HTML syntax:	`<KBD> ... </KBD>`	
Argument list:	*anElementID*	The `ID` attribute of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

The appearance of the content described by this object is likely to look similar to that enclosed in `<CODE>`, `<LISTING>` or `<PRE>` tags.

See also:	`Element` object, `LISTING` object, `PRE` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	1.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

Keyboard events (Definition)

Some events within the event-handling complex of a browser are related to keyboard handling.

The following events relate to keyboard handling:

- `onKeyDown`
- `onKeyUp`
- `onKeyPress`

These events are classified as keyboard events because they are generated as a result of user interactions with the keyboard.

Note that the `onKeyPress` event is triggered as a result of a matching pair of `onKeyDown` and `onKeyUp` events. You should not rely on the events arriving in any particular order, although `onKeyPress` probably arrives before `onKeyUp`.

For example, as a key is pressed, an `onKeyDown` event is fired. As it is released, an `onKeyUp` event and an `onKeyPress` event are fired. An `onKeyPress` is only fired once for each `onKeyDown` and `onKeyUp` pair.

In Netscape, you can capture keyboard events by calling the `captureEvents()` method like this:

```
window.captureEvents(Event.KEYPRESS);
```

This need not necessarily apply to the window; the area of interest can be more limited by selecting an appropriate object.

Example code:

```
<!-- Event programming example supplied by Alex.Abacus -->
<SCRIPT LANGUAGE="JavaScript1.2">

// Object sensing routine
var isNN4up = (window.Event)? true : false;

// Key press handler designed for cross platform use
function key_press_event_handler(e)
{
   if (isNN4up)
   {
      var whichKey = e.which;
   }
   else
   {
      var whichKey = window.event.keyCode;
   }
   var realKey = String.fromCharCode(whichKey);
   window.status = 'You pressed ' + realKey +
   ' (Key code: ' + whichKey + ')'
}

// Register event handler for NNav
if (isNN4up)
{
   document.captureEvents(Event.KEYPRESS);
}

// Register event handler for MSIE
document.onkeypress = key_press_event_handler;
</SCRIPT>
```

Keyword (Definition)

The keywords that ECMAScript defines should be avoided when you create your own identifier or variable names.

A keyword is a word that has special significance in the JavaScript language. It follows the rules that ECMA lays down for describing identifiers. All of the JavaScript keywords are reserved and define the language syntax. You must not use any of them as identifier names for variables, properties, methods and functions that you define.

ECMAScript reserves a set of keywords for future use. These are intended to make provision for future language features and to give developers warning that they should avoid using these keywords in order that their scripts should continue to operate when the language is revised.

Other special names are defined by JavaScript to identify properties of the `Global` object and constructor functions of the built-in data types. You should avoid these too, unless you are intentionally overriding their functionality with your own.

Here is a list of keywords that ECMA edition 2 mandates a compliant implementation should support:

- `break`
- `continue`
- `delete`
- `else`
- `for`
- `function`
- `if`
- `in`
- `new`
- `return`
- `this`
- `typeof`
- `var`
- `void`
- `while`
- `with`

In addition, these are constants that should also be avoided:

- `true`
- `false`
- `null`

The third edition of the ECMA standard adds these keywords which in the earlier edition were reserved for future use:

- `case`
- `catch`
- `default`
- `do`
- `finally`
- `instanceof`
- `switch`
- `throw`
- `try`

The remaining reserved keywords as of edition 3 are:

- `abstract`
- `boolean`
- `byte`
- `char`
- `class`
- `const`
- `debugger`
- `double`
- `enum`
- `export`
- `extends`
- `final`
- `float`
- `goto`
- `implements`
- `import`
- `int`
- `interface`
- `long`
- `native`
- `package`
- `private`
- `protected`
- `public`
- `short`
- `static`
- `super`
- `synchronized`
- `throws`
- `transient`
- `volatile`

However, you should note that Netscape anticipates a future standard and supports these already:

- `export`
- `import`

The JavaScript 2.0 project defines these which should also be avoided and which will likely be added to a later edition of the ECMAScript standard:

- `namespace`
- `use`

Many implementations of JavaScript will introduce additional keywords. Some will provide functional behavior for the reserved keywords. To remain ECMAScript compliant, the reserved words specified in edition 3 must be supported sufficiently to prevent parsing errors, but need not provide any meaningful functionality.

You can code defensively to avoid any future problems. Using an underscore character or digit in your identifier names should improve the chances of your script continuing to operate properly in later versions of the language. Using upper case may help, but is less of a guarantee of safety. In particular, you should be very careful to avoid the names of properties and methods belonging to the `Global` object.

Label (Definition)

An identifier marking a section of code.

Availability:	ECMAScript edition –3

In JavaScript version 1.2, the `case` and `default` labels were added, which introduced as a by-product the fact that any fragment of code can be labelled with an identifier.

The identifier can be any legal JavaScript identifier that does not match a reserved keyword.

The namespace that labels exist in, is separate to that of variables and function names. This means you can use the same identifier names over again, although it's probably good practice not to.

Adding a label in front of an iterator allows you to associate a label name with a `break` or `continue` statement. This means that you can break or continue nested iterators from deep inside them. This can greatly simplify the logic of a looping system.

If the `goto` keyword is ever implemented, it would depend on this labelling mechanism being extended to provide a useful destination.

Example code:

```
// An example break to a labelled line
outerLoop:
for (var i=0; i <= max; i++)
{
   for (var j=0; j <= max2; j++)
   {
      if (i== someNum && j ==someNum2)
      {
         break outerLoop;
      }
    }
}
```

ECMA 262 edition 3 –section –12.12

Label object (Object/HTML)

Adds a legend label to an input object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	Element object	
JavaScript syntax:	IE	*myLabel* = *myDocument*.all.*anElementID*
	IE	*myLabel* = *myDocument*.all.tags("LABEL")[*anIndex*]
	IE	*myLabel* = *myDocument*.all[*aName*]
	-	*myLabel* = *myDocument*.getElementById(*anElementID*)
	-	*myLabel* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myLabel* = *myDocument*.getElementsByTagName("LABEL")[*anIndex*]
HTML syntax:	<LABEL> ... </LABEL>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, dataFld, dataFormatAs, dataSrc, form, htmlFor, tabIndex	
Object methods:	blur(), click()	
Event handlers:	onBlur, onClick, onDblClick, onDragStart, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

MSIE supports this object type with a LABEL object, and because we often don't need to know the specific class of an object, this does not cause us any significant problems with labels. But the inconsistent object class names across browsers may need to be standardized in a more reliable way in the future.

Inheritance chain:

`Element` object, `Node` object

Label.htmlFor (Property)

A means of associating the label with an `Input` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLabel*`.htmlFor`

The value of this property should correspond with the `ID="..."` HTML tag attribute for the `<INPUT>` tag that instantiates the `Input` object the label belongs to.

LANG="..." (HTML Tag Attribute)

A tag attribute that specifies the international language of some content.

This tag attribute allows the current national language to be overridden on a tag by tag basis if necessary. There are many values for international languages.

Refer to the Language codes topic for a list of language code values.

See also:	`Element.lang`, Language codes

Language codes (Definition)

Language codes are used to define locale specific handling.

The `Element.lang` property controls the locale specific text rendering. It allows special characters to be handled appropriately and special character sets to be supported properly according to the national language variants.

Here is a partial list of some example language codes to be used with it:

Code	Language	Country

The language codes are derived from the ISO 639 language standard and the ISO 3166 country codes standard. A language code is an ISO 639 value followed by an underscore and the ISO 3166 value.

The language code is typically presented in lower case while the country code is in upper case, although this is by no means consistent across browsers and platforms.

It is therefore probably safe to assume this value is case-insensitive.

Layer object (Object/Navigator)

An object representing an HTML `<LAYER>` tag.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer* = *myDocument*.*aLayerName*
	N	*myLayer* = *myLayerArray*[*anIndex*]
HTML syntax:	`<ILAYER><LAYER>`	
Argument list:	*anIndex*	An index into the layer array
Object properties:	`above`, `background`, `below`, `bgColor`, `clip`, `document`, `hidden`, `left`, `name`, `pageX`, `pageY`, `parentLayer`, `siblingAbove`, `siblingBelow`, `src`, `top`, `visibility`, `window`, `x`, `y`, `zIndex`	
Object methods:	`load()`, `moveAbove()`, `moveBelow()`, `moveBy()`, `moveTo()`, `moveToAbsolute()`, `offset()`, `resizeBy()`, `resizeTo()`	
Functions:	`captureEvents()`, `handleEvent()`, `releaseEvents()`, `routeEvent()`	
Event handlers:	`onBlur`, `onFocus`, `onLoad`, `onMouseOut`, `onMouseOver`, `onMouseUp`	
Collections:	`layers[]`	

Each layer in Netscape is somewhat like a separate window or frame. This means it has its own document associated with it which can itself also contain layers. The individual objects cannot be positioned themselves but the layers they live in can be.

The Netscape `Layer` object has many properties that are similar to the MSIE `Style` object. However although they bear some similarities, they also have many differences. Furthermore a layer is not a style and therefore it is difficult to conveniently map one to the other and build cross-platform solutions without constructing a compatibility layer.

Note that Netscape prior to version 6.0 instantiates an absolutely positioned `<DIV>` container as a `Layer` object.

Event handling support via properties containing `function` objects was added to `Layer` objects at version 1.1 of JavaScript.

The example demonstrates how to control a scrolling panel and do it in a way that is cross browser compliant for MSIE and Netscape version 4. There are a lot of issues to deal with, not least the fact that Netscape supports layers but MSIE does not. It is necessary to use layers for scrolling in Netscape because you can only scroll windows or frames in Netscape if they have visible and active scrollbars. Also, the two browsers scroll vertically in opposing directions. If you are careful about the sizing of your objects, and relate the size of the window/frame the layer is drawn in, you can accomplish a continuous scrolling effect by duplicating items from the top of the list to the bottom. Then at an appropriate point, you can jump scroll back to the top of the list. If you do this right, it will appear as if the list is endless and scrolling gently in a continuous loop. This technique is a much simplified example taken from the Video On Demand console at http://www.bbc.co.uk/news where there is a panel showing a listing of live TV programs in a scrolling pane.

Warnings:

- If you are using layers to position items temporarily on the screen, then you should be careful when using absolute positioning. This can cause the layer to be absolutely positioned relative to the current mouse position and not the window border. The effect is that an item in the positioned layer will appear to follow the mouse as it is clicked. You may need to work out the mouse position and then calculate an offset to relocate the layer where you want it. You may be able to detect the mouse by removing focus from the layer that has the problem, or it may be necessary to create an empty layer which can be safely attached to the mouse. All of these issues are Netscape 4 specific.
- Layers are no longer supported in Netscape 6.0.

Example code:

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
// Initialize globals
var theScrollValue = 0;
var theMaxScroll = 50;
// Work out what kind of browser we are on
function getBrowserType()
{
   var myUserAgent;
   var myMajor;
   myUserAgent   = navigator.userAgent.toLowerCase();
   myMajor       = parseInt(navigator.appVersion);
   if( (myUserAgent.indexOf('mozilla')    != -1) &&
       (myUserAgent.indexOf('spoofer')    == -1) &&
       (myUserAgent.indexOf('compatible') == -1) &&
       (myUserAgent.indexOf('opera')      == -1) &&
       (myUserAgent.indexOf('webtv')      == -1)
      )
   {
      if (myMajor > 3)
      {
         return "nav4";
      }
      return "nav";
```

```
    }
    if (myUserAgent.indexOf("msie") != -1)
    {
       if (myMajor > 3)
       {
          return "ie4";
       }
       return "ie";
    }
    return "other";
}
// Start the correct scroller for this browser
function startScroller()
{
    eval(getBrowserType() + "_scrollPage()");
}
// Browser specific scroller (IE)
function ie4_scrollPage()
{
    self.scrollTo(0,theScrollValue);
    theScrollValue++;

    if(theScrollValue == theMaxScroll)
    {
       theScrollValue = 0;
    }

    setTimeout("ie4_scrollPage()", 100);
}
// Browser specific scroller (Navigator)
function nav4_scrollPage()
{
    self.document.layer1.moveTo(0,-theScrollValue);
    theScrollValue++;

    if(theScrollValue == theMaxScroll)
    {
       theScrollValue = 0;
    }
setTimeout("nav4_scrollPage()", 20);
}
</SCRIPT>
</HEAD>

Layer() (Constructor)

A means of creating new layers in Netscape.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	`new Layer()`

This constructor function should be used with the `new` operator to instantiate a new layer when needed. This provides a way to create new layers without needing to describe them in the HTML document source.

Warnings:

- No longer supported in Netscape 6.0.

Layer.above (Property)

The layer immediately above the receiving `layer` object, (or `null`, if this is the highest layer).

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Layer object`	
JavaScript syntax:	N	`myLayer.above`

Warnings:

- No longer supported in Netscape 6.0.

Property attributes:

`ReadOnly`.

Layer.background (Property)

The `background` object of a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Background object`	
JavaScript syntax:	N	*myLayer*`.background`

If a background image is available, then its URL is contained in the `src` property of the object. Changing the `Layer.background.src` property value will replace the background with a new one. However, there may be a perceptible delay while the new image is fetched from the web server.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Background` object

Layer.below (Property)

The layer immediately below the receiving `layer` object.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Layer object`	
JavaScript syntax:	N	*myLayer*`.below`

The layers area arranged into a hierarchy and presented to the user as a stack viewed from one end. Given that you are referencing any particular layer, if there is one below it in the stack, this property will yield an object that encapsulates it.

Warnings:

- There are various intermediate layers created by the browser that may be placed into the layer hierarchy without you having put `<LAYER>` tags into the document.
- No longer supported in Netscape 6.0.

Property attributes:

`ReadOnly`.

Layer.bgColor (Property)

The background color of a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myLayer*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.The color can be set using a Hexadecimal triplet, or a plain language color value. The default is a transparent background.

Warnings:

- No longer supported in Netscape 6.0.

See also:	Color names, Color value

Layer.captureEvents() (Function)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myLayer*`.captureEvents(`*anEventMask*`)`
Argument list:	*anEventMask*	A mask constructed with the manifest event constants

This is part of the event management suite which allow events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method allows you to specify what events are to be routed to the receiving `Layer` object.

The events are specified by using the bitwise OR operator (|) to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

A limitation of this technique is that ultimately, only 32 different kinds of events can be combined in this way and this may limit the number of events the browser can support. Since this is only supported by Netscape, the functionality is likely to be deprecated when the standards bodies agree on a standard way of handling events. Then we simply need to wait for the browser manufacturers to support the standardized behavior.

In the meantime, we shall have to implement scripts using this capability if we need to build complex event handling systems. A different script will be required for MSIE.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers and can call common handling routines that can be shared between MSIE and Netscape.

Warnings:

- Since a bit mask is being used, this must be an `int32` value. This suggests that there can only be 32 different Event types supported by this event propagation model.
- This capability is deprecated and is not supported in Netscape 6.0. It never was supported by MSIE which implements a completely different event model. As it turns out, the DOM level 2 event model converges on the MSIE technique.

See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event propagation, Event type constants, `Frame` object, `Layer.releaseEvents()`, `onMouseMove`, `Window` object, `Window.captureEvents()`, `Window.releaseEvents()`

Layer.clip (Property)

An object that represents the `clip` region within a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Rect object`	
JavaScript syntax:	N	*myLayer*`.clip`

This object represents a clipping rectangle that the visible part of a `display` object is viewed through. This is most likely used with a `layer` object. The layer contents would be drawn off-screen and then that part which falls within the clipping rectangle would be displayed in the window.

This can be useful for performing wipes and making parts of a layer progressively visible within some kind of transition loop.

This object exposes the following properties for accessing `Layer` clip rectangles:

- `clip.bottom`
- `clip.height`
- `clip.left`

- `clip.right`
- `clip.top`
- `clip.width`

If you are developing scripts that only run in MSIE, there is a rather nice collection of filters that can provide these transitions very elegantly. It's a pity they aren't available in other browsers. But then layers and clip rectangles aren't supported in the same way in MSIE so at least there seems to be some alternative approach to creating visual effects on each platform.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip` object, `Rect` object

Layer.clip.bottom (Property)

The bottom edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.bottom`
	N	*myRect*`.bottom`

This defines the bottom edge of the clip region. You could modify this in a loop to create a vertical downwards wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.bottom`, `Rect.bottom`

Layer.clip.height (Property)

The height of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.height`
	N	*myRect*`.height`

The clip region is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.height,Rect.height`

Layer.clip.left (Property)

The left edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.left`
	N	*myRect*`.left`

This defines the left edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.left,Rect.left`

Layer.clip.right (Property)

The right edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.right`
	N	*myRect*`.right`

This defines the right edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.right, Rect.right`

Layer.clip.top (Property)

The top edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.top`
	N	*myRect*`.top`

This defines the top edge of the clip region. You could modify this in a loop to create a vertical upward wipe transition effect.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.top, Rect.top`

Layer.clip.width (Property)

The width of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.clip.width`
	N	*myRect*`.width`

The clip region is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Clip.width`, `Rect.width`

Layer.document (Property)

The `document` object containing this layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Document object`	
JavaScript syntax:	N	*myLayer*`.document`

This is the document contained within a Netscape `layer` object. Because each layer has its own separate document, you can use the `document.open()`, `document.close()` and `document.write()` methods to operate on it.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Document` object, `Element.document`

Property attributes:

`ReadOnly`.

Layer.handleEvent() (Function)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myLayer`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`handleEvent(),Layer.routeEvent()`

Layer.hidden (Property)

A deprecated property that indicates whether a `layer` is hidden or not.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myLayer`*`.hidden`

You should not use this property in new projects. If you encounter it in existing ones, if you have the time you should remove it and use the `visibility` property instead.

Warnings:

- This property is deprecated in favor of the `Layer.visibility` property. However, even though it is deprecated some versions of Netscape require that it is forcibly set to `false` otherwise the `visibility` property will not function correctly.
- If an object is hidden, the gap will not be filled by any surrounding content.
- No longer supported in Netscape 6.0.

See also:	`Layer.visibility`

Layer.layers[] (Collection)

A deprecated property providing a list of child layers within this layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`LayerArray object`	
JavaScript syntax:	N	*myLayer*`.layers`

You should access this collection via the `document` object associated with this layer. That is the recommended technique for new projects. If you see this in an old project, then it should be removed if possible and replaced with the preferred means of access.

Warnings:

- This property is deprecated in favor of using `Layer.document.layers` in its place.
- No longer supported in Netscape 6.0.

See also:	`Document.layers[]`, `LayerArray` object

Property attributes:

`ReadOnly`.

Layer.left (Property)

The x-coordinate relative to the containing `layer`.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.left`

In Netscape this defines the left coordinate of a layer. It corresponds to the `pixelLeft` property of an MSIE `style` object.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`style.pixelLeft`, `style.posLeft`

Layer.load() (Method)

A method to load a new URL and resize a `layer`.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*`.load(`*aURL, aWidth*`)`
Argument list:	*aURL*	A document to load into the layer
	aWidth	A new width value for the layer

This is an alternative way to load a new document into a layer. You can accomplish something similar by assigning a new value to the `src` property. This method will adjust the width of the layer at the same time.

This can work very effectively if you generate dynamic content via a `javascript:` URL as the value passed to the `load()` method.

In fact this works so much better, that the `Layer.src` property can be ignored for most purposes. This seems to work well with an absolutely positioned `<DIV>` container.

Warnings:

- This doesn't work for `ILayer` elements in Netscape 4.
- No longer supported in Netscape 6.0.

See also:	`javascript:` URL, `Layer.src`

Layer.moveAbove() (Method)

Adjusts the Z ordering of a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*`.moveAbove(`*aLayer*`)`
Argument list:	*aLayer*	The `layer` object to be moved above

This method provides a way to move a layer above another layer without needing to do complex Z index computations.

Warnings:

- No longer supported in Netscape 6.0.

Layer.moveBelow() (Method)

Adjusts the Z ordering of a `layer`.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.moveBelow(*aLayer*)
Argument list:	*aLayer*	The `layer` object to be moved below

This method provides a way to move a layer behind another layer without needing to do complex Z index computations.

Warnings:

- No longer supported in Netscape 6.0.

Layer.moveBy() (Method)

Adjusts the X,Y position of a `layer`.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.moveBy(*anX, aY*)
Argument list:	*anX*	A relative distance in the X axis
	aY	A relative distance in the Y axis

This method provides a way to locate a Netscape layer to a new position relative to its old one, by specified pixel amounts along both axes. Positive values move to the right or up, and negative values to the left or down.

Warnings:

- No longer supported in Netscape 6.0.

