ReadOnly`.

IMG.dynsrc (Property)

The URL of a video clip that can be played where an image would normally have been located.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*.dynsrc

This is part of the dynamic HTML model although the dynamism is inside the asset encapsulated by the object.

You can playback a video clip or traverse a VRML panorama at any location where an image would have been placed.

If you use the `DYNSRC="..."` HTML tag attribute, you should not specify the `SRC="..."` HTML tag attribute.

The loop property of the `IMG` object controls how many iterations of the animation take place.

Warnings:

- This is not even remotely portable so it is not recommended that you use this, unless your user base is captive and using a controlled release of the MSIE browser. Using a plugin video player is far more portable.

See also:	`IMG.loop`, `IMG.start`

IMG.fileCreatedDate (Property)

The date that the image file was created.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*.fileCreatedDate

Where it is possible to distinguish properties of document source files, this can tell you about the history of the document.

This read-only property described the date that an image file was created. With this you can calculate the age of the image file by subtracting that date from the current date and time.

See also:	`Document.fileCreatedDate`

Property attributes:

`ReadOnly`.

IMG.fileModifiedDate (Property)

The date that image file was last modified.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*`.fileModifiedDate`

Where it is possible to distinguish properties of image files, this can tell you about the history of the image.

This read-only property describes the date that a file was last modified. With this you can calculate the age of the file content by subtracting that date from the current date and time.

See also:	`Document.fileModifiedDate`

Property attributes:

`ReadOnly`.

IMG.fileSize (Property)

The size of the image file.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myIMG*`.fileSize`

This is the exact length of the received HTTP body portion of the image. This does not count any HTTP headers that the web server may have sent prior to the HTTP body.

On the Macintosh operating system, some image editors hide additional resource data in the file. This is not included and on that platform, the `fileSize` property is a measurement of the data fork of the file and does not include the resource fork.

See also:	`Document.fileSize`

Property attributes:

`ReadOnly`.

IMG.fileUpdatedDate (Property)

The date that the image file was last updated.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*`.fileUpdatedDate`

According to the available documentation from Microsoft, there is no distinction made between this and the `fileModifiedDate`. However this property is only available for `IMG` objects whereas the other file metrics can be obtained for `IMG` and `document` objects.

Property attributes:

`ReadOnly`.

IMG.height (Property)

The height of the image within the client display surface.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*`.height`

The image space is defined by an extent rectangle that surrounds the space occupied by it on the screen. The extent rectangle is the smallest rectangle that can completely enclose the item. This property specifies the height of that extent rectangle.

Including height and width information on images is optional but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the image has been fetched before reserving sufficient space for it in the display.

See also:	`Image.height`, `Image.width`, `IMG.width`

IMG.href (Property)

The URL where the image was loaded from. This is identical to the `SRC="..."` HTML tag attribute.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*`.href`

Image tags can have their HREF defined by JavaScript code. To do this, you need to place a JavaScript: URL in the HREF and return a valid location on exit from the function or expression that is invoked.

See also:	`IMG.src`

IMG.hspace (Property)

The horizontal spacing either side of the image.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*`.hspace`

Margins placed around objects are either modified separately with all four margin sides having a different property, or by adjusting the horizontal margins and vertical margins using just two values.

The `hspace` property controls the margin to the left and right of the object.

See also:	`Image.hspace`

IMG.iccProfile (Property)

The color of an image may appear different from one platform to another. This indicates the color profile that was used when the image was created so you can make adjustments if necessary.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myIMG*`.iccProfile`

Color correction software is something that should be performed on a workstation in a consistent manner across all applications. This is because they all share the same visual display, and that display needs to be calibrated to conform to a particular color temperature and gamma curve.

An ICC profile is a preset collection of values that may be accessed by symbolic name and from that you may be able to select a particular setting in the browser to ensure the images and colors in the web page are displayed exactly as the designer intended.

IMG.isMap (Property)

Indicates whether the image is acting as a server-side image map.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myIMG*`.isMap`

This Boolean value determines whether an image is used as a server-side image map. If it is a server-side image map, then a click on the image will return a URL request to the server that includes an X-Y coordinate pair describing where on the image the mouse was positioned when the button was clicked.

You can set this property yourself from a script, although it would most likely be set from HTML.

The value `true` signifies that the image is a server-side image map and the value `false` signifies that it is not.

IMG.longDesc (Property)

This is a long description of the image file.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*`.longDesc`

Warnings:

- This is a separate property to the `alt` text or the title value for the image. It does not appear to work on the Macintosh platform and only yields an empty string.

IMG.loop (Property)

This controls the looping of a video clip that is loaded with the `dynsrc` attribute.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myIMG*`.loop`

The value of this loop property of the `IMG` object controls how many iterations of the animation take place.

By setting the value to -1, continuous looping is achieved. Otherwise, the number of cycles is defined by a positive integer.

See also:	`IMG.dynsrc`

IMG.lowsrc (Property)

The URL of a low-resolution image that can be loaded quickly.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*`.lowsrc`

This is a useful technique to make the site appear to be faster than it really is. You specify a low resolution version of the image that can be contained in a much smaller file. This is then loaded first by the browser while it downloads the larger image.

Although this property is read/write, changing it does not force the image to be reloaded again.

The DOM level 1 specification refers to this as the `lowSrc` property. Note the capitalization.

For this to work as intended, you must specify the `lowsrc` (`lowSrc`) property value prior to the `src` property value otherwise the high quality image will be fetched first.

See also:	`Image.lowsrc`

IMG.name (Property)

This corresponds to the NAME attribute of the <IMG> tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.0 Netscape –2.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myIMG*.name

Objects are identified either by the NAME="..." HTML tag attribute or by the ID="..." HTML tag attribute.

Netscape shows a marginal preference for the name property while MSIE seems slightly better disposed towards the ID property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

This property cannot be used with IMG objects that are manufactured at run-time from the IMG() constructor. They can be collected in an array and accessed associatively as named array elements. Images you create in script aren't part of the document and therefore can't be addressed as if they are.

See also:	Image.name

IMG.protocol (Property)

The protocol that was used in the image URL.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myIMG*.protocol

This should yield the value HTTP or FILE or one of the other available protocols according to how the image was accessed. This allows you to build script code than can behave differently according to how the image was loaded.

Typically this might allow for a different page content to be displayed when an image is loaded from a local file system.

Refer to the URL topic for details of a variety of URL protocol values.

See also:	Anchor.protocol, Document.protocol, URL, Url.protocol

Property attributes:

ReadOnly.

IMG.prototype (Property)

The prototype for the `IMG` object that can be used to extend the interface for all `IMG` objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Image` object	
JavaScript syntax:	IE	`IMG.prototype`
	IE	*`myIMG`*`.constructor.prototype`

Property attributes:

`ReadOnly`.

Refer to:

`prototype` property

IMG.readyState (Property)

The current disposition of the image as it is being loaded.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myIMG`*`.readyState`

This property reflects the loading status of an image.

Sometimes, you can design scripts to execute while the document is downloading –inline scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

If it is important that the document has completed loading, you can check this property for one of the following values:

State	Value
uninitialized	The object is first instantiated but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed, but is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the `ActiveX` object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`onReadyStateChange`

Property attributes:

`ReadOnly`.

IMG.src (Property)

The URL where the image can be loaded from.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*`.src`

If you change the `src` property of an image it will be replaced on the browser's display screen. The only limitation is that the images that are replaced are exactly the same shape and size as the previous image.

Some browsers may forgive you if you display differently sized images, some may scale the images to fit.

Changing the `src` property of an image can lead to all manner of creative effects such as rollover highlights, clocks, animations, progress bars etc. You can also simulate checkboxes graphically as well as all manner of other useful and 'pretty' user interface widgets.

For animations to work smoothly, you should ensure that the images have been cached locally first, otherwise the animation will appear somewhat jerky while they are fetched from a server.

See also:	`Image.src`, `IMG.href`

IMG.start (Property)

The state of the image when it started loading a dynamic source.

Availability:	DOM level –2 JScript –3.0 Internet Explorer –3.02	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myIMG*.start

This property indicates when the dynamic content should start to play. It can take two values as follows:

- `fileopen`
- `mouseover`

You should only specify this value when the IMG object has a meaningful `dynsrc` property value.

See also:	`IMG.dynsrc`

IMG.useMap (Property)

The URL of a `<MAP>` defined hash element that defines a client side image map.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.useMap

This property reflects the value of the `USEMAP="..."` HTML tag attribute which should refer to the named `<MAP>` tag containing an image map. The reference is by means of a `"#NAME"` value in this property that corresponds to the `NAME="..."` HTML tag attribute of the `<MAP>` tag describing the image map to use.

See also:	`Map.name`

IMG.vspace (Property)

The vertical margin above and below the image.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.vspace

Margins placed around objects are either modified separately with all four margin sides having a different property, or by adjusting the horizontal margins and vertical margins using just two values.

The `vspace` property controls the margin at the top and bottom of the object.

See also:	`Image.vspace`

IMG.width (Property)

The width of the image on the client display surface.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myIMG*.width

The image space is defined by an extent rectangle that surrounds the space occupied by it on the screen. The extent rectangle is the smallest rectangle that can completely enclose the item. This property specifies the width of that extent rectangle.

Including height and width information on images is optional but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the image has been fetched before reserving sufficient space for it in the display.

See also:	`Image.height`, `Image.width`, `IMG.height`

Implementation (Definition)

A JavaScript interpreter provided in a usable form that can execute scripts.

An implementation is a program or set of programs that can read, interpret and execute script source text according to the conventions of the JavaScript language.

An ECMA compliant implementation is one that does so according to the precepts laid down in the ECMA 262 standard. This would be an ECMAScript interpreter although it should also state what edition of the standard it is compliant with.

A DOM compliant interpreter would be compatible with DOM level 1 or level 2. Other levels are in the course of being standardized.

An implementation will usually supply additional functionality over and above that specified by the standard.

See also:	Definition, ECMA, ECMAScript, ECMAScript –edition 2, ECMAScript – edition 3, Interpret

Implementation object (Object/DOM)

A special core object that describes the DOM implementation.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
JavaScript syntax:	-	*myImplementation* = *myDocument*.implementation
Object methods:	hasFeature()	

This is part of the DOM compliant implementation that MSIE now provides.

It has no enumerable properties and is a member of a the `Implementation` object class. It describes the DOM implementation that is supported.

The DOM level 2 specification adds the following two methods:

- `createDocumentType()`
- `createDocument()`

Warnings:

- The DOM level 1 standard calls this a `DOMImplementation` object. MSIE calls it an `Implementation` object.

See also:	`Document.implementation`

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`hasFeature()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Implementation.hasFeature() (Method)

A means of enquiring whether a certain feature is supported by the DOM implementation.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myImplementation*.*hasFeature*(*aFeature*, *aVersion*)
Argument list:	*aFeature*	The name of a feature
	aVersion	The feature version

Here is a list of feature and version codes that have been obtained by inspecting the DOM specifications. Note that this list may not be complete or exhaustive as only those values that are mentioned in the DOM specifications published to date have been included:

String	Version	Feature described
CSS	2.0	DOM level 2 CSS support
CSS2	2.0	DOM level support for CSS extended interfaces
Events	2.0	DOM level 2 event model
HTML	1.0	DOM level 1 HTML model
HTML	2.0	DOM level 2 HTML model
HTMLEvents	2.0	DOM level 2 HTML event support
MouseEvents	2.0	DOM level 2 mouse event support (part of Events)
MutationEvents	2.0	DOM level 2 mutation event support (part of Events)
Range	2.0	DOM level 2 text range module
StyleSheets	2.0	DOM level 2 StyleSheets module
Traversal	2.0	DOM level 2 document traversal module
UIEvents	2.0	DOM level 2 user interface event support (part of Events)
Views	2.0	DOM level 2 views module
XML	1.0	DOM level 1 XML extended interfaces
XML	2.0	DOM level 2 XML extended interfaces

See also:	`Event` object, `MouseEvent` object, `MutationEvent` object, `UIEvent` object

Implementation-defined behavior (Definition)

Correct behavior that is specific to a particular implementation.

Some behavior falls outside the ECMAScript standard but is nevertheless correct. Implementers should try to adhere to the spirit of the standard as far as possible. If other standards are built into the implementation (such as DOM for example), the standards working groups generally try to make the standards interoperable, and this helps to make sure that an implementation can support them both easily.

It is important that the implementers properly document any implementation specific behavior.

See also:	Behavior, Host environment, Host object, Implementation-supplied code, Implementation-supplied function

Implementation-supplied code (Definition)

Script source that is provided by the implementation.

Availability:	ECMAScript edition –2

The implementation-supplied code is provided by the hosting environment when it creates an implementation defined function.

As the function is created, the hosting environment may or may not additionally provide a formal parameter list for the function.

On initialization, the scope chain is set up to contain the activation object as its first element.

The caller provides this value, but in some situations the value `null` may be passed. In that case, the global object will be used in its place.

The `ImplicitThis` and `ImplicitParents` attributes affect the way that other lists of objects are attached to the scope chain. They interact to some extent as illustrated in this table:

ImplicitThis	ImplicitParents	First item	Second item	Third item	Fourth item
no	no	`activation` object	`global` object	-	-
no	yes	`activation` object	list of objects provided by this value	`global` object	-
yes	no	`activation` object	this value	`global` object	-
yes	yes	`activation` object	this value	list of objects provided by this value	`global` object

Finally the global object is placed in the scope chain after all other objects.

Variable instantiation is performed using the activation object as the `variable` object and any initial variables are flagged with a `DontDelete` attribute.

Implementation-supplied function (Definition)

The script interpreter can provide functions.

Availability:	ECMAScript edition –2

Implementation supplied functions are part of the hosting implementation, although it may depend on the core functionality of the interpreter to provide the necessary services.

The source text for an implementation supplied function is provided by the host environment. The mechanisms by which they are created is host dependent.

The functions created by the implementation may have any combination of `ImplicitThis` and `ImplicitParents` attributes. These control the way that the scope chain is set up when the function is initialized. Note that these are function `object` attributes and `notProperty` attributes. Depending on the host implementation you may or may not have access to these attributes to be able to define their settings.

Implicit conversion (Definition)

Type conversions that happen automatically.

In JavaScript, the type of a value may be promoted or demoted (coerced) from one kind to another according to the context in which it is used.

A number becomes a string if it is used in a string concatenation.

A string becomes a number if it contains a numeric value and if it is used in an arithmetic expression.

This happens automatically as expressions are evaluated.

The specific behavior depends on the data type of the value at the time the expression is invoked. It also depends on the type of expression being invoked.

This also affects the values yielded by expressions when they are used as operands in other expressions. In this case the value is an ephemeral item not stored in a variable nor in a visible container that the script can access, nevertheless, it behaves as any other value would.

The result of a function call may be affected in the same way when it is used in an expression.

Refer to the descriptions of each of the primitive value types for details of the result of a type conversion on a value of that type.

See also:	Array(), Boolean literal, Boolean(), Cast operator, Date(), Function(), Number(), Numeric literal, Object(), String literal, String(), ToBoolean, ToInt32, ToInteger, ToNumber, ToObject, ToPrimitive, ToString, ToUint16, ToUint32

ImplicitParents (Attribute)

An internal attribute of a function object referred to by an object property.

Availability:	ECMAScript edition –2

This internal attribute controls the way that the scope chain might be modified when an implementation defined function is being executed. If this attribute is set, then the list of objects defined by the `'this'` value will be added to the scope chain after the implementation supplied activation object.

The difference between the behavior of the `ImplicitParents` and the `ImplicitThis` internal attributes is quite subtle and you should consult and fully understand the ECMA standard as it relates to them.

See also:	`ImplicitThis`

Cross-references:

ECMA 262 edition 2 –section –10.1.1

ECMA 262 edition 2 –section –10.2.4

ImplicitThis (Attribute)

An internal `Function` object property.

Availability:	ECMAScript edition –2

This internal attribute controls the way that the scope chain might be modified when an implementation defined function is being executed. If this attribute is set, then the `'this'` value will be added to the scope chain after the implementation supplied activation object.

The difference between the behavior of the `ImplicitParents` and the `ImplicitThis` internal attributes is quite subtle, and you should consult and fully understand the ECMA standard as it relates to them.

See also:	`ImplicitParents`

Cross-references:

ECMA 262 edition 2 –section –10.1.1

ECMA 262 edition 2 –section –10.2.4

import (Statement)

Import some properties that have been exported from another execution context.

Availability:	ECMAScript edition –2 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –3.0

JavaScript syntax:	-	`import anObject.aFunction;`
	-	`import anObject.aProperty;`
Argument list:	*aFunction*	A function object to imprt
	anObject	An object that is exporting some property values
	aProperty	A property value to import

ECMAScript edition 2 suggests this is a future extension. As of the third edition of the ECMAScript standard it is still denoted as a reserved word.

Navigator 4 anticipates that a future standard will endorse this capability and provides it anyway.

A layer might import a function exported by another layer so that they can exchange values or operate on one another.

The imported property name can include the wildcard asterisk character to match several properties.

Warnings:

- This only works in Netscape 4 when the `LANGUAGE` attribute is set to "`JavaScript1.2`". Using import will affect the behavior of the `==` and `!=` operators as well.
- This can affect the security policy regarding the "same-signer" trustworthiness of a page.

See also:	export, Same origin, Signed scripts

ECMA 262 edition 2 –section –7.4.3

ECMA 262 edition 3 –section –7.5.3

in (Operator/logical)

Test for the existence of a property in an object.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*aProperty* `in` *anObject*
Argument list:	*aProperty*	A specific property to test for the existence of

The object is examined to see if the property exists. If it does, then a Boolean `true` value is returned, otherwise the expression returns `false`.

This might be useful as a work-around for when you need to test for the existence of a property but to do so by referring to it directly might cause a run-time error.

The logical operator yields `true` if the property exists in the object and `false` if the property is not available.

Warnings:

- This is not available for use server-side with Netscape Enterprise Server 3.

Cross-references:

ECMA 262 edition 3 –section –11.8.7

in ... (Keyword)

Part of the `for ... in` code execution mechanism.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
JavaScript syntax:	-	`for(`*`aVariable`* `in` *`anObject`*`)` `{` *`someCode`* `}`
Argument list:	*`anObject`*	An object to be examined for properties.
	`aVariable`	A variable to store each enumerated property name in
	`someCode`	Some script source to execute for each enumeration

See also:	in, `for( ... in ... ) ...`

Cross-references:

ECMA 262 edition 2 –section –12.6.3

ECMA 262 edition 3 –section –11.8.7

In leap year (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

It is useful to know whether you are in a leap year. ECMA compliant implementations use an extended Gregorian system to compute dates and can compute leap year flag values internally. This facility may not be available within scripts in all implementations. It can be simulated however.

ECMA compliant implementations use an extended Gregorian system to map a day number to a year number and to determine the month and date within that year. In this system, leap years are summarized thus:

```
DaysInYear(y) =

365 if ((y modulo 4) != 0)

366 if ((y modulo 4) == 0) and ((y modulo 100) != 0)

365 if ((y modulo 4) == 0) and ((y modulo 400) != 0)

366 if ((y modulo 400) == 0)
```

All non-leap-years years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non-leap years to adjust the day numbers and yield the day number of the first day of the given year and then use that to work out the time in milliseconds when the year started:

```
DayFromYear(y) =

365 * (y – 1970) +

floor((y – 1969) / 4) -

floor((y – 1901) / 100) +

floor((y – 1601) / 400)

msPerDay = 86400000

TimeFromYear(y) = msPerDay * DayFromYear(y)

YearFromTime(t) = The largest integer y to make TimeFromYear(y) less than or equal
to t.
```

This leap year method would yield a 1 for years that are leap years and 0 for the others:

```
InLeapYear(y) = 0 if DaysInYear(y) == 365

= 1 if DaysInYear(y) == 366
```

To use a time value instead of a year number, the function can be modified like this:

```
InLeapYear(t) = 0 if DaysInYear(YearFromTime(t)) == 365

= 1 if DaysInYear(YearFromTime(t)) == 366
```

Example code:

```
// Test for leap year
document.write("<TABLE BORDER=1>");
for(ii=1980; ii<2009; ii++)
{
   document.write("<TR><TD>");
   document.write(ii);
   document.write("</TD><TD>");
   document.write(inLeapYear(ii));
   document.write("</TD></TR>");
}
document.write("</TABLE>");

// Flag a leap year with a Boolean value
function inLeapYear(aYear)
{
   if((aYear % 4) != 0)
   {
      return false;
   }

   if(((aYear % 100) != 0) ||
      ((aYear % 400) == 0))
   {
      return true;
   }

   return false;
}
```

Included JavaScript files (Definition)

The technique of including JavaScript files from external locations.

Refer to:

`<SCRIPT SRC="...">`

Increment value (++) (Operator/postfix)

Pre or post incrementing operator.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`++anOperand`*
	-	*`anOperand`*`++`
Argument list:	*`anOperand`*	A numeric value that can be incremented

The operand is incremented by one.

A prefixing incrementor will add 1 to the operand value before it is used in an expression.

A post-fixing incrementor will add 1 to the operand after it is used in an expression.

Be careful how you use this pre/post placement as you can easily generate 'off by one' errors in your algorithms by placing the operator on the wrong side of the operand.

This operator is more or less functionally equivalent to:

```
anOperand += 1
```

which is equivalent to:

```
anOperand = anOperand + 1
```

See also:	Add then assign (+=), Additive expression, Additive operator, Decrement value (––), Postfix expression, Postfix increment (++), Prefix expression

ECMA 262 edition 2 –section –11.3.1

ECMA 262 edition 3 –section –11.3.2

Infinity (Constant/static)

A literal constant whose type is a built in primitive value.

Availability:	ECMAScript edition –2 JavaScript –1.3 JScript –3.0 Internet Explorer –4.0 Netscape –4.06	
Property/method value type:	`Number primitive`	
JavaScript syntax:	`-`	`Infinity`

The primitive value Infinity represents the positive infinite number value.

In JavaScript you can use the values positive infinity and negative infinity. They make reference to a global special variable called Infinity, and you can place an optional unary plus or unary minus in front to yield the positive and negative extremes.

If you are in an environment that does not have the `Infinity` value implemented, then you may be able to create one yourself like this:

```
var Infinity = 1e300 * 1e300;
```

You can check for infinity values with `Number.POSITIVE_INFINITY` and `Number.NEGATIVE_INFINITY`. They should be identical to `Infinity` and `-Infinity` which are properties of the `Global` object.

Note that although the type of result when testing the value `Infinity` or the copies available from the `Number` object is number, the value will print as "Inf" when displayed with a `document.write()` method.

Warnings:

- This constant is available as a property of the `global` object in MSIE version 4 but not in Netscape 4.
- This is not available for use server-side with Netscape Enterprise Server 3.
- Note that you can assign a new value to the `Infinity` property on some browsers. This is somewhat dangerous and may cause unpredictable results later on.

See also:	Arithmetic constant, Exception, Global object, Global special variable, isFinite(), NaN, Number, Number, Number.NEGATIVE_INFINITY, Number.POSITIVE_INFINITY, Range error, Special number values, Value property, Zero value

Property attributes:

`DontEnum`.

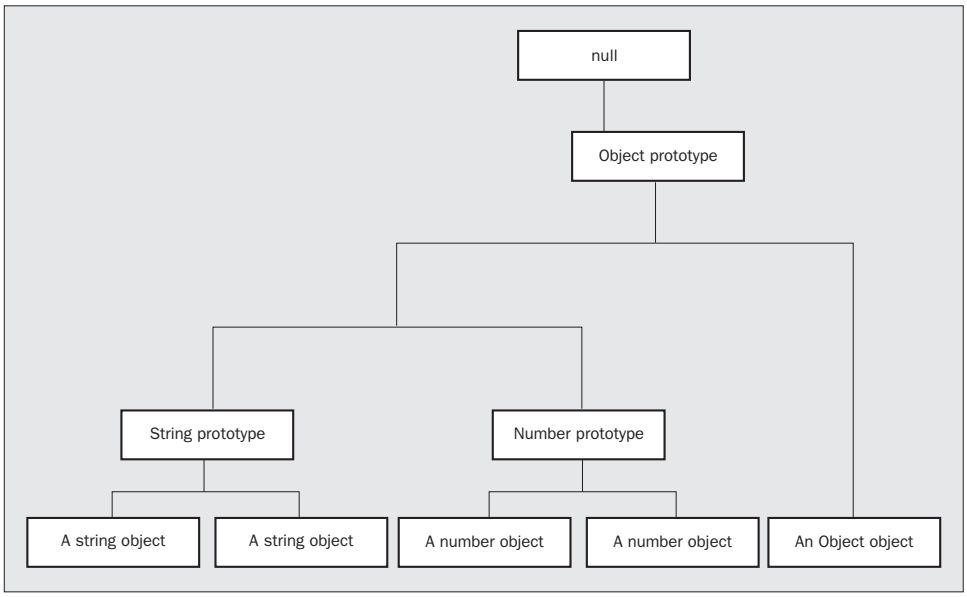
Wrox *Instant JavaScript* –page –14

Inheritance (Definition)

Inheritance is provided through a prototype chain.

Availability: ECMAScript edition –2

Inheritance in JavaScript is implemented by means of a chain of prototypes that link upwards from child to parent until a `null` reference is encountered.



See also: Prototype Based Inheritance

Cross-references:

ECMA 262 edition 2 –section –4.2.1

ECMA 262 edition 3 –section –4.2.1

Initialization (Definition)

Setting a variable to its initial condition.

Initialization code is very similar to assignment statements in the main body of the code. There is a slight difference in that the assignment takes place before any code is executed.

If variables are not initialized they will contain the value undefined.

The initialization happens when the variable is declared using the `var` keyword.

Objects are initialized when they are constructed. This is a somewhat different process to that of initializing a variable.

If a variable is initialized to equal an object, it is really a reference to that object and not the object itself that gets stored in the variable.

See also:	Constant expression, Declaration, `var`

Inline script (Definition)

Code that is embedded in a page or executed during page loading.

Strictly speaking, inline code is code that is embedded into the page in some enclosing `<SCRIPT></SCRIPT>` tags. However, some code can be included from an external file using the `SRC` attribute. This code is not inline code because it no longer lives in the page. However, when the page is loaded, it executed inline as if it had been part of the page all the time.

You may find yourself arguing over the fine points of whether included code is inline code, but to the browser it simply does not matter.

See also:	`<SCRIPT ARCHIVE="...">,<SCRIPT SRC="...">`

Cross-references:

Wrox *Instant JavaScript* –page –43

Inline tags (Definition)

An inline element can be placed anywhere inside a line of text.

An inline tag does not cause a line break in the way that a block level tag does. Inline tags can be placed at the start, end or in the middle of the line. They may cause the line spacing to adjust to accommodate them if they are particularly high.

Here is a list of inline tags:

- `<A>`
- `<EM>`
- `<I>`
- `<IMG>`
- `<SPAN>`
- `<STRONG>`
- `<TT>`

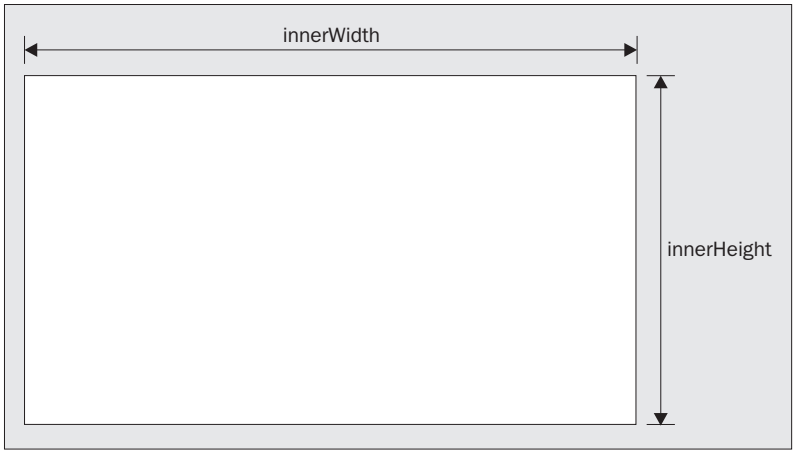
Some block level tags can appear to be inline tags if they control the alignment and text flow around them in such a way as to clear the alignment at one or other side.

Layers complicate things –they can make any block level tag appear to be an inline tag, however, positioning and text flow on separate layers is difficult to control effectively.

innerHeight (Property)

An alias for the `window.innerHeight` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`innerHeight`
	-	*`myWindow`*`.innerHeight`



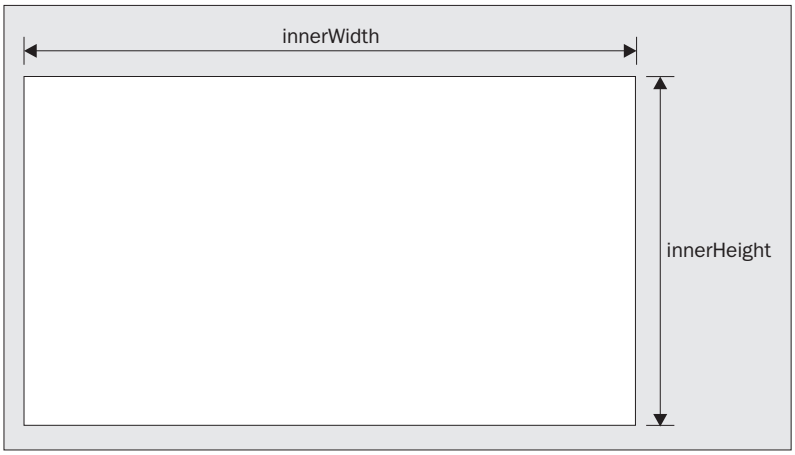
Refer to:

`Window.innerHeight`

innerWidth (Property)

An alias for the `window.innerWidth` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`innerWidth`
	-	*`myWindow`*`.innerWidth`



Refer to:

`Window.innerWidth`

Input event (Definition)

Another name for a raw input event. These are sometimes called HTML control events.

See also:	`onBlur`, `onChange`, `onFocus`, `onReset`, `onSelect`, `onSelectStart`, `onSubmit`, Event propagation

Input object (Object/DOM)

Another name for a `FormElement` object.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0
Inherits from:	`Element` object

JavaScript syntax:	-	*myInput* = *myDocument*.*aFormName*.*anElementName*
	-	*myInput* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*myInput* = *myDocument*.all.*anElementID*
	IE	*myInput* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myInput* = *myDocument*.all[*aName*]
	-	*myInput* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myInput* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*myInput* = *myDocument*.getElementById(*anElementID*)
	-	*myInput* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myInput* = *myInputArray*[*aName*]
	-	*myInput* = *myInputArray*[*anIndex*]
	-	*myInput* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	<INPUT TYPE="aType">	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The ID attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the forms collection
Object properties:	accept, accessKey, align, alt, checked, dataFld, dataFormatAs, dataSrc, defaultChecked, defaultSelected, defaultValue, disabled, form, length, maxLength, name, readOnly, recordNumber, selected, selectedIndex, size, src, status, tabIndex, type, value	
Object methods:	blur(), click(), createTextRange(), focus(), handleEvent(), select()	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onChange, onClick, onDblClick, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit, onSelect	

This is a generic description of a form element object. The object will really be a concrete manifestation of a particular class, but is available generally as an item in the elements array that belongs to the form.

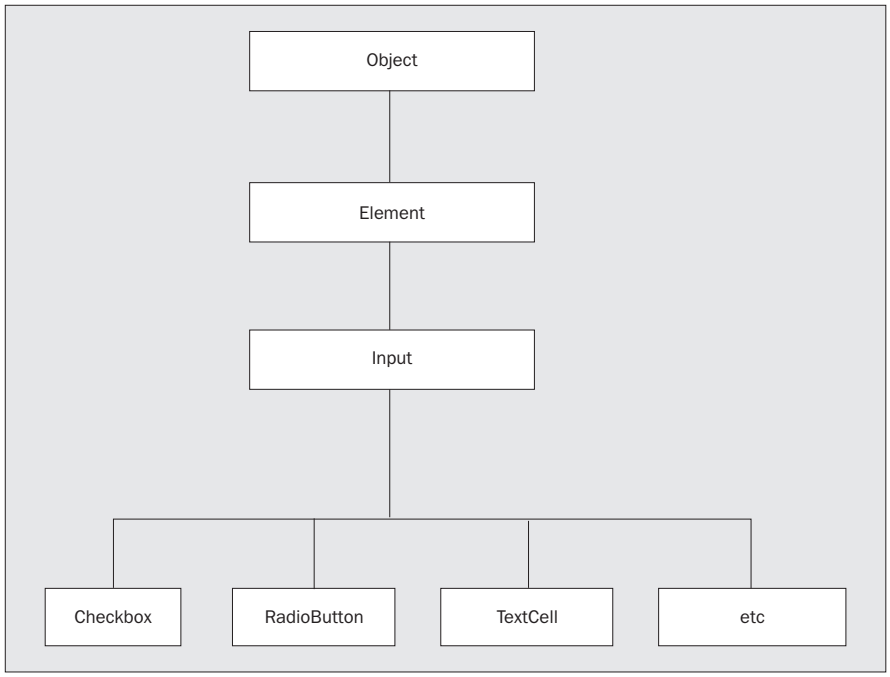
We have tried to conceive a general model of the object relationships in a browser, a difficult task –we document a general purpose class referred to as an `Element` object. Most displayable items in a document that are instantiated by an HTML tag can be considered to be sub-classes of the `Element` object.

Input objects, collectively, are a sub-class of the `Element` object class so to avoid over-duplicating the same coverage, properties, methods, events and collections that are specific to `Input` objects are discussed here and are omitted from the discussion topics relating to the `Element` object. They are listed in the property, method, collection and event summary for the `Element` object.

Likewise, under the `Input` object, those properties, method, collections and events that apply generally to all kinds of `Input` objects are documented here, but those that are specific to only a particular kind of `Input` object sub-class are covered under specific topics relating to that class.

Some properties and methods of the `Input` objects and its specific sub-classes are platform specific. The `dataFld`, `dataSrc` and `dataFormatAs` properties are only available in MSIE. Assigning event handlers to `onevent...` properties may also support different event sets in each browser platform.

MSIE supports an `INPUT` object class rather than an `Input` object class.



Warnings:

- Note that on MSIE, `Input` objects are actually `INPUT` objects because MSIE follows a general rule of naming object classes after the capitalised name of the HTML tag that instantiates them.
- Beware that although a small sub-set of the complete range of properties and methods are supported on all browsers, there are many properties and methods that are only available on one browser or the other.

Inheritance chain:

`Element` object, `Node` object

Input.accept (Property)

Defines an acceptable MIME type to be submitted to the server.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myInput`*`.accept`

Refer to:

`BUTTON.accept`

Input.accessKey (Property)

A key that needs to be pressed before the input object will respond to data entry.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInputObject*`.accessKey`

This is an MSIE extension that allows the input elements to be deadlocked unless a certain key is held down. For some input elements, this key is the one that selects the item, as is the case with the checkbox.

See also:	`!` object, `Anchor` object, `Applet` object, `Area` object, `BODY` object, `Element` object, `Embed` object, `FIELDSET` object, `Label` object, `Legend` object, `MARQUEE` object, `OBJECT` object, `TBODY` object, `TD` object

Input.align (Property)

The alignment of the `paragraph` object with respect to its parent object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInput*`.align`

Input.alt (Property)

An alternative text, used when an image is defined as an input item.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –3.02 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInput*`.alt`

See also:	`BUTTON.alt, IMG.alt`

Input.blur() (Method)

Removes input focus from the input element.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*myInputObject*`.blur()`

This will trigger the `Blur` event handler function attached to the `onblur` property of the object.

See also:	`Input.focus(),onBlur,onFocus,Window.blur(), Window.focus()`

Input.checked (Property)

The state of the button is returned by this property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myInput*`.checked`

See also:	`Checkbox.checked, RadioButton.checked`

Input.click() (Method)

Sends an artificial mouse click event to the input element.

Availability:	DOM level –1 JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*myInputObject*.click()

This will trigger the `Click event` handler function attached to the `onClick` property of the object.

See also:	`onClick`

Input.createTextRange() (Method)

Used in MSIE for creating a text range.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`TextRange object`	
JavaScript syntax:	IE	*myInputObject*.createTextRange()

This method should only be used if the receiving object responds `true` to its `isTextEdit` property request.

See also:	`Element.isTextEdit`, `TextRange` object

Input.dataFld (Property)

This binds the `input` object to a remote data source in MSIE.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myInputObject*.dataFld

This is part of the MSIE data binding mechanism that associates a column name in the data source with the value property of an `Input` object. You must also set the `dataSrc` property for the object. Normally, both the `dataFld` and `dataSrc` values would be defined with the `DATAFLD="..."` and `DATASRC="..."` HTML tag attributes in the document source.

Note that the value is case sensitive and must refer to a column that exists within the data source.

Setting both the `dataFld` and `dataSrc` properties to an empty string will disconnect the element from the database.

Input.dataFormatAs (Property)

Indicates whether data loaded from the database should be treated as text or HTML.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myInputObject*.dataFormatAs

This property can legally only contain one of two values:

- `HTML`
- `text`

Input.dataSrc (Property)

The name of a remote ODBC data source is stored in this property.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myInputObject*.dataSrc

This is part of the MSIE data binding support. It contains the name of an ODBC data source (which might be any kind of SQL database that supports such an adapter). This data source is then associated with the element and various columns of it may provide the values of different element objects by means of their `dataFld` property.

Normally, both the `dataFld` and `dataSrc` values would be defined with the `DATAFLD="..."` and `DATASRC="..."` HTML tag attributes in the document source.

Setting both the `dataFld` and `dataSrc` properties to an empty string will disconnect the element from the database.

Input.defaultChecked (Property)

The default checked state for a radio button or checkbox in a form.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myInput*.defaultChecked

See also:	`Checkbox.defaultChecked`, RadioButton.defaultChecked

Input.defaultValue (Property)

The default value of the `input` object when the page was loaded.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInputObject*.defaultValue
HTML syntax:	`<INPUT VALUE="aValue">`	
Argument list:	*aValue*	A value string for the input element

This is the value of the `Input` element originally furnished by the `VALUE="..."` HTML tag attribute when the page was first loaded. You cannot change this value and it is provided so that a JavaScript can restore the default value or test that the current value is the same or different to it.

Property attributes:

`ReadOnly`.

Input.disabled (Property)

Activates and deactivates the input element within the form.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myInputObject*`.disabled`

If this value is set `true`, then the input element can no longer receive focus or be interacted with. It will also no longer be submitted with the other input elements when the form is submitted back to the server.

Setting this value to `false` renders the input element active again.

See also:	`TextCell.readOnly`

Input.focus() (Method)

Brings input focus back to the input element.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*myInputObject*`.focus()`

The receiving `Input` element will receive a `Focus` event trigger and execute its function referred to by the onfocus property.

The element that previously had focus (if any element did) will receive a `Blur` event trigger.

See also:	`Input.blur(),onBlur,onFocus,Window.blur(), Window.focus()`

Input.form (Property)

The form object that the `input` element belongs to.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Form object`	
JavaScript syntax:	-	*`myInputObject`*`.form`

Input elements must belong to a containing form. The form is the next outermost `<FORM>` tag (although `<FORM>` tags should not be nested). This is represented by a `Form` object (or a `FORM` object in MSIE).

See also:	`Form` object

Property attributes:

ReadOnly.

Input.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*`myInputObject`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

On receipt of a call to this method, the input object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent()`

Input.maxLength (Property)

The maximum length allowed for an input entry field.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myInput*.maxLength

This defines the maximum number of characters that are allowed to be entered into the input text field. The browsers differ in how they handle this value. Some will warn the user with a beep or flash on the screen, others simply stop accepting keystrokes when this number of characters have been entered.

See also:	`Password.maxLength, TextCell.maxLength`

Input.name (Property)

This corresponds to the `NAME` attribute of the `<INPUT>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInputObject*.name
HTML syntax:	`<INPUT NAME="`*aName*`">`	
Argument list:	*aName*	A name for the input element

Objects are identified either by the `NAME="..."` HTML tag attribute or by the `ID="..."` HTML tag attribute.

Netscape shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`BUTTON.name`

Input.onevent (Property)

Input objects support a variety of different events.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Event handler`	
JavaScript syntax:	-	*myInputObject*`.onevent`

Although this property is named `onevent`, there is actually no such property. All event handlers for `input` objects have names that begin with the 'on' prefix. The name then describes the event.

The properties contain references to a handler function that is invoked for each kind of event. Events that are not handled are represented by a `null` value in the corresponding handler property.

The event model is different for each browser, and the way that events are propagated is different as well. As long as you define only a single handler and keep the event trapping simple, both browsers behave similarly enough that you will be able to realize a portable script implementation.

Note that the event model undergoes a significant revision with the introduction of DOM level 2 capabilities which are currently provided in the new Netscape 6.0 browser.

Refer to the topic describing each kind of `Input` object sub-class for details of the events that this can handle.

Input.readOnly (Property)

Set to `true` if the input text field cannot be changed.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myInput*`.readOnly`

The value of the input text field is defined but cannot be changed by the user.

Do not confuse this with the `ReadOnly` internal attribute that controls whether an object property value can be changed.

See also:	`Password.readOnly`, `ReadOnly`, `TEXTAREA.readOnly`, `TextCell.readOnly`

Input.recordNumber (Property)

The record number within the data set that created the input element's content.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myInputObject`*`.recordNumber`

This is a property that is part of the MSIE data binding support. It contains an integer value that is the record number within the data set that created this object.

This is useful when you are building pages with ASP and Active Data Objects (ADO).

See also:	Active Server Pages, ADO

Property attributes:

`ReadOnly`.

Input.select() (Method)

Triggers a `Select` event on an `input` object.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	*`myInputObject`*`.select()`

If the `Input` object is a `FileUpload`, this selects all the text in the `FileUpload` object so that it can be cut or copied by the user if necessary or used as `TextRange` and have a command executed on it. It also triggers a `Select` event.

See also:	`FileUpload.select(),OptionsArray.select(),`
	`Password.select(),TEXTAREA.select(),`
	`TextCell.select()`

Input.size (Property)

Returns the size of the file to be uploaded when the `Input` object represents a file upload.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInput*`.size`

It may be important to limit the size of files being uploaded to the server.

It is very possible that vindictive users may use this as an opportunity to try and crash your server or deny its availability to other users by uploading massive files to it.

In addition, there may be limits you want to impose as a courtesy to the network managers who run the LANs and WANs where your users will be browsing. Allowing the user to upload unnecessarily large files will saturate their network as well as your server.

By testing this property, you can impose limits of acceptability on file uploads.

See also:	`FileUpload.size`, `Password.size`, `TextCell.size`

Input.src (Property)

The URL where the image is located when an `input` object represents a clickable image.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInput*`.src`

Refer to:

`Image.src`

Input.tabIndex (Property)

A control of where the form input element appears in the tabbing order of the page.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myInputObject*`.tabIndex`

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms. Pressing the `[tab]` key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

Input.type (Property)

The type of a form input element.

Availability:	DOM level –1 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myInputObject*`.type`
HTML syntax:	`<INPUT TYPE="...">`	

The following values can be assigned to the `type` attribute:

- `button`
- `checkbox`
- `file`
- `hidden`
- `image`
- `password`
- `radio`
- `reset`
- `submit`
- `text`
- `textarea`

The `file` value really represents a file-upload.

These values can be used in the `type` property of a `Select` object even though it is not derived from an `Input` object:

- `select-multiple`
- `select-one`

For images, the description of the Input-type in MSIE and Netscape differ because each browser uses a different object class and supports a different set of methods, properties and events.

Refer to the `IMG` object for MSIE and the `Image` object for Netscape.

DOM level 2 specifies that this property should not be read-only. This implies that DOM level 2 allows for the type of an `input` object to change. How the browsers cope with this, given that some of them create objects of specific classes for each type, will be interesting to see.

See also:	`Button.type`, `BUTTON.type`, `Checkbox.type`, `File.Type`, `FileUpload.type`, `Hidden.type`, `Image` object, `Password.type`, `RadioButton.type`, `ResetButton.type`, `selection.type`, `SubmitButton.type`, `TEXTAREA.type`, `TextCell.type`

Property attributes:

`ReadOnly`.

Input.value (Property)

The value associated with the `input` element.

Availability:	DOM level –1 JavaScript –1.5 JScript –1.0 Internet Explorer –3.02 Netscape –6.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myInputObject`*`.value`
HTML syntax:	`<INPUT VALUE="...">`	

When the `input` element is a button, this will be the legend text displayed in the button.

When it is a hidden field, it is the value carried in the hidden field and back to the server again on submitting the form.

See also:	`Button.value`, `BUTTON.value`, `Checkbox.value`, `FileUpload.value`, `Hidden.value`, `Option.value`, `Password.value`, `RadioButton.value`, `ResetButton.value`, `Select.value`, `SubmitButton.value`, `TEXTAREA.value`, `TextCell.value`

Input-output (Definition)

Reading data in and writing data out.

JavaScript was first developed for use in web browsers. Its input and output capabilities in that context are somewhat limited, this mainly being due to the security considerations of allowing a third party to run a script on your computer.

In a web browser implementation, the I/O is limited to being able to access form data, the inner text or HTML of document objects, or perform document writes.

When JavaScript is used server-side, or as a general purpose scripting language for automation, then the implementation adds much more sophisticated I/O capabilities. For example, ScriptEase adds many file and stream based I/O capabilities found in the C language.

See also:	Debugging –client side, Debugging –server side, `Document.write()`, `Document.writeln()`, Error handling

Cross-references:

Wrox *Instant JavaScript* –page –13

InputArray object (Object/browser)

A collection of identically named input elements.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Inherits from:	`Collection` object	
JavaScript syntax:	-	*myInputArray* = *myDocument.aFormName.anElementName*
	IE	*myInputArray* = *myDocument*.all[*aName*]
	-	*myInputArray* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myInputArray* = *myDocument*.getElementsByName(*aName*)
	-	*myInputArray* = *myDocument*.getElementsByTagName("INPUT")
Argument list:	*aName*	An associative array reference
	aFormIndex	A reference to a particular form in the forms collection
	anIndex	A valid reference to an item in the collection
Object properties:	`length`	

You may encounter this if you have several `Input` objects with the same name. It is better to make sure they have unique names.

Warnings:

- In Netscape, this array is of the type `InputArray`. However, in MSIE it is an object of type `Collection`. Be careful if your code depends on testing object types because you may find it breaks when used across the two browsers.

See also:	`Input` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.2 +	3.0 +	4.0 +	4.0 +	-	-	Warning

Inheritance chain:

`Collection` object

INS object (Object/HTML)

An object representing an `<INS>` tag in the document.

Availability:	JScript –3.0 Internet Explorer –4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myINS* = *myDocument*.all.*anElementID*
	IE	*myINS* = *myDocument*.all.tags("INS")[*anIndex*]
	IE	*myINS* = *myDocument*.all[*aName*]
	-	*myINS* = *myDocument*.getElementById(*anElementID*)
	-	*myINS* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myINS* = *myDocument*.getElementsByTagName("INS")[*anIndex*]
HTML syntax:	`<INS> ... </INS>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`cite, dateTime`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

This is a means of marking a section of the page that has been inserted since the previous version of the page. The appearance is styled to indicate the inserted text as distinct from the surrounding text. The `cite` property refers to a document that describes the reason for the insertion.

The DOM level 1 specification includes this in the `ModElement` object functionality.

See also:	`DEL` object, `Element` object, `ModElement` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`cite`	-	5.0 +	-	5.0 +	-	-	-	-
`dateTime`	-	5.0 +	-	5.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.0 +	1.0 +	2.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.2 +	3.0 +	4.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseOver`	1.0 +	1.0 +	2.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseUp`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

INS.cite (Property)

A string of characters citing the reason for the `<INS>` element being placed into the document.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myINS*`.cite`

The URL of the document that describes why the text being inserted is noted in this property.

INS.dateTime (Property)

The date and time relating to the owning `<INS>` element.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myINS*`.dateTime`

This is the date and time value for when the insertion change occurred. If you are maintaining change control down to the sub-document level in a content management system, these values can be defined from change records in the database.