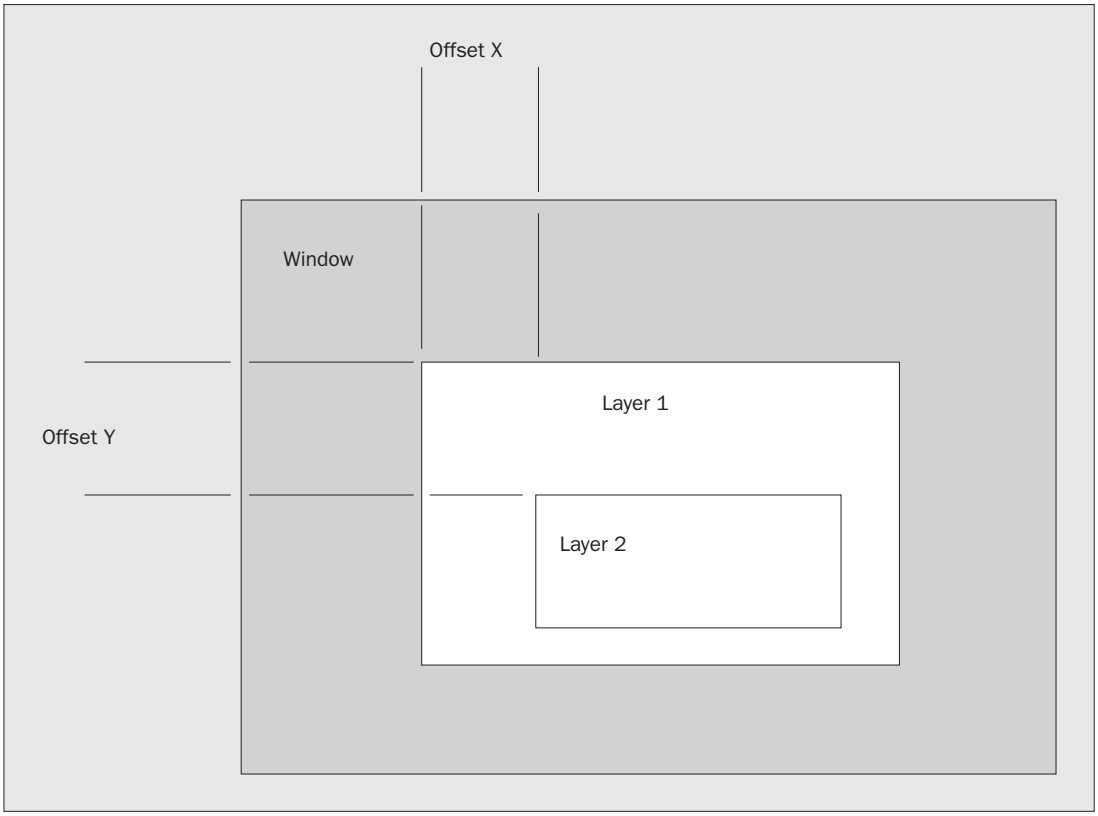
See also:	`Layer.offset()`

Layer.moveTo() (Method)

Adjust the X,Y position of a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.moveTo(*anX, aY*)
Argument list:	*anX*	An X coordinate relative to the parent element
	aY	A Y coordinate relative to the parent element

This method provides a way to locate a Netscape layer to a new absolute position relative to its containing parent object.



Warnings:

- No longer supported in Netscape 6.0.

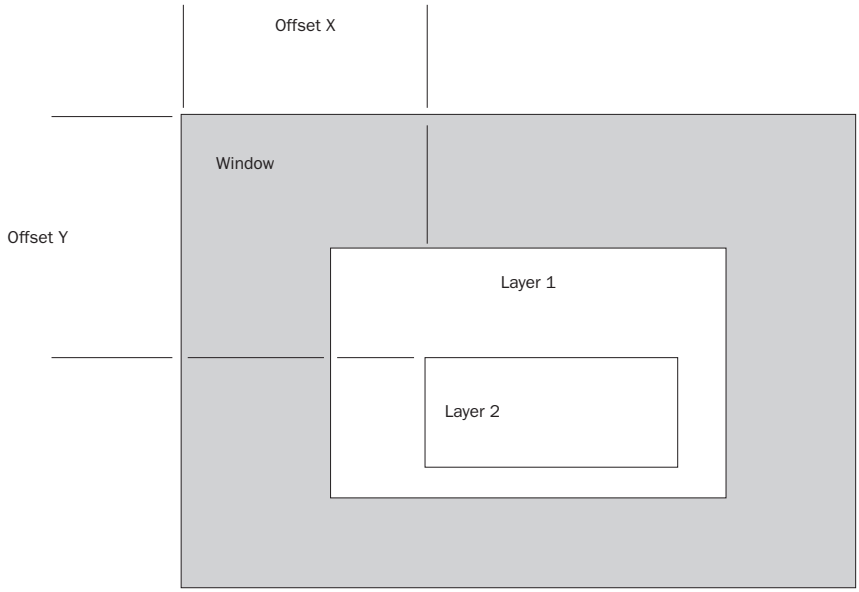
See also:	Layer.parentLayer

Layer.moveToAbsolute() (Method)

Adjust the X,Y position of a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	`myLayer.moveToAbsolute(anX, aY)`
Argument list:	`anX`	An X coordinate relative to the page
	`aY`	A Y coordinate relative to the page

This method provides a way to locate a Netscape layer to a new absolute position relative to the document window.



Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.pageX`, `Layer.pageY`

Layer.name (Property)

This corresponds to the NAME attribute of the <LAYER> tag.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myLayer*.name
HTML syntax:	<LAYER NAME="aName">	
Argument list:	*aName*	A name for the layer object

Objects are identified either by the NAME="..." HTML tag attribute or by the ID="..." HTML tag attribute.

Netscape shows a marginal preference for the name property while MSIE seems slightly better disposed towards the ID property.

W3C comes down fairly and squarely on the ID property as being the favorite.

However in many cases, both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

Warnings:

- No longer supported in Netscape 6.0.

Property attributes:

ReadOnly.

Layer.offset() (Method)

A deprecated means of moving layers.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.offset(*anX, aY*)
Argument list:	*anX*	A relative distance in the X axis
	aY	A relative distance in the Y axis

You should now use the moveBy() method to change the layer ordering. This method should be replaced when possible.

Warnings:

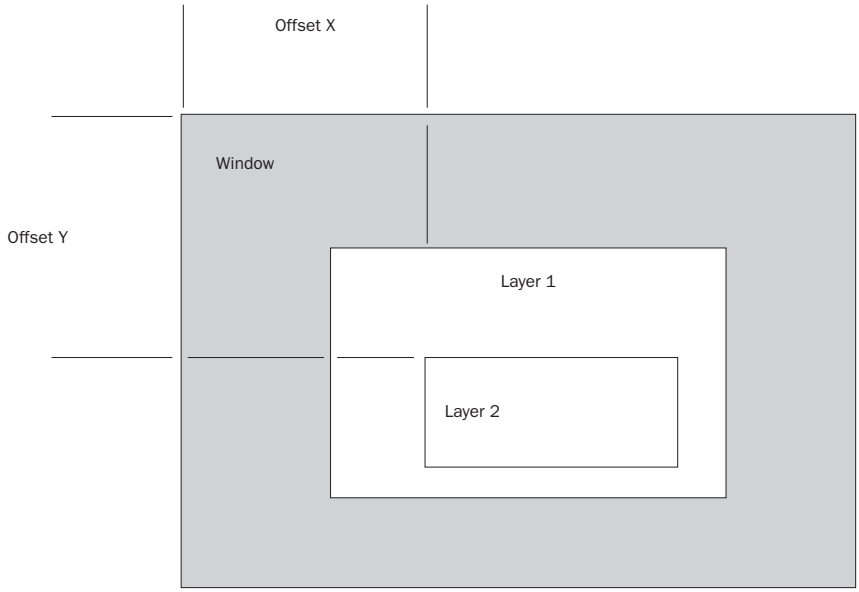
- This method is deprecated in favor of the `Layer.moveBy()` method in Netscape 4.
- No longer supported in Netscape 6.0.

See also:	`Layer.moveBy()`

Layer.pageX (Property)

The X-coordinate of the layer relative to the top level document.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.pageX`



Warnings:

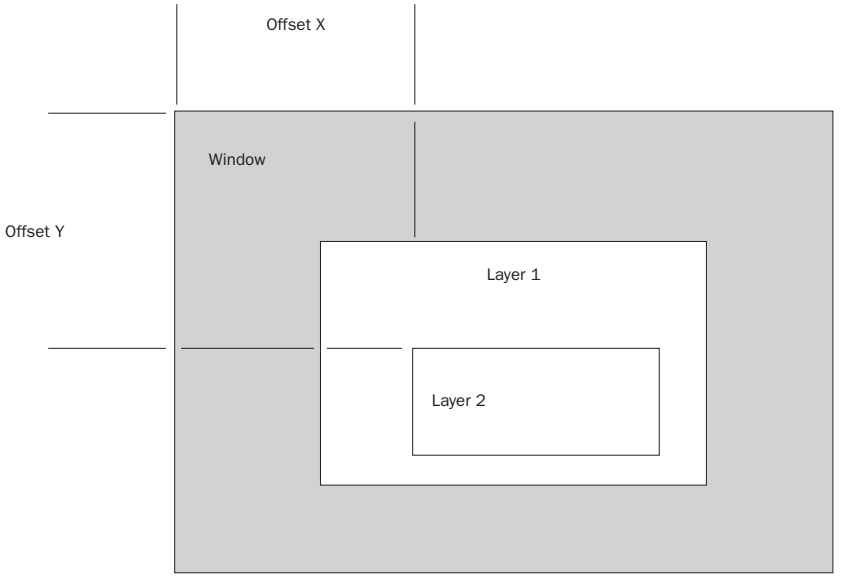
- No longer supported in Netscape 6.0.

See also:	`Layer.moveToAbsolute()`

Layer.pageY (Property)

The Y-coordinate of the layer relative to the top level document.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.pageY`



Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.moveToAbsolute()`

Layer.parentLayer (Property)

The layer containing the current layer (for a single layer, this is the `window` object).

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Layer or Window object`	
JavaScript syntax:	N	*myLayer*`.parentLayer`

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.moveTo()`

Property attributes:

`ReadOnly`.

Layer.releaseEvents() (Function)

Part of the Netscape 4 event propagation complex.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myLayer`*`.releaseEvents(`*`anEventMask`*`)`
Argument list:	*`anEventMask`*	A mask defined with the manifest event constants

This is part of the event management suite which allows events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method provides a means of indicating which events are no longer needing to be captured by the receiving `Layer` object.

The events are specified by using the bitwise OR operator (`|`) to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

Since this is only supported by Netscape, the functionality is likely to be deprecated when the standards bodies agree on a standard way of handling events. In the meantime, we shall have to implement scripts using this capability if we need to build complex event handling systems. A different script will be required for MSIE.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers, and can call common handling routines that can be shared between MSIE and Netscape.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event propagation, Event type constants, `Event.modifiers`, `Frame` object, `Layer.captureEvents()`, `onMouseMove`, `Window` object, `Window.releaseEvents()`

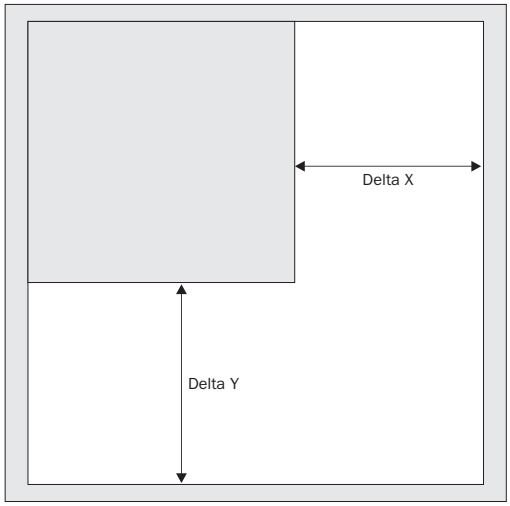
Layer.resizeBy() (Method)

Adjusts the size of a layer by a relative amount.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.resizeBy(*anX, aY*)
Argument list:	*anX*	A relative distance in the X axis
	aY	A relative distance in the Y axis

The layer can have its size adjusted by a value measured in `pixels`. This can apply to the horizontal or vertical axis or both if necessary. The value can be positive or negative causing the layer to grow or shrink respectively.

Although the size changes, the top left corner will remain pinned to its current location growing or shrinking the layer to the right and bottom of its extent.



Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.resizeTo()`

Layer.resizeTo() (Method)

Adjusts the size of a layer to an absolute value.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayer*.resizeTo(*anX, aY*)
Argument list:	*anX*	An X axis value
	aY	A Y axis value

This method provides a way to set the absolute size of a layer as opposed to the relative sizing offered by the `resizeBy()` method.

Although the size changes, the top left corner will remain pinned to its current location growing or shrinking the layer to the right and bottom of its extent.

Warnings:

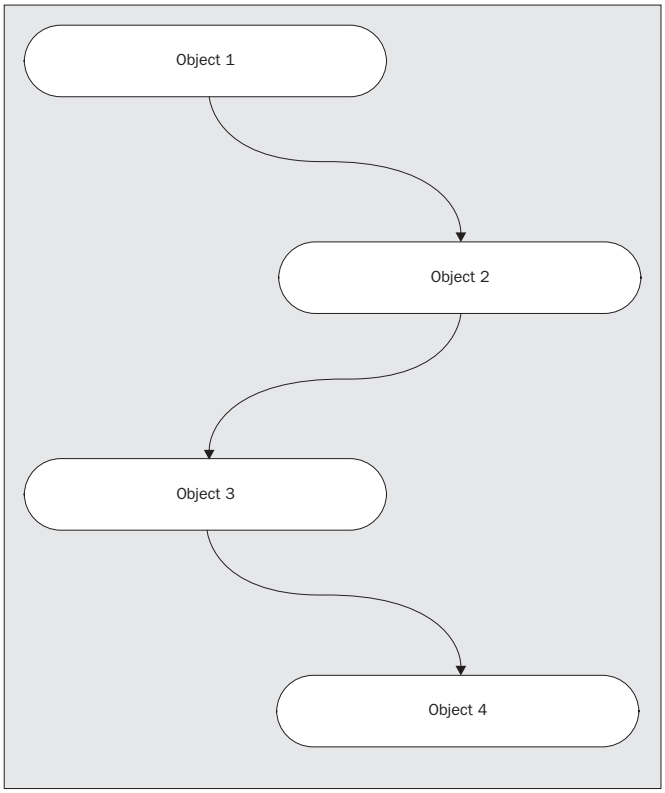
- No longer supported in Netscape 6.0.

See also:	`Layer.resizeBy()`

Layer.routeEvent() (Function)

Part of the Netscape event propagation complex.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myLayer*.routeEvent(*anEvent*)
Argument list:	*anEvent*	An `event` object



Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer.handleEvent(),Window.routeEvent()`

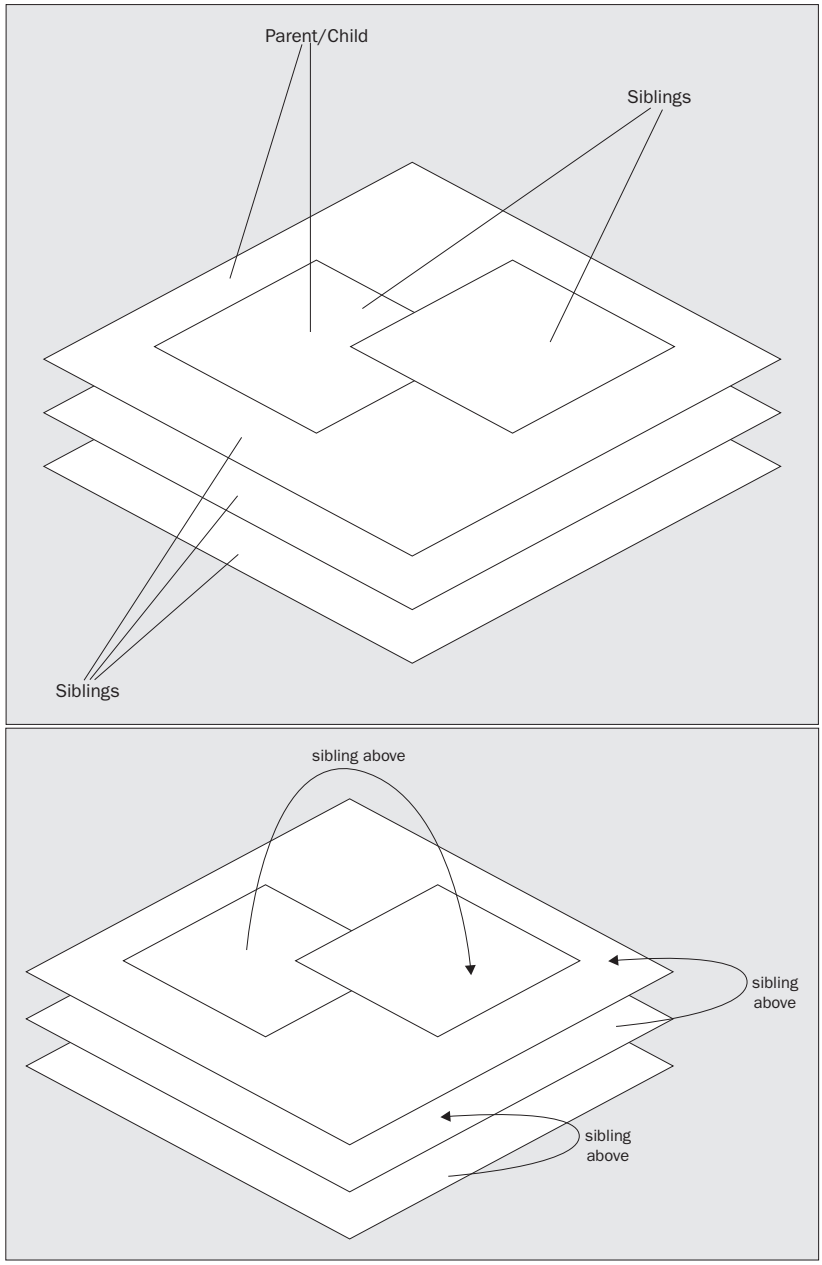
Layer.siblingAbove (Property)

A layer that is related to this layer and above it in the Z ordering.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Layer object`	
JavaScript syntax:	N	*myLayer*`.siblingAbove`

Given that a layer arrangement is yet another example of a tree structured hierarchy within a page, this property yields the next higher sibling belonging to the same parent (or `null` if this is the highest element).

Any layers sharing a common parent layer will all be present in the same `layers[]` collection. They are considered to be siblings and can be ordered with respect to one another. They are ordered collectively by their parent's relationship with its siblings and you cannot interleave siblings from different sets with one another; the set as a whole must be ordered within its parent's z-axis location.



Warnings:

- No longer supported in Netscape 6.0.

See also:	Hierarchy of objects, `Layer` object, `Layer.siblingBelow`

Property attributes:

`ReadOnly`.

Layer.siblingBelow (Property)

A layer that is related to this layer and below it in the Z ordering.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Layer object`	
JavaScript syntax:	N	*myLayer*`.siblingBelow`

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Layer` object, `Layer.siblingAbove`

Property attributes:

`ReadOnly`.

Layer.src (Property)

The source URL for a layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myLayer*`.src`

Changing this layer property value forces the browser to load a new document into the layer.

This can work very effectively if you generate dynamic content via a `javascript:` URL as the value assigned to the `src` property.

Warnings:

- If you are having problems with this, try creating an absolute positioned `<DIV>` container and then use the `Layer.load()` method instead. According to reports from other developers, that works better in Netscape 4.
- This doesn't work with `ILAYER` elements, in Netscape 4.
- No longer supported in Netscape 6.0.

See also:	`javascript: URL`, `Layer.load()`

Layer.top (Property)

The y-coordinate (in pixels) of the layer relative to its containing layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*`.top`

In Netscape this defines the top edge coordinate of a layer. It corresponds to the `pixelTop` property of an MSIE `style` object.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`style.pixelTop`, `style.posTop`

Layer.visibility (Property)

Whether a layer is visible or not.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myLayer*`.visibility`
	N	*myLayer*`.visibility = "hide"`
	N	*myLayer*`.visibility = "show"`

This controls the visibility of a Netscape layer.

It accepts the following values:

- `hide`
- `inherit`
- `show`

It also accepts these CSS syntax values (which it converts internally):

- `hidden`
- `visible`

Warnings:

- When set to `hide`, the gap won't be filled by surrounding content.
- No longer supported in Netscape 6.0.

See also:	`Layer.hidden`, `style.visibility`

Layer.window (Property)

The window that this layer belongs to.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Window object`	
JavaScript syntax:	N	*myLayer*`.window`

Warnings:

- No longer supported in Netscape 6.0.

See also:	`Frame` object, `Window` object

Layer.x (Property)

The present X position of this layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*.x

The horizontal position of the object in the display measured in `pixels`. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- No longer supported in Netscape 6.0.

Layer.y (Property)

The present Y position of this layer.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*.y

The vertical position of the object in the display measured in `pixels`. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- No longer supported in Netscape 6.0.