Inset() (Filter/transition)

A diagonal wipe across the image, revealing a new image.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `Inset()`

Instance method (Definition)

A method belonging to an instance of a class.

Refer to:

Method

Instance variable (Definition)

A variable property belonging to an instance of a class.

Refer to:

Property

instanceof (Operator/logical)

Checks to see if an object is an instance of another object.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *`anObject`* `instanceof` *`anotherObject`*
Argument list:	*`anObject`* — The object to test *`anotherObject the object to test against`* — -

The object referred to by the left operand is examined, and its type compared with the type of the object on the right. The object on the right should be an object with a constructor (that is, a class object) although this likely works with instances as well if they also have constructors inherited.

The ECMA standard (second edition) reserves this keyword for future use in anticipation of the JavaScript 1.4 implementation. That means that a compliant implementation does not need to support this feature.

This operator yields the `true` value if both objects are of the same class, otherwise it is `false`.

Warnings:

- Use with caution. Be aware that there are some bugs in the class instantiation of some objects in Netscape and MSIE. This may always not yield `true` when you expect it to.
- This is not available for use server-side with Netscape Enterprise Server 3.

Instantiating Function (Definition)

Another name for a constructor mechanism.

Availability:	ECMAScript edition –2

An instantiating function is a `Function` object that can be used as a constructor to make new instances of itself. These new instances are anonymous functions.

See also:	Anonymous function

Cross-references:

ECMA 262 edition 2 –section –10.1.1

ECMA 262 edition 3 –section –10.1.1

int (Reserved word)

Reserved for future language enhancements.

The provision of this reserved keyword suggests that future versions of the ECMAScript standard may provide for a stronger data-typing model than is currently available.

This keyword also represents a Java data type and the `int` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	Identifier, java.lang.Integer, JavaScript language, Lexical element, LiveConnect, Reserved word, Type

ECMA 262 edition 2 –section –7.4.3

ECMA 262 edition 3 –section –7.5.3

Integer (Definition)

A type of number value.

The inclusion of this reserved keyword in the ECMAScript standard suggests that future versions of ECMAScript may be more strongly typed.

See also:	`double`, `float`, Integer promotion, `long`, `Math.ceil()`, `Math.floor()`, `Number`, Reserved word, `short`

Cross-references:

O'Reilly *JavaScript Definitive Guide* –page –35

Integer arithmetic (Definition)

Arithmetic operations performed on integer values.

Arithmetic in the JavaScript interpreter is basically floating point although many values will be integers. If a numeric value is output then it will automatically be truncated to an integer if there is no fractional part. There are several functions and operators available for explicitly converting floating point values to integer values:

- `Math.abs()` function
- `Math.ceil()` function
- `Math.floor()` function
- `Math.round()` function
- `% Remainder`
- `%= Remainder` and assign to an `LValue`

See also:	Math object, Math.abs(), Math.ceil(), Math.floor(), Math.round(), Mathematics, Remainder (%), Remainder then assign (%=)

Integer constant (Definition)

A numeric value expressed as an integer.

An integer constant is a special case of the arithmetic constant. It's values must be integers –no decimal places.

It could be composed of several components if a constant expression is being created.

Integer constants can be defined as decimal, octal or hexadecimal values. Here are some examples:

- Decimal notation – *`myVariable`* = 150
- Hexadecimal notation – *`myVariable`* = 0xFF
- Octal notation – *`myVariable`* = 0377

With a little creativity in the scripting, you can assign string constants to the value of string objects, then decode the character value to yield an integer constant:

```
myString = new String("A");

myVariable = myString.charCodeAt(0);
```

See also:	Arithmetic constant, Constant, Constant expression, Conversion, Decimal value, Hexadecimal value, Octal value, String.charCodeAt()

Integer promotion (Definition)

The action of converting a value during expression evaluation.

Integer promotion is a concept that is used in compilers where there are many more strongly enforced data typing rules.

All the same, JavaScript does the same thing automatically without you realizing it.

The process of promoting a value is to convert it to a higher resolution data type, so that an expression can be evaluated in that higher data type's context without any loss of value.

For example, adding a floating point and an integer value together would be promoted to a floating point addition. The result would stay as a floating point value. However it is conceivable that adding an integer and two floating points together might yield a result that had a zero value fractional part. That resulting value could then be demoted safely back to an integer with no loss of value.

That would be a value preserving demotion.

Most current implementations of JavaScript do not do a great deal of internal promotion and demotion other than conversions between numeric values and strings. This is because the language is currently a weakly typed language and is somewhat forgiving in the area of data types.

Many reserved words are specified by the ECMA standard. There is a comment in the standard that allows implementations to support these reserved words. This suggests that sometime in the future the standard may allow for more strongly typed data vales. Indeed, some implementations may already provide that functionality and still be ECMAScript compliant.

At such a time that an implementation does more strongly type its data values, then this integer promotion may be more visible.

See also:	Conversion, Integer

Integer-value-remainder (Definition)

Integer rounding functions.

The ECMAScript standard provides several functions and operators that yield an integer value or remainder based on a floating point value:

- `Math.abs()` function
- `Math.ceil()` function
- `Math.floor()` function
- `Math.round()` function
- `% Remainder`
- `%= Remainder` and assign to an `LValue`

See also:	Exponent-log function, Function, `function( ... ) ...`, `Math.abs()`, `Math.ceil()`, `Math.floor()`, `Math.round()`, Mathematics, Power function, Remainder (`%`), Remainder then assign (`%=`), Trigonometric function

interface (Reserved word)

Reserved for future language enhancements.

ECMA 262 edition 2 –section –7.4.3

ECMA 262 edition 3 –section –7.5.3

Internal function (Definition)

Internal functions are built into the language interpreter but are private.

Availability:	ECMAScript edition –2

Internal functions are built into the language interpreter.

These may also sometimes be referred to as internal methods.

A host implementation may provide additional non-ECMA compliant built-in functions by extending the `Global` object and other core objects that the ECMA standard defines.

See also:	`Function` object, Internal Method

Cross-references:

ECMA 262 edition 2 –section –10.1.1

ECMA 262 edition 3 –section –10.1.1

Internal Method (Definition)

ECMAScript describes internal methods that are private.

Availability:	ECMAScript edition –2

Internal methods are not exposed to the programmer using ECMA compliant JavaScript. However, some implementations may allow you to view them through a debugging interface. The reserved words suggest that at least some of these internal methods may be made visible at a later stage of the language development.

Run time errors may be generated due to faults in the interpreter logic trying to access internal methods that do not exist.

Property	Parameters	Description
Call	A list of argument values	This method executes some code associated with the object via a function call mechanism. Objects that implement this internal method are called functions.
CanPut	A property name	Returns a Boolean value indicating whether you can put values into the named property.
Class	none	A string value describing what kind of object this is.
Construct	A list of argument values	This constructs an object and is normally invoked by the new operator. Objects that implement this internal method are called constructors.
DefaultValue	A hint value	Returns a default value for the object which should be a primitive value and not an object or a reference to one.
Delete	A property name	Removes the specified property from the object.
Get	A property name	This method returns the value of the named property.
HasInstance	A value	Returns a Boolean value indicating whether there is an instance. This only applies to `Function` objects.
HasProperty	A property name	Returns a Boolean value indicating whether that property is available as a member of this object.
Match	A string and an index	Tests for a regular expression and returns a match result.
Prototype	none	Returns the prototype of this object.
Put	A property name and a value	This method stores the value in the named property.
Scope	none	A scope chain for the `Function` object to be executed in.
Value	none	Internal state information associated with this object.

The table describes the base set of ECMA compliant internal methods. Hosted implementations may add to these and implement special methods in any way they need to, however they are not required to implement all of these methods.

Every object must implement the `Get`, `Put`, `HasProperty`, `Delete` and `DefaultValue` functions. This also applies to host objects. Note that the `DefaultValue` method may for some objects generate a runtime error.

ECMA edition 3 introduces the following internal methods/properties:

- `HasInstance`
- `Scope`
- `Match`

See also:	`Call`, `CanPut()`, Construct, `DefaultValue()`, `Delete()`, `Get()`, `HasProperty()`, Internal function, Internal Property, Object, `Put()`

Cross-references:

ECMA 262 edition 2 –section –8.6.2

ECMA 262 edition 3 –section –8.6.2

Internal Property (Definition)

ECMAScript describes internal methods that are private.

Availability:	ECMAScript edition –2

Internal properties are not exposed to the programmer using ECMA compliant JavaScript. However, some implementations may allow you to view them through a debugging interface. The reserved words suggest that at least some of these internal properties may be made visible at a later stage of the language development.

Run time errors may be generated due to faults in the interpreter logic trying to access internal methods that do not exist.

Property	Parameters	Description
Call	A list of argument values	This method executes some code associated with the object via a function call mechanism. Objects that implement this internal method are called functions.
CanPut	A property name	Returns a Boolean value indicating whether you can put values into the named property.
Class	none	A string value describing what kind of object this is.
Construct	A list of argument values	This constructs an object and is normally invoked by the new operator. Objects that implement this internal method are called constructors.
DefaultValue	A hint value	Returns a default value for the object which should be a primitive value and not an object or a reference to one.
Delete	A property name	Removes the specified property from the object.
Get	A property name	This method returns the value of the named property.
HasInstance	A value	Returns a Boolean value indicating whether there is an instance. This only applies to `Function` objects.
HasProperty	A property name	Returns a Boolean value indicating whether that property is available as a member of this object.
Match	A string and an index	Tests for a regular expression and returns a match result.
Prototype	none	Returns the prototype of this object.
Put	A property name and a value	This method stores the value in the named property.
Scope	none	A scope chain for the `Function` object to be executed in.
Value	none	Internal state information associated with this object.

The table describes the base set of ECMA compliant internal properties. Hosted implementations may add to these and implement special properties in any way they need to. Host implementations may not implement all of these properties.

Every object must implement the `Class` property.

The value of the `Prototype` property must be either an object or `null`. Every prototype chain must have finite length, that is to say starting from any object, traversing the prototype chain must ultimately yield a `null` value. Whether or not a native object can refer to a host object as its prototype is implementation dependent.

ECMA edition 3 introduces the following internal methods/properties:

- `HasInstance`
- `Scope`
- `Match`

See also:	Class, class, Internal Method, Object, `prototype` property, `Value` property

Internet Explorer (Web browser)

A Microsoft web browser product.

In this publication, we refer to this browser by the commonly used abbreviation MSIE.

Many values that MSIE exposes as JavaScript properties reflect the value of an HTML tag attribute. Likewise, many of its special objects are counterparts to the HTML tags.

Where the information is available, the version number that objects, properties and methods became accessible to JavaScript is indicated. In many cases, this may be a later version than when the instantiating HTML tag or attribute was first supported by the browser.

Because the Windows platform in particular and Microsoft products in general are componentized, the JScript interpreter can be replaced over the top of the Internet Explorer browser. This means that you can be running a version of JScript that is later than the browser version you are using. Scripts will work although they may not be able to exploit features of the later browser. For example, JScript 5.5 can be installed over the top of JScript 5.0 in a version 5.0 MSIE browser.

We wrote many scripts to inspect and enumerate various properties of the objects in the MSIE and Netscape browsers –the exposed object types and properties that were hitherto undocumented. They may have been available in earlier versions of the browser, however, where language elements were discovered for the first time, they are initially documented as being available from version 5 of MSIE. A limited amount of further testing was applied where it was suspected that language elements may have been available in earlier releases and the availability modified accordingly.

Because the MSIE browser is componentized to the extent that the JSscript interpreter is actually a separate installation to the MSIE browser, it is very difficult to arrive at a definitive version of JScript that correlates with a particular version of MSIE. For example, several different versions of JScript were extant with the version 3 MSIE browser.

Perhaps this may become less important as browsers converge on a single standard benchmark of functionality. For the time being, current practice suggests that version 4 browsers are rapidly being taken over by version 5 MSIE browsers. Version 2 and 3 of MSIE have declined to such small usage levels as to not require any further serious attempts to support them on new projects.

Refer to the JScript version topic for details of interpreter vs browser revisions.

Warnings:

- Version 3.02 has these problems with identifier names:
  - Do not use dollar signs in identifier names.
  - Identifier names are caseless and this version cannot tell the difference between `AAA` and `aaa`.

Interpret (Definition)

The act of parsing a JavaScript script source text.

To execute a JavaScript script source text, you first have to convert its textual representation into a series of executable steps. This interpretation phase involves the stripping out of commented blocks and the division of the script into tokens –each token is then evaluated and executed sequentially.

Interpretation is distinct from compiling a program. A compiler renders the interpreted code down to a machine-readable form that can be executed directly in terms of CPU opcodes. An interpreted program partially compiles the program to an intermediate form and may store this interpreted data as a series of byte codes. These are then executed in a virtual machine.

Java applets work like this and so do many JavaScript implementations although you cannot normally store the byte-coded version of a JavaScript script. This is beginning to change however and some interactive TV platforms are delivering byte-code forms of JavaScript sourced software to set-top boxes. This is particularly appropriate, since the available bandwidth is much reduced compared to web delivery and a byte-code form takes less time to transmit.

The same applies to the delivery of WMLScript code to WAP enabled mobile phones.

See also:	ATVEF, DVB-MHP, Implementation, Liberate TV Navigator, OpenTV, WAP, WebTV, WML, WMLScript

Interval handlers (Definition)

You can set event handlers to be called periodically on a regular basis.

This is a mechanism for scheduling the execution of a script at regular intervals. The interval is specified with the `setInterval()` method.

See also:	`Window.clearInterval(),Window.setInterval()`

Intrinsic events (Definition)

Those events that pertain to HTML rather than any other host-based triggers.

See also:	Event, Event model

Invert() (Filter/visual)

A visual filter for inverting image colors.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

Filter – `Invert()`

Invoke a function (Definition)

To execute a function when the script is running.

Refer to:

Function call

Iris() (Filter/transition)

A transition effect with the appearance of an iris opening or closing.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `Iris()`

isAlnum() (Simulated functionality)

Check if a character is a number or letter.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well, and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is a letter or a number. A letter is any character for which the `isAlpha()` function returns `true`. Likewise a number is any character for which `isDigit()` returns `true`.

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for letters and digits
function isAlnum(aChar)
{
   return (isDigit(aChar) || isAlpha(aChar));
}

// Test for digits
function isDigit(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 47) && (myCharCode <  58))
   {
      return true;
   }

   return false;
}
```

```
// Test for letters (only good up to char 127)
function isAlpha(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if(((myCharCode > 64) && (myCharCode <  91)) ||
      ((myCharCode > 96) && (myCharCode < 123)))
   {
     return true;
   }

   return false;
}

alert(isAlnum("5"));
alert(isAlnum("a"));
alert(isAlnum("%"));
```

See also:	Character handling, Character testing, Enquiry functions, `isAlpha()`, `isDigit()`, `isPunct()`, Letter

isAlpha() (Simulated functionality)

Check if a character is a letter.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is a letter. It will return `true` for any character in the following set:

`A B C D E F G H I J K L M`

`N O P Q R S T U V W X Y Z`

`a b c d e f g h i j k l m`

`n o p q r s t u v w x y z`

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for letters (only good up to char 127)
function isAlpha(aChar)
{
   myCharCode = aChar.charCodeAt(0);
```

```
    if(((myCharCode > 64) && (myCharCode <  91)) ||
       ((myCharCode > 96) && (myCharCode < 123)))
    {
       return true;
    }

    return false;
}

alert(isAlpha("a"));
alert(isAlpha("5"));
```

See also:	Character handling, Character testing, Enquiry functions, `isAlnum()`, Letter

isCtrl() (Simulated functionality)

Check if a character is a control code.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is a control code. It will return `true` for any character in the following set:

Value	Character	Meaning
01	<ctrl-A>	SOH
03	<ctrl-C>	ETX
04	<ctrl-D>	EOT
05	<ctrl-E>	ENQ
06	<ctrl-F>	ACK
07	<ctrl-G>	BEL
08	<ctrl-H>	BS
09	<ctrl-I>	HT
0A	<ctrl-J>	LF
0B	<ctrl-K>	VT
0C	<ctrl-L>	FF
0D	<ctrl-M>	CR
0E	<ctrl-N>	SO
0F	<ctrl-O>	SI
10	<ctrl-P>	DLE
11	<ctrl-Q>	DC1

Table continued on following page

Value	Character	Meaning
12	<ctrl-R>	DC2
13	<ctrl-S>	DC3
14	<ctrl-T>	DC4
15	<ctrl-U>	NAK
16	<ctrl-V>	SYN
17	<ctrl-W>	ETB
18	<ctrl-X>	CAN
19	<ctrl-Y>	EM
1A	<ctrl-Z>	SUB
1B	<ctrl-[>	ESC
1C	<ctrl-\>	FS
1D	<ctrl-]>	GS
1E	<ctrl-^>	RS
1F	<ctrl-_>	US
7F	-	DEL

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for control codes
function isCtrl(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if(((myCharCode > -1) && (myCharCode <  32)) ||
      ((myCharCode == 127)))
   {
      return true;
   }

   return false;
}

alert(isCtrl("\u0011"));
alert(isCtrl("a"));
```

See also:	Character handling, Character testing, Control character, Enquiry functions, Letter

isDigit() (Simulated functionality)

Check if a character is a digit.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is a digit. It will return `true` for any character in the following set:

```
0 1 2 3 4 5 6 7 8 9
```

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for digits
function isDigit(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 47) && (myCharCode <  58))
   {
      return true;
   }

   return false;
}

alert(isDigit("a"));
alert(isDigit("3"));
```

See also:	Character handling, Character testing, Enquiry functions, `isAlnum()`, `isODigit()`, `isXDigit()`, Letter

isElementProperty() (Simulated functionality)

A function that tells you whether a property name is inherited from `Element` objects.

Property/method value type:	Boolean primitive

This function switches according to the value of a text string that is passed in. If the string is in the set of strings that enumerate properties that belong to an `Element` object then the value `true` will be returned. This indicates that the property is defined in a super-class.

You can build property enumeration loops that test for this value to build debugging displays of object properties that are less cluttered than simply displaying all the object properties.

The result of this method is `true` if the property has been inherited from the `Element` object otherwise the `false` value is returned.

Example code:

```
function isElementProperty(aProperty)
{
   switch(aProperty)
   {
      case "all"             :
      case "attributes"      :
      case "childNodes"      :
      case "children"        :
      case "className"       :
      case "currentStyle"    :
      case "dir"             :
      case "document"        :
      case "filters"         :
      case "firstChild"      :
      case "id"              :
      case "innerHTML"       :
      case "innerText"       :
      case "isTextEdit"      :
      case "lang"            :
      case "language"        :
      case "lastChild"       :
      case "nextSibling"     :
      case "nodeName"        :
      case "nodeType"        :
      case "nodeValue"       :
      case "offsetHeight"    :
      case "offsetLeft"      :
      case "offsetParent"    :
      case "offsetTop"       :
      case "offsetWidth"     :
      case "outerHTML"       :
      case "outerText"       :
      case "ownerDocument"   :
      case "parentNode"      :
      case "parentElement"   :
      case "parentTextEdit"  :
      case "previousSibling" :
      case "sourceIndex"     :
      case "style"           :
      case "tagName"         :
      case "title"           :
         return true;
   }
   return false;
}
```

See also:	`Element` object

isFinite() (Function/global)

Test a numeric value for infinity.

Availability:	ECMAScript edition –2 JavaScript –1.3 JScript –3.0 Internet Explorer –4.0 Netscape –4.06	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`isFinite(`*`aValueToTest`*`)`
Argument list:	*`aValueToTest`*	A numeric value to check for validity

This is a built-in function to check for the infinity value. Because it is a member of the `Global` object, and the `Global` object is permanently in the prototype inheritance chain, you don't need to identify which object the function belongs to.

Applies the internal `ToNumber` operator to its argument, then returns `true` or `false` depending on whether the value is a finite number or not.

The result is `true` for a valid and finite numeric value and false if the value is `NaN` or one of the Infinities.

Warnings:

- This is not available for use server-side with Netscape Enterprise Server 3.

See also:	Enquiry functions, Function property, `Global` object, Infinity, Special type, `ToNumber`

Property attributes:

`DontEnum`.

ECMA 262 edition 3 –section –15.1.2.5

isGraph() (Simulated functionality)

Check if a character is a printable glyph.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is printable. However it does exclude the space character from the set of valid characters that return `true`. It is likely that implementation provided versions of this will only support the lower 255 characters in the Unicode character set. Some may only support the lower 128 that correspond to the ASCII character set.

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for visibly printable characters
// (only good up to char 127)
function isGraph(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 32) && (myCharCode <  127))
   {
      return true;
   }

return false;
}
```

See also:	Character handling, Character testing, Control character, Enquiry functions, `isPrint()`, `isPunct()`, Letter

ISINDEX object (Object/HTML)

A deprecated object that represents the `<ISINDEX>` tag. Do not use this in new projects. This tag describes text entry field with an associated prompting text.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0 Deprecated
Inherits from:	`Element` object

JavaScript syntax:	IE	*myISINDEX* = *myDocument*.all.*anElementID*
	IE	*myISINDEX* = *myDocument*.all.tags("ISINDEX")[*anIndex*]
	IE	*myISINDEX* = *myDocument*.all[*aName*]
	-	*myISINDEX* = *myDocument*.getElementById(*anElementID*)
	-	*myISINDEX* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myISINDEX* = *myDocument*.getElementsByTagName("ISINDEX")[*anIndex*]
HTML syntax:	<ISINDEX>	
Object properties:	prompt, form, prompt	
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

Warnings:

- This element object is deprecated as of HTML version 4.0 and should not be used for any new projects. Refer to the <INPUT> tag and its corresponding objects for a better and more functional replacement.

Inheritance chain:

`Element` object, `Node` object

ISINDEX.form (Property)

Returns a reference to a containing `Form` object. If there is none, then a `null` is returned instead.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0 Deprrecated	
Property/method value type:	`Form` object	
JavaScript syntax:	-	*myISINDEX*.form

Property attributes:

`ReadOnly`.

Refer to:

`Form` object

ISINDEX.prompt (Property)

A property relating to the deprecated `<ISINDEX>` object. Avoid the use of this object and property in new projects. This property provides a prompting text message for the text entry field.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myISINDEX*.prompt

Refer to:

`Input` object

isInNet() (Function/proxy.pac)

This is a convenience function for use with `proxy.pac` files.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	`isInNet(`*`aHostname`*`, `*`aSubNet`*`)`
Argument list:	*`aHostname`*	A host name whose IP address is compared with the sub-net
	`aSubNet`	A sub-net to test against the host IP address

This function performs a name to IP translation by means of an IP lookup. This involves connecting to a name server and waiting for its reply. This is not something you will want to do often as it can severely affect your performance.

Once the host IP address is known, it can be checked against the sub-net value and a `true` or `false` value returned.

The value `true` is returned if the host is a valid member of the sub-net and `false` if it is part of another sub-net.

See also:	`FindProxyForURL()`, `isPlainHostName()`, Proxies, `proxy.pac`

Cross-references:

Wrox *Instant JavaScript* –page –58

isLower() (Simulated functionality)

Check if character is lower case.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function will return `true` for any character in the following set:

```
a b c d e f g h i j k l m

n o p q r s t u v w x y z
```

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for lowercase letters (only good up to char 127)
function isLower(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 96) && (myCharCode < 123))
   {
      return true;
   }

   return false;
}
```

See also:	ASCII, Character handling, Character set, Character testing, Character-case mapping, Enquiry functions, isUpper(), Letter, Unicode

isNaN() (Function/global)

Test a numeric value for validity.

Availability:	ECMAScript edition –1 JavaScript –1.3 JScript –1.0 Internet Explorer –3.02 Netscape –2 Netscape Enterprise Server version –2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`isNaN(`*`aValueToTest`*`)`
Argument list:	*`aValueToTest`*	A numeric value to be tested for validity

This is a built-in function to check for the Not-a-Number value. Because it is a member of the `Global` object, and the `Global` object is permanently in the prototype inheritance chain, you don't need to identify which object the function belongs to.

Applies the internal `ToNumber` operator to its argument and returns `true` or `false` depending on whether the value is a number or not.

The values may not always yield the result you expect.

These all yield a `false` value:

- "4"
- true
- false

- 100.00
- Infinity
- null

These all yield a `true` value:

- "4A"
- "true"
- "false"
- undefined

The result is `true` for valid numeric values and `false` for invalid numerics.

Warnings:

- This is not very useful on MSIE version 3.02 since it cannot understand what a `NaN` is in the first place.
- Although this was added to some browsers in version 1.0 of JavaScript, it was not available in all versions of Netscape until it was added to the Unix variants for JavaScript 1.1. Most browsers being used these days are at least version 1.1 compliant so this issue is becoming less important.
- Comparing the `NaN` value with anything using the == operator will always yield the Boolean `false` value.

See also:	Enquiry functions, Function property, `Global` object, `NaN`, Number, Special type, `ToNumber`

Property attributes:

`DontEnum`.

ISO 639 (Standard)

An ISO standard that defines language code values.

See also:	ISO 3166, Language codes

isObjectEqual() (Simulated functionality)

Compare the properties of two objects for equality.

Property/method value type:	Boolean primitive

This function tests two objects for equality. This is not the same as identity. Two objects may be deep copies of one another but still be distinctly different objects. If they have the same properties because they are both of the same class, you can compare their enumerable properties for equality.

The example code is fairly simple and could be enhanced in several ways. For example, you should possibly enumerate the second object as well if the first pass proves to yield a `true` value. This would ensure that if the second object has additional attributes, the test will properly yield a Boolean `false` result.

You could also test for object type and return `false`. This would allow the test to be applied to dissimilar objects and still yield a meaningful result.

The result will be `true` if all enumerable properties are equal and `false` if any of them are not.

Example code:

```
// Test objects for equality
function isObjectEqual(anObject1, anObject2)
{
   for(myProp in anObject1)
   {
      if(anObject1[myProp] != anObject2[myProp])
      {
         return false;
      }
   }
   return true;
}
```

See also:	Element.currentStyle

isODigit() (Simulated functionality)

Check if character is an octal numeral.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is an octal digit. It will return `true` for any character in the following set:

```
0 1 2 3 4 5 6 7
```

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for octal only digits
function isODigit(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 47) && (myCharCode <  56))
   {
      return true;
   }

   return false;
}
```

See also:	Character handling, Character testing, Enquiry functions, `isDigit()`, `isXDigit()`, Letter

isPlainHostName() (Function/proxy.pac)

This is a convenience function for use with `proxy.pac` files.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	`isPlainHostName(`*`aHostname`*`)`
Argument list:	*`aHostname`*	The name of a host to check

This function will check to see if the passed-in `HostName` parameter is just a host name on its own or if it has a full domain specified too. This functionality can probably be simulated outside of a `proxy.pac` file by testing for the existence of a full stop within the passed `HostName` parameter.

This function returns `true` if the `HostName` parameter contains a plain host name with no domain specified. If the `HostName` parameter specifies a domain as well then this method returns `false`.

See also:	`FindProxyForURL()`, `isInNet()`, `proxy.pac`

Cross-references:

Wrox *Instant JavaScript* –page –58

isPrint() (Simulated functionality)

Check if a character is printable.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is printable. Unlike the `isgraph()` function, however it does include the space character in the set of valid characters that return `true`. It is likely that implementation provided versions of this will only support the lower 255 characters in the Unicode character set. Some may only support the lower 128 that correspond to the ASCII character set.

Functionally then, it is the result of testing for space and then cascading into the `isgraph()` test.

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for printable characters (only good up to char 127)
function isPrint(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 31) && (myCharCode <  127))
   {
      return true;
   }

   return false;
}
```

See also:	Character handling, Character testing, Control character, Enquiry functions, isGraph(), Letter, Printing character

isPunct() (Simulated functionality)

Check if a character is a punctuation mark.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

A punctuation character is any character in the `isGraph()` set except for those in the `isAlnum()` set.

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for punctuation characters
function isPunct(aChar)
{
   return (isGraph(aChar) && !(isAlnum(aChar)));
}

// Test for printable characters (only good up to char 127)
function isGraph(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 32) && (myCharCode <  127))
   {
      return true;
   }

   return false;
}

// Test for letters and digits
function isAlnum(aChar)
{
   return (isDigit(aChar) || isAlpha(aChar));
}

// Test for digits
function isDigit(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 47) && (myCharCode <  58))
   {
      return true;
   }

   return false;
}

// Test for letters (only good up to char 127)
function isAlpha(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if(((myCharCode > 64) && (myCharCode <  91)) ||
      ((myCharCode > 96) && (myCharCode < 123)))
   {
      return true;
   }
   return false;
}
```

See also:	Character handling, Character testing, Enquiry functions, isAlnum(), isGraph(), Letter

isSpace() (Simulated functionality)

Check if a character is whitespace.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

Any whitespace character should return `true` for this function. The following character codes are considered to be whitespace:

- The space character
- A form feed character
- A Newline character
- A carriage return
- A tab character
- A vertical tab

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for space characters
function isSpace(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if(((myCharCode >  8) && (myCharCode < 14)) ||
      (myCharCode == 32))
   {
      return true;
   }

return false;
}
```

See also:	Character handling, Character testing, Enquiry functions, Letter

isUpper() (Simulated functionality)

Check if a character is upper case.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function will return `true` for any character in the following set:

```
A B C D E F G H I J K L M

N O P Q R S T U V W X Y Z
```

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for upper case letters (only good up to char 127)
function isUpper(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 64) && (myCharCode <  91))
   {
      return true;
   }

   return false;
}
```

See also:	ASCII, Character handling, Character set, Character testing, Character-case mapping, Enquiry functions, `isLower()`, Letter, Unicode

isXDigit() (Simulated functionality)

Check if character is a hexadecimal numeral.

Property/method value type:	Boolean primitive

This is a function normally found in the C language. However, it is useful to script developers as well and may be available in some implementations as an extension to the ECMA standard functionality.

This function tests to see if a character is a hexadecimal digit. It will return `true` for any character in the following set:

```
0 1 2 3 4 5 6 7 8 9 A B C D E F
```

Strictly speaking, this function should be coded to be aware of locale specific issues. You may want to take the example simulation provided here and modify it to your own needs to support that. This is just a basic working example.

Example code:

```
// Test for hexadecimal digits
function isXDigit(aChar)
{
   return (isDigit(aChar) || isA2F(aChar));
}
```

```
// Test for digits
function isDigit(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if((myCharCode > 47) && (myCharCode <  58))
   {
      return true;
   }

   return false;
}

// Test for letters A to F
function isA2F(aChar)
{
   myCharCode = aChar.charCodeAt(0);

   if(((myCharCode > 64) && (myCharCode <  71)) ||
      ((myCharCode > 96) && (myCharCode < 103)))
   {
      return true;
   }

   return false;
}

alert(isXDigit("G"));
alert(isXDigit("A"));
```

See also:	Character handling, Character testing, Enquiry functions, `isDigit()`, `isODigit()`, Letter

Iteration statement (Definition)

A block of repeating code –a loop.

Availability:	ECMAScript edition –2

An iteration statement executes a body of code iteratively –that is, over and over again, while a certain condition is `true` or until a terminating condition becomes `true`.

An iteration statement consists of a header and a body. The header is a keyword and a set of control parameters in parentheses. The body is a statement block enclosed in braces.

The following iteration statements are supported by ECMA compliant implementations:

- `while()`
- `for ()`
- `for( ... in)`

All of these loop-controlling statements test the condition each time round the loop. In the case of some iterators, the test happens before the code is executed. For others it happens after the code has been executed.

An infinite loop is one for which the terminating condition never happens or where the iterating condition remains `true` forever.

Here are some infinite loops:

```
for(;;){// do this forever}while(true){// do this forever}
```

You can break out of a loop with a break or return. The return statement should only be used when the loop is contained in a called function body. You can call the next iteration prematurely with a continue statement.

Warnings:

- That statement about enclosing code in braces sometimes elicits arguments from developers who routinely prefer to omit braces when the code block consists of a single line.
- However, I stand by the assertion that putting in the braces tends to result in fewer misunderstandings when another programmer is maintaining your source. On the whole I can see no advantages in leaving out the enclosing braces even when the code block is a single line. It helps to remind you that the code is part of an iteration or condition and allows you to add a second line without worrying about the braces.
- In a rush to add a second line, you might very easily omit the braces. That would cause the added line to be executed outside of the iteration loop, whether the condition matched or not. Because of the way people indent braces it is hard to spot when this has happened.

See also:	`break`, `continue`, `for( ... ) ...`, `for( ... in ... ) ...`, `return`, Statement, `while( ... ) ...`

Wrox *Instant JavaScript* –page –25

.jar (File extension)

Java archive file.

JavaScript include files normally have a `.js` file extension. In some rare cases, a `.jar` file may be used. This is really a Java archive file type.

It contains a collection of `.js` files and is normally requested with the `ARCHIVE` tag attribute in the `<SCRIPT>` tag.

A `.jar` file is a ZIP compressed archive of the `.js` files with a small amount of additional information that carries a manifest. The web browser extracts the manifest so that it can then index the archive to retrieve the items it needs. You can make a simple archive like this with a zip compression utility (e.g. Winzip). There is nothing special about it other than making sure the names are consistent with what you refer to from a script or HTML document.

Archives are also useful for attaching digital signatures to scripts. The web reference points to a Netscape resource on archiving, including a link to a downloadable Signtool Archive generator tool.

Java (Definition)

A language developed by Sun Microsystems that is useful for building plugins for web pages.

Java applets can call JavaScript by means of the exception event mechanism.

You can also embed fragments of JavaScript inside Java applets although there are some limitations to what you can accomplish with this.

For this to work, Java and JavaScript both have to be enabled and working. This may require some preference setting. It also only works in Netscape for the time being.

Things are slightly different with Netscape 6.0. No longer do you get a Java VM packed and embedded in the browser. Instead, it depends on the one you have installed in the OS. If you don't have one installed or if Netscape can't find it, then Java won't work. There's not a great deal of help provided on this aspect of the installation.

Once you do have it installed and working, the Java connectivity should behave as it did before.

Warnings:

- Writing a Java applet to handle a rollover effect is not such a challenging task as you might think, and is one of the things that can be accomplished quite early in your career as a Java programmer. Java is capable of much more than that, but if you are going to tackle a large Java-driven project, you need to think it through and plan it much more carefully.
- Scripting in general seems to be amenable to being developed on the fly and with a minimum of forethought and planning and it's good for putting something together really quickly. Of course getting good at it takes some time. Getting good at Java will probably take longer still. There's a lot more to consider with Java (considerably more than with JavaScript) and the process of creation and deployment is far more unwieldy than putting JavaScript in web pages.
- Your Java code will be far better for having thought the object model through and constructed it carefully. JavaScript lets you get right in there and start manipulating a pretty good object model right away. Of course there are objects already there in Java, but you do need to start building from a lot lower down.

.java (File extension)

Java source file.

A very obscure situation is when JavaScript is hidden inside Java source code. In that case it will be contained in a file with a `.java` extension.

See also:	File extensions, Web browser

Cross-references:

Wrox *Instant JavaScript* –page 3

Java calling JavaScript (Definition)

Java has mechanisms for calling back to JavaScript directly.

For Java to call JavaScript functionality, it needs to have access to the `netscape.javascript.JSObject` class. This is a Java wrapper that encapsulates a JavaScript object and makes it accessible to the Java environment.

Warnings:

- This is only available in Netscape and there is presently no equivalent capability in MSIE.

See also:	`JSObject` object, LiveConnect, `netscape.javascript.JSObject`

Cross-references:

O'Reilly *JavaScript Definitive Guide* –page 568

Java exception events (Definition)

Exceptions in Java applets can trigger JavaScript code in the containing web page.

A Java exception can be coupled to JavaScript handlers using the Netscape BeanConnect technology built into Netscape 4.0 browsers.

This can be used without a great deal of effort on the part of the Java applet programmer. A Java exception could cause a trigger for a call-back event at any time. This may be a way to develop more sophisticated scheduling machines although if you are going to that much trouble, you might choose to implement the bulk of your functionality in the applet itself.

However, this may yield a solution to the portability issues with media players. Given that the providers of the different media players generally provide an API, you may be able to hide the complexity of the different players by embedding the video inside an applet. This would allow you to normalize the JavaScript API it presents to the outside worlds and also deal with any cross-platform problems.

The applet becomes the player but deals with all the differences between different video players and all the nasty cross-platform stuff gets dealt with by the JVM. It's certainly feasible to embed QuickTime inside Java and there also a kit for doing the same with Real Player. Windows media player may be more tricky.

Java method calls (Definition)

JavaScript allows Java methods to be called natively.

Access to the methods of Java objects is very simple. They appear to be native JavaScript methods. To all intents and purposes, they are no different to the other built-in objects such as `Math`, `Boolean`, `String`, `Date` etc.

There is a subtle difference between the two environments in that JavaScript methods are forgiving about the number and type of arguments whereas Java is not. There is also some ambiguity regarding data types when calling Java methods. It is possible to overload a method in Java and provide alternative interfaces to support different data types. JavaScript can only cope with calling the first interface it encounters and cannot select an appropriate one based on the data type of the method arguments.

You may be able to limit the problems here by carefully considering the data types and coercing them in the script.

Warnings:

- Netscape 3.0 supported Java method calls with a special `JavaMethod` object that was deprecated as of Netscape 4.0.

Wrox *Professional JavaScript* –page 537

Java method data conversion (Definition)

Data types are mapped and converted between JavaScript and Java when methods are called.

When Java methods are called from JavaScript in Netscape they are translated via LiveConnect so that the Java objects appear to be as much like JavaScript objects as possible.

When methods are called, often you want to pass some data to the method. JavaScript supports a variety of primitive data types and more complex objects. These need to be mapped usefully to their corresponding Java equivalent values and types. A similar thing happens when the methods return a result value.

There is some hysteresis effect here because there are not always direct equivalents and so it is possible for the data type to mutate across this boundary, even if the method does nothing other than to echo an input value without modifying it.

It simplifies things a great deal to consider the input arguments and returned values as a separate issue although many factors about the data conversion are similar. On the one hand, we are converting JavaScript values to their nearest and most sensible Java equivalents. On the other hand, we are converting Java values to their best possible JavaScript counterparts.

Java to JavaScript values (Definition)

Conversion of Java primitives and objects to JavaScript compatible types.

When a Java method returns a value to JavaScript, the Java values need to be converted to compatible and useful data types. This is accomplished with LiveConnect in Netscape Navigator and ActiveX in MSIE.

In some cases a single Java primitive data type will be compatible with JavaScript primitives and objects of many different types. An example of this is the JavaScript Number primitive that will readily accept half a dozen different Java numeric and logical types.

Some Java data types correspond exactly to a single and specific JavaScript type. Examples of this are `null`, `Boolean` and `void`.

A third possibility is that many different Java object types will become a single JavaScript object type. In fact Java objects all become a generic JavaObject.

Here is a table that summarizes the correspondence between Java and JavaScript types when converting to Java. This would be used when passing values into methods under control of JavaScript:

Java	JavaScript
boolean	boolean primitive
byte	number primitive
char	number primitive
double	number primitive
float	number primitive
int	number primitive
long	number primitive

Table continued on following page

Java	JavaScript
null	null
short	number primitive
void	undefined
java.lang.Boolean	JavaObject object
java.lang.Character	JavaObject object
java.lang.Class	JavaObject object
java.lang.Double	JavaObject object
java.lang.Float	JavaObject object
java.lang.Integer	JavaObject object
java.lang.Long	JavaObject object
java.lang.String	JavaObject object
All Java arrays regardless of what they contain	JavaArray
netscape.javascript.JSObject	generic JavaScript object
All other Java objects	JavaObject object

When this happens under the control of Java, there are further limitations as to what can be exchanged between the environments. This is discussed under the individual methods that are affected in the JSObject description.

This table summarizes the relationships at the method return interface. JavaScript values may need to be converted further if they are assigned to JavaScript `LValues`.

JavaScript objects are wrapped so that Java can access them as a `netscape.javascript.JSObject` object. When they are passed back to JavaScript, the encapsulation is removed and the intrinsic JavaScript object is accessed directly again.

Warnings:

- Be aware that you can lose precision when passing data into and out of a Java applet method. As well as type conversion, value truncation may occur. You may not get out what you put in –in terms of accuracy. An example of this is passing a number from JavaScript to a short primitive data type inside Java and back again.
- JavaScript number values can interface to `java.lang.Double` method arguments but will be mapped back to a JavaObject. You may need to extract the numeric value to yield a number primitive again.
- Because JavaScript does not have a character data type, the Java `char` values will be converted to number primitives. You will need to convert them to strings yourself by converting the character's numeric value to a character with the `String.fromCharCode()` method.
- Although number primitives in JavaScript can convert to a `java.lang.Double` value, converting back again yields a JavaObject and not a number primitive. You will need to extract the numeric value again manually.
- the `java.lang.String` object becomes a JavaObject. This means the `String` and `netscape.javascript.JSObject` items mutate as they pass into Java and back again. You may need to do additional work to get the string value back out in a form that you need.
- All Java arrays are returned in a `JavaArray` object. This means that arrays of strings, numbers and objects all appear to be the same from JavaScript and you may need to provide special code to unwrap them properly.

java (Property)

A short cut reference to the `Packages.java` object.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`JavaPackage java`	
JavaScript syntax:	N	`java`
	N	*`myWindow`*`.java`
	N	*`myWindow`*`.Packages.java`
	N	`Packages.java`

See also:	`java.awt`, `Window.java`, `Window.Packages`

Property attributes:

`ReadOnly`.

Refer to:

`Packages`.java

java.awt (Java package)

A JavaPackage that represents the Abstract Windowing Toolkit.

Availability:	JavaScript –1.1 Netscape –3.0

The Abstract Windowing Toolkit is a set of Classes that provide a platform-independent way to develop graphical user interfaces on your applets or Java applications. It was introduced quite early on in the Java history at version 1.0 and had some major additions at Java 1.1, and it has now been supplemented by the Swing components which override some AWT functionality but do not render it entirely obsolete.

java.awt.Button (Java class)

A JavaClass object that represents the `java.awt.Button` class.

Availability:	JavaScript –1.1 Netscape –3.0
Object methods:	`action(), addNotify(), bounds(), checkImage(), createImage(), deliverEvent(), disable(), enable(), equals(), getBackground(), getClass(), getColorModel(), getFont(), getFontMetrics(), getForeground(), getGraphics(), getLabel(), getLocale(), getParent(), getPeer(), getToolkit(), gotFocus(), hashCode(), hide(), imageUpdate(), inside(), invalidate(), isEnabled(), isShowing(), isValid(), isVisible(), keyDown(), keyUp(), layout(), list(), locate(), location(), lostFocus(), minimumSize(), mouseDown(), mouseDrag(), mouseEnter(), mouseExit(), mouseMove(), mouseUp(), move(), nextFocus(), notify(), notifyAll(), paint(), paintAll(), postEvent(), preferredSize(), prepareImage(), print(), printAll(), removeNotify(), repaint(), requestFocus(), reshape(), resize(), setBackground(), setFont(), setForeground(), setLabel(), setVisible(), show(), size(), toString(), update(), validate(), wait()`

This is a sub-class of the AWT Component Class. It describes a button labelled with a text legend which the user can click on. Clicking on the button initiates an action. Each button has an action associated with it and when it is clicked, it will generate an `ActionEvent` object.

Method	JavaScript	JScript	N	IE	Opera	Notes
`action()`	1.1 +	-	3.0 +	-	-	-

java.awt.image (Java class)

A JavaClass object that represents the `java.awt.image` class.

Availability:	JavaScript –1.1 Netscape –3.0

This is an abstract class provided as the super-class of all classes that describe and encapsulate images within AWT. Because it is an abstract class, the methods are mostly place holders and will need to be overridden in the concrete classes that are sub-classed from this class.

java.lang (Java package)

The Java language package.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`JavaPackage object`	
JavaScript syntax:	N	`java.lang`

This JavaPackage provides the main language support classes for Java. There are classes for handling variables, multi-threaded programming, system classes, string-handling and error/exception handler support.

It's not likely you would want to delve deeply into these issues, but occasionally you may need to enquire of some readable attributes of a Java applet and this package may help.

java.lang.Boolean (Java class)

The Java Boolean class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`FALSE, TRUE, TYPE`
Class methods:	`getBoolean(), valueOf()`
Object methods:	`booleanValue(), equals(), getClass(), hashCode(), notify(), notifyAll(), toString(), wait()`

Support for Boolean primitives in Java.

Values of this type are visible to JavaScript as a JavaObject, which encapsulates the Java created value.

See also:	boolean, Java to JavaScript values, JavaScript to Java values

Method	JavaScript	JScript	N	IE	Opera	Notes
`booleanValue()`	1.1 +	-	3.0 +	-	-	-
`equals()`	1.1 +	-	3.0 +	-	-	-
`getClass()`	1.1 +	-	3.0 +	-	-	-
`hashCode()`	1.1 +	-	3.0 +	-	-	-
`notify()`	1.1 +	-	3.0 +	-	-	-
`notifyAll()`	1.1 +	-	3.0 +	-	-	-
`toString()`	1.1 +	-	3.0 +	-	-	-
`wait()`	1.1 +	-	3.0 +	-	-	-

java.lang.Character (Java class)

The Java Character class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`COMBINING_SPACING_MARK, CONNECTOR_PUNCTUATION, CONTROL, CURRENCY_SYMBOL, DASH_PUNCTUATION, DECIMAL_DIGIT_NUMBER, ENCLOSING_MARK, END_PUNCTUATION, FORMAT, LETTER_NUMBER, LINE_SEPARATOR, LOWERCASE_LETTER, MATH_SYMBOL, MAX_RADIX, MAX_VALUE, MIN_RADIX, MIN_VALUE, MODIFIER_LETTER, MODIFIER_SYMBOL, NON_SPACING_MARK, OTHER_LETTER, OTHER_NUMBER, OTHER_PUNCTUATION, OTHER_SYMBOL, PARAGRAPH_SEPARATOR, PRIVATE_USE, SPACE_SEPARATOR, START_PUNCTUATION, SURROGATE, TITLECASE_LETTER, TYPE, UNASSIGNED, UPPERCASE_LETTER`
Class methods:	`digit(), forDigit(), getNumericValue(), getType(), isDefined(), isDigit(), isIdentifierIgnorable(), isISOControl(), isJavaIdentifierPart(), isJavaIdentifierStart(), isJavaLetter(), isJavaLetterOrDigit(), isLetter(), isLetterOrDigit(), isLowerCase(), isSpace(), isSpaceChar(), isTitleCase(), isUnicodeIdentifierPart(), isUnicodeIdentifierStart(), isUpperCase(), isWhitespace(), toLowerCase(), toTitleCase(), toUpperCase()`
Object methods:	`charValue(), equals(), getClass(), hashCode(), notify(), notifyAll(), toString(), wait()`

Support for character based data in the Java environment.

Values of this type are visible to JavaScript as a JavaObject which encapsulates the Java created value.

See also:	`char`, Java to JavaScript values

Method	JavaScript	JScript	N	IE	Opera	Notes
`charValue()`	1.1 +	-	3.0 +	-	-	-
`equals()`	1.1 +	-	3.0 +	-	-	-
`getClass()`	1.1 +	-	3.0 +	-	-	-
`hashCode()`	1.1 +	-	3.0 +	-	-	-
`notify()`	1.1 +	-	3.0 +	-	-	-
`notifyAll()`	1.1 +	-	3.0 +	-	-	-
`toString()`	1.1 +	-	3.0 +	-	-	-
`wait()`	1.1 +	-	3.0 +	-	-	-

java.lang.Class (Java class)

The Java Class class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class methods:	`forName()`

Support for access to the Java Classes that define the structure of objects.

Values of this type are visible to JavaScript as a JavaObject which encapsulates the Java created value.

You cannot instantiate new objects of this class because the constructor is not public.

See also:	class, Java to JavaScript values

Cross-references:

O'Reilly *JavaScript Definitive Guide* –page 358

java.lang.Double (Java class)

The Java numeric double precision class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`MAX_VALUE, MIN_VALUE, NaN, NEGATIVE_INFINITY, POSITIVE_INFINITY, TYPE`
Class methods:	`doubleToLongBits(), isInfinite(), isNaN(), longBitsToDouble(), toString(), valueOf()`
Object methods:	`byteValue(), doubleValue(), equals(), floatValue(), getClass(), hashCode(), intValue(), isInfinite(), isNaN(), longValue(), notify(), notifyAll(), shortValue(), toString(), wait()`

Support for double precision floating point numbers.

Values of this type are visible to JavaScript as a JavaObject which encapsulates the Java created value.

See also:	`double`, Java to JavaScript values, JavaScript to Java values

Method	JavaScript	JScript	N	IE	Opera	Notes
byteValue()	1.1 +	-	3.0 +	-	-	-
doubleValue()	1.1 +	-	3.0 +	-	-	-
equals()	1.1 +	-	3.0 +	-	-	-
floatValue()	1.1 +	-	3.0 +	-	-	-
getClass()	1.1 +	-	3.0 +	-	-	-
hashCode()	1.1 +	-	3.0 +	-	-	-
intValue()	1.1 +	-	3.0 +	-	-	-
isInfinite()	1.1 +	-	3.0 +	-	-	-
isNaN()	1.1 +	-	3.0 +	-	-	-
longValue()	1.1 +	-	3.0 +	-	-	-
notify()	1.1 +	-	3.0 +	-	-	-
notifyAll()	1.1 +	-	3.0 +	-	-	-
shortValue()	1.1 +	-	3.0 +	-	-	-
toString()	1.1 +	-	3.0 +	-	-	-
wait()	1.1 +	-	3.0 +	-	-	-

java.lang.Float (Java class)

The Java Floating point numeric class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`MAX_VALUE, MIN_VALUE, NaN, NEGATIVE_INFINITY, POSITIVE_INFINITY, TYPE`
Class methods:	`floatToIntBits(), intBitsToFloat(), isInfinite(), isNaN(), toString(), valueOf()`
Object methods:	`byteValue(), doubleValue(), equals(), floatValue(), getClass(), hashCode(), intValue(), isInfinite(), isNaN(), longValue(), notify(), notifyAll(), shortValue(), toString(), wait()`

Support for single precision floating point numbers.

Values of this type are visible to JavaScript as a JavaObject, which encapsulates the Java created value.

See also:	`float`, Java to JavaScript values

Method	JavaScript	JScript	N	IE	Opera	Notes
byteValue()	1.1 +	-	3.0 +	-	-	-
doubleValue()	1.1 +	-	3.0 +	-	-	-
equals()	1.1 +	-	3.0 +	-	-	-
floatValue()	1.1 +	-	3.0 +	-	-	-
getClass()	1.1 +	-	3.0 +	-	-	-
hashCode()	1.1 +	-	3.0 +	-	-	-
intValue()	1.1 +	-	3.0 +	-	-	-
isInfinite()	1.1 +	-	3.0 +	-	-	-
isNaN()	1.1 +	-	3.0 +	-	-	-
longValue()	1.1 +	-	3.0 +	-	-	-
notify()	1.1 +	-	3.0 +	-	-	-
notifyAll()	1.1 +	-	3.0 +	-	-	-
shortValue()	1.1 +	-	3.0 +	-	-	-
toString()	1.1 +	-	3.0 +	-	-	-
wait()	1.1 +	-	3.0 +	-	-	-

java.lang.Integer (Java class)

The Java integer numeric class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`MAX_VALUE, MIN_VALUE, TYPE`
Class methods:	`decode(), getInteger(), parseInt(), toBinaryString(), toHexString(), toOctalString(), toString(), valueOf()`
Object methods:	`byteValue(), doubleValue(), equals(), floatValue(), getClass(), hashCode(), intValue(), longValue(), notify(), notifyAll(), shortValue(), toString(), wait()`

Support for integer values in the Java environment.

Values of this type are visible to JavaScript as a JavaObject which encapsulates the Java created value.

See also:	`int`, Java to JavaScript values

Method	JavaScript	JScript	N	IE	Opera	Notes
byteValue()	1.1 +	-	3.0 +	-	-	-
doubleValue()	1.1 +	-	3.0 +	-	-	-
equals()	1.1 +	-	3.0 +	-	-	-
floatValue()	1.1 +	-	3.0 +	-	-	-
getClass()	1.1 +	-	3.0 +	-	-	-
hashCode()	1.1 +	-	3.0 +	-	-	-
intValue()	1.1 +	-	3.0 +	-	-	-
longValue()	1.1 +	-	3.0 +	-	-	-
notify()	1.1 +	-	3.0 +	-	-	-
notifyAll()	1.1 +	-	3.0 +	-	-	-
shortValue()	1.1 +	-	3.0 +	-	-	-
toString()	1.1 +	-	3.0 +	-	-	-
wait()	1.1 +	-	3.0 +	-	-	-

java.lang.Long (Java class)

The Java long numeric class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class properties:	`MAX_VALUE, MIN_VALUE, TYPE`
Class methods:	`getLong(), parseLong(), toBinaryString(), toHexString(), toOctalString(), toString(), valueOf()`
Object methods:	`byteValue(), doubleValue(), equals(), floatValue(), getClass(), hashCode(), intValue(), longValue(), notify(), notifyAll(), shortValue(), toString(), wait()`

Support for long integer values in the Java environment.

Values of this type are visible to JavaScript as a JavaObject, which encapsulates the Java created value.

See also:	Java to JavaScript values, `long`

Method	JavaScript	JScript	N	IE	Opera	Notes
byteValue()	1.1 +	-	3.0 +	-	-	-
doubleValue()	1.1 +	-	3.0 +	-	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
equals()	1.1 +	-	3.0 +	-	-	-
floatValue()	1.1 +	-	3.0 +	-	-	-
getClass()	1.1 +	-	3.0 +	-	-	-
hashCode()	1.1 +	-	3.0 +	-	-	-
intValue()	1.1 +	-	3.0 +	-	-	-
longValue()	1.1 +	-	3.0 +	-	-	-
notify()	1.1 +	-	3.0 +	-	-	-
notifyAll()	1.1 +	-	3.0 +	-	-	-
shortValue()	1.1 +	-	3.0 +	-	-	-
toString()	1.1 +	-	3.0 +	-	-	-
wait()	1.1 +	-	3.0 +	-	-	-

java.lang.Object (Java class)

This is the super-class of all objects in the Java `lang` environment.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Object methods:	`equals(), getClass(), hashCode(), notify(), notifyAll(), toString(), wait()`

Support for generic objects in the Java environment.

Methods and properties belonging to this object are inherited by objects such as the `JavaArray` object (as it appears to JavaScript).

This class is presented to the JavaScript programmer as a JavaObject object.

See also:	JavaObject object

Method	JavaScript	JScript	N	IE	Opera	Notes
equals()	1.1 +	-	3.0 +	-	-	-
getClass()	1.1 +	-	3.0 +	-	-	-
hashCode()	1.1 +	-	3.0 +	-	-	-
notify()	1.1 +	-	3.0 +	-	-	-
notifyAll()	1.1 +	-	3.0 +	-	-	-
toString()	1.1 +	-	3.0 +	-	-	-
wait()	1.1 +	-	3.0 +	-	-	-

O'Reilly *JavaScript Definitive Guide* –page 566

java.lang.String (Java class)

The Java String class.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`JavaObject object`
Class methods:	`copyValueOf(), valueOf()`
Object methods:	`charAt(), compareTo(), concat(), endsWith(), equals(), equalsIgnoreCase(), getBytes(), getChars(), getClass(), hashCode(), indexOf(), intern(), lastIndexOf(), length(), notify(), notifyAll(), regionMatches(), replace(), startsWith(), substring(), toCharArray(), toLowerCase(), toString(), toUpperCase(), trim(), wait()`

Support for string values in the Java environment.

Values of this type are visible to JavaScript as a JavaObject, which encapsulates the Java created value.

See also:	Java to JavaScript values, JavaScript to Java values, `String`

Method	JavaScript	JScript	N	IE	Opera	Notes
`charAt()`	1.1 +	-	3.0 +	-	-	-
`compareTo()`	1.1 +	-	3.0 +	-	-	-
`concat()`	1.1 +	-	3.0 +	-	-	-

java.util (Java package)

The Java utility package.

Availability:	JavaScript –1.1 Netscape –3.0

This package provides a collection of classes and interfaces that are generally useful to the programmer. These fall into the following categories:

- Arrays
- Calender functions and date support
- Collections
- Event objects
- Mapping classes
- Random numbers
- Resource bundle support
- String tokenizer
- Timers
- Timer tasks

See also:	Method, Property

java.util.Date (Java class)

The Java Date object.

Availability:	JavaScript –1.1 Netscape –3.0
Class methods:	parse(), UTC()

Object methods:	`after()`, `before()`, `equals()`, `getClass()`, `getDate()`, `getDay()`, `getHours()`, `getMinutes()`, `getMonth()`, `getSeconds()`, `getTime()`, `getTimezoneOffset()`, `getYear()`, `hashCode()`, `notify()`, `notifyAll()`, `setDate()`, `setHours()`, `setMinutes()`, `setMonth()`, `setSeconds()`, `setTime()`, `setYear()`, `toGMTString()`, `toLocaleString()`, `toString()`, `wait()`

This class is an encapsulation of the machine date and time measured in milliseconds since January the 1st, 1970. Fortunately, this is the same reference time that the JavaScript standard (ECMA) prescribes.

See also:	Date object, Universal coordinated time

Method	JavaScript	JScript	N	IE	Opera	Notes
`after()`	1.1 +	-	3.0 +	-	-	-
`before()`	1.1 +	-	3.0 +	-	-	-
`equals()`	1.1 +	-	3.0 +	-	-	-
`getClass()`	1.1 +	-	3.0 +	-	-	-
`getDate()`	1.1 +	-	3.0 +	-	-	-
`getDay()`	1.1 +	-	3.0 +	-	-	-
`getHours()`	1.1 +	-	3.0 +	-	-	-
`getMinutes()`	1.1 +	-	3.0 +	-	-	-
`getMonth()`	1.1 +	-	3.0 +	-	-	-
`getSeconds()`	1.1 +	-	3.0 +	-	-	-
`getTime()`	1.1 +	-	3.0 +	-	-	-
`getTimezoneOffset()`	1.1 +	-	3.0 +	-	-	-
`getYear()`	1.1 +	-	3.0 +	-	-	-
`hashCode()`	1.1 +	-	3.0 +	-	-	-
`notify()`	1.1 +	-	3.0 +	-	-	-
`notifyAll()`	1.1 +	-	3.0 +	-	-	-
`setDate()`	1.1 +	-	3.0 +	-	-	-
`setHours()`	1.1 +	-	3.0 +	-	-	-
`setMinutes()`	1.1 +	-	3.0 +	-	-	-
`setMonth()`	1.1 +	-	3.0 +	-	-	-
`setSeconds()`	1.1 +	-	3.0 +	-	-	-
`setTime()`	1.1 +	-	3.0 +	-	-	-
`setYear()`	1.1 +	-	3.0 +	-	-	-
`toGMTString()`	1.1 +	-	3.0 +	-	-	-
`toLocaleString()`	1.1 +	-	3.0 +	-	-	-
`toString()`	1.1 +	-	3.0 +	-	-	-
`wait()`	1.1 +	-	3.0 +	-	-	-

JavaArray object (Object/Navigator)

A JavaScript data type that encapsulates a Java array.

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	*myJavaArray = myWindow.Packages*
Object properties:	`length`	
Object methods:	`toString()`	

In Java, objects can be collected together into arrays. This is also true of JavaScript. However, as you might expect, some encapsulation of the Java array is necessary to be able to operate on it from a JavaScript environment. The `JavaArray` object does just this. It supports some JavaScript-like behavior in that it has a length property and can be accessed element by element using the JavaScript `[]` notation. JavaArray objects can be stacked to make multidimensional arrays and they can also be traversed with a `for( ... in ... ) ...` loop.

At version 1.4 of JavaScript, a `JavaArray` object inherits properties from the `java.lang.Object` super-class.

See also:	`Array` object, `Collection` object, Java to JavaScript values, JavaScript to Java values, LiveConnect, `Window.Packages`

Property	JavaScript	JScript	N	IE	Opera	Notes
`length`	1.1 +	-	3.0 +	-	-	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	Notes
`toString()`	1.1 +	-	3.0 +	-	-	-

JavaArray.length (Property)

The length of the Java array encapsulated by the `JavaArray` object.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	`myJavaArray.length`

See also:	LiveConnect, `Collection.length`

Property attributes:

`ReadOnly`.

JavaArray.toString() (Method)

A string primitive representation of the JavaArray contents.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myJavaArray`*`.toString()`

In version 1.4 of JavaScript, this method is overridden by the `toString()` method belonging to the `java.lang.Object` super-class.

Prior to that, it yielded a string like this:

```
[object JavaArray]
```

If you expect to use this for any useful purpose in scripting, you will need to override it with a custom handler that converts the object to a string that delivers the instance value rather than the type of its prototype object.

JavaClass object (Object/Navigator)

A JavaScript data type that encapsulates a Java Class.

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	*`myJavaClass = myWindow`*`.Packages.java`

The static fields of the Java Class are presented as properties of the JavaClass object.

The static methods of the Java Class are presented as methods available to the JavaClass object. They may be presented as `JavaMethod` objects depending on how you access them from JavaScript.

The only properties and methods this object has, correspond to the public properties and methods of the Java class that it represents. You can enumerate these properties in a loop.

Java classes are either stored in individual class files or are collected together into groups stored in a ZIP file. Groups of classes will be represented by a `JavaPackage` object. Each individual class is represented by a JavaClass object. The JavaClass objects belong to a parent `JavaPackage` object.

To operate on these objects, you really need to know something about the Java classes they encapsulate. There are many standard classes and some that may have been custom written for your project.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Create a JavaScript object that encapsulates a Java Class
var myJavaDateClass  = Packages.java.util.Date;
var myJavaDateObject = new Packages.java.util.Date;
// Write the date to a web page
document.write(myJavaDateObject.toString());
// Write the same date value date to the Java console
java.lang.System.out.println(myJavaDateObject);
</SCRIPT>
</BODY>
</HTML>
```

See also:	JavaScript to Java values, LiveConnect, `Packages.java`, `Packages.netscape`, `Window.Packages`

Cross-references:

O'Reilly *JavaScript Definitive Guide* –page 358

JavaMethod object (Object/Navigator)

A deprecated way of encapsulating method calls on Java objects from JavaScript.

Availability:	JavaScript –1.1 Netscape –3.0 Deprecated	
JavaScript syntax:	N	*myJavaMethod = myJavaObject.aMethod()*
Argument list:	*aMethod*	A method belonging to the Java object

See also:	JavaScript to Java values, Window.Packages, Java method calls

Cross-references:

Wrox *Professional JavaScript* –page 527

JavaObject object (Object/Navigator)

A JavaScript data type that encapsulates a Java object. These are generally going to be members of the Java component class

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	*myJavaObject* = new java.lang.Object
	N	*myJavaObject* = document.applets[*anIndex*];
Object properties:	description, filename, length, name	
Object methods:	booleanValue(), destroy(), disable(), doubleValue(), enable(), getAppletContext(), getAppletInfo(), getBackground(), getClass(), getCodeBase(), getDocumentBase(), getLocale(), getParameter(), getParameterInfo(), getToolkit(), hide(), init(), isActive(), isEnabled(), isShowing(), isValid(), isVisible(), minimumSize(), refresh(), start(), stop(), toString()	

To make any serious use of this object, you need to know a little Java –at least enough to be able to be familiar with the class structures and creating and modifying objects. If you know how to make your own applets then that is probably sufficient to get started with.

The public properties of the Java Class of which the JavaObject is an instance are presented as properties of the JavaObject object. A JavaObject also inherits the properties from the `java.lang.Object` Class and any other classes which are in its superclass hierarchy. These are generally available by means of accessor methods so they will likely be listed as methods rather than properties.

The public methods of the Java Class of which the JavaObject is an instance are presented as methods of the JavaObject object. A JavaObject also inherits the methods from the `java.lang.Object` Class and any other classes which are in its superclass hierarchy.

The only properties and methods this object has, correspond to the public properties and methods of the Java object that it represents. You can enumerate the properties in a loop to inspect the interface to the object from your own scripts; like this:

```
for(myProp in myJavaObject) {
   document.write(myProp);
   document.write("<BR>");
}
for(myProp in myJavaObject) {
   document.write(myProp);
   document.write("<BR>");
```

There may be some properties that are not revealed by this and you may need to resort to some Java documentation for further details. Properties and methods for the objects in Java are documented in more depth in *Java Programmer's Reference*, written by Grant Palmer and published by Wrox Press, which covers JDK 1.3 extensively.

To operate on the `JavaObject` objects, you really need to know something about the Java objects they encapsulate. There are many standard classes and some that may have been custom written for your project.

Beware that the object may report accessors that don't actually have any purpose in the object you have enumerated.

For properties and methods that apply to the `Applet` object in the context of an MSIE browser, examine the Applet object topic and its related items. This is documented separately because it does not support the same Java –JavaScript bridging mechanism and provides a mutually exclusive set of properties for communication with the `Applet` object.

Although JavaScript exposes a great many of the properties of an Applet by means of `Accessor` Methods, it is probably not safe to call the more destructive of them from JavaScript. However, you may usefully want to use the various enquiry methods to find out about the Applet and its internals. Many of these `Accessor` Methods yield other objects whose properties can also be inspected by using the same enumeration techniques.

Having examined some applets and other miscellaneous Java objects, a summary list of the accessor methods is presented at the head of this topic.

Some fragments of example code are given here and a couple of important methods are described in adjacent topics. Documenting all the interfaces to an Applet or Java object is so dependent on the object that you should refer to the Applet documentation and source and a Java reference manual for details of the internals of Java code.

Warnings:

- When JavaObject objects are used in JavaScript expressions, even though internally they may contain a value that could be represented by a JavaScript primitive type, they do not behave like that JavaScript primitive type. Instead, they behave according to the rules of the Java object type that contains the value. This can sometimes cause scripts to behave in unexpected ways, for example you might get a concatenation instead of a numeric addition. You should also explicitly test for values and not make assumptions that a `null` or undefined value is returned.
- The JavaObject in Netscape is notably unforgiving. Many other JavaScript objects will yield the value undefined if you ask for a property that does not exist. A JavaObject will generate a run time error and so you cannot easily test for the existence of an unknown property.
- Some objects also support a strangely named function that is referred to by an enumerable but apparently unnamed property. It is exposed when you enumerate the properties in a `for( ... in ... )` loop and output their names with a `document.write()`. A property appears in the list that seems to have no name. Checking the property names with the `typeof` operator reports this as a string so it's not an undefined name. OK, so lets measure its length. The suspect property reports a length of 6 in the example I was testing but it is still invisible. Here's where we try hunches and use our debugging instincts. Wrap the property name in the `escape()` function. That should tell us what weird characters are there. Voila. It reports that the name is now `%3CInit%3E`. So the name is the word `Init` wrapped in < and > characters, which explains why we couldn't see it. The web browser thought it was a tag and didn't recognize it so it was hidden.
- The second piece of example code shows how the properties were enumerated and how to display the hidden property name.

Example code:

```
// Output some text to the Java console
java.lang.System.out.println("Some text message");
// Create a JavaScript object that encapsulates a Java Objectvar
```

```
myJavaDateObject = new Packages.java.util.Date;

-----------------------------------------------------------------

<!-- Debugging hidden property values -->
<HTML>
<HEAD>
</HEAD>
<BODY>
<TABLE BORDER=1>
<SCRIPT>
// Create a JavaScript object that encapsulates a Java Class
var myJavaDateClass = new Packages.java.util.Date;
// Now enumerate its properties
var myIndex = 0;
for(myProp in myJavaDateClass)
{
   document.write("<TR><TD>");
   document.write(myIndex);
   document.write("</TD><TD>");
   document.write(myProp);
   document.write("</TD><TD>");
   document.write(typeof(myProp));
   document.write("</TD><TD>");
   document.write(myProp.length);
   document.write("</TD><TD>");
   document.write(escape(myProp));
   document.write("</TD></TR>");

   myIndex++;
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

JavaObject.booleanValue() (Method/Java)

This is the value that is used when the JavaObject is used in a Boolean context.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myJavaObject*.booleanValue()

Java Boolean objects support this method. It is a Java method but it is analogous to the `valueOf()` method used on a JavaScript Boolean object.

Because all Java objects become members of the JavaObject class they respond to `valueOf()` and `toString()` but those can be overridden in the JavaScript environment. The `booleanValue()` method penetrates to the Java environment and is executed there with its result encapsulated. The `valueOf()` and `toString()` methods are executed in the JavaScript environment even if there is a corresponding Java method for each.

The example shows all three methods being invoked but the `toString()` and `valueOf()` are masked. Note that by masking `toString()`, `valueOf()` is affected too. That may not be common to all object types.

There are other similar methods to support different Java primitive data types when they are encapsulated in an object. Only this one is illustrated. The others are different only in the data type and the name they have.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Create a JavaScript object that encapsulates a Java Class
var myJavaBooleanClass = new Packages.java.lang.Boolean(true);
// Mask the JavaScript environment values
myJavaBooleanClass.toString = mask;
// Write the object to a web page
document.write("toString() : ");
document.write(myJavaBooleanClass.toString());
document.write("<BR>");
document.write("valueOf() : ");
document.write(myJavaBooleanClass.valueOf());
document.write("<BR>");
document.write("booleanValue() : ");
document.write(myJavaBooleanClass.booleanValue());
document.write("<BR>");
// Masking function
function mask()
{
return "Masked";
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`JavaObject` object, LiveConnect

JavaObject.getClass() (Method/Java)

A JavaScript method for obtaining the class of a JavaObject.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myJavaObject*`.getClass()`

This returns the Java class of the encapsulated Java object. This is not necessarily the same as a JavaScript class name. In fact what is returned is an object reference to a class object which may need further work to extract the name of the class.

The example shows how a Java object is instantiated and then enquired to as of its class. Using the LiveConnect, the `getClass()` method requests the class name from the Java code and then converts that to a JavaScript message. Inspecting the constructor of the new object and extracting its name property tells you what class JavaScript has wrapped around the Java object.

Warnings:

- Beware that you don't confuse this JavaScript `getClass()` method with the Java `getClass()` method. Although they have the same name, they yield a different result. The JavaScript method yields a JavaScript object of the class JavaClass. The Java method yields a Java object of the class `java.lang.Class`, which is not the same thing.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Instantiate a Java object
myJavaString = new java.lang.String;
// Display its Java class
document.write("Java class : ");
document.write(myJavaString.getClass());
document.write("<BR><BR>");
// Display its JavaScript class
document.write("JavaScript class : ");
document.write(myJavaString.constructor.name);
document.write("<BR><BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	LiveConnect

JavaPackage object (Object/Navigator)

A JavaScript data type that encapsulates a Java Package.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	`myJavaPackage = myWindow.Packages`

A collection of Java classes are represented as a package. The complete set of all available Java Packages are contained within a single parent `JavaPackage` object. This constructs a hierarchy of `JavaPackage` and `JavaClass` objects.

The properties of the `JavaPackage` object are those that refer to any Java Class or Java Packages that belong to it. However, these are generally not enumerable so you do need to know what they are called before you can access them.

Because you cannot enumerate the properties of this object you won't be able to walk a Java package hierarchy with a script driven tree walker.

The `JavaPackage` tree structure resembles the directory structure that the Java class files are stored in. Some class files are collected into ZIP archives but even then the hierarchy is still intact and there will be one package that represents the ZIP file and corresponds to that node in the tree. Any arbitrary collection of classes will be represented by a `JavaPackage` object, regardless of how they are stored in the file system.

Example code:

```
// Create a JavaScript object that encapsulates a Java Package
var myJavaPackage = Packages.java.util;
```

JavaScript Bookmark URLs (Advice)

Bookmarks composed of JavaScript calls.

You can build a bookmark by typing in a JavaScript URL. You do need to be careful as you type it in.

To create a JavaScript bookmark, open the bookmark manager and create a new entry. Be careful to only refer to objects that are likely to exist regardless of the page on view. You can crash the logic of the browser if your bookmark script tries to manipulate objects that belong to a page other than that which you are browsing.

It is necessary to work within these limitations because the user may request a bookmark at any time.

These JavaScript-coded bookmarks are sometimes known as Bookmarklets.

It is possible to create bookmarklets to aid in a number of information-gathering and debugging tasks. The example demonstrates how to display form elements in a pop up window. This only works if your bookmarks can hold a long enough URL value. It works fine in MSIE and Netscape 6.0, but not in version 4.0 of Netscape although you can paste it into the location bar and hit return for the same effect.

Upon testing it was found that only the Opera 5 browser has a security check to ask whether the script is allowed to check the password.

Example code:

```
// Provided for our enjoyment by Jon Stephens
// Note, the line breaks and space have been added to aid
// readability.  You should omit the line breaks when
// inserting this into the bookmark. Any unnecessary spaces
// can also be removed to prevent URL buffer overruns.
// This also works fine when wrapped in a function
// declaration and called from a button on the form page.
```

```
javascript:var output = "";

for(var i = 0; i < document.forms.length; i++)
{
   for(var j = 0; j < document.forms[i].elements.length; j++)
   {
      output += "Form " +  i+  " -- # " + j + " -- Type: "
        +  document.forms[i].elements[j].type +  "; "
        +  document.forms[i].elements[j].name +  ": "
        +  document.forms[i].elements[j].value +  "<br>";
   }
}
var newWin = window.open("","newWin","width=350,height=350");
with(newWin.document)
{
   open();
   write(output);
   close();
}
```

JavaScript debugger console (Advice)

Netscape JavaScript debugger console window for viewing error logs.

If you type the `javascript:` URL method into the location box on a Netscape 4 browser and then press return, the web browser will display a debugging console window that gives you some helpful messages about what is happening in your script. It can certainly speed up the debugging process when you are trying to trace a fault.

You can type short pieces of JavaScript source code into the type-in box and press return and the results will be executed in console.

For example, to see the value of some mathematical constants, you type these lines into the location box:

```
Math.PI

Math.LOG10

Number.MAX_VALUE
```

Warnings:

- A small bug in the console requires that the first item be triggered with two carriage returns. For some reason the console eats the first message and then spits it out with the second. Everything is fine after that.

Wrox *Instant JavaScript* –page 48

JavaScript Document Source URL (Definition)

JavaScript can be called directly instead of fetching a page.

JavaScript URLs can be used in the `HREF` attribute of an anchor tag. If this technique is used, a fragment of JavaScript code can call in an external function and generate the content of another page without ever calling a web server for the page.

Quite sophisticated dynamic page generation can be accomplished like this, however, at some stage you will have to have downloaded the JavaScript code to be executed in the first place.

Example code:

```
<HTML>
<BODY>
<SCRIPT>
var the_value = 100;
function increment()
{
   the_value++;
}
</SCRIPT>
<A HREF="javascript:alert(the_value)">Click to display the value</A>
<A HREF="javascript:increment()">Click to increment the value</A>
</BODY>
</HTML>
```

See also:	JavaScript Image Source URL, `javascript`: URL

JavaScript embedded in Java (Definition)

Java applets can contain JavaScript code fragments that can be executed by the applet.

You can embed fragments of JavaScript inside Java applets although there are some limitations to what you can accomplish with this. For this to work, Java and JavaScript both have to be enabled and working. This may require some preference setting. Currently, it only works in Netscape.

The `<APPLET>` tag is the main way to embed a Java applet within an HTML document. That much generally works across all browsers.

JavaScript scripts should always have access to all the internals of a Java applet that it cares to make publicly available. However, the converse is not necessarily true. Java applets may not access the script-owned object space unless you give them permission to do so.

This is done with the `MAYSCRIPT` tag attribute on the `<APPLET>` tag.

The Java applet can then mimic JavaScript methods using the Java syntax, and there are mechanisms for accessing `eval()` functionality for interpreting JavaScript source text.

See also: Java, Java exception events, `JSObject` object, MAYSCRIPT

Cross-references:

Wrox *Instant JavaScript* –page 57

JavaScript entity (Pitfall)

This functionality is deprecated and should not be used in new projects.

The HTML character entities are useful for describing hard to type characters.

They are functionally similar to the back-quote substitutions that are available server-side with Netscape Enterprise Server.

MSIE version 3.0 introduced a means of passing JavaScript values into the HTML source space using a syntax that is similar to the character entity syntax. However, it is used in contexts that character entities were never intended to be used in. It is also advised as deprecated functionality in the HTML version 4.0 standard.

You might indicate an image width like this:

```
<IMG SRC="..." WIDTH="100">
```

The value for the image width can be taken from a JavaScript expression like this:

```
<IMG SRC="..." WIDTH="&{myWidth * myScaleFactor};">
```

This assumes that the values *`myWidth`* and *`myScaleFactor`* have already been defined in some earlier fragment of JavaScript.

The entity can be used to replace a single character in the tag attribute value so you can concatenate other characters such as percent signs if you use it in `<HR>` tags for example.

This functionality should be avoided and the usual client or server methods used to define the values in HTML tags.

Example code:

```
<HTML>
<BODY>
<FORM>
<INPUT TYPE="text" VALUE="&{top.name;}">
</FORM>
</BODY>
</HTML>
```

JavaScript Image Source URL (Definition)

Image data can be generated in some browsers.

Within some limitations, you can generate image data within a web browser's JavaScript environment. This seems to work best on the Netscape version 4.0 browser, but it is worth exploring somewhat to see if it can be exploited on other browsers.

If you store this text into a script variable it describes a 1 pixel image:

```
#define x_width 1

#define x_height 1

static char x_bits[] = {0x00};
```

This is the code for an XBM image. It is only black and white but it may be useful to be able to create an image with a script.

Now you can call this as the source of an image like this:

```
<IMG SRC="javascript:variablename">
```

The example works as it is in Netscape 4.0. Adding a MIME type header will help browsers to determine what the content type is and this technique doesn't need to be confined to just image data.

Example code:

```
<HTML>
<BODY>
<SCRIPT>
var the_image_data;
the_image_data  = "Content-type: image/x-xbm";
the_image_data  = "";
the_image_data  = "#define x_width 10\n";
the_image_data += "#define x_height 1\n";
the_image_data += "static char x_bits[] = {";
the_image_data += "0xFF,0xFF,0xFF,0xFF,0xFF,";
the_image_data += "0xFF,0xFF,0xFF,0xFF,0xFF";
the_image_data += "};";
</SCRIPT>
<IMG SRC="javascript:the_image_data">
</BODY>
</HTML>
```

JavaScript interactive URL (Request method)

An interactive JavaScript statement executor.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0

You can type short pieces of JavaScript source code into the location box and press return and the results will be executed in the document window.

For example, to see the value of some mathematical constants, you type these lines:

```
javascript:Math.PI

javascript:Math.LOG10

javascript:Number.MAX_VALUE

javascript:alert(top.location)
```

JavaScript language (Overview)

JavaScript overview summary.

Availability:	ECMAScript edition –2

JavaScript is a so-called third generation language.

JavaScript was originally developed by Netscape Communications and is influenced by many other languages. Most notably, it borrows from:

- C language
- Pascal
- BASIC
- Java
- Perl
- Other scripting languages

This means that if you have already used any of these other languages, it is likely that you will become proficient in JavaScript fairly quickly.

JavaScript and Java are two distinctly different languages. They even operate in a different architectural way. JavaScript is interpreted while Java is compiled. It is a lot simpler to get started using JavaScript and designers find it's a good way to become accustomed to the more intense software developer issues.

Java code tends to be quite self-contained and not require the help of any additional systems. On the other hand, JavaScript is often more like a kind of glue that joins various parts of the web together so they can inter-operate more effectively.

JavaScript is object-based. That is to say, the basic language operation and access to the hosting environment is by means of objects that represent items in the real world. A JavaScript application is built from a collection of various kinds of objects, which communicate with one another.

Every JavaScript environment comes with a set of Core Objects. These provide the fundamental basis on which the language is built. It is these objects that are defined in the ECMAScript standard. There is a `Global` Object which is the topmost object in the hierarchy. Other objects such as the `Math` Object provide more specialized capabilities.

In JavaScript we talk about primitive values having a type. There are a set of standard types built-in to the core JavaScript interpreter. Although JavaScript is object-based, it is not a class based object oriented language, and so while these Primitive Types behave very much like object oriented classes, they aren't really implemented as such. The language does provide some facilities for creating new object types however.

An Object in the JavaScript environment is a collection of Properties which you can access by name. Some you can only access in a read-only fashion while others can be modified. The Properties have attributes such as a read-only flag, which controls this access to the values contained in the property. Properties may have other attributes as well and can often be a reference to another object. Requesting a property from an object can therefore yield another object, which in turn has properties of its own. If you think of the properties as containers you'll soon feel comfortable with the concept.

Objects can also respond to messages, each of which will invoke a named Method. Those methods may behave much like a property request or they may cause some action to happen. At the JavaScript programming level, methods and properties begin to lose their distinction. Methods are often analogous to Functions in other languages. Indeed, methods are implemented as functions that are attached to objects by means of properties. You may use functions in a traditional way, very much like you would in C, but the functions you use in the scripts are actually methods that belong to the `global` object. However, in that case you don't need to specify which object should execute the method.

The syntax of JavaScript intentionally mimics that of Java but many rules are relaxed to make the language easier to use. For example, you don't need to declare the type of a variable before using it. Properties don't need to have their type specified and functions do not need to be placed earlier in the script than when they are first invoked.

Although JavaScript is intended to be forgiving and therefore easy to be comfortable with and yet not be a hard-core programmer, beyond the simple basics, it certainly is not a simple language to learn and exploit fully.

Wrox *Instant JavaScript* –page 1

Wrox *Instant JavaScript* –page 11

JavaScript Style Sheets (Definition)

A standard for describing style sheets.

The JavaScript Style Sheet facility (JSS) is based on the CSS level 1 capabilities. They are only supported in the version 4.0 Netscape browsers and are now completely deprecated. Netscape 6.0 does not support them at all. This gives rise to some concerns on portability issues.

However, if your web server is capable of recognizing the user agent value and serving different content accordingly, you may be able to ensure that JSS style sheets are served only to requesting Netscape 4.0 browsers and that other browsers will be presented with CSS style sheets instead.

The main difference is in the notation used to describe the JSS rules.

There are two ways to call in a JSS defined style sheet, either with the `<STYLE>` tag, which embeds the style definitions into the page, or with the `<LINK>` tag, which includes them from an external document.

Creating styles in JavaScript comes down to correctly forming the object model that refers to the `style` properties of the `document` object. This is managed by means of a `tags` object, which is the root of a collection of objects for which the style can be defined as properties. By and large the `tags` object has a property that corresponds to every style controllable HTML tag. It's fairly easy to guess the likely syntax and give a CSS reference, you can probably figure out the properties of the individual objects. The properties correspond with those attributes of the instances of the tags described in the browser object model (or the DOM if you prefer).

There are some special methods and functions defined for JSS to be used when creating styles. These are:

- `margins()`
- `rgb()`
- `contextual()`

For JavaScript to be able to modify style settings, it needs to be able to read the current values and to be able to write new values into the object properties.

In Netscape 4.0, the absolute and relative style properties apply to positioning of an object. If these are present, the objects are assumed to be in layers. Layers can be controlled very effectively from within JavaScript. they can be moved, sized and have their visibility changed. However there are rendering issues and the effects are complex and hard to control when some styled objects are already rendered on the page. Some tags can have absolute positioning applied directly but it is not portable across minor revision changes of the browser.

MSIE version 4.0 provides dynamic style control. It is improved significantly in version 5.0 and 5.5 and the same DOM based model is built into Netscape 6.0. The styles are available as `host` objects. You can modify the appearance of styled object in MSIE even after they have already been displayed. Changing the style or position of an object gives you all the capabilities that layers provided in Netscape, and an automatic damage repair redraw is also triggered if necessary when the style of an object is modified.

Warnings:

- JSS comes about because internally Netscape 4.0 converts CSS rules into JavaScript code and executes it as such. That is why you lose styling when you turn off JavaScript for security reasons.
- Netscape decided to make this interface available to the developer and exposed it as JSS. This means there is a conflicting alternative to CSS. It is very unlikely that JSS would be supported in any other browser than Netscape 4.0 given that most browser manufacturers are striving for standards compliance. They will all be supporting CSS2 fully in due course.
- It is therefore recommended that while you may want to experiment with JSS, it is a deprecated item. As such you probably should avoid deploying it in any mission critical projects or using it in new developments.
- MSIE 3.0 does not allow JavaScript access to style properties.
- The JSS functionality is removed from Netscape 6.0.

Example code:

```
<STYLE TYPE="text/JavaScript">tags.P.borderWidth = 10;tags.B.color =
"#FF0000";</STYLE>
```

JavaScript to Java values (Definition)

Conversion of JavaScript primitives and objects to Java compatible types.

When a Java method is called from JavaScript, the JavaScript values need to be converted to compatible and useful data types.

In some cases a single JavaScript type will be compatible with arguments of many different types. An example of this is the JavaScript Number primitive that will convert readily into half a dozen different Java types.

Some JavaScript data types correspond exactly to a single and specific Java type. An example of this is `null`.

A third possibility is that many different JavaScript types will become a single Java type. This is what happens to objects which all become a generic JavaScript object represented by the Java class `JSObject`.

Here is a table that summarizes the correspondence between JavaScript and Java types when converting to Java. This would be used when passing values into methods under control of JavaScript:

JavaScript	Java
boolean primitive	boolean
boolean primitive	java.lang.Boolean
null	null
number primitive	byte
number primitive	char
number primitive	double
number primitive	float
number primitive	int
number primitive	java.lang.Double
number primitive	long
number primitive	short
string primitive	java.lang.String
Function object	netscape.javascript.JSObject
JavaArray object	netscape.javascript.JSObject
JavaClass object	netscape.javascript.JSObject
JavaMethod object	netscape.javascript.JSObject
JavaObject object	The encapsulated Java object unwrapped
JavaPackage object	netscape.javascript.JSObject
netscape.javascript.JSObject	java.lang.String
All other JavaScript objects	netscape.javascript.JSObject

When this happens under the control of Java, there are further limitations as to what can be exchanged between the environments. This is discussed under the individual methods that are affected in the JSObject description.

This table summarizes the relationships at the passing interface. JavaScript values may have been converted during the expression evaluation. You may also need to coerce some values as they are passed so they are correctly mapped to the Java interface for the method.

Java objects are wrapped so that JavaScript can access them as a `JavaObject` object. When they are passed back to Java, the encapsulation is removed and the intrinsic Java object is accessed directly.

Warnings:

- Be aware that you can lose precision when passing data into and out of a Java applet method. As well as type conversion, value truncation may occur.
- JavaScript number values can interface to `java.lang.Double` method arguments but not to `java.lang.Integer` or `java.lang.Float`.

- Because JavaScript does not have a character data type, numbers can map to Java `char` data types. A character in a string in JavaScript is presented as a `String` primitive but is only one character long. This will convert to `java.lang.String` but will not naturally convert to a Java `char` data value unless you make some effort in the script to prepare it first. A `String.charCodeAt()` conversion may be necessary.
- Some Java encapsulations are not unwrapped when the value is passed to Java. A `JavaPackage`, `JavaArray`, `JavaClass` and the deprecated `JavaMethod` are all encapsulated as a `JSObject`. This may cause problems if the objects are passed backwards and forwards as the encapsulation might become increasingly nested. This behavior would be classed as erroneous and may be platform dependent. It may also depend on what happens inside the applet code when the method is called.
- JavaScript arrays are not converted to Java arrays of `JSObject` items. They are passed as a JSObject encapsulated as a whole.

See also:	Boolean, `Function` object, Java method data conversion, Java to JavaScript values, `JSObject` object, `JSObject.call()`, `JSObject.eval()`, `JSObject.getMember()`, JSObject.getSlot(), `JSObject.toString()`, LiveConnect, `netscape.javascript.JSObject, null`

JavaScript version (Standard)

The version history for JavaScript.

JavaScript was initially developed by Netscape Communications and was originally called LiveScript 1.0. Around that time, the Java language was becoming more popular and possibly as a marketing ploy, the name of LiveScript was changed to JavaScript. It was first available to the public in version 2.0 of Netscape.

Version	ECMA	Notes
LiveScript 1.0	No	The original precursor to JavaScript
JavaScript 1.0	No	Netscape 2.0 implemented this. Now mostly obsolete.
JavaScript 1.1	Yes	Supported in Netscape 3.0 and Netscape Enterprise Server 2.0. Also supported in Opera 3.0. More robust and better support for arrays. Image replacement and access to plugin properties. Scroll control.
JavaScript 1.2	No	Netscape 4.0 to 4.05 added `RegExp`, `switch` and `delete`. `Screen` object and interval timer. `Window move` & `resize`. Object and array literals added.
JavaScript 1.3	Yes	Version 4.06 to 4.76 of Netscape adds better exception handling. Also supported by Netscape Enterprise Server 3.
JavaScript 1.4	Yes	Netscape version 5.0 (not widely released).
JavaScript 1.5	Yes	Netscape 6.0 (final beta stages at time of writing).

javascript: URL (Request method)

Execute some JavaScript code instead of fetching a document.

When you specify a URL in a web browser, the intent is usually to fetch a document from a remote web server.

The `javascript`: URL method is used to execute a fragment of JavaScript code when the URL is requested.

You can use the `javascript` URL as follows:

- To call up the debugger console
- To interactively execute statements
- As document source
- As bookmarks

The view-source: URL can be used in Netscape to call up a source view of a document under script control. Its not very portable and not much use for anything other than debugging.

These are all described in separate topics.

You can call up the JavaScript debugger by setting a document location to "`javascript`:", "`livescript`:" or "`mocha`:".

Looking at the internals of the Netscape browser, this debugging console is itself written in HTML with JavaScript dynamic actions.

Mostly, these special URLs will be useful for debugging –getting details of the disk cache may be useful for example. Pulling up the JavaScript debugger page if you detect an error in your script might also be a cool trick.

With a `javascript:` URL, you can also type the code directly into the location bar of your Netscape browser to see the results of evaluating it right away.

As of JavaScript version 1.1, you can use the void operator to discard the result of an expression.

This `javascript:` URL form is vailable in the WebTV set top boxes effective from the Summer 2000 release. However, it cannot be typed in manually by the user as it can be in the desktop computer based web browsers.

Warnings:

- This technique does not work with MSIE 3.0.
- The JavaScript debugger is not present in MSIE at all, although it may be possible to use the Visual J++ debugging tools if you have them installed.
- Almost too late for inclusion was a report that `History.back()` calls that worked in JScript 5.1 started to fail on upgrade to JScript 5.5 service pack 1. In the end it turned out to be related to calling a `javascript:` URL within an `<A HREF="...">` context. In earlier versions of MSIE, you could omit the single and double quotes around the URL. Version 5.5 is no longer forgiving that omission. This may affect other kinds of URL values and other HTML tag attributes in an MSIE 5.5 browser.

Example code:

```
<HTML>
<HEAD>
<SCRIPT>
function test()
{
alert("Test function called");
}
</SCRIPT>
</HEAD>
<BODY>
<DIV onClick="javascript:test();">Click on me</DIV>
</BODY>
</HTML>
```

JellyScript (Definition)

The JavaScript interpreter inside a WebTV set-top box is referred to as JellyScript.

This interpreter is based on the normal web browser JavaScript with a few limitations and some additional functionality. The interpreter functionality is mainly limited due to the small amount of memory available in the set-top box. Low memory is important to keep the manufacturing costs as small as possible.

The JellyScript interpreter underwent an upgrade in late Spring 2000 and was released for public use during the Summer. It is generally referred to as the Summer 2000 release.

Versions prior to Summer 2000 did not care about case-sensitivity of built-in property and method names. This was also the case with MSIE 3.0

The Summer 2000 version introduces support for user-defined properties and such like. This means that DHTML effects created by authoring tools such as DreamWeaver should work better in WebTV boxes that are shipped after this date or are upgraded in the field.

Event handling support is improved in the latest release. Earlier versions had problems with event handlers that had not yet completed their execution after 10 seconds. The WebTV documentation still suggests that the `Window.onunload` event handler is not used.

The `javascript:` URL format can be used with the minor limitation that it cannot be typed manually by the user.

Anonymous functions are properly supported by the WebTV set-top box from the Summer 2000 release onwards. Earlier versions of this product only partially supported anonymous functions.

Referring to page element objects by their names is more flexible. Versions of WebTV prior to the Summer 2000 release required that the references were fully qualified. This is still recommended but the JellyScript interpreter is now more forgiving, along the lines of the JScript interpreter in the MSIE browser. Some care still needs to be taken when building web pages for use in cross browser situations.

Security was enhanced in the Summer 2000 release. This is now correctly implemented inline with the rules of access to window content from different domains.

The `screen` property was added to the `Window` object and contains a reference to the `Screen` object that describes the size and attributes of the TV display screen.

The `Window.open()` method will behave differently in JellyScript when compared with the behavior in a normal computer-based web browser. It creates a pseudo window in an IFRAME and appends it to the end of the current display. The user can then scroll down to this window. On the whole this behavior is so different to the normal `Window.open()` usage that it is probably best to avoid using it.

The Summer 2000 release of JellyScript now supports full double-precision math routines. Date object support is now up to ECMA standard specifications with full support for all properties and methods. The identity (`===`) and non identity (`!==`) operators are also now supported (consistent with the support in the MSIE browser).

There are some areas of functionality that are considered weak or are completely unsupported on this platform:

- `Window.open()`
- Regular Expression support
- Signed scripts
- Custom sort ordering
- Array sizes limited to 32768 elements
- Error handling is silent

Be careful when accessing form elements within a document. In fact you should generally fully qualify all references to objects within the page. This is mandatory with form elements, which should have the `document` object referred to as the first item in the hierarchy chain that describes the element's location in the DOM.

You should also be careful when testing for browser types in the user agent string. Eliminate the possibility of the browser being a WebTV box before testing for the Netscape browser. If you don't, then it is likely you will test `true` for being a Netscape browser even when executing the JavaScript code on a WebTV box. You will need to scan the entire user agent string. To parse out the string "WebTV" it might be worth converting to lowercase first to increase your chances of a match.

http://developer.webtv.net/authoring/javascript/javascript.htm

.js (File extension)

JavaScript include file.

You can include external shared fragments of JavaScript into a web page by calling in a `.js` file.

A `.js` file simply contains that JavaScript which would have been placed inside a `<SCRIPT>` tag.

In the case of the Netscape browser, it can store configuration and preferences data in `.js` files.

These `.js` files can also be used server-side with Netscape Enterprise Server. They can be compiled with the LiveWire JavaScript compiler and linked with the HTML to create `.web` files that Netscape Enterprise Server can deliver very quickly to a requesting client browser.

The MIME type for a `.js` file used to be `application/x-javascript` but is now `text/javascript`. Either should work but `text/javascript` is preferred. This may necessitate you carrying out some server configuration changes if you don't already serve this kind of file.

The file is included by specifying its URL with the `SRC="..."` HTML tag attribute. You must also include a closing `</SCRIPT>` tag because `<SCRIPT>` is a block level item.

Example code:

```
<SCRIPT SRC="http://www.mydomain.com/include.js"></SCRIPT>
```

.jsc (File extension)

JavaScript configuration file.

See also: netscape.lck, Preferences

JScript version (Standard)

The version history for JScript.

Microsoft added scripting capabilities to version 3.0 of the MSIE browser. The JScript interpreter is perhaps named differently so that detractors would not accuse Microsoft of modifying the JavaScript language.

Version 1.0 of JScript was also available in Internet Information Server as well as the MSIE version 3.0 browser. That first version of JScript is broadly compatible with JavaScript version 1.0 although there are differences between them:

Interpreter	ECMA	Notes
JScript 1.0	No	Equivalent to JavaScript 1.0 and released with MSIE 3.0
JScript 1.1	No	Never released
JScript 1.2	No	Evidence of its existence but status unknown
JScript 2.0	No	Released with IIS 1.0
JScript 3.0	Yes	Equivalent to JavaScript 1.2 and released with MSIE 4.0, IIS 4.0 and WSH 1.0 (some features are in MSIE 3.02)
JScript 4.0	Yes	Released with Visual Studio 6.0
JScript 5.0	Yes	Equivalent to JavaScript 1.5 and supported on all 32 bit Windows operatings systems with MSIE.
JScript 5.1	Yes	Released with IIS 5.0 on Windows 2000
JScript 5.5	Yes	Released with MSIE 5.5

The JScript support in MSIE is excellent. However, if you limit yourself purely to the JavaScript sub-set, there are some limitations in the support. The language has been extended somewhat but not in the same way as Netscape Communications Inc provided enhancements to their interpreter.

If the JScript interpreter is reinstalled without upgrading the browser, you may be using a version of JScript that is later than the browser. Scripts should work normally as long they do not exploit features of Jscript that have changed. However, the scripts may not be able to access some new features of the later version. For example, JScript 5.5 can be installed over the top of JScript 5.0 in a version 5.0 MSIE browser. You get the later core language features but continue to use the old document model. This can get utterly confusing for script developers.

JSObject object (Java class)

A Java class that encapsulates JavaScript objects for access from Java code.

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	*myJSObject* = netscape.javascript.JSObject
Class methods:	getWindow()	
Object methods:	call(), eval(), getMember(), getSlot(), removeMember(), setMember(), setSlot(), toString()	

This Java class is otherwise known as `netscape.javascript.JSObject` (to give it its full name within the Java context). This provides a way for Java code to interact fully with the JavaScript native environment.

`JSObject` is a sub-class of the generic `Object` class within Java. Its public interface defines the following methods and properties:

- `getWindow()`
- `getMember()`
- `getSlot()`
- `setMember()`
- `setSlot()`
- `removeMember()`
- `call()`
- `eval()`
- `toString()`

Note that these are hooks to Java methods although they may look like JavaScript methods.

When member properties and slot values are accessed from arrays, you get an `Object` object returned. If this object is really a JavaObject, then it will be unwrapped and the encapsulated Java object will be returned without its JavaScript wrapper. It will still be returned as an `Object` object but it can then be cast to a native Java object type rather than another JSObject.

The `setMember()` and `setSlot()` methods perform the converse although there are some subtle limitations.

Your Java development environment should give you plenty of help with the compilation of applets. The key point is that you have a copy of the `netscape.javascript.JSObject` class available for the applet to be linked against. This may involve setting your CLASSPATH to defined where the Java classes are located. The file you need may be browser version specific. In Netscape Navigator version 4.0, the file is called `java40.jar` but it may be named differently in other versions. Where it is located also may depend on how and where you installed Netscape.

See also:	Java calling JavaScript, Java to JavaScript values, JavaScript embedded in Java, JavaScript to Java values, `JSObject.call()`, `JSObject.eval()`, `JSObject.getMember()`, `JSObject.getSlot()`,`JSObject.getWindow()`, `JSObject.removeMember()`, `JSObject.setMember()`, `JSObject.setSlot()`, `JSObject.toString()`, LiveConnect, MAYSCRIPT, `netscape.javascript.JSObject`

Method	JavaScript	JScript	N	IE	Opera	Notes
`call()`	1.1 +	-	3.0 +	-	-	-
`eval()`	1.1 +	-	3.0 +	-	-	-
`getMember()`	1.1 +	-	3.0 +	-	-	-
`getSlot()`	1.1 +	-	3.0 +	-	-	-
`removeMember()`	1.1 +	-	3.0 +	-	-	-
`setMember()`	1.1 +	-	3.0 +	-	-	-
`setSlot()`	1.1 +	-	3.0 +	-	-	-
`toString()`	1.1 +	-	3.0 +	-	-	-

O'Reilly *JavaScript Definitive Guide* –page 8-570

Wrox *Professional JavaScript* –page 544

JSObject.call() (Java method)

Calls a method in the JavaScript object from the Java environment.

Availability:	JavaScript –1.1 Netscape –3.0
Property/method value type:	`Object object`

Java syntax:	*myJSObject*.call("*aMethod*", *anArgArray*)	
Argument list:	*aMethod*	The name of a method to call.
	anArgArray	An array of arguments to pass to the method

This is the way in which a Java applet can call back to a JavaScript function in a page. Once you know the window, you can invoke methods that belong to it as well as access properties. This will always yield an `Object` object as a result.

There are quite restricted Java to JavaScript limitations on passing non-primitive values in the arguments array.

The values passed to JavaScript will conform to the following conversions as they are passed to the JSObject methods:

Java	JavaScript
java.lang.Boolean	JavaObject object
java.lang.Double	JavaObject object
java.lang.Integer	JavaObject object
java.lang.String	JavaObject object
netscape.javascript.JSObject	generic JavaScript object
all other Java objects	JavaObject object

The return values will conform to the following conversions as they are passed between the environments:

JavaScript	Java
boolean primitive	java.lang.Boolean
number primitive	java.lang.Double
string primitive	java.lang.String
JavaObject object	The encapsulated Java object unwrapped
all other JavaScript objects	netscape.javascript.JSObject

The result of this method call will be an `Object` object which needs to be cast to some other value for use in the Java environment.

See also:	Call, Java to JavaScript values, JavaScript to Java values, `JSObject` object, `JSObject`.eval(), LiveConnect

Cross-references:

Wrox *Professional JavaScript* –page 542-3

JSObject.eval() (Java method)

A means of invoking native JavaScript `eval()` functionality.

Availability:	JavaScript –1.1 Netscape –3.0	
Java syntax:	*myJSObject*`.eval("`*someScript*`")`	
Argument list:	*someScript*	Some valid JavaScript source

This is a much simpler way to execute JavaScript than by the `call()` method. Here there is no need to construct an array to pass in the method arguments.

The return values will conform to the following conversions as they are passed between the environments:

JavaScript	Java
boolean primitive	java.lang.Boolean
number primitive	java.lang.Double
string primitive	java.lang.String
JavaObject object	The encapsulated Java object unwrapped
all other JavaScript objects	netscape.javascript.JSObject

The `JSObject.eval()` method eliminates many of the parameter passing problems associated with the `JSObject.call()` method as far as type conversion is concerned. You will need to convert any parameters you want to pass into strings, but this does allow you to pass primitive values which you simply cannot do with the `JSObject.call()` method.

See also:	Eval code, eval(), JavaScript to Java values, JSObject object, JSObject.call(), LiveConnect

JSObject.getMember() (Java method)

Returns the value of a named property of the object belonging to a JavaScript object to a calling in the Java environment.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Object object`	
Java syntax:	*myJSObject*`.getMember("`*aMemberName*`")`	
Argument list:	*aMemberName*	The name of a property belonging to the JSObject

As you read properties of JSObjects, you get more JSObjects returned. In this way, you can walk the document hierarchy to locate any item in the window referred to by the root JSObject.

The return values will conform to the following conversions as they are passed between the environments:

JavaScript	Java
boolean primitive	java.lang.Boolean
number primitive	java.lang.Double
string primitive	java.lang.String
JavaObject object	The encapsulated Java object unwrapped
all other JavaScript objects	netscape.javascript.JSObject

The result of this method call will be an `Object` object which needs to be cast to some other value for use in the Java environment.

See also:	JavaScript to Java values, `JSObject` object, LiveConnect

JSObject.getSlot() (Java method)

A means of accessing elements within an array encapsulated in a JSObject.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`Object object`	
Java syntax:	*`myJSObject`*`.getSlot(`*`anIndex`*`)`	
Argument list:	*`anIndex`*	The array index equivalent to [*`anIndex`*]

This is a means of accessing array elements in JavaScript arrays when they are encapsulated inside a JSObject.

The return values will conform to the following conversions as they are passed between the environments:

JavaScript	Java
boolean primitive	java.lang.Boolean
number primitive	java.lang.Double
string primitive	java.lang.String
JavaObject object	The encapsulated Java object unwrapped
all other JavaScript objects	netscape.javascript.JSObject

The result of this method call will be the element of the array at the slot location returned as an `Object` object which needs to be cast to some other value.

See also:	JavaScript to Java values, `JSObject` object, LiveConnect

JSObject.getWindow() (Java static method)

A static method to return a new JSObject that belongs to the window containing the applet.

Availability:	JavaScript –1.1 Netscape –3.0	
Property/method value type:	`JSObject object`	
JavaScript syntax:	N	`new JSObject(`*`anApplet`*`)`
Java syntax:	*`myJSObject`*`.getWindow(`*`anApplet`*`)`	
Argument list:	*`anApplet`*	The applet whose window is to be referenced by the new JSObject

When called from a Java applet, this method returns a new JSObject for the window containing the applet.

This is a way of creating a JSObject that relates to the correct window, that is, the one containing the applet. This factory method is called because there is no constructor for the JSObject class. It creates a JSObject appropriate for the applet whose reference is passed in its only parameter.

Example code:

```
// Create a JSObject for the applet we are running in
JSObject myJSObject = JSObject.getWindow(this);
```

See also:	`JSObject` object, LiveConnect

JSObject.removeMember() (Java method)

Remove a property from a JavaScript object.

Availability:	JavaScript –1.1 Netscape –3.0
Java syntax:	*`myJSObject`*`.removeMember()`

This is equivalent to the delete property mechanism in JavaScript.

See also:	delete, `JSObject` object, LiveConnect

JSObject.setMember() (Java method)

Stores a new value in a property.

Availability:	JavaScript –1.1 Netscape –3.0	
Java syntax:	`myJSObject.setMember("aName", "aValue")`	
Argument list:	*aName*	The name of the property to be changed
	aValue	The new value to be stored in the property

This method allows the Java code to set a property of a JSObject to a new value There is a minor limitation in that you must pass a Java object and cannot set a primitive value.

The values passed to JavaScript will conform to the following conversions as they are passed to the JSObject methods:

Java	JavaScript
java.lang.Boolean	JavaObject object
java.lang.Double	JavaObject object
java.lang.Integer	JavaObject object
java.lang.String	JavaObject object
netscape.javascript.JSObject	generic JavaScript object
all other Java objects	JavaObject object

See also:	Java to JavaScript values, `JSObject` object, LiveConnect

JSObject.setSlot() (Java method)

Store an element in the JavaScript array.

Availability:	JavaScript –1.1 Netscape –3.0	
Java syntax:	`myJSObject.setSlot(anIndex, "aValue")`	
Argument list:	*anIndex*	The array index equivalent to [*anIndex*].
	aValue	The new value to be stored in the array element

This method allows the Java code to set an element of a JavaScript array stored in a `JSObject`. There is a minor limitation in that you must pass a Java object and cannot set a primitive value.

The values passed to JavaScript will conform to the following conversions as they are passed to the JSObject methods:

Java	JavaScript
java.lang.Boolean	JavaObject object
java.lang.Double	JavaObject object
java.lang.Integer	JavaObject object
java.lang.String	JavaObject object
netscape.javascript.JSObject	generic JavaScript object
all other Java objects	JavaObject object

See also:	Java to JavaScript values, JSObject object, LiveConnect

JSObject.toString() (Java method)

Converts the object to a string value.

Availability:	JavaScript –1.1 Netscape –3.0
Java syntax:	`myJSObject.toString()`

The string equivalent value of the object is returned as a Java String.

See also:	JavaScript to Java values, `JSObject` object, LiveConnect, `ToString`, Type conversion

JSS (Definition)

A standard for describing style sheets in Netscape 4.0.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	JavaScript Style Sheets

JSSClasses object (Object/JSS)

A collection of JavaScript Style Sheet classes.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSClasses* = *myDocument*.classes
Object properties:	className	

This style sheet control mechanism is becoming deprecated as it is only supported on Netscape 4.0 and will not be ratified by a W3C standard. It is not recommended that you use these facilities in new projects.

This object is somewhat like an array in that it contains a collection of objects that can be accessed associatively by name. However, unlike an array, it does not respond to the length property request. Also unlike an array, you cannot access its members using index values.

The only meaningful property of this object is one of its array elements corresponding to a named class in the style sheet. That property is also associated with a named CLASS="..." attribute of an HTML tag in the document.

You cannot enumerate this object to inspect its properties.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Document.classes[]

Property	JavaScript	JScript	N	IE	Opera	Notes
className	1.2 +	-	4.0 +	-	-	WarningDeprecated

Property attributes:

DontEnum.

JSSClasses.className (Property)

A JSS object corresponding to a single style class.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`JSSTags object`	
JavaScript syntax:	N	*myDocument*.classes.*aClassName*
Argument list:	*aClassName*	A named class within the style sheet

This object represents a class within the style sheet. However it is only available in Netscape 4.0 and is a means of access that leads ultimately to a `Style` object.

This mechanism is radically different to and much more complex than the simple `style` property belonging to an `Element` object in MSIE and Netscape 6.0.

From the value in this property, you would traverse the style tree down another level to find a style collection relating to a particular tag.

You cannot enumerate this object to inspect its properties.

This was mainly provided to give access to a style definition in Netscape 4.0 as opposed to the way it is used in MSIE and Netscape 6.0, where it is used to apply a style definition to a styled element within the document.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

JSSTag object (Object/JSS)

A single style object for use in Netscape 4.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSTag* = *myDocument*.classes.*aClassName*.*aTagName*
	N	*myJSSTag* = *myDocument*.contextual(...)
	N	*myJSSTag* = *myDocument*.ids.*anElementName*
	N	*myJSSTag* = *myDocument*.tags.*aTagName*
	N	*myJSSTag* = *myJSSTags*.*aTagName*

Argument list:	*aClassName*	A named class within the style sheet
	anElementName	The value of a NAME="..." or ID="..." tag attribute.
	aTagName	The name of an HTML tag
Object properties:	align, apply, background, backgroundColor, backgroundImage, bgColor, borderBottomWidth, borderColor, borderLeftWidth, borderRightWidth, borderStyle, borderTopWidth, clear, clip, color, display, fontFamily, fontSize, fontStyle, fontWeight, height, left, lineHeight, listStyleType, marginBottom, marginLeft, marginRight, marginTop, paddingBottom, paddingLeft, paddingRight, paddingTop, textAlign, textDecoration, textIndent, textTransform, top, verticalAlign, visibility, whiteSpace, width, zIndex	
Object methods:	borderWidths(), margins(), paddings(), rgb()	

This is the Netscape 4.0 JSS equivalent of the DOM style object. You assign values to the properties of this object to define the styles according to the JSS rules. Browsers sometimes use different object types with incompatible properties and methods to represent the same thing. We cover them as distinctly different objects where it seems sensible. The Netscape 4.0 style settings are properties of a JSSTag object. Refer to the style object for details of the MSIE and Netscape 6.0 style control properties.

The property values for this object each represent a style attribute of an HTML tag.

To define a style setting with JSS, assign a value to this property according to the class name and tag name hierarchy.

These values are write-only and must be defined in the <HEAD> of the document. You cannot read them back or change them after the <BODY> has commenced loading.

You cannot enumerate the properties of this object so it is impossible to inspect them. Indeed, after repeated attempts to access them, they appear to be write-only properties.

Because you can only define them during the <HEAD> of a document, they don't provide much helpful facilities as regards dynamic style control.

It is highly recommended that you refrain from using these JSS facilities in any new projects. They are deprecated now that Netscape 6.0 adopts a more standardized DOM based approach to style settings.

The CSS support in Netscape 4.0 is available up to CSS level 1. In MSIE and Netscape 6.0, much of CSS level 2 is available through its more sophisticated and easier to manage style model.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

Property attributes:

DontEnum.

JSSTag.align (Property)

Specified the alignment of objects.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myJSSTag*.align
	N	*myJSSTag*.align = *aValue*
CSS syntax:	float	
HTML syntax:	<... ALIGN="...">	
Argument list:	*aValue*	An alignment value

The `JSSTag.align` property does not correspond to any CSS property as there is not a specific `align` property in CSS even though some HTML 4.0 tags do.

It is based on values that are specified with HTML `ALIGN="..."` tag attributes.

The alignment of the styled object with respect to its containing parent object is defined in this property. The folllowing expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

JSSTag.apply (Property)

A special JSS supporting property that holds a reference to a callback function.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Function object`	
JavaScript syntax:	N	*`myTags.anItem.apply = aHandler`*
Argument list:	*`aHandler`*	A JavaScript function to call when setting the object's style
	`anItem`	A tag name such as P or B or H1

This is a mechanism that allows the style engine in Netscape 4.0 to call for help when things get too complicated. Basically it calls the handler when an object is created and that handler sets the properties of the receiving object. There is an implied `this` on the front of any property names that are assigned with new values.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0

See also:	JavaScript Style Sheets

JSSTag.backgroundColor (Property)

The background color for objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated
Property/method value type:	`String primitive`
JavaScript syntax:	N *myJSSTag*.backgroundColor N *myJSSTag*.backgroundColor = "transparent" N *myJSSTag*.backgroundColor = *aColor*
CSS syntax:	background-color: *aColor*background-color: transparent
HTML syntax:	<BODY BGCOLOR="...">
Argument list:	*aColor* color value specified as #numeric or color name

The `JSSTag.backgroundColor` property corresponds to the `background-color` CSS property.

This property controls the background color of the element.

The value should be a color specified using the normal numeric or symbolic name notation.

In addition, the value "`transparent`" can be specified to allow the background to be "see-through".

The default value is "`transparent`".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	`style.backgroundColor`

JSSTag.backgroundImage (Property)

The URL of a background image for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.backgroundImage
	N	*myJSSTag*.backgroundImage = "none"
	N	*myJSSTag*.backgroundImage = *aURL*
CSS syntax:	background-image: *aURL*	
HTML syntax:	<BODY BACKGROUND="...">	
Argument list:	*aURL*	A URL that points at an image

The JSSTag.backgroundImage property corresponds to the background-image CSS property.

This property is used to specify the URL of an image file to be loaded and used as the background. Alternatively the value "none" can be specified to deactivate the image background.

The default value for this property is "none".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Background.src, style.backgroundImage

JSSTag.borderBottomWidth (Property)

The thickness of the bottom edge of border round objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.borderBottomWidth`
	N	*myJSSTag*`.borderBottomWidth = `*aWidth*
CSS syntax:	`border-bottom-width: `*aWidth*	
HTML syntax:	`<... MARGINHEIGHT="...">`	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.borderBottomWidth` property corresponds to the `border-bottom-width` CSS property.

The content of an object is enclosed in a bounding extent rectangle. Around this is placed a padding space controlled by the padding parameters. The padding expands the bounding. Then the border is placed around this. The border width increases the bounding rectangle around the object still further. Last of all the margin is placed around the outside. This forms a rectangle that is used to locate the object adjacent to any other objects or page margins.

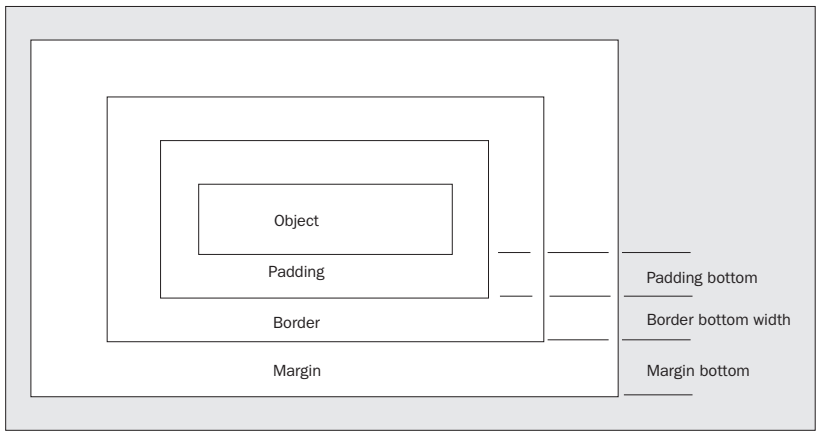
The value of this property can be specified as follows:

- thin
- medium
- thick

It can also be specified with a length value in one of several units of measure.

The initial value is set to "medium".

This value is not inherited from its parent container element.



Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.borderColor (Property)

The color of the border around objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.borderColor
	N	*myJSSTag*.borderColor = *aColor*
CSS syntax:	border-color: *aColor*	
HTML syntax:	<... BORDERCOLOR="...">	
Argument list:	*aColor*	color value specified as #numeric or color name

The JSSTag.borderColor property corresponds to the border-color CSS property.

This property controls the color of all four borders of the object. The value is a color specified in the normal numeric or symbolically named fashion.

The initial value is taken from the color property of the element around which the border is placed.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.borderColor

JSSTag.borderLeftWidth (Property)

The thickness of the left edge of the border around objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.borderLeftWidth
	N	*myJSSTag*.borderLeftWidth = *aWidth*
CSS syntax:	border-left-width: *aWidth*	
HTML syntax:	<... MARGINWIDTH="...">	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.borderLeftWidth` property corresponds to the `border-left-width` CSS property.

Refer to the `JSSTag.borderBottomWidth` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.borderRightWidth (Property)

The thickness of the right edge of the border around objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.borderRightWidth
	N	*myJSSTag*.borderRightWidth = *aWidth*
CSS syntax:	border-right-width: *aWidth*	

HTML syntax:	<... MARGINWIDTH="...">	
Argument list:	*aWidth*	A CSS length value

The JSSTag.borderRightWidth property corresponds to the border-right-width CSS property.

Refer to the JSSTag.borderBottomWidth topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.borderStyle (Property)

The type of line used for the border around objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myJSSTag*.borderStyle
	N	*myJSSTag*.borderStyle = *aStyle*
CSS syntax:	border-style: *aStyle*	
Argument list:	*aStyle*	A border style value

The JSSTag.borderStyle property corresponds to the border-style CSS property.

The following style values can be applied to borders with this property:

- none
- hidden
- dotted
- dashed
- solid
- double
- groove
- ridge

- inset
- outset

The initial value for this property is "none".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.borderStyle

JSSTag.borderTopWidth (Property)

The thickness of the top edge of the border around objects.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.borderTopWidth
	N	*myJSSTag*.borderTopWidth = *aWidth*
CSS syntax:	border-top-width: *aWidth*	
HTML syntax:	<... MARGINHEIGHT="...">	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.borderTopWidth` property corresponds to the `border-top-width` CSS property.

Refer to the `JSSTag.borderBottomWidth` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.borderWidths() (Method)

Sets all of the border width values for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSTag*.borderWidths(*aTop*, *aHoriz*, *aBottom*)
	N	*myJSSTag*.borderWidths(*aTop*, *aRight*, *aBottom*, *aLeft*)
	N	*myJSSTag*.borderWidths(*aValue*)
	N	*myJSSTag*.borderWidths(*aVert*, *aHoriz*)
CSS syntax:	border-width: *aTop*, *aHoriz*, *aBottom*border-width: *aTop*, *aRight*, *aBottom*, *aLeft*border-width: *aValue*border-width: *aVert*, *aHoriz*border: *aValue*	
HTML syntax:	<... BORDER="...">	
Argument list:	*aBottom*	A border width applied at the bottom
	aHoriz	A border width applied left and right
	aLeft	A border width applied to the left
	aRight	A border width applied to the right
	aTop	A border width applied at the top
	aValue	A border width value applied all round
	aVert	A border width applied top and bottom
Event handlers:	This controls the border attribute of an image objects	

This method provides a way to set all four border width values at once. The number of arguments is variable and the values are applied in different ways according to how many are supplied.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.borderWidth

Event name	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
This controls the border attribute of an image object.	1.2 +	-	4.0 +	-	-	-	-	-	1 +	-	Warning, Deprecated

JSSTag.clear (Property)

A property that clears the style and forces the object to be displayed below a left or right aligned image.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.clear
	N	*myJSSTag*.clear = *aControl*
CSS syntax:	clear: *aControl*	
HTML syntax:	<... CLEAR="...">	
Argument list:	*aControl*	a clear control value

The `JSSTag.clear` property corresponds to the `clear` CSS property.

This property is used to control the floating elements around the element to which the styling applies. Clearing the float attribute to one side or the other forces a line break on that side and will not allow floating elements to flow into an adjacent position.

The following values are permitted:

- none
- left
- right
- both

The default value for this property is "none".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.clear

JSSTag.color (Property)

A foreground color for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape Navigator version –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.color`
	N	*myJSSTag*`.color = `*aColor*
CSS syntax:	`color: aColor`	
HTML syntax:	`<... COLOR="...">`	
Argument list:	*aColor*	color value specified as #numeric or color name

The `JSSTag.color` property corresponds to the color CSS property.

This property controls the foreground color of text in the element.

The value should be a color specified using the normal numeric or symbolic name notation.

The default value depends on the settings in the user preferences of the user agent (the browser).

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	color names, color value, `style.color`

JSSTag.display (Property)

Controls the display visibility of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.display`
	N	*myJSSTag*`.display = `*aControl*
CSS syntax:	`display: `*aControl*	
Argument list:	*aControl*	a display control value

The `JSSTag.display` property corresponds to the `display` CSS property.

This property controls the way that a styled element is displayed on-screen. It can cause the element to appear as a block item, something that is inline, a list or other possibilities. The following values are accepted:

- inline
- block
- list-item
- run-in
- compact
- marker
- table
- inline-table
- table-row-group
- table-header-group
- table-footer-group
- table-row
- table-column-group
- table-column
- table-cell
- table-caption
- none

Elements having the display property set to "block" will be forced to start on a new line.

The "inline" value keeps items running together on the same line.

Setting the display property to "none" will completely hide an item.

The other property values are quite complex and beyond the scope of our coverage here and are documented thoroughly in other works that specifically cover the CSS presentation styling standard. In any case, the whole JSS style complex is deprecated and will likely fall into disuse.

The default value for this property is "inline".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	`style.display`

JSSTag.fontFamily (Property)

The font family or typeface name for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.fontFamily
	N	*myJSSTag*.fontFamily = *aFontList*
CSS syntax:	font-family: *aFontList*	
HTML syntax:	<FONT FACE="...">	
Argument list:	*aFontList*	A list of one or more font names

The `JSSTag.fontFamily` property corresponds to the `font-family` CSS property in a style sheet. It allows you to select a font for use in the object within the document.

Some example values of specific font families are listed below:

- Arial
- Courier
- Times
- Garamond
- Palatino
- Helvetica
- "New Century Schoolbook"

Font names containing spaces will need to be enclosed in quotes.

These are generic family names and allow the browser to choose its own best matching font:

- serif
- sans-serif
- monospace
- cursive
- fantasy

You should provide your list of fonts as a comma separated list with the most preferred fonts to the left.

The default value for this property depends on the browser font settings in the user preferences.

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.fontFamily

JSSTag.fontSize (Property)

The font size for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.fontSize
	N	*myJSSTag*.fontSize = *aSizeValue*
CSS syntax:	font-size: *aSizeValue*	
HTML syntax:	<FONT SIZE="...">	
Argument list:	*aSizeValue*	A size value as described

The JSSTag.fontSize property corresponds to the font-size CSS property. It controls the size of the text as it appears on the screen.

This is notoriously unportable and text always looks smaller on a Macintosh than it does on a Windows system. This is because the native screen resolution of a Macintosh is 72 dpi and a Windows system is 96 dpi.

You can specify the size in a variety of ways. There are four classifications for the font size value:

- Length
- Percentage
- Absolute size
- Relative size

The length value can be specified in units of measure as follows:

Points –e.g. 12pt

Millimetres –e.g. 0.4mm

Pixels –e.g. 16px

The percentage value is computed relative to the enclosing object's corresponding property (hence the cascading effect of style sheets). A percentage value is indicated with an integer followed by a percent sign, for example 120%.

The absolute size is based on the browser knowing the screen display resolution and computing some preferred font sizes. It is specified using the following keywords:

- xx-small
- x-small
- small
- medium
- large
- x-large
- xx-large

Note that some of the smaller sizes render so small on a Macintosh as to be unreadable.

The relative sizing is controlled by the two keywords:

- larger
- smaller

You can use a combination of absolute and relative sizing or any combination of sizes as this property is cascaded down through the styles.

The default value for this property is "medium".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	`Measurement` units, style.fontSize

JSSTag.fontStyle (Property)

The font attributes for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.fontStyle
	N	*myJSSTag*.fontStyle = *aStyle*
CSS syntax:	font-style: *aStyle*	
Argument list:	*aStyle*	A font presentation style

The `JSSTag.fontStyle` property corresponds to the CSS `font-style` property.

You can choose a value from these available styles:

- normal
- italic
- oblique

For some fonts, the italic and oblique fonts are simply slanted versions of the normal upright fonts. This can lead to some unattractive artefacts and so the italic form is sometimes specially designed and uses a markedly different glyph. It is intended to improve readability of italic characters.

The default value for this property is "normal".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.fontStyle

JSSTag.fontWeight (Property)

The weight of a font for an object. This is otherwise known as the boldness.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myJSSTag*.fontWeight
	N	*myJSSTag*.fontWeight = *aWeight*
CSS syntax:	font-weight: *aWeight*	
HTML syntax:	<FONT WEIGHT="...">	
Argument list:	*aWeight*	A font weight control value

The JSSTag.fontWeight property corresponds to the font-weight CSS property.

This property controls the weight of the characters on the screen. this is sometimes called boldness although it provides a much finer level of control than simply using a bold tag. The following numerical values select a progressive weight increase:

- 100
- 200
- 300

- 400
- 500
- 600
- 700
- 800
- 900

These keywords select a pair of reasonably similar settings across platforms:

- normal
- bold

The normal setting is equivalent to 400 and the bold setting matches 700.

In addition there are two relative boldness controls:

- bolder
- lighter

Not all font families support as wide a range of possible weights as the `fontWeight` property can control. Nevertheless, the browser makes its best efforts to deliver the requested appearance.

The default value for this property is "normal".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units, `style.fontWeight`

JSSTag.height (Property)

The height of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.height`
	N	*myJSSTag*`.height = `*aHeight*
CSS syntax:	`height: `*aHeight*	

HTML syntax:	`<... HEIGHT="...">`	
Argument list:	*aHeight*	An object height value
Event handlers:	This controls the height of an image object on screen for example.	

The `JSSTag.height` property corresponds to the `height` CSS property.

This property can be used to control the height of an object on the screen. The value can be specified as a length measured in units, a percentage of the containing block the element is located in or an "auto" value that lets the browser compute the size.

The default value for this property is "auto".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	`JSSTag.width, style.height`

JSSTag.lineHeight (Property)

The line height spacing for an object. This is the distance between the baselines of two adjacent lines of text.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.lineHeight`
	N	*myJSSTag*`.lineHeight =` *aLineHeight*
CSS syntax:	`line-height:` *aLineHeight*	
Argument list:	*aLineHeight*	A spacing between lines of text

The `JSSTag.lineHeight` property corresponds to the `line-height` CSS property.

This value specifies the distance between the baselines for adjacent lines; more accurately, it indicates the minimum distance, because an object larger than the line height value will cause lines to be leaded further apart to accommodate the item within the display.

The following values are meaningful in this property:

- A numeric line height measured in points
- A value in pixels
- A distance in mm
- A percentage of the parent line height value

The default value for this depends on the user preference settings for font sizes.

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units, `style.lineHeight`

JSSTag.listStyleType (Property)

A list style bullet selector for the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.listStyleType`
	N	*myJSSTag*`.listStyleType = `*aStyle*
CSS syntax:	`list-style-type: `*aStyle*	
HTML syntax:	`<... TYPE="...">`	
Argument list:	*aStyle*	A list style control

The `JSSTag.listStyleType` property corresponds to the `list-style-type` CSS property.

This is used to control the appearance of lists of items. It can have the following values:

- disc
- circle
- square
- decimal
- decimal-leading-zero

- lower-roman
- upper-roman
- lower-alpha
- lower-latin
- upper-alpha
- upper-latin
- lower-greek
- hebrew
- armenian
- georgian
- cjk-ideographic
- hiragana
- katakana
- hiragana-iroha
- katakane-iroha
- none

The value "none" suppresses labels on the list.

There are various graphic symbols.

You can also number the list items using different documentation conventions (numbers, roman numerals, letters etc).

There is also support for international character fonts and localization requirements.

The default value for this property is "disc".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4 and is completely removed from Netscape 6.0.

See also:	style.listStyleType

JSSTag.marginBottom (Property)

The margin at the bottom of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.marginBottom
	N	*myJSSTag*.marginBottom = *aWidth*
CSS syntax:	margin-bottom: *aWidth*	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.marginBottom` property corresponds to the `margin-bottom` CSS property.

The content of an object is enclosed in a bounding extent rectangle. Around this is placed a padding space controlled by the padding parameters, which expands the bounding –the border is then placed around this. The border width increases the bounding rectangle around the object still further. Last of all the margin is placed around the outside. This forms a rectangle that is used to locate the object adjacent to any other objects or page margins.

The value of this property can be specified as follows:

- A length value in one of several units of measure
- A percentage of the width of the object

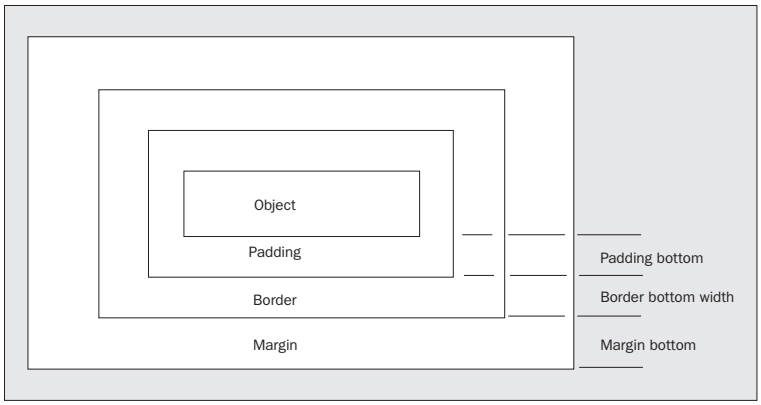
In addition a keyword can be used:

- auto

The auto setting need not be applied to all of the margins, but according to how it is used, some fairly complex margin computation is applied. You should consult one of the standard texts on CSS styles.

The initial value is set to 0 allowing for no margin value at all.

This value is not inherited from its parent container element.



Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.marginLeft (Property)

The margin at the left of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.marginLeft
	N	*myJSSTag*.marginLeft = *aWidth*
CSS syntax:	margin-left: *aWidth*	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.marginLeft` property corresponds to the `margin-left` CSS property.

Refer to the `JSSTag.marginBottom` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.marginRight (Property)

The margin at the right of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.marginRight
	N	*myJSSTag*.marginRight = *aWidth*

CSS syntax:	`margin-right: aWidth`	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.marginRight` property corresponds to the `margin-right` CSS property.

Refer to the `JSSTag.marginBottom` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.margins() (Method)

Set all margin values for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSTag*.margins(*aTop*, *aHoriz*, *aBottom*)
	N	*myJSSTag*.margins(*aTop*, *aRight*, *aBottom*, *aLeft*)
	N	*myJSSTag*.margins(*aValue*)
	N	*myJSSTag*.margins(*aVert*, *aHoriz*)
CSS syntax:	margin: *aTop*, *aHoriz*, *aBottom*margin: *aTop*, *aRight*, *aBottom*, *aLeft*margin: *aValue*margin: *aVert*, *aHoriz*	
Argument list:	*aBottom*	A margin applied at the bottom
	aHoriz	A margin applied left and right
	aLeft	A margin applied to the left
	aRight	A margin applied to the right
	aTop	A margin applied at the top
	aValue	A margin value applied all round
	aVert	A margin applied top and bottom

This method provides a way to set all four margin values at once. The number of arguments is variable and the values are applied in different ways according to how many are supplied.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	JavaScript Style Sheets, style.margin

JSSTag.marginTop (Property)

The margin at the top of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.marginTop`
	N	*myJSSTag*`.marginTop = `*aWidth*
CSS syntax:	`margin-top: `*aWidth*	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.marginTop` property corresponds to the `margin-top` CSS property.

Refer to the `JSSTag.marginBottom` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.paddingBottom (Property)

The padding at the bottom of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.paddingBottom`
	N	*myJSSTag*`.paddingBottom = `*aWidth*
CSS syntax:	`padding-bottom: `*aWidth*	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.paddingBottom` property corresponds to the `padding-bottom` CSS property.

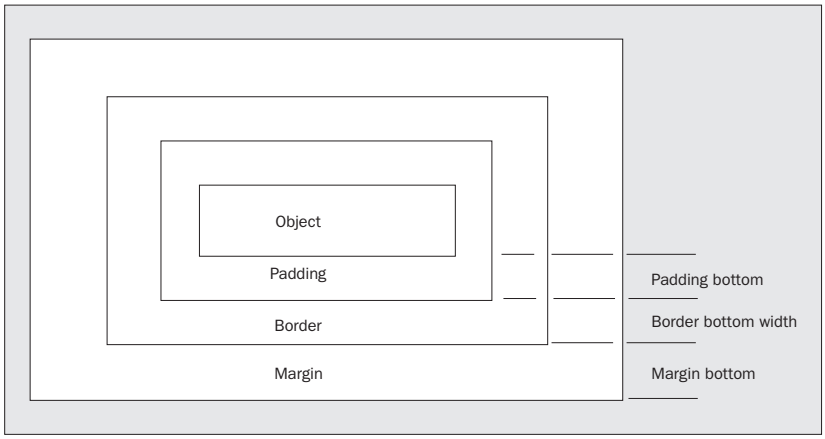
The content of an object is enclosed in a bounding extent rectangle. Around this is placed a padding space controlled by the padding parameters. The padding expands the bounding. Then the border is placed around this. The border width increases the bounding rectangle around the object still further. Last of all the margin is placed around the outside. This forms a rectangle that is used to locate the object adjacent to any other objects or page margins.

The value of this property can be specified as follows:

- A length value in one of several units of measure
- A percentage of the width of the object

The initial value is set to 0 allowing for no padding value at all.

This value is not inherited from its parent container element.



Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.paddingLeft (Property)

The padding at the left of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive Deprecated`	
JavaScript syntax:	N	*myJSSTag*.paddingLeft
	N	*myJSSTag*.paddingLeft = *aWidth*

CSS syntax:	`padding-left: aWidth`	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.paddingLeft` property corresponds to the `padding-left` CSS property.

Refer to the `JSSTag.paddingBottom` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.paddingRight (Property)

The padding at the right of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.paddingRight
	N	*myJSSTag*.paddingRight = *aWidth*
CSS syntax:	`padding-right: aWidth`	
Argument list:	*aWidth*	A CSS length value

The *JSSTag.paddingRight* property corresponds to the *padding-right* CSS property.

Refer to the *JSSTag.paddingBottom* topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.paddings() (Method)

Set all padding values for an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSTag*.paddings(*aTop*, *aHoriz*, *aBottom*)
	N	*myJSSTag*.paddings(*aTop*, *aRight*, *aBottom*, *aLeft*)
	N	*myJSSTag*.paddings(*aValue*)
	N	*myJSSTag*.paddings(*aVert*, *aHoriz*)
CSS syntax:	padding: *aTop*, *aHoriz*, *aBottom*padding: *aTop*, *aRight*, *aBottom*, *aLeftpadding*: *aValuepadding*: *aVert*, *aHoriz*	
Argument list:	*aBottom*	A padding applied at the bottom
	aHoriz	A padding applied left and right
	aLeft	A padding applied to the left
	aRight	A padding applied to the right
	aTop	A padding applied at the top
	aValue	A padding value applied all round
	aVert	A padding applied top and bottom

This method provides a way to set all four padding values at once. The number of arguments is variable and the values are applied in different ways according to how many are supplied.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.padding

JSSTag.paddingTop (Property)

The padding at the top of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myJSSTag*.paddingTop
	N	*myJSSTag*.paddingTop = *aWidth*
CSS syntax:	padding-top: *aWidth*	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.paddingTop` property corresponds to the `padding-top` CSS property.

Refer to the `JSSTag.paddingBottom` topic for details.

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units

JSSTag.rgb() (Method)

A JSS style control method.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myTags*`.`*anItem*`.rgb(`*aRed*`, `*aGreen*`, `*aBlue*`)`
Argument list:	*aBlue*	Blue intensity value
	aGreen	Green intensity value
	anItem	A tag name such as P or B or H1
	aRed	Red intensity value

The `rgb()` method provides a convenient way to define an RGB triplet in a single call.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

Example code:

```
// Some red texttags.P.rgb(255, 0, 0);
```

Cross-references:

Wrox *Instant JavaScript* –page 50

JSSTag.textAlign (Property)

The text alignment within the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.textAlign
	N	*myJSSTag*.textAlign = *anAlignment*
CSS syntax:	text-align: *anAlignment*	
HTML syntax:	<... ALIGN="...">	
Argument list:	*anAlignment*	A text alignment control

The `JSSTag.textAlign` property corresponds to the `text-align` CSS property.

This property controls the justification of text between the left and right margins. The following values are supported:

- left
- right
- center
- justify

IN addition a string can be used to indicate a character to use for decimal alignment. This need not be a dot but can be other characters to present a neatly laid out tabular column.

The default value for this property depends on the user preference settings in the user agent.

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.textAlign

JSSTag.textDecoration (Property)

The text decoration (underline, overline etc) for text in the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.textDecoration
	N	*myJSSTag*.textDecoration = *aDecoration*
CSS syntax:	text-decoration: *aDecoration*	
Argument list:	*aDecoration*	A list of decorations for some text

The `JSSTag.textDecoration` property corresponds to the `text-decoration` CSS property.

This controls the decoration of the text on screen with additional overprinting or dynamics.

The following values are permitted:

- underline
- overline
- line-through
- blink

Beware when you use the underline attribute, people may think that it is a hyperlink. Also avoid using the blink decoration unless you really need to. It can become very annoying for the user unless it is used with taste and discretion.

The default value for this property is "none".

This value is not inherited from its parent container element although the attributes of the parent will persist.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.textDecoration

JSSTag.textIndent (Property)

The indentation of text in the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.textIndent
	N	*myJSSTag*.textIndent = *anIndent*
CSS syntax:	text-indent: *anIndent*	
Argument list:	*anIndent*	A value to indent the first line of text

The *JSSTag.textIndent* property corresponds to the *text-indent* CSS property.

This value is used to indent the first line of text in the styled element.

The value is numeric but can be specified in several ways:

- Absolute (10)
- Relative (-5)
- Percentage of paragraph width (10%)

The default value for this property is 0, meaning no indent at all.

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	Measurement units, style.textIndent

JSSTag.textTransform (Property)

The transformation of text in the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated
Property/method value type:	`String primitive`

JavaScript syntax:	N	*myJSSTag*.textTransform
	N	*myJSSTag*.textTransform = *aTransformation*
CSS syntax:	text-transform: *aTransformation*	
Argument list:	*aTransformation*	A character glyph transform

The JSSTag.textTransform property corresponds to the text-transform CSS property.

This property provides a means to change the glyphs that are used without affecting the underlying source text. The following values are permitted:

- capitalize
- uppercase
- lowercase
- none

The default value is "none".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.textTransform

JSSTag.verticalAlign (Property)

Control over the vertical alignment of the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myJSSTag*.verticalAlign
	N	*myJSSTag*.verticalAlign = *anAlignment*
CSS syntax:	vertical-align: *anAlignment*	
HTML syntax:	<... VALIGN="...">	
Argument list:	*anAlignment*	A vertical alignment control

The `JSSTag.verticalAlign` property corresponds to the `vertical-align` CSS property.

This property controls the vertical alignment of an element. It provides a way to raise or lower individual letters to create subscript or superscript effects. The technique can be used to move images relative to a line of text.

The following values are meaningful for this property:

- baseline
- sub
- super
- top
- text-top
- middle
- bottom
- text-bottom

In addition you can specify a percentage value and a length value in various units of measure.

The default value for this property is "baseline".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	style.`verticalAlign`

JSSTag.whiteSpace (Property)

The control of white space collapsing or retention in the object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*.whiteSpace
	N	*myJSSTag*.whiteSpace = *aControl*
CSS syntax:	white-space: *aControl*	
Argument list:	*aControl*	A whitespace preservation control

The `JSSTag.whiteSpace` property corresponds to the `white-space` CSS property.

This property controls how tabs, newline characters and additional whitespace inside an element is presented. The following values are available:

- normal
- pre
- nowrap

The default value for this property is "normal".

This value is inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

See also:	`style.whiteSpace`

JSSTag.width (Property)

This is the width of an object.

Availability:	CSS level –1 JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myJSSTag*`.width`
	N	*myJSSTag*`.width = `*aWidth*
CSS syntax:	`width: `*aWidth*	
HTML syntax:	`<... WIDTH="...">`	
Argument list:	*aWidth*	A CSS length value

The `JSSTag.width` property corresponds to the `width` CSS property.

This property can be used to control the width of an object on the screen. The value can be specified as a length measured in units, a percentage of the containing block the element is located in or an "auto" value that lets the browser compute the size.

The default value for this property is "auto".

This value is not inherited from its parent container element.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

JSSTags object (Object/JSS)

Part of the Netscape Navigator style JSS rendering support.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myJSSTags* = *myDocument*.classes.*aClassName*
	N	*myJSSTags* = *myDocument*.ids.*anIdValue*
Argument list:	*aClassName*	The name of a style class
	anIdValue	The value of an ID="..." HTML tag attribute
Object properties:	<tagName>	

This object is somewhat like an array in that it contains a collection of objects that can be accessed associatively by name. However, unlike an array, it does not respond to the length property request. Also unlike an array, you cannot access its members using index values.

The only meaningful property of this object is one of its array elements corresponding to an HTML tag name. There is one item in this collection for each HTML tag.

This is part of the deprecated JSS support in Netscape 4.0. It is not recommended that you use these facilities in new projects.

You cannot enumerate this object to inspect its properties.

The `document.tags` object has properties that correspond to each of the stylable tags –for example, there is a `document.tags.P`, `document.tags.B` and `document.tags.H1` object.

Each of those objects has properties such as `borderWidth` and `color` so you can set or get the property value.

Note that the `tags` object properties can be specified in mixed case as it is case-insensitive. Its properties contain objects that correspond to HTML tags and therefore they also have case-insensitive properties that correspond to each tag's attributes.

Its an interesting way to control style from JavaScript, but since it was only ever supported in Netscape 4.0 and is no longer available in Netscape 6.0 (which fully supports CSS), there is no future for JSS.

Warnings:

- This is sometimes called `tags` object but if you inspect the object with some script that reveals its constructor, you will see it is really a member of the `JSSTags` class.
- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
`<tagName>`	1.2 +	-	4.0 +	-	-	-	-	-	-	-	Warning, Deprecated

Property attributes:

DontEnum.

JSSTags.<tagName> (Property)

A JSS object corresponding to a single HTML tag.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`JSSTag object`	
JavaScript syntax:	N	*myDocument*`.classes.`*aClassName*`.`*aTagName*
Argument list:	*aClassName*	The name of a style class
	aTagName	The name of an HTML tag

This object represents an HTML tag. However it is only available in Netscape 4.0 and is a means of access that ultimately leads to a `Style` object.

You can refer to a specific HTML tag name or you can use the value "all" to indicate that all HTML tags of any kind with the appropriate CLASS name will be affected.

This mechanism is radically different to and much more complex than the simple style property belonging to an `Element` object in MSIE.

From the value in this property, you would traverse the style tree down another level to find a style object with properties that directly affect the appearance of the document.

Warnings:

- Deprecated for any further use. This was available only in Netscape 4.0 and is completely removed from Netscape 6.0.

Jump statement (Definition)

Unconditionally jump to a new location in the script.

A jump statement is one, which forces the flow of execution to jump unconditionally to another location in the script.

Jump statements in JavaScript are used to terminate iteration statements.

A function call causes execution to go unconditionally to a new location (the beginning of the function's script source text block –its body) but a function call is not strictly a jump statement because the flow of control returns eventually to the line following the function call.

A return statement is considered to be a jump statement.

See also:	`break, continue, goto, return,` Statement

KBD object (Object/HTML)

An object representing content to be displayed as if typed on the keyboard.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myKBD* = *myDocument*.all.*anElementID*
	IE	*myKBD* = *myDocument*.all.tags("KBD")[*anIndex*]
	IE	*myKBD* = *myDocument*.all[*aName*]
	-	*myKBD* = *myDocument*.getElementById(*anElementID*)
	-	*myKBD* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myKBD* = *myDocument*.getElementsByTagName("KBD")[*anIndex*]