Layer.zIndex (Property)

The location of the layer within the Z ordered list of layers.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLayer*.zIndex

In Netscape, this is a means of ordering the layers front to back and works identically to the `zIndex` property of the MSIE `Style` object.

Warnings:

- No longer supported in Netscape 6.0.

See also:	`style.zIndex`

LayerArray object (Object/Navigator)

An array containing a list of layers in the document.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
JavaScript syntax:	N	*myLayerArray* = *myDocument*.layers
Object properties:	`length`	

Each item in this array corresponds to a `<LAYER>` tag in the document. This array also includes layers that are created in Netscape by setting the `position` attribute of an HTML `<DIV>` tag to `absolute`.

The layers in this array are ordered according to the order in which they appear in the document. Layers can be accessed associatively if they have been given an `ID` with the `ID="..."` or `NAME="..."` tag attribute. This means you can refer to an element whose `ID` is set to `ABC` by its unique name either as `document.ABC` or `document.layers["ABC"]`.

Warnings:

- There is a bug in the layer management code in Netscape. If a `<LAYER>` tag is placed into the document without an `ID="..."` or `NAME="..."` HTML tag attribute, it will increment the length count for the `LayerArray` but an object will not be placed into the array.
- Now if you try to enumerate through all the layers in the array using the `length` value, your enumeration loop will cause errors when it tries to access elements beyond the physical length of the array.
- To avoid this, you should always add `NAME="..."` HTML tag attributes to the `<LAYER>` tags to ensure the layers are stored in the array. `ID="..."` HTML tags are important and helpful when trying to access objects in MSIE and in Netscape 6.0.
- No longer supported in Netscape 6.0.

See also:	`Collection` object, `DIV` object, `Document.layers[]`, `Layer` object, `Layer.layers[]`

Property	JavaScript	JScript	N	IE	Opera	Notes
length	1.2 +	-	4.0 +	-	-	Warning, ReadOnly, Deprecated

LayerArray.length (Property)

This value reflects the number of <LAYER> tags that are in the document.

Availability:	JavaScript –1.2 Netscape –4.0 Deprecated	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myDocument*.layers.length

Warnings:

- No longer supported in Netscape 6.0.

See also:	Collection.length

Property attributes:

ReadOnly.

.lck (File extension)

Netscape configuration file (old style).

See also:	netscape.lck, Preferences

Left shift (Operator/bitwise)

A leftwards shift of a bit pattern.

Refer to:

Bitwise shift left (<<)

Left-Hand-Side expression (Definition)

Left values are the destination of an assignment.

Availability:	ECMAScript edition –2

This kind of expression identified the destination of an assignment (even if that assignment operation is only implied). Sometimes these are called LValues.

Left-hand-side expressions comprise the following:

- Variables
- Property accessors
- `new` operator
- Argument lists

See also:	Argument list, Expression, Function, `function( ... ) ...`, LValue, `new`, Property accessor

ECMA 262 edition 2 –section –11.2

ECMA 262 edition 3 –section –11.2

Legend object (Object/HTML)

The `Legend` object relates to a field-set within a form.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0 Deprecated	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myLegend* = *myDocument*.all.*anElementID*
	IE	*myLegend* = *myDocument*.all.tags("LEGEND")[*anIndex*]
	IE	*myLegend* = *myDocument*.all[*aName*]
	-	*myLegend* = *myDocument*.getElementById(*anElementID*)
	-	*myLegend* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myLegend* = *myDocument*.getElementsByTagName("LEGEND")[*anIndex*]

HTML syntax:	<LEGEND> ... </LEGEND>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, align, form, padding, tabIndex	
Event handlers:	onBlur, onChange, onClick, onDblClick, onDragStart, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onScroll, onSelectStart	

This is the legend that is associated with the field-set. It must be placed immediately inside the <FIELDSET> containing HTML tags in the document source.

Now that as CSS has become more widely available and is capable of doing the same thing, the Legend object has become deprecated.

See also:	Element object, FIELDSET object, Form object, Input object, Input.accessKey

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
accessKey	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Deprecated
align	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning, Deprecated
form	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Deprecated
padding	-	3.0 +	-	4.0 +	-	-	-	-
tabIndex	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Deprecated

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onBlur	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	Warning
onChange	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	-
onClick	1.5 +	3.0 +	6.0 +	3.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

Legend.align (Property)

The alignment of the `legend` object relative to its surrounding objects.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`mylegend`*`.align`

The alignment of the `Legend` object with respect to its containing parent object is defined in this property. The expected and widely available set of alignment specifiers are:

- `absbottom`
- `absmiddle`
- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

Warnings:

- Note that there are sometimes problems with aligning `Legend` objects using the top and bottom values in MSIE version 4.

Legend.padding (Property)

The padding around a `Legend` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`mylegend`*`.padding`

The padding around the legend separates it from the container in much the same way as cells in a table are padded apart from one another.

The value can be specified as a floating point value followed by a unit of measure indicator. These indicators are valid:

- `cm`
- `mm`
- `in`
- `pt`
- `pc`
- `px`

The `em` and `ex` relative unit of measure are also available as well as a percentage value measured against the width of the parent container.

See also:	Measurement units

length (Property)

The length, magnitude, or size of an object depending on its type.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`frames.length`
	-	`length`
	-	*`myObject`*`.length`
	-	*`myWindow`*`.frames.length`
	-	*`myWindow`*`.length`

Many objects respond to the `length` property accessor message. They don't all yield the same sort of value, although the value they yield will always be numeric.

For example, `Window` objects have a `length` property. In this case it will yield the number of frames in the window, and it is also available as a global variable called `length`.

The other objects that provide a `length` property don't reflect its value into so many alternative ways of accessing it. Apart perhaps from the `Form.length` value which is the same as the `Form.elements.length` value. This is necessary because the `Form.elements` collection is superimposed on the `Form` object so that you can access individual elements of the form as if they were direct member properties of the `Form` object. If you try to enumerate the `Form` object, you get lots of properties enumerated which are not form elements. You should therefore enumerate the `Form.elements` array.

This table lists objects which have a `length` property, and describes what it counts.

Object	Length value
`AnchorArray`	The number of named anchors in a document
`AppletArray`	The number of applets installed in a document
`Arguments`	The number of arguments presented to a function when it was called
`Array`	One greater than the highest numbered index in an array
`Attributes`	The size of the complete set of HTML tag attributes defined for an HTML `Element` object
`CharacterData`	The length in characters of a DOM character data node
`Collection`	One greater than the highest numbered index in a collection
`Date`	The number of arguments expected (always 7)
`EmbedArray`	The number of plugins installed into a document
`Filters`	The number of filters stacked up on a displayable object in MSIE

Table continued on following page

Object	Length value
Form	The number of input elements in a form
Form.elements	The number of input elements in a form
FormArray	The number of forms in a document
FormElementsArray	The number of input elements in a form
FrameArray	The number of frames in a frameset
Frames	The number of frames in a frameset, window or iframes in a document
Function	The number of arguments expected by a function
History	The length of the historical record of pages visited
ImageArray	The number of images in a document
JavaArray	The length of a Java array encapsulated by JavaScript
JavaObject	The number of MIME types supported by a plugin encapsulated in a JavaObject
LayerArray	The number of layers in a document
LinkArray	The number of HREF links in a document
MimeTypeArray	The number of discrete MIME types that the browser supports
NamedNodeMap	The number of named DOM nodes in a node map.
NodeList	The size of a DOM node collection
OptionsArray	The range of options in a popup menu
Plugin	The number of MIME types supported by a plugin
PluginArray	The variety of plugins currently installed in the browser
ScriptArray	The number of script blocks in a document
Select	The range of options in a popup menu
SelectorArray	The number of rules in a style sheet
String	The length of a string in characters
style	The number of individual style components in a style rule
styleSheets	The number of style sheets called in by the document
textNode	The length of a textNode in characters
Window	The number of frames in a window

Although the `length` property is marked here as `ReadOnly`, in some circumstances it may be useful to assign a value to it to extend, or truncate an `Array` object.

See also:	`Array.length`, `Form.elements.length`, `Form.length`, `Window.length`

Property attributes:

`ReadOnly`.

Length units (Definition)

A sub-set of the available set of measurement units used with CSS style sheets and `style` object properties.

See also:	`Legend.padding`, `style.layoutGridChar`, `style.layoutGridLine`, Measurement units

Less than (<) (Operator/relational)

Compare two operands to determine which is nearer to -Infinity.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*anOperand1* `<` *anOperand2*
Argument list:	*anOperand1*	A value that can be compared numerically or lexically
	anOperand2	A compatible value

Returns `true` if the left operand is numerically less than the right operand or is sorted earlier in the Unicode collating sequence when two string values are compared.

In numeric comparisons, the presence of `NaN` in either or both operands will yield undefined instead of `true` or `false`.

When comparing two strings, a prefixing plus sign is present, then a numeric coercion of a string takes place before the comparison. Numeric coercion takes place when either of the operands is numeric.

In ECMA compliant JavaScript implementations, string values are simply compared according to the Unicode character code point values with no attempt to provide the more complex semantically oriented definitions of character and string equality defined in the Unicode version 2.0 specification.

The associativity is from left to right.

Refer to the operator precedence topic for details of execution order.

The result is the Boolean value `true` if *anOperand1* is numerically or lexically less than *anOperand2*, otherwise `false` is returned.

Letter (Definition)

A valid and printable character.

Since JavaScript is available across such a wide variety of platforms, locales and environments, you may introduce some characters that appear to mutate as the script moves from one environment to another.

It is fairly safe to use any character in the lower 128 set that corresponds to ASCII. Even then, you may find that hash (#) and GB pound signs (£) get confused in some editors.

It is somewhat less safe to use the next 128 character codes up to 255 because these are mapped quite differently on Macintosh, UNIX and Windows systems.

If you can use a Unicode compliant environment, these problems may be minimized and the character you type will be the same on other platforms if they fully support Unicode. However they may not appear the same on non Unicode platforms. In any case, a non-Unicode compliant platform may not support the 16 bit (double-byte) characters that Unicode requires and may only be able to cope with 8 bit characters.

Historically, only 7 bit character codes could be guaranteed to arrive intact, but these days 7 bit serial connections are in decline. Even so, you may find them on some ancillary equipment; in particular you may find rack mounted units that have an RS232 serial interface. You should be very wary of these since they may not support 16 bit character values.

This set of characters (plus the space, newline and tab characters) is the smallest safe set to write your script in. Any other characters can be encoded as escape sequences using these characters.

a b c d e f g h i j k l m

n o p q r s t u v w x y z

A B C D E F G H I J K L M

N O P Q R S T U V W X Y Z

0 1 2 3 4 5 6 7 8 9

! " # % & ' ( ) * + , –.

/ : ; < = > ? [`] ^ _ { | } ~

A fully ECMA compliant interpreter should allow you the full use of the Unicode character set for specifying identifier names but this whole area of localization and internationalization is under discussion at the time of writing. Future versions of the ECMA 262 standard or appendices to it may clarify the situation.

Lexical convention (Definition)

ECMAScript defined certain lexical conventions.

Availability:	ECMAScript edition –2

According to the ECMAScript standard, a compliant interpreter should follow a certain logical process when converting the source text of a script into an executable form. The standard defines a set of logical entities, which can be combined to make a program. This abstract definition is broad enough that all JavaScript interpreters can be considered to be ECMAScript compliant on this issue.

A script is composed of an unordered collection of the following kinds of entities:

- Whitespace
- Line terminators
- Comments
- Tokens

Whitespace is used to improve the readability of the script and to separate tokens from one another, where they could be misinterpreted if they were concatenated together.

Line terminators are used to improve the readability of the source text and to separate tokens. However, unlike whitespace, line terminators can affect the behavior of the script when placed in certain places. In general, a line terminator can occur between any two tokens but cannot appear in a token or inside a string literal. Line terminators in string literals must be escaped if they are required as part of the string. Line terminators also affect the automatic semicolon insertion process.

Comments can be contained completely on a single line or can span multiple lines.

A single line comment must finish at the end of the line and cannot contain a line terminator. You can place multiple single line comments one after another if required, each one separated by a line terminator.

Multiple line comments are replaced by a single line terminator during parsing. It doesn't matter how many line terminators they actually contain. This means that a multiple line comment behaves syntactically as if it were a line terminator.

Tokens are the actual components that your executable script is built from. They may be reserved words, identifiers, punctuator symbols or literals.

See also:	Automatic semicolon insertion, Comment, Comment (`//` and `/* ... */`), Escape sequence (`\`), Line terminator, Multi-line comment, Script Source Text, Token, Whitespace

O'Reilly JavaScript Definitive Guide –page –9-201

Lexical element (Overview)

A component from which a script is constructed.

A lexical element is a component from which you can construct a script. It is the smallest (or most atomic) fragment that a script can be decomposed into to allow the execution mechanisms in the interpreter to operate. Each lexical element is represented by a token and the script is tokenized through a process of lexical analysis.

The following lexical elements are used to construct a script:

- Whitespace
- Line terminator
- Literal (Constant)
- Identifier
- Keyword
- Reserved word
- Operator
- Punctuator
- Comment

See also:	Associativity, Comment, Constant, Identifier, `int`, JavaScript language, Keyword, Line terminator, Literal, Operator, Operator Precedence, Punctuator, Reserved word, Token, Whitespace

Lexical scoping (Definition)

The scope within which functions are executed.

Functions are lexically scoped in JavaScript and because they are not dynamically scoped, they are static to within the location they are defined. This means they run in the global scope of the document in which they live and not the one they are called from.

In versions of JavaScript prior to 1.2, the scope for a function declaration was limited to the global scope. This was a simple scope arrangement and caused little confusion and difficulty. From version 1.2 onwards, because functions can now be defined inside functions, they cannot be called from outside those functions and the scoping rules start to become more complex.

There becomes an issue of persistence of the scope of a function and if a nested function is called from outside its containing function, the containing function's scope is still present and added to the scope chain along the way when the inner function is called.

To illustrate this, suppose a function `AAA` is created and within it, another `BBB` is created.

You can call `AAA` and while executing its code, a call to `BBB` might be made. Inside `BBB`, the scope chain contains the `global` object, the `call` object of `AAA` and the `call` object of `BBB`. If `BBB` is called from outside `AAA`, as in `AAA.BBB()`, then the exact same scope chain is constructed.

This can become even more complex if `function` objects are manufactured at run-time. It might be possible to conceive a `function` object factory that can preserve the scope chain that persisted at the time the functions were created. If those `function` objects are preserved and executed later, the scope chain that was in existence at the time they were created will be restored when they are executed. This is far too confusing to be of great use and may turn out to be somewhat non-portable.

This capability is realized by storing the function that has been manufactured in a special kind of object. These are called `Closure` objects and are implemented visibly in Navigator 4.

See also:	`__parent__`, `Closure` object

LI object (Object/HTML)

An object that represents an `<LI>` object in the document.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0

Inherits from:	`Element object`	
JavaScript syntax:	IE	*myLI* = *myDocument*.all.*anElementID*
	IE	*myLI* = *myDocument*.all.tags("LI")[*anIndex*]
	IE	*myLI* = *myDocument*.all[*aName*]
	-	*myLI* = *myDocument*.getElementById(*anElementID*)
	-	*myLI* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myLI* = *myDocument*.getElementsByTagName("LI")[*anIndex*]
HTML syntax:	`<LI> ... </LI>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`type, value`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The `<LI>` tag is a block-level tag. That means that it forces a line break before and after itself.

The DOM level 1 specification refers to this as a `LIElement` object

See also:	`Element` object, `OL.compact`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

Element object, Node object

LI.type (Property)

A type indicator that controls the presentation style of an item in the list that the <LI> object belongs to.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myLI*.type

There are a variety of different list types that can be displayed. The type value can be defined on an item by item basis within the ordered or unordered list collections.

Lists support an enumeration display of the following types:

<UL>/<OL>	Type code	Presentation style
OL	1	Numeric
OL	a	Alphabetical –lower case
OL	A	Alphabetical –upper case
OL	i	Roman numerals –lower case
OL	I	Roman numerals –upper case
UL	circle	a small open circular bullet
UL	disc	a small solid circular bullet
UL	square	a small square bullet

Some browsers may provide extended functionality, and use of characters other than those specified will yield undefined behavior. This is largely superseded by the CSS styling mechanisms now and is likely to become deprecated in due course.

See also:	OL.type, UL.type

LI.value (Property)

A means of resetting an enumerator in an ordered list contained in an <OL> block.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myLI*.value

You may want to reset an enumerator in a list sequence. This allows you to start the list at zero or one or perhaps to split the list and continue enumerating items after a body of text has been interposed into the list.

Of course this property is meaningless in an unordered list and is only therefore useful when the <LI> tag and LI object are contained within an <OL> tag and its corresponding OL object.

See also:	OL.start

Liberate TV Navigator (TV Set-top Box)

An interactive TV set-top box environment.

This is possibly the most advanced of the TV set top boxes that provide a 'Browser in a box'.

This system is gaining much popularity in the UK and Europe and is also becoming more prevalent in the United States. It has the backing of several very large players in the digital TV market and was founded as a joint venture between Netscape Communications and Oracle Inc.

Broadcast head end systems are generally built on Unix systems. Since the heritage of Liberate is that of the Netscape browser, the Liberate platform relates to the Microsoft TV platform in much the same way as the Netscape browser does to the MSIE browser.

From the consumer's point of view, one of the benefits of the Digital TV revolution is that generally the set-top boxes are supplied by the broadcasters. The broadcaster already has control over what gets transmitted from the head end and can now control how it is received. Although we have competing standards for set-top boxes, a TV set-top box will generally receive a predictable content model from the broadcast head end.

The Liberate platform does all that the WebTV and Microsoft TV platform does and possibly more besides, although both are competing with one another and raising the stakes all the time, just like it was during the 'Browser Wars'.

For example, you can request content from an ISP via a dial-up connection or from an always-on cable modem. This uses the normal HTTP request method. However, you can also request resources from the in-band broadcast video signal. These are done with additional request methods. These will allow you to request an item from a particular carousel. A carousel is a collection of assets that are transmitted in a cyclic manner and are embedded into the digital TV transport stream. Requesting an item from a carousel is no more complicated than requesting it from a web server. When the object is delivered on the next carousel cycle it is displayed by the browser in the normal way. Pages can be constructed with any mixture of in-band or online content.

Carousels can be associated with a particular channel or can be shared by many channels being broadcast on a digital TV multiplex.

This platform works very well in Digital Satellite (DSat), Digital Cable (DCable) and Digital Terrestrial (DTT) systems, although at this time it is becoming very popular on DCable.

The present version of Liberate in wide circulation is 1.1 and it is in the process of being upgraded to 1.2. The upgrade process is accomplished by downloading a new browser core into the set-top box which then updates its persistent Flash ROM.

Liberate 1.2 supports much enhanced carousel delivery, ATVEF triggers and also some basic Flash animation support. The JavaScript support is basically 1.2 and the HTML is based on version 3.2, which poses some difficulties in achieving the display effects people are used to deploying with HTML 4. These limitations are imposed because the set-top box hardware is based on a cost-limited CPU which has limited memory and performance. This is necessary to be able to deploy the boxes at a cost that is commercially viable.

As the cost/performance ratio improves, boxes will become more capable and support higher level functionality. It is likely that the Flash support for example will receive some considerable attention, because it allows the designers of the program related material to achieve more advanced and animated effects.

The JavaScript functionality has a few limiting factors when compared with the Netscape browser used in a PC. This extends to a few objects and methods being unavailable. However, there are additional TV-related objects and methods that provide the control of channel switching, volume control and TV overlays. You can for example use HTML to design a semi-transparent overlay that is placed on top of the video or you can place the window into a web page so it resembles an embedded video player plugin.

Major Cable operators and AOL TV are among the services offering contents that work with the Liberate platform.

Light() (Filter/visual)

A visual filter for simulating a lighting model.

Availability:	JScript –3.0 Internet Explorer –4.0

See also:	filter – `Light()`

Limits (Definition)

A set of constraints within which the script must operate.

There are mainly two kinds of limits that an implementation imposes on a JavaScript script source text. There are those constraints required by the environment and there are numerical limits dictated by the internal data type representations.

Environmental limits are, for example, the security mechanisms in a web browser. Other environmental limits may impose a maximum limit to the size of a JavaScript source text. It is unusual to encounter this limit, but in an embedded interpreter the storage available to buffer the script as it is interpreted may be limited to 32K or 64K in situations where the script interpreter is used in a home appliance.

Numeric limits are those such as the size of the smallest and largest numeric value that can be represented or the maximum length of a string.

In general, the limits are either self-evident from the context in which the script is being executed or can be deduced by using certain properties of the `Global` object or the `Number` class.

See also:	Compliance, Environment, `Global` object, Minima-maxima, `Number` object

Line (Definition)

A fragment of script source text.

A line of script source text is that fragment of script that is placed between two consecutive line terminators.

The placement of comment blocks can affect where the line terminator appears to be.

Implementations may or may not strip off leading and trailing whitespace.

Trailing whitespace that is inside a string literal should not span a line terminator.

A line of script source is interpreted and executed as a whole.

Some implementations may place limits on the maximum length of a line of script source text. These limitations are most likely to be a problem in embedded interpreters and are least likely to cause any problems in web browsers.

See also:	Comment, Comment (// and /* ... */), Line terminator, Multi-line comment, Single line comment

Line terminator (Definition)

Line terminators separate individual lines of executable code.

Availability:	ECMAScript edition –2

Line terminators are used to improve the readability of the source text and to separate tokens. However, unlike whitespace, line terminators can affect the behavior of the script when placed in certain places.

In general, a line terminator can occur between any two tokens but cannot appear in a token or inside a string literal. Line terminators in string literals must be escaped if they are required as part of the string. Line terminators also affect the automatic semicolon insertion process.

Line terminators occurring during a single line comment delimited by a pair of slash characters (`//`) are considered to be the end of the comment, and any remaining comment text be interpreted as if it were executable code.

Line terminators occurring during a multiple line comment block (`/* ... */`) will be discarded and the entire comment block will be replaced with a single line terminator.

The following characters are considered to be line terminators in ECMAScript conformant JavaScript interpreters:

Escape Sequence	Unicode Value	Name	Symbol
\n	\u000A	Line Feed	<LF>
\r	\u000D	Carriage Return	<CR>
-	\2028	Line separator	<LS>
-	\2029	Paragraph separator	<PS>

The terms Line Terminator and Newline can for most purposes be used interchangeably. Newline is preferred when referring to a `\n` escape sequence since it more clearly suggests the meaning of the escape.

ECMA edition 3 adds the Unicode line separator and paragraph separator code points to the list of valid line terminators.

See also:	Automatic semicolon insertion, Comment (// and /* ... */), Lexical convention, Lexical element, Line, Newline, Semicolon (;), String literal

LINK object (Object/HTML)

An object that represents HTML <LINK> tags in documents.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myLINK* = *myDocument*.all.*anElementID*
	IE	*myLINK* = *myDocument*.all.tags("LINK")[*anIndex*]
	IE	*myLINK* = *myDocument*.all[*aName*]
	-	*myLINK* = *myDocument*.getElementById(*anElementID*)
	-	*myLINK* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myLINK* = *myLinkArray*[*anIndex*]
	-	*myLINK* = *myDocument*.getElementsByTagName("LINK")[*anIndex*]
HTML syntax:	<LINK>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	charset, disabled, href, hreflang, media, readyState, rel, rev, title, type	
Event handlers:	onClick, onDblClick, onError, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReadyStateChange	

The <LINK> tag is used to link in external style sheet files. You can link in CSS or JSS style sheets with this technique. It allows the style sheets to be shared amongst many documents and for the site appearance to be changed globally simply by modifying a single file.

When referring to style sheets, the REL attribute has the STYLESHEET value.

The TYPE attribute indicates that the style sheet is formatted as text and contains JavaScript source text.

The REL and TYPE attributes combined tell us it is a JSS file.

The HREF attribute points at the document containing the style sheet definition to be loaded at the <LINK> point in the calling document.

This a LINK object because it refers to a document that is accessed via a URL.

The <LINK> tag conveys no apparent visible effect on the document. It is considered to be an invisible tag.

MSIE supports a LINK object as a property of its styleSheet object.

Warnings:

- This object is related to but not identical to a `Link` object. It does share some property names but adds others.
- This a special MSIE object class, although Netscape would probably support something functionally similar internally.

See also:	`Anchor` object, `Area` object, `Document.anchors[]`, `Element` object, `Element.all[]`, `LinkArray` object, `Location` object, `String.link()`, URL, `Url` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`charset`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`disabled`	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	-	-
`href`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`hreflang`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-

`onReadyStateChange`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

LINK.charset (Property)

The character set that the document at the other end of a link's URL is expected to use.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.charset`

This would contain the character set being used by the target document at the other end of the link. For example the value "`iso-8859-1`" is likely to be returned but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry.

See also:	`Anchor.charset,Url.charset`

Web-references:

ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets

LINK.disabled (Property)

A switch property to enable or disable a link.

Availability:	DOM level –2 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myLINK*`.disabled`

Setting this property to `true` will disable a link from performing any action when clicked on by the user. Setting this property `false` restores its normal operation.

LINK.href (Property)

The URL of a document belonging to the `link` object (this is readonly in IE4 on the Macintosh).

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.href`

See also:	`Anchor.href`, `Location.href`, `Url.href`

LINK.hreflang (Property)

The language that the document at the other end of the URL is expected to conform to.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.hreflang`

This property should contain values that use the international language two-letter abbreviation codes. These are not the same as the country codes, which are also two letter values.

Refer to the Language codes topic for a list of the available language codes.

See also:	`Anchor.hreflang`, Language codes, `Url.hreflang`

LINK.media (Property)

The target media that the document will be output to.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.media`

This property is provided speculatively for a time when pages can be formatted differently according to the medium they are being delivered to.

One of the following values would be appropriate:

- `all`
- `print`
- `screen`
- `aural`
- `braille`
- `embossed`
- `handheld`
- `projection`
- `tty`
- `tv`

Warnings:

- Note that although this is supported by MSIE version 4, it does not work on the Macintosh implementation of that browser version.

LINK.readyState (Property)

The current disposition of the link as it is being loaded from the server.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myLINK*`.readyState`

This property reflects the downloading state of an object associated with a `<LINK>` tag.

Sometimes, you can design scripts to execute while the document is downloading; inline scripts for example. At that time, you may even be able to trigger interval-timed, deferred executions, as well.

If it is important that the document has completed loading before your script attempts to execute, you can check this property for one of the following values:

State	Value
uninitialized	The object is first instantiated but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed but is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the `ActiveX` object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`LINK.title`, `onReadyStateChange`

Property attributes:

`ReadOnly`.

LINK.rel (Property)

The relationship between the current element and the remote document.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.rel`
HTML syntax:	`<LINK REL="...">`	

This is sometimes called a forward link. Although the `HREF="..."` HTML tag attribute is normally the only means used to identify a target document, the browser is permitted to use the `REL="..."` HTML tag attribute to decide whether to use the `HREF` value or how it should be used.

The following HTML version 4.0 standard link types are permitted in this property:

- `alternate`
- `appendix`
- `bookmark`
- `chapter`
- `contents`
- `copyright`
- `glossary`
- `help`
- `index`
- `next`
- `prev`
- `section`
- `start`
- `stylesheet`
- `subsection`

MSIE adds these as well:

- `same`
- `next`
- `parent`
- `previous`

When used or tested within a script, any comparisons should be case-insensitive.

See also:	`Anchor.rel,Url.rel`

LINK.rev (Property)

The relationship between the remote document and the current element.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.rev`

This is sometimes called a reverse link. It defines the relationship between a document and another that calls it. The linkage is defined from the destination document's viewpoint.

This property supports the same HTML version 4.0 standard link types as the `rel` property. Refer to that topic for details.

When used or tested within a script, any comparisons should be case-insensitive.

As `rel` and `rev` properties are complementary, the values in them are likely to be related. For example, if one contains the value "`next`" then the other is likely to contain "`previous`".

See also:	`Anchor.rev`, `Url.rev`

LINK.title (Property)

The title name text of the link.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.title`

This is the text that is presented as a '`ToolTip`' when the mouse rolls onto an object and pauses there for a few moments. The MSIE browser will display this text as small popup comment box.

When aural style sheet support is provided by a browser, this value might be spoken as the mouse rolls over it.

See also:	`Document.title`, `Element.title`, `LINK.readyState`

LINK.type (Property)

The MIME type of the document that the link points at.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLINK*`.type`

The MIME type of the document associated with the LINK is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

See also:	`Anchor.type`, MIME types, `Url.type`

LinkArray object (Object/browser)

A collection of `link` object, belonging to a document.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0	
JavaScript syntax:	-	*myLinkArray* = *myDocument*.links
Object properties:	`length`	

This is a collection of `Url` objects. In Netscape, you can inspect the constructor to establish the class name which is masked by the `toString()` method of the `Url` object. In MSIE, you cannot get at the constructor so we have to assume that the object is a `Url` object.

`Url` objects are created when an `<AREA>` or `<A>` tag refers to a document. Anchors that are simply named locations within a document but which don't have an `HREF` get added to the anchors array but not to the links array.

Netscape prior to version 6.0 calls this a `LinkArray` (as opposed to a `LinksArray` which might be more appropriate). In MSIE it is just a `Collection` and in Netscape version 6.0 it has become an `HTMLCollection` because that is what DOM specifies it should be.

Warnings:

- Be careful not confuse the elements of this array with `LINK` objects. These are used in MSIE to support styling of `Url` objects on the screen. Other documentation may refer to `Link` objects but there is no evidence to support the existence of an object of that class. After inspection there appear to be `Url` objects in Netscape, LINK objects in MSIE and an object in MSIE that corresponds to the Netscape `Url` class but which provides no means of examining its constructor.

See also:	`Area` object, `Collection` object, `Document.anchors[]`, `Document.links[]`, `HyperLink` object, `LINK` object, `Url` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.0 +	3.0 +	2.0 +	4.0 +	-	-	ReadOnly.

LinkArray.length (Property)

The number of HREF links in the current document.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myDocument*.links.length

The length of the links array, which indicates the number of <A> and <AREA> tags that contain HREF attributes in the document.

See also:	Collection.length, Document.links[], Url.name

Property attributes:

ReadOnly.

LinkStyle object (Object/DOM)

Added at DOM level 2 to support linked stylesheets.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myLinkStyle* = new LinkStyle()

DOM level 2 specifies that this object should support the following property:

- sheet

List type (Definition)

An internal type used by the interpreter.

Availability:	ECMAScript edition –2

This is an internal type used by the interpreter for processing expression evaluation results. It cannot be stored as an object property.

Although the List type does not really exist as a data type accessible from a script, the internal behavior of the interpreter appears as if it did. Especially when looking at the way argument lists are processed in new operator expressions.

See also:	`new`, Type

Cross-references:

ECMA 262 edition 3 –section –11.2.4

LISTING object (Object/HTML)

An object that represents the `<LISTING>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myLISTING* = *myDocument*.all.*anElementID*
	IE	*myLISTING* = *myDocument*.all.tags("LISTING")[*anIndex*]
	IE	*myLISTING* = *myDocument*.all[*aName*]
	-	*myLISTING* = *myDocument*.getElementById(*anElementID*)
	-	*myLISTING* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myLISTING* = *myDocument*.getElementsByTagName ("LISTING")[*anIndex*]
HTML syntax:	`<LISTING>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The `LISTING` object is instantiated when the browser encounters a `<LISTING>` tag in the HTML for a document. This tag is used to enclose a section of text that should be presented as if it were a computer code listing.

The appearance will be similar to that rendered by a <CODE>, <PRE> or <KBD> tag.

Use of this tag is highly deprecated but it still persists in some legacy content.

See also:	Element object, KBD object, PRE object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning

onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

Element object, Node object

Literal (Definition)

Constant values used to initialize or assign a value.

Literals are constant values used in assignments or as arguments to functions or expressions. A literal is considered to be a primary expression when it is being evaluated.

There are several kinds of literals. They are all based on the primitive types. The ECMA standard defines four basic data types, which should be sufficient for most purposes; however, a hosted interpreter may provide other more esoteric primitive values. Here are the four core standard types:

- Null
- Boolean
- Numeric
- String

These are objects that can also be manufactured from literals:

- Array
- Date
- Regular expression
- Object
- Void

String literals also include escaped character literals which may also be used in regular expressions.

Host environments additionally define others for special purposes depending on the implementation.

See also:	Boolean literal, Character constant, Constant, Lexical element, Null literal, Numeric literal, Primary expression, String literal, Token

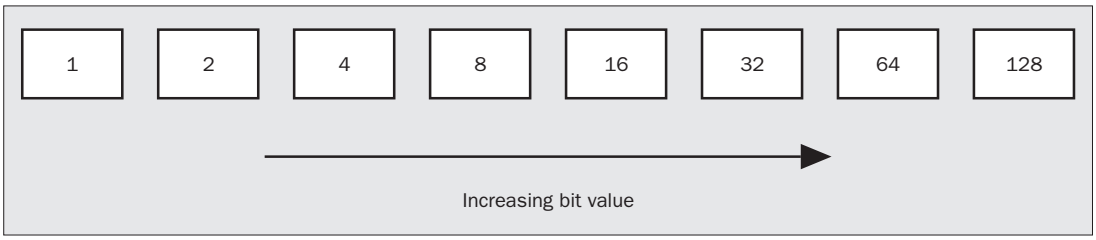
O'Reilly JavaScript Definitive Guide –page –30

Little endian (Definition)

A bit ordering standard for some CPU models.



See also:	byte

LiveConnect (Product)

A Netscape Communications technology that provides a means of communicating between plugins and Java applets.

In Netscape, communication between scripts and Java applets takes place via the LiveConnect interface. LiveConnect was originally designed for just this purpose. LiveConnect is only implemented in Netscape. However, similar but not identical functionality is available in MSIE via the ActiveX interface.

LiveConnect is most effective if you can also understand the internals of Java applets and can program in Java yourself. You can use LiveConnect to gain read and write access to the public fields of an applet and you can also invoke public methods. You can also interact with standard Java system classes that are built into the Netscape browser.

If a plugin is Java-enabled, then in Netscape you can interact with that plugin in the same way.

From the opposite direction, applets and Java-enabled plugins can invoke JavaScript functions and can read and write JavaScript object properties. The Real Video plugin uses this to great effect as do many other media plugins.

LiveConnect is constructed around some built-in objects that encapsulate various Java classes and objects. These are:

- `JavaObject` –An encapsulation of an instance of a Java object that belongs to a `JavaClass`
- `JavaClass` –An encapsulation of a Java class for access to static properties and methods
- `JavaPackage` –A collection of `JavaClass` and `JavaPackage` objects in a tree-like hierarchy

With these encapsulations, you can operate on Java objects as if they were JavaScript objects. That is necessary because although you can generally convert between primitive types, the object types are too dissimilar to convert properly.

There are some interesting opportunities here for extending the capabilities of your scripts with the facilities offered by Java. However, the downside is that you need to have a VM running. Netscape supports its own internal VM at least up to version 4, but the trend is for browsers to use the OS hosted VM and to not provide any embedded Java execution context. This may provide additional benefits such as sharing Java classes amongst several applications and shortening the start-up time since the VM could be expected to be running already.

LiveConnect becomes particularly useful when accessing the `java.lang.System` class from scripts running in Netscape. In MSIE, you could create a special applet that then gained access to the system class for you. Using this capability to any useful extent starts to impinge on the security model and requires that trusted scripts are used. This is usually enough to deter most people from exploring it more deeply. However, if you can gain that trust, by using signed scripts, you may then be able to access the Java IO facilities and read/write files.

Working the other way, LiveConnect provides a way for Java code to execute a string as JavaScript. This is very like an `eval()` call from the native JavaScript environment.

Warnings:

- Be careful not to confuse the following:
  - LiveWire
  - LiveScript
  - LiveConnect
- In Netscape version 3, a bug in the conversion routines yielded all Java primitives as JavaScript objects instead of JavaScript primitives. This causes a few problems because `Number` and `Boolean` objects in JavaScript behave slightly differently to the primitive representations, mostly to do with operator overloading and precedence. Objects will prefer to concatenate as strings rather than add as numbers for example. The `valueOf()` method will provide a way to work around this.

See also:	ActiveX, Glue code, Java calling JavaScript, Java method calls, Java method data conversion, Java to JavaScript values, JavaScript to Java values, LiveScript, Plugin events, `Plugin.isActive()`

LiveScript (Product)

This was the original name for JavaScript when it was first introduced by Netscape Communications.

Maybe LiveScript wouldn't have caught on and become so popular, but now people routinely confuse it with Java. Even more so now that interpreters for JavaScript are available written in Java and some server-side application tools allow you to write Java code but run it in a script interpreter. That would be Java script not JavaScript.

Warnings:

- Be careful not to confuse the following:
  - LiveScript
  - LiveWire
  - LiveConnect
- LiveWire is the former name for Server-Side Javascript.
- LiveConnect is a mechanism for allowing JavaScript to talk to Java in a Netscape browser.

See also:	JavaScript language, JavaScript version, LiveConnect, LiveWire

livescript: URL (Request method)

This is a pseudonym for the `javascript:` URL.

See also:	URL, `javascript:` URL

LiveWire (Product)

Netscape Communications' server-side JavaScript compiler.

This was the original name for JavaScript when used in the server. Now it is simply called Server-Side JavaScript. Sometimes SSJS for short.

The LiveWire JavaScript interpreter is used in Netscape Enterprise Server. In this environment you can also compile the JavaScript code which further blurs the distinction between Java and JavaScript.

Warnings:

- Be careful not to confuse the following:
  - LiveWire
  - LiveScript
  - LiveConnect

See also:	LiveScript, Server-side JavaScript

Local time (Definition)

The locale specific time value.

Availability:	ECMAScript edition –2

Local time is the calendar time for the current locale.

Local time and UTC time differ by an amount derived by adding the Local Time Zone Adjustment and the Daylight Savings Time Adjustment together. Adding these to the UTC time gives the local time.

Conversion of UTC time (`ut`)to local time is defined by:

```
LocalTime(t) = ut + LocalTZA + DaylightSavingTA(ut)
```

Conversion from local time (`lt`)to UTC is defined by:

```
UTC(lt) = lt - LocalTZA - DaylightSavingTA(lt - LocalTZA)
```

The following expression may not always test `true`:

```
t = UTC(LocalTime(t))
```

Converting from UTC to local time and back may not yield an identical value due to deficiencies in daylight savings time computations. ECMA does not mandate that a compliant implementation needs to take DST into account only that it be aware that DST may be in force. Some locales use the same DST setting all year round in some years and that is difficult to predict and encapsulate into an algorithm.

See also:	Broken down time, Calendar time, Date and time, Daylight savings time adjustment, Local time zone adjustment

Cross-references:

ECMA 262 edition 2 –section –15.9.1.9

ECMA 262 edition 3 –section –15.9.1.9

Local time zone adjustment (Definition)

An adjustment to locale specific time.

Availability:	ECMAScript edition –2

ECMA compliant implementations are expected to determine the local time zone adjustment.

The local time zone adjustment is a value (internally referred to as LocalTZA) which is measured in milliseconds and can be added to the UTC value representing the local standard time.

The ECMA standard states that daylight savings time is not reflected in the LocalTZA value. LocalTZA does not vary with time but depends only on the geographic location.

See also:	Broken down time, Daylight savings time adjustment, Local time

Cross-references:

ECMA 262 edition 2 –section –15.9.1.7

ECMA 262 edition 3 –section –15.9.1.7

Locale-specific behavior (Definition)

Behavior that depends on a locale setting.

The locale setting is a way of defining how programs operate in an international or geographic context. Running software in London and New York may be very similar apart from the instantaneous time setting. The time in New York is 5 hours behind London. If the software running in both locations needs to communicate with the other and will have to perform time based operations on data, then to remain properly synchronized they may need to be aware of the number of time zones between the two systems and make adjustments accordingly.

Other behavior may dictate date formats, currency symbols, the format of decimal values, thousands separators and spelling. Non English speaking locales may use the same textual presentation (Roman Scripting) but spell words in the local language. Character set substitution may accomplish much of what's required although this is somewhat ameliorated by the use of Unicode. Sometimes the direction that the text flows may be different. For example, European, Middle-Eastern and Asian languages use different character alphabets and text directions.

The implementors should thoroughly document all of this locale specific behavior.

See also:	Behavior, Broken down time, Character set, Character-case mapping, Unicode

Localization (Definition)

The process by which geographic, international and regional differences are managed.

JavaScript is used all over the world in a wide variety of environments, platforms and contexts. Portability issues arise when moving between platforms. They are also present when relocating a platform geographically. At the very least a time setting will need to change, and to record an event in a coordinated time framework, the offset from that known time reference needs to be known. There will be cultural, language and currency changes necessary as well as number formatting rule variations that need to be taken account of.

Indeed the differences in some locales may completely change the native alphabet that the user is prepared to work with. Even the direction of the text flow may change in extreme circumstances. Moving around Europe certainly requires that different accented symbols be used in each country.

Fortunately the Unicode standard covers a great many of these national variants.

Even so, JavaScript is fundamentally based on the American English language and even with the international support of the Unicode character set, the structural layout of the script source text may still conform to the underlying English language form. Even so there are issues with the spelling of words such as Color.

Typically, a localized implementation may allow the use of accented and national characters in identifier names but would still retain the English spelled keywords and punctuation characters.

As well as character sets, the issue of collation into the correct sorting sequence needs to be managed properly. In JavaScript, this issue is largely confined to the way that `Array` objects manage their `sort()` method's behavior.

Date and time formats tend to be arranged differently in each country. The United States and the United Kingdom commonly place the day number and month number the opposite way round. For day numbers above 12, this can be detected automatically but otherwise the context needs to be examined to decide which way round these values are.

Numeric formats may dictate a different punctuation symbol to be used for the decimal point and thousands separator. Confusingly, the comma and period characters may be used in both contexts. This means that a value could be misinterpreted and might yield a result that is several orders of magnitude in error when parsed.

Currency symbols will need some attention. The United States dollars symbol is in the lower 128 character set. The cents symbol is not. The UK pounds symbol is within the lowest 255 characters.

Warnings:

- Be careful of the following:
  - Date formats
  - Time settings
  - Character sets
  - Currency symbols
  - Sort ordering
  - Decimal points and thousands separators
- The entire concept and scope of localization of JavaScript is being discussed as part of the standardization project. This area is prone to change or, at the very least, some definition of a standard conforming behavior.

See also:	Character set, Collation sequence, Currency symbol, Date and time, Decimal point (.), Multi-byte character

location (Property)

An alias for the `window.location` property.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Location object`	
JavaScript syntax:	-	`location`
	-	*`myWindow`*`.location`

See also:	`Window.navigate(),Window.location`

Property attributes:

`ReadOnly.`

Location object (Object/DOM)

An object that represents the location of a document.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Inherits from:	`Url object`
JavaScript syntax:	- *myLocation* = *myWindow*.location
Object properties:	`hash, host, hostname, href, pathname, port, protocol, search, target, text, x, y`
Object methods:	`assign(), reload(), replace()`
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`

This is a more or less portable encapsulation of a URL value and is most commonly used to describe the location of a document in a window. Changing its `href` property value has become the preferred means of loading a new document into a window or frame.

This is useful because it can also operate very conveniently across frame boundaries. That is, a script in one frame can modify the contents of another.

There are some security implications when accessing frames from different servers or domains. These can overcome in Netscape by using signed scripts.

See also:	`Anchor` object, `Area` object, `Document.location`, `LINK` object, `Map` object, URL, `Url` object, `Window.location`, `Window.navigate()`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

Inheritance chain:

`Element` object, `Node` object, `Url` object

Location.assign() (Method)

Equivalent to setting the `HREF` attribute to load a new page.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Deprecated	
JavaScript syntax:	-	*myLocation*`.assign(`*aURL*`)`
Argument list:	*aURL*	A new URL to load into the `location.href`

This is functionally equivalent to making an assignment with an equals (=) operator.

Warnings:

- This method was not originally intended for use by script level code and should be avoided.

See also:	Assign value (=)

Location.hash (Property)

The hash target portion of the `href` property. (The hash after the URL refers to an anchor location in the document).

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.hash
See also:	`Anchor.hash,Url.hash`	

Location.host (Property)

The hostname and port number portion of the `href` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.host
See also:	`Anchor.host,Url.host`	

Location.hostname (Property)

The hostname-only portion of the `href` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.hostname
See also:	`Anchor.hostname,Url.hostname`	

Location.href (Property)

The URL for the page currently on display in the window owning this location.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.href

If you set this property, the window will load the new URL in, and replace the old content with the new.

See also:	`Anchor.href,Url.href`

Location.pathname (Property)

The file path portion of the `href` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.pathname

See also:	`Anchor.pathname,Url.pathname`

Location.port (Property)

The port number within the `href` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0

Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myLocation*.port

See also:	`Anchor.port`, `Url.port`

Location.protocol (Property)

The protocol portion of the `href` property, such as: `http:`,`ftp:`,`mailto:`,`file:`,etc.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myLocation*.protocol

See also:	`Anchor.protocol`, `IMG.protocol`, URL, `Url.protocol`

Property attributes:

`ReadOnly`.

Location.reload() (Method)

Reload the currently displayed page in the window that owns this `location` object.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	-	*myLocation*.reload()
	-	*myLocation*.reload(*aFlag*)
Argument list:	*aFlag*	A Boolean flag forcing a reload from the server when set to `true`

This causes the document that owns the `Location` object to be reloaded. Any form elements would be reset to their initial values.

Unless you specify an unconditional reload, the page will be reloaded from the cache if the file is still in the cache, and caching is still active. This may involve a check on the server to see if the copy in the cache is up to date. If the cache copy is out of date, a new document may be fetched from the server.

You can use the keyword unconditional as an argument in the `location.reload(true)` method call to force a new copy of the document to be fetched from the server regardless of the disposition of any documents in the local cache. This should also defeat any proxies and force them to reload from the server but it depends on how they are configured.

Refer to the `History.go()` topic for details of how to perform a benign soft load.

See also:	`History.go()`

Location.replace() (Method)

Load a new page and replace the history entry.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	-	*myLocation*`.replace(`*aURL*`)`
Argument list:	*aURL*	A URL to load into the layer, window or frame this location belongs to

This method is a useful way of loading new pages if you want to make sure the history list does not get filled up with unwanted pages. This makes the back button more useful to the user.

While the replace goes on, the existing page will continue to be displayed. This also applies if the replace is called during the `<HEAD>` portion of a page. The new URL is requested but the browser will continue loading and building the previous page until the web server responds and delivers the new replacement page. Termination of the old page therefore happens when the new page begins to arrive and not when it is first requested.

Location.search (Property)

The query portion of the `href` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myLocation*.search

See also:	Anchor.search, Url.search

Location.target (Property)

The target window or frame that a location belongs to when its object represents an <A> tag.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myLocation*.target

This yields the value of the TARGET attribute in an <A>, <AREA> or <MAP> tag.

You can assign a new value to this property so that the URL will be directed to a different window or frame.

Here are some example target values:

- _parent
- _self
- _top
- _blank
- Window name
- Frame name

See also:	Anchor.target, BASE.target, Form.target, Url.target

Location.text (Property)

The text contained within the <A> and </A> tags when the location describes an anchor.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myLocation*.text

See also:	Anchor.text, Url.text

Location.x (Property)

The X coordinate of the anchor on the client display surface.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLocation*.x

The horizontal position of the object in the display measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

See also:	`Anchor.x`, `Area.x`, `Url.x`

Location.y (Property)

The Y coordinate of the anchor on the client display surface.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myLocation*.y

The vertical position of the object in the display measured in pixels. You can use the x and y coordinates of the object as targets of the `scrollTo()` method for the window it lives in.

See also:	`Anchor.y`, `Area.y`, `Url.y`

locationbar (Property)

An alias for the `window.locationbar` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	locationbar
	-	*myWindow*.locationbar

See also:	`Bar` object, `Window.locationbar`

Property attributes:

`ReadOnly.`

Lock object (Object/NES)

Provides a way of locking objects against multiple simultaneous access by several clients at once.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
JavaScript syntax:	NES	*myLock* = Lock
	NES	*myLock* = new Lock()
Object properties:	constructor, prototype	
Object methods:	isValid(), lock(), unlock()	

In a server back end environment, you may have some objects which you share amongst several sessions. This means that they could be accessed on behalf of several clients all at once. You may want to prevent this happening by locking the object as the first client's request accesses it, and then unlocking it again as the request handler for that client no longer needs access to it.

You can create new `lock` objects with the `Lock()` constructor.

It is good manners to unlock resources as soon as you can so that other processes can carry on running. You should not rely on the script exit handler unlocking the locks you place on objects.

Warnings:

- Be careful when you use locks. It is possible to place mutually exclusive locks on objects and introduce a deadlocking situation. There is a potential for this if your script is locking more than one object and the locks are not correctly nested.
- If you don't implement locks when necessary, you run the risk of run-time errors as your system can run out of resources.

See also:	Netscape Enterprise Server, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
constructor	1.2 +	-	3.0 +	-
prototype	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
isValid()	1.2 +	-	3.0 +	-
lock()	1.2 +	-	3.0 +	-
unlock()	1.2 +	-	3.0 +	-

Lock() (Constructor)

A constructor for creating new `Lock` objects.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
Property/method value type:	`Lock` object	
JavaScript syntax:	NES	`new Lock();`

See also:	`Lock` object

Lock.constructor (Property)

A reference to the constructor for making new `Lock` objects.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	NES	*`myLock`*`.constructor`

The constructor is that of the built-in `Lock` prototype object.

You can use this as one way of creating locks although it is more popular to use the `new Lock()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Lock.isValid() (Method)

A method that returns an indication as to the validity of the lock.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	*`myLock`*`.isValid()`

This method will return a Boolean `true` value if the `Lock` is still in force and a Boolean `false` value if it has been relinquished.

See also:	`Lock.lock(),Lock.unlock()`

Lock.lock() (Method)

Place a lock on the object.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
JavaScript syntax:	NES	*myLock*.lock()

As you attempt to lock the object, the method first tests the `Lock` to see if another script already has a lock pending. If it does, then this method stalls and will not return until it can successfully place a lock on the object. That will happen when the previous locking script calls the `unlock()` method.

See also:	`Lock.isValid()`

Lock.prototype (Property)

The prototype for the `Lock` object that can be used to extend the interface for all `Lock` objects, by allowing you to add methods and properties.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
Property/method value type:	`Lock object`	
JavaScript syntax:	NES	`Lock.prototype`
	NES	*myLock*.constructor.prototype

See also:	`prototype` property

Lock.unlock() (Method)

Relinquish a lock on the object.

Availability:	JavaScript –1.2 Netscape Enterprise Server version –3.0	
JavaScript syntax:	NES	*myLock*.unlock()

You should always aim to relinquish a lock as soon as you can. They are not intended for use as a means of reserving server facilities but as a means of preventing clashes between sessions. If the unlocking is successful, then `true` will be returned, and `false` otherwise.

See also:	`Lock.isValid()`

Logical AND (&&) (Operator/logical)

Logical AND of two operands.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*anOperand1* `&&` *anOperand2*
Argument list:	*anOperand1*	A Boolean value
	anOperand2	Another Boolean value

Traditionally in programming environments, the logical AND operator yields `true` only when both operands are true. However, the specifics of this are slightly different in JavaScript, and although the results may appear to be functionally the same, there is a subtle but important difference.

First, lets deal with the normal and expected behavior of a Logical AND operator. The truth table shows the result of this operator for two Boolean primitive values:

A	B	AND
false	false	false
false	true	false
true	false	false
true	true	true

Now, the implementation is expected to conform to the ECMA standard. This sets out the following method of evaluation for a Logical AND operator:

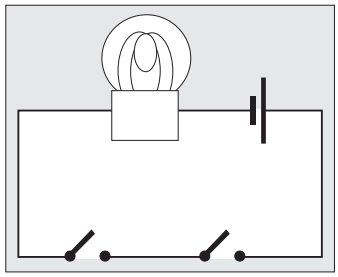
- Evaluate and convert the first operand using the `ToBoolean()` method.
- If it is `false`, then evaluate and return the second operand.
- Otherwise return the evaluation of the first operand.

To all intents and purposes the external perceived behavior is the same because another `ToBoolean()` conversion is likely to take place in the context that the expression is used –an `if()` statement or an outer logical expression for example.

The associativity is from left to right.

Refer to the operator precedence topic for details of execution order.

The result is the Boolean value `true` if both operands are true, otherwise Boolean `false` is returned.



Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=1 CELLPADDING=2>
<TR>
<TH>A</TH>
<TH>B</TH>
<TH>AND</TH>
</TR>
<SCRIPT>
for(a=0; a<2; a++)
{
   for(b=0; b<2; b++)
   {
      document.write("<TR ALIGN=CENTER><TD>");
      document.write(Boolean(a));
      document.write("</TD><TD>");
      document.write(Boolean(b));
      document.write("</TD><TD>");
      document.write(Boolean(a && b));
      document.write("</TD></TR>");
   }
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

ECMA 262 edition 2 –section –11.11

ECMA 262 edition 3 –section –11.11

Logical constant (Definition)

A Boolean constant value.

There are only two possible values for a Boolean constant. That is `true` or `false`.

A Boolean variable may contain the value undefined.

See also:	Constant expression

Logical entity (Definition)

Boolean logical values are represented as an entity internally.

Availability:	ECMAScript edition –2

Logical entities always evaluate as a Boolean result.

Logical entities are used to form conditions and control branching among other uses. They are often used to hold state information or control switches. A logical entity may be the result of a relational expression or the use of one or more logical operators. A logical entity may be the result of enquiring the property of an object that returns a Boolean value as a result. Logical entities can only contain a `true` or `false` value.

Cross-references:

ECMA 262 edition 2 –section –4.3.14

ECMA 262 edition 3 –section –4.3.14

Logical expression (Definition)

An expression whose result is a Boolean value.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

Logical operators perform a test of the Boolean value of the two operands either side of the operator.

See also:	Equal to (==), Expression, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), Logical AND (&&), NOT Equal to (!=), NOT Identically equal to (!==)

Cross-references:

ECMA 262 edition 2 –section –11.11

ECMA 262 edition 3 –section –11.11

Logical NOT – complement (!) (Operator/logical)

Logical NOT operator.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`!` *`anOperand`*
Argument list:	*`anOperand`*	A Boolean value to be complemented

The result is the Boolean complement of the operand value.

The exclamation mark is the logical negation operator. The operand is evaluated and its result converted to a binary value. The value is then reversed and used to replace the expression in whatever context it has been used.

The truth table shows the result of this operator for a Boolean primitive value:

A	NOT
false	true
true	false

Although this is classified as a logical operator here, it is also classified as a unary operator since it only has one operand.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=1 CELLPADDING=2>
<TR>
<TH>A</TH>
<TH>NOT</TH>
</TR>
<SCRIPT>
for(a=0; a<2; a++)
{
```

```
    document.write("<TR ALIGN=CENTER><TD>");
    document.write(Boolean(a));
    document.write("</TD><TD>");
    document.write(Boolean(!a));
    document.write("</TD></TR>");
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

Logical operator (Definition)

An operator that creates a logical (Boolean) expression.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

Logical operators perform a one bit operation on the Boolean value of the operands. The input values may not be Boolean values but will be converted to a Boolean value using the `toBoolean` rules for that type. The conversion happens automatically but may not always be what you expect.

The JavaScript interpreter is also quite smart, in that it can for some operator and value combinations perform a lazy evaluation. For example if an expression like this is presented:

A AND B

Then if A is false, B does not need to be evaluated to know that the result will be `false`. This can significantly speed up the interpreter because evaluating B might have involved an object reference or perhaps an expression evaluation. It almost always would involve a type conversion from some other type to a Boolean value. This suggests you may effect some performance gains by coding your logical operations to take advantage of this.

There are specific logical operators in the set for performing logical AND as well as logical OR operations. However, generally speaking any operator that yields a Boolean result could be used in the same place. The following table summarizes the logical operators as well as those, which come under that general heading of providing a Boolean result:

Operator	Description
`&&`	Logical AND
`||`	Logical OR
`!`	Logical NOT
`==`	Equal to
`!=`	NOT equal to
`<`	Less than
`<=`	Less than or equal to
`>`	Greater than
`>=`	Greater than or equal to

The Boolean constants `true` and `false` need to be considered too, because they are often used in conditional tests to force the conditions to be `true` or `false`. Although they are not operators as such they can be useful when constructing expressions for debugging purposes.

Type conversions indicate these relationships:

- `false` becomes 0
- `true` becomes 1
- 0 becomes `false`
- Any non-zero value becomes `true`

Note that this is going to lose some information if you convert a non-zero value other than 1 to a Boolean value and back again.

Warnings:

- This is not to be confused with the bitwise operators, which yield a 32-bit integer value instead of the Boolean value yielded by a logical expression.
- The bitwise operators may yield a value that in other languages is the same as the logical operator. However although in C language, `true` and `false` are really integer values, in JavaScript the Boolean and Number values are distinctly different types.
- Be careful to use the correct number of ampersands, and vertical bars to select the logical version of the operator. Refer to the Bitwise operator topic for a list of operators to avoid in logical expressions.

Wrox *Instant JavaScript* –page –19

Logical OR (||) (Operator/logical)

Logical OR of two operands.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*anOperand1* `||` *anOperand2*
Argument list:	*anOperand1*	A Boolean value
	anOperand2	Another Boolean value

Traditionally in programming environments, the logical OR operator yields `true` when either or both of the operands are `true`. It yields `false` only when both are `false`. However, the specifics of this are slightly different in JavaScript and although the results may appear to be functionally the same, there is a subtle but important difference.

First, lets deal with the normal and expected behavior of a Logical OR operator. The truth table shows the result of this operator for two Boolean primitive values:

A	B	OR
false	false	false
false	true	true
true	false	true
true	true	true

Now, the implementation is expected to conform to the ECMA standard. This sets out the following method of evaluation for a Logical OR operator:

- Evaluate and convert the first operand using the `ToBoolean()` method.
- If it is `true`, then return that operand.
- Otherwise evaluate and return the second operand.

To all intents and purposes the external perceived behavior is the same because another `ToBoolean()` conversion is likely to take place in the context that the expression is used –an `if()` statement or an outer logical expression for example.

The associativity is from left to right.

Refer to the operator precedence topic for details of execution order.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=1 CELLPADDING=2>
<TR>
<TH>A</TH>
<TH>B</TH>
<TH>OR</TH>
</TR>
<SCRIPT>
for(a=0; a<2; a++)
{
   for(b=0; b<2; b++)
   {
      document.write("<TR ALIGN=CENTER><TD>");
      document.write(Boolean(a));
      document.write("</TD><TD>");
      document.write(Boolean(b));
      document.write("</TD><TD>");
      document.write(Boolean(a || b));
      document.write("</TD></TR>");
   }
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

ECMA 262 edition 3 –section –11.11

Logical XOR (Operator/logical)

Logically exclusive OR of two values.

There isn't really an XOR logical operator, but the Bitwise XOR operator should work fine.

This is proven by evaluating the truth table in the example.

This seems to work fine even on MSIE where the sign bit exhibits some instability under Bitwise operations.

This is the truth table for two Boolean primitive values being operated on with the XOR operator.

A	B	XOR
false	false	false
false	true	true
true	false	true
true	true	false

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=1 CELLPADDING=2>
<TR>
<TH>A</TH>
<TH>B</TH>
<TH>XOR</TH>
</TR>
<SCRIPT>
for(a=0; a<2; a++)
{
   for(b=0; b<2; b++)
   {
      document.write("<TR ALIGN=CENTER><TD>");
      document.write(Boolean(a));
      document.write("</TD><TD>");
      document.write(Boolean(b));
      document.write("</TD><TD>");
      document.write(Boolean(a ^ b));
      document.write("</TD></TR>");
   }
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

long (Reserved word)

Reserved for future language enhancements.

The inclusion of this reserved keyword in the ECMAScript standard suggests that future versions of ECMAScript may be more strongly typed.

This keyword also represents a Java data type and the `long` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

See also:	`double`, `float`, `Integer`, `java.lang.Long`, LiveConnect, Reserved word, `short`

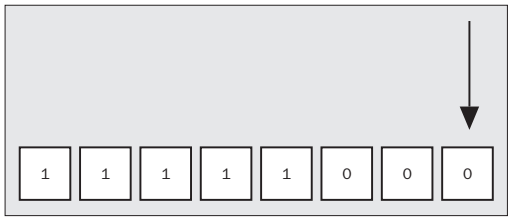
ECMA 262 edition 3 –section –7.5.3

Low order bit (Definition)

The least significant bit in an integer value.



See also:	Bit, Bit-field, Bitwise operator, byte

LValue (Definition)

`LValues` are placed on the left of an assignment.

Availability:	ECMAScript edition –2

An `LValue` is that expression or identifier reference that can be placed on the left hand side of an assignment.

An `LValue` must be a modifiable entity.

These are called Left-Hand-Side expressions in the ECMA standard.

The C language refers to these as Locator Values.

See also:	= (Assign), Add then assign (+=), Assign value (=), Assignment expression, Bitwise AND then assign (&=), Bitwise OR then assign (|=), Bitwise shift left then assign (<<=), Bitwise shift right and assign (>>=), Bitwise unsigned shift right and assign (>>>=), Bitwise XOR and assign (^=), Concatenate then assign (+=), Conversion, Divide then assign (/=), Left-Hand-Side expression, Multiply then assign (*=), Property value, Remainder then assign (%=), RValue

ECMA 262 edition 3 –section –11.2

mailbox: URL (Request method)

Displays the Netscape Message Center window.

You can add keywords to access the individual components within the mailbox as necessary. The following are all valid URL values in Netscape:

- mailbox:
- mailbox:Inbox
- mailbox:Unsent%20Messages
- mailbox:Drafts
- mailbox:Templates
- mailbox:Sent
- mailbox:Trash

Each of these will spawn an additional window as required to display the relevant folder within the mailbox. Note that embedded spaces must be URL escaped for them to work. This mechanism does not seem to provide access to sub-folders.

Warnings:

- Although Netscape 6.0 supports this request method, its support is incomplete as of the first non-beta release.

See also:	javascript: URL, mailto: URL, nethelp: URL, telnet: URL, URL

mailto: URL (Request method)

Activates the mail client to send an e-mail message.

Open up a mail client application or use the browser's built-in mail client to send a message to the indicated recipient.

Netscape supports the predefiniton of the `Subject:`,`Cc:` and `Bcc:` fields in the `mailto:` URL. This is illustrated in the example. This may not work on other browsers or JavaScript-capable mail clients.

Note that you can leave the spaces as they don't need to be escaped in the Subject text. In some versions, you can also define the Body text for the e-mail by appending the `Body` operator. This is also shown in the example.

Warnings:

- This is only allowed under script control if the script has the `UniversalSendMail` privilege.

Example code:

```
<!-- Simple example showing just a mail to link -->
<a href="mailto:someone@somewhere.com">Send Mail</a>
<!-- Adding a subject header -->
<a href="mailto:someone@somewhere.com?Subject=Email From
Link&Cc=access@wrox.com&Bcc=backup@wrox.com">Send Mail</a>
<!-- Adding a subject header -->
<a href="mailto:someone@somewhere.com?Subject=Email From Link">Send Mail</a>
<!-- Adding CC and BCC fields -->
<a href="mailto:someone@somewhere.com?Subject=Email From Link">Send Mail</a>
<!-- Adding a predefined message body -->
<a href="mailto:someone@somewhere.com?Subject=Email From
Link&Cc=access@wrox.com&Bcc=backup@wrox.com&Body=messageText">Send Mail</a>
```

See also:	javascript: URL, mailbox: URL, nethelp: URL, UniversalSendMail, URL

main() function (Definition)

The main entry point to a procedural language program.

Property/method value type:	Implementation defined

Although JavaScript in many circumstances does not have a `main()` function, in some applications of the language it may be necessary.

By implication, the `main()` function of a JavaScript is the global code that is present in a web page in the `<SCRIPT>` tags, but is not part of a function declaration body.

When embedded in a browser, the language is invoked according to an event model and the browser itself is the `main()` for the interpreter. Various script based functions are called by the browser.

In a server-side environment, a script may be used as the result of a CGI call. In that case, a `main()` with passed parameters is a more useful facility.

In some implementations, the `main()` function may be used to make the language accessible to C programmers. Languages often borrow from one another and JavaScript borrows heavily from C language and Java. The exact form of the `main()` function and possibly its name will be implementation dependent and you should check the documentation for the interpreter just make sure it behaves the way you expect.

The result of calling the `main()` function will be implementation specific, but probably an integer.

See also:	`argc` parameter, `argv` parameter, Execution context, Execution environment, Host environment, `Host` object

MakeDate() (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

The `MakeDate()` operator calculates a number of milliseconds from its two arguments. Both arguments must be ECMAScript number values.

All of the arguments must be numeric and finite values. The values should be integers. If they are not then the result will be `NaN`.

The day argument is multiplied by the milliseconds per day and the time argument is added to the result. The sum of the two is a millisecond coded date and time value.

Although this is called an operator in the standard, its behavior is more like that of a function. It is not part of the formal language implementation but is a useful function to have available, and can be simulated by writing a script-based function. It is documented in the standard to assist in the algorithmic breakdown of the `Date` method handlers.

The result is a date value in milliseconds since the base date.

See also:	`Cast` operator, `Date` object, `Date()`, `Date.UTC()`, Time range, Time value

Cross-references:

ECMA 262 edition 2 –section –15.9.1.13

ECMA 262 edition 3 –section –15.9.1.13

MakeDay() (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

The `MakeDay()` operator calculates a number of days from its three arguments. Each argument must be an ECMAScript number value.

All of the arguments must be numeric and finite values. The values should be integers. If they are not then the result will be `NaN`.

The month number is used as a lookup to establish the number of days in the preceding months. This will also take the year number into account because a leap year calculation may be necessary.

The standard does not mandate any range checking, however it would be sensible to include range checks in the implementation of this functionality.

Although this is called an operator in the standard, its behavior is more like that of a function. It is not part of the formal language implementation, but is a useful function to have available and can be simulated by writing a script-based function. It is documented in the standard to assist in the algorithmic breakdown of the `Date` method handlers.

The result is a day value in milliseconds since the base date.

See also:	`Cast` operator, `Date` object, `Date()`, `Date.UTC()`, Time range, Time value

Cross-references:

ECMA 262 edition 2 –section –15.9.1.12

ECMA 262 edition 3 –section –15.9.1.12

MakeTime() (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

The `MakeTime()` operator calculates a number of milliseconds from its four arguments. Each argument must be an ECMAScript number value.

All of the arguments must be numeric and finite values. The values should be integers. If they are not then the result will be `NaN`.

The constant time values giving milliseconds per hour, minute and second are used to multiply each argument. The results are then summed to provide an equivalent time in milliseconds.

No range checking is performed according to the ECMA standard so some degree of overflow can be expected.

Although this is called an operator in the standard, its behavior is more like that of a function. It is not part of the formal language implementation, but is a useful function to have available and can be simulated by writing a script-based function. It is documented in the standard to assist in the algorithmic breakdown of the `Date` method handlers.

The result is a time value since midnight measured in milliseconds.

See also:	`Cast` operator, `Date` object, `Date()`, `Date.UTC()`, Time range, Time value

ECMA 262 edition 3 –section –15.9.1.11

<MAP TARGET="..."> (HTML Tag Attribute)

The frame or window to target by default with the links in an image map.

This is a non-standard tag attribute that is used as a means of linking frames and area maps. You should use `<AREA TARGET="...">` instead of `<MAP TARGET="...">` for portable applications.

Warnings:

- Because this is a non-standard HTML tag attribute, most implementations will not support the `TARGET` attribute on a `<MAP>` tag. In that case, apply the `TARGET` attribute to the `<AREA>` tags in the map instead.

See also:	`Anchor.target`, `Form.target`, `Map.target`, `Window.frames[]`

Deprecated usage:

Yes

Map object (Object/HTML)

An object that represents a `<MAP>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myMap* = *myDocument*.all.*anElementID*
	IE	*myMap* = *myDocument*.all.tags("MAP")[*anIndex*]
	IE	*myMap* = *myDocument*.all[*aName*]
	-	*myMap* = *myDocument*.getElementById(*anElementID*)
	-	*myMap* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myMap* = *myDocument*.getElementsByTagName("MAP")[*anIndex*]
HTML syntax:	`<MAP> ... </MAP>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`name, target`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	
Collections:	`areas[]`	

The `<MAP>` tag in the HTML document source is a container for the `<AREA>` tags. These all belong to a parent `Map` object. This is a means of componentizing a client-side image map and building complex non-rectangular shaped areas.

See also:	`A` object, `Area` object, `Element` object, `Location` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`name`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`target`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.5+	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

Map.areas[] (Collection)

A collection of `Area` objects belonging to the `map` object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	-	*myMap*.areas

The objects instantiated by `<AREA>` tags which are part of this image map, are collected together and accessible as a collection. The collection object is referred to by this property.

Property attributes:

`ReadOnly`

Map.name (Property)

The value of the `NAME="..."` HTML tag attribute.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myMap*.name

Objects are identified either by the `NAME="..."` HTML tag attribute or by the `ID="..."` HTML tag attribute.

Netscape Navigator shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However, in many cases both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`IMG.useMap`

Map.target (Property)

The target window or frame to which a map applied.

Availability:	JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myMap*.target
HTML syntax:	`<MAP TARGET="...">`	

This yields the value of the `TARGET` attribute in an `<A>`, `<AREA>` or `<MAP>` tag.

You can assign a new value to this property so that the URL will be directed to a different window or frame.

Here are some example target values:

- `_parent`
- `_self`
- `_top`
- `_blank`
- Window name
- Frame name

See also:	`<MAP TARGET="...">`,`Anchor.target`,`BASE.target`, `Form.target`,`Url.target`

MARQUEE object (Object/HTML)

An object that represents a `<MARQUEE>` HTML tag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myMARQUEE* = *myDocument*.all.*anElementID*
	IE	*myMARQUEE* = *myDocument*.all.tags("MARQUEE")[*anIndex*]
	IE	*myMARQUEE* = *myDocument*.all[*aName*]
	-	*myMARQUEE* = *myDocument*.getElementById(*anElementID*)
	-	*myMARQUEE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myMARQUEE* = *myDocument*.getElementsByTagName("MARQUEE")[*anIndex*]
HTML syntax:	`<MARQUEE>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey, behavior, bgColor, dataFld, dataFormatAs, dataSrc, direction, height, hspace, loop, scrollAmount, scrollDelay, tabIndex, trueSpeed, vspace, width`	
Object methods:	`start(), stop()`	
Event handlers:	`onAfterUpdate, onBlur, onBounce, onClick, onDblClick, onDragStart, onFilterChange, onFinish, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onScroll, onSelectStart, onStart`	

The `MARQUEE` object is only supported by MSIE and provides means of quickly and easily generating a moving ticker display inside the window area. This can be accomplished with Netscape using layers and some interval timed JavaScript function calls to scroll the layer.

The MSIE `MARQUEE` object is a little more aware of Font Metrics than your average script access can achieve. This means making the `MARQUEE` bounce back and forth when the text hits the edge of the extent rectangle is a lot easier to accomplish in MSIE than in Netscape.

See also:	`Element` object, `Input.accessKey`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`accessKey`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

MARQUEE.behaviour (Property)

A attribute that controls the motion of the text in the `MARQUEE` object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.behavior`

The animated effect in the `MARQUEE` is controlled by this property. The following values are appropriate:

- `alternate`
- `scroll`
- `slide`

The alternate behavior marches left and then on bouncing into a boundary, marches right until it bounces again.

The scroll and slide behaviors use the direction attribute to control the direction of movement.

When set to scroll, the MARQUEE starts empty, the text scrolls in, traverses the MARQUEE and scrolls out again. A complete cycle begins and ends with an empty MARQUEE.

When set to slide, the MARQUEE again starts empty, the text scrolls in until it hits a boundary. Then it is simply zapped out and does not scroll away. Again, a complete cycle begins and ends with an empty MARQUEE.

MARQUEE.bgColor (Property)

The background color for the area occupied by the MARQUEE object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myMARQUEE*.bgColor

The background can be colored independently of whether an image is loaded into the background of an object. In fact, it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	color names, color value

MARQUEE.direction (Property)

The direction of movement of the scrolling text in the MARQUEE.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myMARQUEE*.direction

A MARQUEE object can scroll in all four cardinal directions. Leftward scrolling is most likely the appropriate setting for textual content written in a Roman script that is read from left to right. Diagonal scrolling is not possible with a MARQUEE but could be implemented using layers in Netscape 4 or an IFRAME in MSIE and Netscape 6.0.

The following values are appropriate for this property:

- left
- right
- down
- up

MARQUEE.height (Property)

The height of the area allocated to the `MARQUEE` object as it appears onscreen.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myMARQUEE`*`.height`

The `MARQUEE` space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

MARQUEE.hspace (Property)

The height of the area allocated to the `MARQUEE` object as it appears onscreen.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myMARQUEE`*`.hspace`

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `hspace` property controls the margin to the left and right of the object.

MARQUEE.loop (Property)

A count of the number of times the `MARQUEE` text is to scroll.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myMARQUEE`*`.loop`

You can define the number of cycles the `MARQUEE` animation will cycle round before stopping. When it stops, the text will remain visible.

Continuous looping is specified by setting this property to a value of -1.

MARQUEE.scrollAmount (Property)

The offset of the text between one scroll cycle and the next.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.scrollAmount`

This value is specified in pixels, and controls the distance that the text appears to move on each scroll cycle of the `MARQUEE`. The larger the number, the faster the scrolling appears to travel.

MARQUEE.scrollDelay (Property)

The time-delay in milliseconds between each scroll update.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.scrollDelay`

A short delay and small scroll distance will consume more CPU time but appear to be a smoother scroll.

MARQUEE.start() (Method)

A command method to start the `MARQUEE` scrolling.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myMARQUEE*`.start()`

You can stop and start the `MARQUEE` animation whenever you want. Maybe it is appropriate to scroll a `MARQUEE` when a mouse is positioned over an object. You can call this method as part of a `MouseOver` event handler. Then, you can call its complementary `MARQUEE.stop()` method on the `MoveMouseOut` event handler.

MARQUEE.stop() (Method)

A command method to stop the `MARQUEE` from scrolling.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myMARQUEE*`.stop()`

Refer to:

`MARQUEE.start()`

MARQUEE.trueSpeed (Property)

A switch attribute that controls whether the browser should honor very small scroll delay times.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.trueSpeed`

Extremely small delay times may cause the `MARQUEE` to scroll more than once during each screen retrace interval. It is wasteful of the CPU resources to scroll the `MARQUEE` faster than the viewer can perceive the changes. A longer delay and greater scroll distance is more efficient although it may appear jerky for extreme settings.

MARQUEE.vspace (Property)

The size of a vertical margin above and below the `MARQUEE` with respect to any adjacent objects.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.vspace`

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `vspace` property controls the margin at the top and bottom of the object.

MARQUEE.width (Property)

The width of the area allocated to the `MARQUEE` object as it appears onscreen.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myMARQUEE*`.width`

The `MARQUEE` space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

Mask() (Filter/visual)

A visual filter for creating a transparent mask.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

Filter – `Mask()`

MaskFilter() (Filter/visual)

Uses the transparent color pixels of an object as a mask.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `MaskFilter()`

Math object (Object/core)

A globally available object containing a library of mathematical functions.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
JavaScript syntax:	-	`Math`
Object properties:	`constructor`	
Class constants:	`E, LN10, LN2, LOG10E, LOG2E, PI, SQRT1_2, SQRT2`	
Functions:	`abs(), acos(), asin(), atan(), atan2(), ceil(), cos(), exp(), floor(), log(), max(), min(), pow(), random(), round(), sin(), sqrt(), tan()`	

The `Math` object is merely a single object owned by the `Global` Object and which cannot be instantiated. It has some named properties, some of which are functions while others are constants.

The prototype for the `Math` prototype object is the `Object` prototype object.

Although it cannot be instantiated, it does have a constructor which in turn has a prototype property. By adding functions to that prototype, you can extend the capabilities of the `Math` object. Several examples are provided in nearby topics to illustrate the addition of extra trigonometric and hyperbolic functions.

Warnings:

- The `Math` object provides a collection of static constant values by way of properties belonging to the integral `Math` object. Because the mathematical mechanisms of any application tend to be provided by the operating system, you should find that between different browsers on any particular platform, the values that these constants yield will be very consistent.
- The ECMA standard lays down strict values for these properties and in general, the browser manufacturers try to comply –however, there is always the possibility that an implementation may use a non-compliant calculation.
- However, it may not be quite so reliable across platforms. You might enumerate one of these constants as you are authoring and then hard code that value into your script. When that script is executed on another platform, even in the same browser, the internal mathematics support may yield a different value.
- You should always refer to the static constants using their symbolic names rather than hard code a possibly platform-dependent value into your script.
- Note for the trigonometric functions in general that certain implied identities cannot be assumed in JavaScript. For example:
  - `Math.sin(Math.PI/2)` may not yield exactly 1
  - `Math.cos(Math.PI)` may not return precisely zero
  - `Math.acos(0)` may not return the same value as Math.PI
  - `Math.SQRT1_2` may not be exactly equal to the reciprocal of `Math.SQRT2`

See also:	Constant, Exponent-log function, `Global` object, Integer arithmetic, Java to JavaScript values, `Native` object, Object constant, `Object` object, Range error, Trigonometric function, Type conversion, `unwatch()`, `watch()`

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	Notes
`constructor`	1.0 +	1.0 +	2.0 +	3.02 +	-	-	-	-

Math.abs() (Function)

The absolute value of a positive or negative number.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.abs(`*`aValue`*`)`
Argument list:	*`aValue`*	Some meaningful numeric value

This function returns the absolute value of the argument.

The absolute value of a number is its distance from zero.

In general, the result has the same magnitude as the argument but always has a positive sign.

Special boundary conditions that affect the results are:

Argument	Result
0	0
NaN	NaN
negative infinity	positive infinity

On some implementations, the absolute value of the most negative integer number may not be representable in the positive range.

This is not the same as `Number.MIN_VALUE` and `Number.MAX_VALUE`. They describe the largest and smallest possible positive floating point values.

Warnings:

- It is possible that due to the underlying implementation of the math library, the absolute value of the most negative number may not be representable and it may yield `NaN` instead.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
for(myEnum = 1.5; myEnum > -2; myEnum -= 0.1)
```

```
{
   document.write(myEnum + " " + Math.abs(myEnum) + "<BR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	Integer arithmetic, Integer-value-remainder, `Math` object, `Math.ceil()`,`Math.floor()`, Type conversion

ECMA 262 edition 2 –section –15.8.2.1

ECMA 262 edition 3 –section –15.8.2.1

Math.acos() (Function)

The inverse cosine of the passed-in value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.acos(`*`aValue`*`)`
Argument list:	*`aValue`*	Some meaningful numeric value

This function returns the arc-cosine of the argument.

Special boundary conditions that affect the results are:

Argument	Result
1	0
greater than 1	NaN
less than -1	NaN
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

The result of this method is the arc-cosine of the passed-in value. The result is expressed in radians and ranges from 0 to pi.

Warnings:

- Note that `Math.acos(0)` may not return the same value as `Math.PI`.

See also:	`Math` object, `Math.asin()`, `Math.atan()`, `Math.atan2()`, `Math.cos()`, `Math.PI`, `Math.sin()`, `Math.tan()`, Trigonometric function

Cross-references:

ECMA 262 edition 2 –section –15.8.2.2

ECMA 262 edition 3 –section –15.8.2.2

Math.asin() (Function)

The inverse sine of the passed-in value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.asin(`*`aValue`*`)`
Argument list:	*`aValue`*	Some meaningful numeric value

This function returns the arc-sine of the argument.

Special boundary conditions that affect the results are:

Argument	Result
0	0
greater than 1	NaN
less than -1	NaN
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

The result of this method is the arc-sine of the passed-in value. The result is expressed in radians and ranges from -pi/2 to +pi/2.

See also:	`Math` object, `Math.acos()`, `Math.atan()`, `Math.atan2()`, `Math.cos()`, `Math.sin()`, `Math.tan()`, Trigonometric function

ECMA 262 edition 3 –section –15.8.2.3

Math.atan() (Function)

The inverse tangent of the passed-in value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.atan(`*`aValue`*`)`
Argument list:	*`aValue`*	Some meaningful numeric value

This function returns the arc-tangent of the argument.

Special boundary conditions that affect the results are:

Argument	Result
0	0
minus infinity	-pi/2
NaN	NaN
plus infinity	+pi/2

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

The result of this method is the arc-tangent of the passed-in value. The result is expressed in radians and ranges from -pi/2 to +pi/2.

See also:	`Math` object, `Math.acos()`, `Math.asin()`, `Math.atan2()`, `Math.cos()`, `Math.sin()`, `Math.tan()`, Trigonometric function

Cross-references:

ECMA 262 edition 2 –section –15.8.2.4

ECMA 262 edition 3 –section –15.8.2.4

Math.atan2() (Function)

The inverse tangent of the slope of the two arguments.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.atan2(`*`aValue1, aValue2`*`)`
Argument list:	*aValue1*	Some meaningful numeric value
	aValue2	Some meaningful numeric value

This function computes the quotient of arg2/arg1 and then returns the arc-tangent of the result. It takes into account which quadrant the value falls into according to the signs of the two arguments.

It is provided in several languages other than JavaScript for those situations where very large numbers are involved.

Traditionally, for this function, the Y argument is placed first and the X argument second.

Special boundary conditions that affect the results are:

Argument1	Argument2	Result
+infinity	+infinity	+pi/4
+infinity	-infinity	+3pi/4
+infinity	non zero	+pi/2
-infinity	+infinity	-pi/4
-infinity	-infinity	-3pi/4
-infinity	non zero	-pi/2
0	negative	pi * sign of Argument1
0	positive	0
< 0	-infinity	-pi
< 0	0	-pi/2
> 0	-infinity	+pi
> 0	0	+pi/2
Any value	NaN	NaN
NaN	Any value	NaN
non zero	+infinity	0

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

The result of this method is the arc-tangent of the slope of the two arguments. The result is expressed in radians and ranges from -pi to +pi.

See also:	`Math` object, `Math.acos()`, `Math.asin()`, `Math.atan()`, `Math.cos()`, `Math.sin()`, `Math.tan()`, Trigonometric function

Cross-references:

ECMA 262 edition 2 –section –15.8.2.5

ECMA 262 edition 3 –section –15.8.2.5

Math.ceil() (Function)

The value rounded up to the next higher integer value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.ceil(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

According to the ECMA standard, this function returns the smallest number value that is not less than the argument and is equal to a mathematical integer. If the argument is already an integer, the argument itself is returned.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	+infinity
-1 < argument > 0	0
-infinity	-infinity
0	0
NaN	NaN

Note that if the value is negative, the magnitude decreases while it increases for positive numbers. The `ceil` of 25.4 is 26 whereas the `ceil` of -25.4 is -25.

The result is the input value rounded up to the next higher integer value.

Warnings:

- Other reference sources on this function differ as to its functionality. Some indicate that it rounds up to an integer, others that it rounds down. This suggests that some implementations may behave differently since they may use the available documentation to design their interpreter. The ECMA standard is probably the most reliable specification long term since manufacturers will attempt to build ECMA compliance into their implementations as a selling point.
- Recent browsers from Microsoft, Netscape and Opera are all compliant with the ECMA standard on this point.
- If you are uncertain, you should check the functionality by running some tests. For example, run the test for negative and positive values. Checking a few boundary conditions won't hurt either.

See also:	Integer, Integer arithmetic, Integer-value-remainder, `Math` object, `Math.abs()`,`Math.floor()`,`Math.round()`,`Number()`, `Remainder (%)`, Remainder then assign (%=), Type conversion

ECMA 262 edition 2 –section –15.8.2.6

ECMA 262 edition 3 –section –15.8.2.6

Math.constructor (Property)

A means of creating a new `Math` object.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Math object`	
JavaScript syntax:	-	`Math.constructor`

Both Netscape and MSIE support a constructor property for the `Math` object. It is unlikely you would ever want to construct a copy of the `Math` object.

However, this is useful not for the purpose of cloning the `Math` object but so that you can extend it by adding your own properties and methods to its prototype.

This technique is demonstrated in the example which appears to add a `pythag()` function to the `Math` object although it is really added to the `Object()` object prototype.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the capabilities of the Math object
function pythag(aValue1, aValue2)
{
   return Math.sqrt((aValue1*aValue1) + (aValue2*aValue2));
}
// Register the new function
Math.constructor.prototype.pythag = pythag;
// Test the Math.pythag() method
document.write(Math.pythag(3, 4))
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

Math.cos() (Function)

The cosine of the input argument.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.cos(`*`aValue`*`)`
Argument list:	*`aValue`*	An angle measured in radians

This function returns the cosine of the argument. The argument must be expressed in radians.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	NaN
-infinity	NaN
0	1
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations math routines and the specific algorithm selected to evaluate this function.

Warnings:

- Note that `Math.cos(Math.PI)` may not return precisely zero.

See also:	`Math` object, `Math.acos()`, `Math.asin()`, `Math.atan()`, `Math.atan2()`, `Math.PI`, `Math.sin()`, `Math.tan()`, Trigonometric function

ECMA 262 edition 3 –section –15.8.2.7

Math.cosec() (Simulated functionality)

The `cosec()` function is not available in JavaScript but can be simulated to aid in the porting of existing code.

The example demonstrates how to add the `cosec()` method to the `Math` object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Add the cosec function to the Math object
function cosec(aValue)
{
   return 1/Math.sin(aValue);
}

// Register the new function
Math.constructor.prototype.cosec = cosec;

// Test the Math.cosec() method
document.write(Math.cosec(2));
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Math.cot()`, `Math.sec()`

Math.cosh() (Simulated functionality)

The `cosh()` function is not available in JavaScript but can be simulated to aid in the porting of existing code.

The example demonstrates how to add the `cosh()` method to the `Math` object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Add the cosh function to the Math object
function cosh(aValue)
{
   var myTerm1 = Math.pow(Math.E, aValue);
   var myTerm2 = Math.pow(Math.E, -aValue);
   return (myTerm1+myTerm2)/2;
}

// Register the new function
Math.constructor.prototype.cosh = cosh;

// Test the Math.cosh() method
document.write(Math.cosh(2));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

Math.cot() (Simulated functionality)

The `cot()` function is not available in JavaScript but can be simulated to aid in the porting of existing code.

The example demonstrates how to add the `cot()` method to the `Math` object to provide the capability to calculate cotangents.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Add the cot function to the Math object
function cot(aValue)
{
   return 1/Math.tan(aValue);
}
```

```
// Register the new function
Math.constructor.prototype.cot = cot;

// Test the Math.cot() method
document.write(Math.cot(2));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Math.cosec()`,`Math.sec()`

Math.E (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape Navigator –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.E`

The numeric constant value for e, the base of natural logarithms.

The resulting value is approximately 2.718281828459045 (to 15 d.p.).

Warnings:

- The word approximately is used when describing the result, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Exponent-log function, Floating point constant, `Math` object, `Math.exp()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.1

ECMA 262 edition 3 –section –15.8.1.1

Math.exp() (Function)

The exponential function of the passed-in argument.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.exp(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

This function returns the exponential function of the argument (e raised to the power of the argument, where e is the base of the natural logarithms).

Special boundary conditions that affect the results are:

Argument	Result
+infinity	+infinity
-infinity	0
0	1
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

See also:	Exponent-log function, `Math` object, `Math.E`, `Math.LN10`, `Math.LN2`, `Math.log()`, `Math.LOG10E`, `Math.LOG2E`

Math.floor() (Function)

The value is rounded down to the next integer.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape Navigator –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.floor(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

Returns the greatest number value that is not greater than the argument and is equal to a mathematical integer. If the argument is already an integer, the argument itself is returned.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	+infinity
-infinity	-infinity
0	0
0 < argument > 1	0
NaN	NaN

Note that if the value is negative, the magnitude increases while it decreases for positive numbers. The floor of 25.4 is 25 whereas the floor of -25.4 is -26.

The result is the input value rounded down to the next integer.

Warnings:

- Other reference sources on this function differ as to its functionality. Some indicate that it rounds up to an integer, others that it rounds down. However, all implementations appear to conform to the ECMA specified behavior.

See also:	Integer, Integer arithmetic, Integer-value-remainder, `Math` object, `Math.abs()`,`Math.ceil()`,`Math.round()`,`Number()`, Remainder (%), Remainder then assign (%=), Type conversion

Math.LN10 (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `Math.LN10`

This constant provides the numeric value for the natural logarithm of 10.

The resulting value value is approximately 2.302585092994046 (to 15 d.p.)

Warnings:

- The word approximately is used when describing the result, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Exponent-log function, Floating point constant, `Math` object, `Math.exp()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.2

ECMA 262 edition 3 –section –15.8.1.2

Math.LN2 (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0

Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.LN2`

This constant provides the numeric value of the natural logarithm of 2.

The resulting value returned is approximately 0.693147180559945 (to 15 d.p.)

See also:	Arithmetic constant, Exponent-log function, Floating point constant, `Math` object, `Math.exp()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.3

ECMA 262 edition 3 –section –15.8.1.3

Math.log() (Function)

The natural logarithm of the passed-in value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.log(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

This function returns the natural (base e) logarithm of the input argument.

This function is the inverse of the `Math.exp()` function.

Special boundary conditions that affect the results are:

Argument	**Result**
+infinity	+infinity
0	-infinity
1	0
< 0	NaN
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

See also:	Exponent-log function, `Math` object, `Math.exp()`

Cross-references:

ECMA 262 edition 2 –section –15.8.2.10

ECMA 262 edition 3 –section –15.8.2.10

Math.LOG10E (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera browser –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.LOG10E`

This constant provides the numeric value for the base-10 logarithm of e, the base of natural logarithms.

Note that the value of `Math.LOG10E` is approximately the reciprocal of the value of `Math.LN10`.

The result returned is approximately 0.434294481903252 (to 15 d.p.)

Warnings:

- The word approximately is used when describing the result, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Exponent-log function, Floating point constant, `Math` object, `Math.exp()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.5

ECMA 262 edition 3 –section –15.8.1.5

Math.LOG2E (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `Math.LOG2E`

This constant provides the numeric value for the base-2 logarithm of e, the base of natural logarithms.

By inspection, the resulting value returned is 1.4426950408889634 although this may vary from platform to platform.

Warnings:

- Note that the value of `Math.LOG2E` is approximately the reciprocal of the value of `Math.LN2`. The word approximately is used here, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Exponent-log function, Floating point constant, `Math` object, `Math.exp()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.4

ECMA 262 edition 3 –section –15.8.1.4

Math.max() (Function)

The maximum of the two or more input arguments is returned.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0

Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.max(aValue1, aValue2, ...)`
Argument list:	*aValue1*	Some meaningful numeric value
	aValue2	Some meaningful numeric value

Returns the larger of the two or more arguments.

Special boundary conditions that affect the results are:

Argument1	Argument2	Result
Any value	NaN	NaN
Any value	The same value	The value
larger	smaller	Argument1
NaN	Any value	NaN
smaller	larger	Argument2

See also:	`Math` object

Cross-references:

ECMA 262 edition 2 –section –15.8.2.11

ECMA 262 edition 3 –section –15.8.2.11

Math.min() (Function)

The minimum of the two or more input arguments is returned.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.min(aValue1, aValue2, ...)`
Argument list:	*aValue1*	Some meaningful numeric value
	aValue2	Some meaningful numeric value

This function returns the smaller of the two or more arguments.

Special boundary conditions that affect the results are:

Argument1	Argument2	Result
Any value	NaN	NaN
Any value	The same value	The value
larger	smaller	Argument2
NaN	Any value	NaN
smaller	larger	Argument1

See also:	`Math` object

Cross-references:

ECMA 262 edition 2 –section –15.8.2.12

ECMA 262 edition 3 –section –15.8.2.12

Math.PI (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.PI`

This constant provides the numeric value for pi, the ratio of circumference of a circle to its diameter.

The resulting value returned is approximately 3.141592653589793 (to 15 d.p.)

Warnings:

- Note that `Math.sin(Math.PI/2)` may not yield exactly 1.
- Note that `Math.cos(Math.PI)` may not return precisely zero.
- Note that `Math.acos(0)` may not return the same value as `Math.PI`.

See also:	Arithmetic constant, Floating point constant, `Math` object, `Math.acos(),Math.cos(),Math.sin()`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.6

ECMA 262 edition 3 –section –15.8.1.6

Math.pow() (Function)

The result of raising a value to the power of another value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.pow(`*`aValue1`*`, `*`aValue2`*`)`
Argument list:	*`aValue1`*	Some meaningful numeric value
	`aValue2`	Some meaningful numeric value

This function returns the result of raising the first argument to the power of the second.

Special boundary conditions that affect the results are:

Argument1	Argument2	Result
+0	< 0	+infinity
+infinity	< 0	0
+infinity	> 0	+infinity
-0	< 0 and is an even integer	+infinity
-0	< 0 and is an odd integer	-infinity
-infinity	< 0	0
-infinity	> 0 and is an even integer	+infinity
-infinity	> 0 and is an odd integer	-infinity
0	> 0	0
1	Any value	1
< 0 and finite	finite but non integer	NaN
abs(arg) < 1	+infinity	0

Table continued on following page

Argument1	Argument2	Result
abs(arg) < 1	-infinity	+infinity
abs(arg) == 1	+infinity	NaN
abs(arg) == 1	-infinity	NaN
abs(arg) > 1	+infinity	+infinity
abs(arg) > 1	-infinity	0
Any value	0	1
Any value	NaN	NaN
NaN	non zero	NaN

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

The example shows a simple binary number converter which exhibits some instability in the most significant bit on some platforms.

Warnings:

- There are many boundary conditions that make this function hard to understand and therefore hard to diagnose if it goes wrong. Check both of the input arguments in case of doubt. They may have evaluated out to a strange boundary condition that yields unexpected results.
- Using MSIE on the Macintosh exhibits a instability when you raise 2 to the power 31 and test the resulting value in a bitwise expression. Netscape works correctly in this circumstance. This is demonstrated in the example.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
document.write(-2 + " - " + binary32(-2) + "<BR>");
document.write(-1 + " - " + binary32(-1) + "<BR>");
document.write(0 + " - " + binary32(0) + "<BR>");
document.write(1 + " - " + binary32(1) + "<BR>");
document.write(2 + " - " + binary32(2) + "<BR>");
document.write(3 + " - " + binary32(3) + "<BR>");
function binary32(aValue)
{
   myArray = new Array(32);

   for(myEnum=0; myEnum<32; myEnum++)
   {
      if(aValue & Math.pow(2, myEnum))
      {
         myArray[31-myEnum] = "1";
      }
      else
      {
```

```
            myArray[31-myEnum] = "0";
         }
      }
      return myArray.join("");
   }
   </SCRIPT>
   </BODY>
   </HTML>
```

See also:	`Math` object, `Math.sqrt()`, Power function, Zero value

Math.random() (Function)

Generates a pseudo-random value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –2.02 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.random()`

The `Math.random()` function generates and returns a pseudo-random value; a positive value between 0 and 1.

The resulting value is chosen randomly (or pseudo randomly) depending on the implementation.

In any case, regardless of how it is selected, it should yield a uniform distribution over the range of possible values.

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to generate the random numbers.

Some implementations may provide a way to seed the random number sequence although the ECMAScript standard does not describe this capability.

Some implementations provide predictable series of random numbers that always start at the same seed point.

The algorithm and strategy is implementation dependent and the standard offers no recommendations as to which is best.

Warnings:

- Although this is noted as being available in Netscape 2.02, that only applies to the Unix platform. It wasn't widely available until JavaScript 1.1 was supported in Netscape 3.0 on the remaining platforms.

See also:	`Math` object, Pseudo-random numbers

Cross-references:

ECMA 262 edition 2 –section –15.8.2.14

ECMA 262 edition 3 –section –15.8.2.14

Math.round() (Function)

Rounds to the nearest integer value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape Navigator –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.round(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

This function returns the value that is closest to the argument and is a mathematical integer. It rounds the input value to the nearest integer value either rounding up or down as necessary.

If the input value is equi-distant from two integer values, the result is rounded up towards positive infinity. If the argument is already an integer, the argument itself is returned.

Special boundary conditions that affect the results are:

Argument	**Result**
+infinity	+infinity
-0.5 < arg < 0.5	0
-infinity	-infinity
0	0
NaN	NaN

Note that `Math.round(3.5)` returns the value 4 while `Math.round(-3.5)` returns the value 3.

Math.sec() (Simulated functionality)

The `sec()` function is not available in JavaScript but can be simulated to aid in the porting of existing code.

The example demonstrates how to add the `sec()` method to the `Math` object to provide the capability to calculate secants.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Add the sec function to the Math object
function sec(aValue)
{
   return 1/Math.cos(aValue);
}

// Register the new function
Math.constructor.prototype.sec = sec;

// Test the Math.sec() method
document.write(Math.sec(2));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Math.cosec(),Math.cot()`

Math.sin() (Function)

The sine of the passed in value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.sin(`*`aValue`*`)`
Argument list:	*`aValue`*	An angle measured in radians

This function returns the sine of the input argument. The argument value must be expressed in radians.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	NaN
-infinity	NaN
0	0
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

Warnings:

- Note that `Math.sin(Math.PI/2)` may not yield exactly 1.

See also:	`Math` object, `Math.acos()`, `Math.asin()`, `Math.atan()`, `Math.atan2()`, `Math.cos()`, `Math.PI`, `Math.tan()`, Trigonometric function

Cross-references:

ECMA 262 edition 2 –section –15.8.2.16

ECMA 262 edition 3 –section –15.8.2.16

Math.sinh() (Simulated functionality)

The `sinh()` function is not available in JavaScript but can be simulated to aid in the porting of existing code.

The example demonstrates how to add the `sinh()` method to the `Math` object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Add the sinh function to the Math object
function sinh(aValue)
{
   var myTerm1 = Math.pow(Math.E, aValue);
   var myTerm2 = Math.pow(Math.E, -aValue);
   return (myTerm1-myTerm2)/2;
}
```

```
// Register the new function
Math.constructor.prototype.sinh = sinh;

// Test the Math.sinh() method
document.write(Math.sinh(2));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

Math.sqrt() (Function)

The square root of the input argument.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.sqrt(`*`aValue`*`)`
Argument list:	*`aValue`*	A meaningful numeric value

This function computes the square root of the input argument.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	+infinity
0	0
< 0	NaN
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation, due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

Math.SQRT1_2 (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `Math.SQRT1_2`

This constant returns the numeric value of the square root of 0.5.

The resulting value returned is approximately 0.707106781186548 (to 15.d.p.)

Warnings:

- Note that the value of `Math.SQRT1_2` is approximately the reciprocal of the value of `Math.SQRT2`. The word approximately is used here, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Floating point constant, Math object, `Math.SQRT2`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.7

ECMA 262 edition 3 –section –15.8.1.7

Math.SQRT2 (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0

Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.SQRT2`

This constant provides the value of the square root of 2.

The resulting value returned is approximately 1.414213562373095 (to 15 d.p.)

Warnings:

- Note that `Math.SQRT1_2` may not be exactly equal to the reciprocal of `Math.SQRT2`.

See also:	Arithmetic constant, Floating point constant, `Math` object, `Math.SQRT1_2`

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.8.1.8

ECMA 262 edition 3 –section –15.8.1.8

Math.tan() (Function)

The tangent of the input argument.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Math.tan(`*`aValue`*`)`
Argument list:	*`aValue`*	An angle measured in radians

This function returns the tangent of the input argument. The argument value must be expressed in radians.

Special boundary conditions that affect the results are:

Argument	Result
+infinity	NaN
-infinity	NaN
0	0
NaN	NaN

The exact value yielded by this function may vary slightly from implementation to implementation due to differences in the underlying precision of the implementations, math routines, and the specific algorithm selected to evaluate this function.

See also:	`Math` object, `Math.acos()`, `Math.asin()`, `Math.atan()`, `Math.atan2()`, `Math.cos()`, `Math.sin()`, Trigonometric function

ECMA 262 edition 2 –section –15.8.2.18

ECMA 262 edition 3 –section –15.8.2.18

Mathematics (Definition)

Mathematical support.

The following table summarizes the support for mathematical computation in JavaScript:

Function	Object	Type	Description
`abs()`	Math	Function	Absolute value of a number
`acos()`	Math	Function	Inverse cosine
`asin()`	Math	Function	Inverse sine
`atan()`	Math	Function	Inverse tangent
`atan2()`	Math	Function	Inverse tangent of a slope
`ceil()`	Math	Function	Round up
`cos()`	Math	Function	Cosine of an angle
`E`	Math	Constant	Exponential constant
`exp()`	Math	Function	Exponent function
`floor()`	Math	Function	Round down
`isFinite()`	Global	Function	Test for infinity
`isNaN()`	Global	Function	Test for Not-a-Number
`LN10`	Math	Constant	Natural log of 10
`LN2`	Math	Constant	Natural log of 2

Table continued on following page

Function	Object	Type	Description
`log()`	Math	Function	Natural log of a number
`LOG10E`	Math	Constant	Log to the base 10 of e
`LOG2E`	Math	Constant	Log to the base 2 of e
`max()`	Math	Function	Maximum of two values
`MAX_VALUE`	Number	Constant	Maximum numeric value
`min()`	Math	Function	Minimum of two values
`MIN_VALUE`	Number	Constant	Minimum numeric value
`NaN`	Number	Constant	Not a number
`NEGATIVE_INFINITY`	Number	Constant	Negative infinity
`parseFloat()`	Global	Function	Floating point parser
`parseInt()`	Global	Function	Integer parser
`PI`	Math	Constant	The value of PI
`POSITIVE_INFINITY`	Number	Constant	Positive infinity
`pow()`	Math	Function	A value rased to the power of another
`random()`	Math	Function	A random value
`round()`	Math	Function	Truncating round
`sin()`	Math	Function	Sine of an angle
`sqrt()`	Math	Function	Square root
`SQRT1_2`	Math	Constant	Square root of one half
`SQRT2`	Math	Constant	Square root of two
`tan()`	Math	Function	Tangent of an angle

You should avoid the use of any of these function names as identifiers unless you are intentionally overriding their behavior by adding function properties (methods) to a prototype.

See also:	Arithmetic operator, Error, Integer arithmetic, Integer-value-remainder, Operator, Power function, Range error, Trigonometric function

Matrix() (Filter/visual)

A means of applying sophisticated rotation, translate, and scaling effects to an image using matrix transformation.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `Matrix()`

MAYSCRIPT (HTML Tag Attribute)

An attribute on the `<APPLET>` tag to allow Java to access the JavaScript object space.

This is an HTML tag attribute that can significantly affect the success or failure to run applets and plugins properly.

The `MAYSCRIPT` attribute must be present in the `<APPLET>` tag if you have applets that expect to communicate with JavaScript. This is a way of allowing applets to script under the behest of the web page author who may not be the person who programmed the applet. This way, the author has to know and expect the applet to connect to JavaScript before the applet is able to do so.

Without this attribute, an applet is not able to access the `JSObject` class and communicate with the JavaScript environment.

The `MAYSCRIPT` HTML tag attribute is not reflected into the JavaScript environment.

See also:	JavaScript embedded in Java, `JSObject` object

Measurement units (Definition)

Style position and size properties use measurement units to locate objects on the screen.

Measurement units specify the units of measure of a quantity. These are typically used for length measurement but may also be used for time measurement in aural style sheet properties.

The units include the following:

Unit	Description
`#`	A hash precedes hex color triplet values.
`%`	A percentage of the containing element's value.
`cm`	Absolute measure of a centimeter.
`deg`	A value used for angular positioning of sound sources.
`em`	A floating point value indicating a fractional portion of the length of an em-dash in the current font.
`ex`	A floating point value used to multiply the height of a small x in the current font.
`Hz`	A frequency value for aural style sheets.
`in`	Absolute measure of an inch.
`kHz`	A frequency value for aural style sheets.
`mm`	Absolute measure of a millimeter.
`ms`	A value in milli-seconds (used for aural style durations).
`pc`	Absolute measure of a pica.
`pi`	Absolute measure of a pica (possibly a misprint in some documentation).
`pt`	Absolute measure using a font point size.
`px`	An integer value measured in pixels on the screen.
`s`	A value in seconds (used for aural style durations).

Measurement units referring to a spatial distance on the page are sometimes called Length units.

MediaList object (Object/DOM)

This object is added to DOM level 2 to support media lists in style sheets.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myMedialist* = new MediaList()

DOM level 2 specifies the following properties for this object:

- `mediaText`
- `length`

DOM level 2 specifies these methods:

- `item()`
- `deleteMedium()`
- `appendMedium()`

Member (Definition)

Elements within an object.

Members of structures and unions in other languages have some analogy with methods and properties of an object. In a procedural language you can access members of a structure by name. So also can you access properties within an object.

A member name is an identifier.

The notation for accessing structure members in C language and property values in JavaScript is identical:

- `anObject.aProperty`
- `aCStruct.aMember`

There is a variation in JavaScript that allows properties to be called as functions, thus:

- `anObject.aFunctionProperty()`

This notation can also denote methods that belong to an object.

See also:	Method, Namespace

Memory allocation (Definition)

The process of locating and allocating some memory to store a string or object.

See also:	Reference counting, Memory management

Memory leak (Definition)

The consumption of memory that is not recoverable.

When the reference count for an object is zero, the object can be garbage collected. Also, because there are no references to it, you have no handle by which you can reach it, so if it isn't garbage collected, it will waste the space it occupies. When that happens, you have a memory leak.

Memory leaks typically happen in web-based JavaScript when you create and destroy a lot of strings in a loop. Concatenating many strings together and extending one string incrementally is a typical leak-producing technique.

Garbage collection generally only happens in web browsers when the page is refreshed.

See also:	delete, Garbage collection, Memory management, `Object()`, `Option()`, Reference counting, Variable, `Window.setInterval()`, `Window.setTimeout()`

Cross-references:

Wrox *Instant JavaScript* –page –29

Memory management (Definition)

The process of organizing and keeping track of memory allocation and de-allocation.

Memory management in compiled languages tends to be a primary concern of software developers. Because JavaScript is interpreted and is intended for use by designers as well as developers, a great deal of the complexity of memory management is hidden from view.

It is still possible however to design a script that will consume large amounts of memory due to what is called a memory leak.

A memory leak is when you allocate some storage and you don't subsequently relinquish it and make it available to the system again.

A prime example of a memory leak in the context of a JavaScript execution is the allocation of string data to `String` variables. When a new assignment is made, the old storage is unlinked from the variable and some new storage is allocated. This means that the storage management is far simpler because the strings tend to grow longer as new values are assigned. However, in a web browser, the discarded string values continue to sit around in memory until the page is refreshed. At that stage, all page local values are purged and the memory is freed.

You cannot force a garbage collection in a JavaScript execution session in a web browser other than by setting the `location.href` of the current page to itself. This has the side effect of reloading the page from the web server, presenting the user with a possibly ugly transition artifact and increasing net traffic. However, this may be far more preferable than consuming 50 Megabytes of memory every few minutes in the client.

See also:	Garbage collection, Memory leak

MENU object (Object/HTML)

An object that represents the contents of a `<MENU>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myMENU* = *myDocument*.all.*anElementID*
	IE	*myMENU* = *myDocument*.all.tags("MENU")[*anIndex*]
	IE	*myMENU* = *myDocument*.all[*aName*]
	-	*myMENU* = *myDocument*.getElementById(*anElementID*)
	-	*myMENU* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myMENU* = *myDocument*.getElementsByTagName("MENU")[*anIndex*]
HTML syntax:	`<MENU> ... </MENU>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`compact`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The DOM level 1 specification refers to this as a `MenuElement` object.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`compact`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.0 +	1.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.2 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

MENU.compact (Property)

An attribute that controls the display of `<MENU>` items and the amount of space they require on the screen.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myMENU*`.compact`

Refer to:

`DL.compact`

menubar (Property)

An alias for the `window.menubar` property.

Availability:	JavaScript –1.2 Netscape –4.0
Property/method value type:	`Bar object`

JavaScript syntax:	-	menubar
	-	*myWindow*.menubar

See also:	Bar object, Window.menubar

Property attributes:

ReadOnly.

<META> (HTML Tag)

Document meta-information container.

Availability:	JavaScript –1.2 Netscape –4.0	
HTML syntax:	<META HTTP-EQUIV="*aName*" CONTENT="*aValue*">	
Argument list:	*aName*	A pseudo header name
	aValue	A pseudo header value

The <META> tag is a way of adding information about the document to the document. This information is never intended for display to the user but helps the browser and other server side systems (and proxies) to manage the document.

There are many attributes to the <META> tag. We have only covered the ones that are helpful in the context of script development here.

The items that are particularly useful to us are the HTTP_EQUIV and CONTENT attributes. These are used to add information to the HTTP response body. The browser can see these values in the <META> tag and interprets them as if they had been part of the HTTP header.

So:

```
<META HTTP-EQUIV="name" CONTENT="value">
```

is understood to be equivalent to an HTTP header like this:

```
name: value
```

As far as JavaScript is concerned, there are two <META> tags that are useful.

This one defines the default scripting language:

```
<META HTTP-EQUIV="Content-Script-Type" CONTENT="text/JavaScript">
```

If you have access to the server mechanism, you might be able to effect the same things by forcing it to add this header to the response as it goes out:

```
Content-Script-Type: text/JavaScript
```

The second useful <META> tag is used to define the default style definition language. Given all the warnings about JSS not being portable and it having been deprecated, you could use this in your document <HEAD> block:

```
<META HTTP-EQUIV="Content-Style-Type" CONTENT="text/JavaScript">
```

Again, if you have access to the server mechanism, you might be able to add this header to the response as it goes out:

```
Content-Style-Type: text/JavaScript
```

Warnings:

- Since MSIE does not support JSS and Netscape ignores the tag variants, these <META> tags are of limited use.

See also:	<SCRIPT LANGUAGE="...">, <SCRIPT>, <STYLE TYPE="...">, <STYLE>, JavaScript Style Sheets, META object

Wrox *Instant JavaScript* –page –52

META object (Object/HTML)

An object that represents the contents of a <META> tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	Element object	
JavaScript syntax:	IE	*myMETA* = *myDocument*.all.*anElementID*
	IE	*myMETA* = *myDocument*.all.tags("META")[*anIndex*]
	IE	*myMETA* = *myDocument*.all[*aName*]
	-	*myMETA* = *myDocument*.getElementById(*anElementID*)
	-	*myMETA* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myMETA* = *myDocument*.getElementsByTagName("META")[*anIndex*]
HTML syntax:	<META>	

Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`charset, content, httpEquiv, name, scheme, url`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

These tags and their corresponding object instantiations are used to convey hidden information about the document. This information might be useful to a search engine for example. Sometimes the server uses the `META` information to control the way the pages are cached into a proxy. Likewise, a client browser may use these values to control the local caching and expiry times of a document.

There may be several `META` objects associated with a document. There is no collection object that provides an enumerable set containing only the `META` objects but you can traverse the `document.all[]` collection and extract them in MSIE or use the collection returned by the DOM compliant `document.getElementsByTagName("META")` method which is supported on Netscape 6.0 and recent versions of MSIE. It is possible you might know the unique `ID="..."` HTML tag attribute value in which case you can access the required object directly.

This is not currently supported at all in Netscape 4.0 although, because it is part of the DOM specification, it is added to Netscape 6.0.

Warnings:

- Netscape 6.0 returns an undefined value for the charset property and incorrectly appends it to the content property.
- For this meta tag:
  - `<META http-equiv="Content-Type" content="text/html; charset=iso-8859-1">`
- Netscape Navigator 6.0 returns these values:
  - `myMeta.httpEquiv` is defined as "`Content-Type`"
  - `myMeta.content` is defined as "`text/html; charset=8859-1`"
  - `myMeta.charset` is undefined

See also:	`<META>`, `Element` object, `META.charset`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`charset`	-	3.0 +	-	4.0 +	-	-	-	-
`content`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`httpEquiv`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`name`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`scheme`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`url`	-	3.0 +	-	4.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.0 +	1.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.2 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

META.charset (Property)

A value containing the character encoding of the content in the `<META>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myMETA*`.charset`

This would contain the character set being used by the document referred to by the `HREF="..."` HTML tag attribute. For example the value `"iso-8859-1"` is likely to be returned but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry.

See also:	`META` object, `META.content`

Web-references:

ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets

META.content (Property)

The contents of the VALUE="..." HTML tag attribute belonging to the <META> tag that the object represents.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myMETA*.content

A <META> tag will contain a name-value pair stored in two separate HTML tag attributes. The content property relates to the value part of that name-value pair. The name property is contained in a NAME="..." HTML tag attribute.

The web server hides additional information in header records that the client browser uses, but which are invisible to the user and generally hard to access from JavaScript. The <META> tags support an HTTP-EQUIV="..." HTML tag attribute which, although encoded as part of the document source, will behave as if it were a server response header value. This is also used in conjunction with the content property as an alternative way of forming a name-value pair.

See also:	META.charset, META.httpEquiv

META.httpEquiv (Property)

The contents of the HTTP-EQUIV="..." HTML tag attribute belonging to the <META> tag that the object represents.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myMETA*.httpEquiv

This property will also reflect the value of the NAME-="..." HTML tag attribute if that was used in preference to the HTTP-EQUIV="..." HTML tag attribute. However only one or the other may be present in the <META> tag in the document source.

This property is used in conjunction with the content property to construct a name-value pair.

See also:	META.content

META.name (Property)

The name of the meta information this object describes.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myMETA*.name

This is the value of the `NAME="..."` HTML tag attribute in the `<META>` tag that instantiated this object.

META.scheme (Property)

A describer for the content form.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myMETA*.scheme

The meta data in the tags may use the same names in a `name=value` pair to mean something different according to who defined the meta tag contents.

The scheme property reflects the `SCHEME="..."` HTML tag attribute and defines separate namespaces so the meta information can be interpreted more correctly. It offers a context within which the meta data values are defined.

META.url (Property)

A special MSIE supported property containing the URL associated with a `<META>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myMETA*.url

Occasionally, most likely in an auto-refresh `META` tag, you will need to specify a URL value. An auto-refresh tag uses a client-pull technique to request a page update automatically after a timed interval.

Metacharacter (Definition)

A special symbolic way of describing some property of a character. Used in regular expressions.

Refer to:

`RegExp` pattern

Method (Definition)

A method is an action that can be performed on an object.

Availability:	ECMAScript edition –2

Functions are implemented in the script interpreter objects and are accessed as methods when they are themselves associated with an object.

Methods are owned by objects. An instance of a class can own some private methods, which it does not share. It can also share methods it inherits from its prototype. Privately owned methods are sometimes called instance methods.

Those functions that are associated with the `Global` object do not need an object prefix to be used. The `Global` object is always present and available and in the scope chain and prototype inheritance tree. Therefore the identifiers for those functions can be resolved easily, and in your script code they appear to be like functions in C language.

When you declare functions in your script, as they are constructed they are associated with the `Global` object and are also available in the same way.

Functions associated with the `Math` object require the `Math` object to be cited when they are called. Because they are visibly associated with the object and are called via the object, they are methods.

You can specifically associate one of your own functions with an object other than the `Global` object. If you do that, then you can refer to the owner object with the variable named `'this'`. It is a special variable that is like the `'self'` variable in Smalltalk.

Because a function is an object and associating it with your own object is by means of a reference to the function object, you can share function code between several objects.

So, a method is simply a function that is written in a particular way that means it works well when associated with an object.

As soon as you start to use the `'this'` variable, then it's likely your function is no longer useful as a stand-alone function and ought to really be called as a method from that point onwards.

Example code:

```
// Function to print an owner object property
function my_name()
{
  document.write(this.name);
}
// Create a new object instance
var myObject = new Object;
// Define the name property for the object
myObject.name = "Example";
// Associate the function so it can be used as a method,
// note that we omit the parentheses
myObject.my_name = my_name;
// Call the function via the method interface
myObject.my_name();
// Call the function normally
my_name();
```

Wrox *Instant JavaScript* –page –30

Microsoft TV (TV Set-top Box)

A digital TV set-top box.

This is a more enhanced version of the WebTV box. It may well work on analogue but is really intended for deployment in a digital TV environment.

The triggering and standard HTML support is defined according to the ATVEF platform specifications, which are evolving and are not yet complete but are looking to be the definitive profile that 'Browser in a box' type of system needs to conform to.

Technically, this platform is more advanced than WebTV but it is fundamentally the same.

The JavaScript capabilities in this system would be broadly in line with what you would expect a normal PC browser to cope with but there may be a few limitations here and there. There are also likely to be extensions provided as new object types and possibly some additional methods added to existing objects but these would be quite minimal.

Detecting that you are running in a set-top box may not always be easy. The user agent values may not tell you that you have a DTV environment available and you may need to be a little more clever and test for the existence of specific object classes. You need to do that in a way that does not cause a run-time error of course. It's a good technique to practice to ensure your scripts run reliably regardless of whether they are designed for use with Microsoft TV or not.

MIME types (Definition)

An Internet standard way of distinguishing between different kinds of container files.

The MIME types mechanism was originally developed for sending attachments in mail messages. Nowadays it has become a commonplace way of describing the content of a document in a way that many non e-mail client applications can understand.

This is defined as part of the HTML 4.0 standard.

Here is a list of some relevant MIME types for JavaScript programmers:

MIMEType	Description
*	Wildcard match everything
/	Wild card match both parts separately
application/applefile	AppleSingle file
application/AppleLink	AppleLink Package
application/ArcMac	PC ARChive
application/BBEdit	ML Source
application/binary	Application Binary Data
application/Canvas	Canvas Drawing
application/cdf	Channels
application/CodeWarrior	Java Class File
application/Compact_Pro	Compact Pro Archive
application/DeArj	ARJ Archive
application/DiskCopy	Apple DiskCopy Image
application/Envoy	Envoy Document
application/Excel	Lotus Spreadsheet r2.1
application/FileMaker_Pro	FileMaker Pro Database
application/FileMaker_Pro_3	FileMaker Pro Database
application/Finder	OpenType Font
application/FoxBase+	DBase Document
application/fractals	Fractal Image Format
application/futuresplash	FutureSplash Player
application/GraphicConverter	Animated NeoChrome
application/gzip	application/gzip
application/HexEdit	Untyped Binary Data
application/java-archive	Java Archive
application/JPEGView	OS/2 Bitmap
application/mac-binhex40	Binhex File
application/MacAmp	MPEG-1 Layer 3

Table continued on following page

MIMEType	Description
application/MacAnim_Viewer	DL Animation
application/macbinary	MacBinary
application/MacBooz	Zoo Archive
application/MacLHA	LHArc Archive
application/macwriteii	MacWrite Document
application/Microsoft_Word	Word for Windows Template
application/MoviePlayer	DV Video
application/ms-powerpoint	application/MS-PowerPoint
application/msword	Word Document
application/netcdf	Channels
application/octet-stream	Binary Executable
application/oda	ODA Document
application/PageMaker	PageMaker 3 Document
application/pdf	PDF File
application/PF_Encrypt	Private File
application/pgp-keys	PGP Key File
application/Photoshop	PhotoShop Document
application/PictureViewer	OS/2 Bitmap
application/PlayerPro	669 MOD Music
application/postscript	PostScript File
application/pre-encrypted	Pre-encrypted Data
application/QuarkXpress	QuarkXpress Document
application/Replica	Replica Document
application/ResEdit	Resource File
application/rtf	Rich Text Format File
application/sdp	Session Description Protocol
application/self-extracting	Self-Extracting Archive
application/Self_Extracting_Archive	Self-Extracting Archive
application/SimpleText	Apple documentation file
application/smil	SMIL Document
application/SoftWindows	MS-DOS Executable
application/SoundApp	Amiga OctaMed music
application/SoundHack	IRCAM Sound
application/streamingmedia	Standard Streaming Metafile
application/StuffIt	StuffIt Archive
application/StuffIt_Expander	PackIt Archive
application/SunTar	Unix BAR Archive
application/vnd.fdf	Forms Data Format

Table continued on following page

MimeType object (Object/browser)

An object representing a MIME type.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	*myMimeType* = *myWindow*.navigator.mimeTypes[*anIndex*]
	-	*myMimeType* = navigator.mimeTypes[*anIndex*]
	-	*myMimeType* = *myMimeTypeArray*[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
Object properties:	`description, enabledPlugin, name, suffixes, type`	
Collections:	`suffixes[]`	

The example code fragment will list all the available MIME types supported by the browser.

Example code:

```
// List the available mimeTypes
for(ii=0; ii<navigator.mimeTypes.length; ii++)
{
   document.write(navigator.mimeTypes[ii].suffixes);
   document.write(" - ");
   document.write(navigator.mimeTypes[ii].type);
   document.write(" - ");
   document.write(navigator.mimeTypes[ii].description);
   document.write(" - ");

   if(navigator.mimeTypes[ii].enabledPlugin)
   {
      document.write(navigator.mimeTypes[ii].enabledPlugin.name);
   }
   else
```

```
    {
       document.write("<no_plugin>");
    }
    document.write("<BR>");
}
```

See also:	`MIME` types, `MimeTypeArray` object, `Navigator.mimeTypes[]`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`description`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly
`enabledPlugin`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly
`name`	1.5 +	5.0 +	6.0 +	5.0 +	-	-	ReadOnly
`suffixes`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	-
`type`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly

MimeType.description (Property)

The descriptive text for a MIME type.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myMimeType`*`.description`

This will not be consistent from browser to browser. In some cases there are similarities in the description. In Netscape Navigator there are bugs in the descriptive text content for some MIME types.

Property attributes:

`ReadOnly`.

MimeType.enabledPlugin (Property)

The plugin object that handles this MIME type.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`Plugin object`	
JavaScript syntax:	-	*`myMimeType`*`.enabledPlugin`

You can use this property to check for the existence of an enabled plugin and generate some kind of dialog that gracefully degrades the performance of your web pages for users who need to download and install a vital plugin module.

Property attributes:

`ReadOnly`.

MimeType.name (Property)

The name of this particular MIME type.

Availability:	JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myMimeType`*`.name`

Although the MIME type names are more consistent between browsers than the descriptive text, there are still significant and annoying differences between them. Use with caution as part of your graceful degradation when you find local client support lacks some vital functionality your pages require.

Property attributes:

`ReadOnly`.

MimeType.suffixes[] (Collection)

A list of file type suffixes that contain data of this MIME type.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	*`myMimeType`*`.suffixes`

This is another example of cross browser inconsistencies. In addition, the result of accessing this property is not truly a collection but a comma delimited string which needs to be unpacked into an array. In some cases, the string is empty where there are no appropriate file types.

Any code you develop needs to take account of the separator being a comma in MSIE and a comma+space in Netscape.

Property attributes:

`ReadOnly`.

MimeType.type (Property)

The name of a MIME type.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myMimeType*`.type`

This value is the recognized MIME type value for this object.

See also:	MIME types

Property attributes:

`ReadOnly`.

MimeTypeArray object (Object/browser)

A collection of `MimeType` objects.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	*myMimeTypeArray* `= navigator.mimeTypes`
Object properties:	`length`	

On MSIE, this array contains an element for each supported `MimeType` object that the browser can respond to.

Likewise on Netscape, a collection of somewhat different `MimeType` objects are available.

Warnings:

- MSIE prior to version 5.0 does not support this facility and returns the undefined value even though it has a place holder for the property.
- Note that Netscape 4.7 on Macintosh exhibits some careless `MimeType` instantiation with at least two of the items in this array.

- Item 50 does not exhibit an associative value because the type property for that `MimeType` is undefined. There is no apparent fix because the type property of a `MimeType` object is read-only although there is no error generated when trying to assign a new value to it. The proper type value for this item should be "`application.gzip`".
- Item 64 has a similar problem but just presents a `null` string rather than its index. This `MimeType` represents UU encoded files. It doesn't show up in the list of applications that map to file types in the Netscape preferences.
- This problem may be extant on other platforms, although it is possible that the problems may be related to your user preference settings and the indices that have problems may not be the same number or `MimeType` values.
- The implications are that GZIP and UU encoded files are handled internally by the browser and therefore, although it creates `MimeType` objects, they may not be derived from the preferences settings although changing your preferences may relocate these objects to different positions in the collection.
- Build an enumerator to examine the `MimeType` objects in the collection. You'll see a fragment of script that would do this in the example. There is no real fix for this other than to build some conditional check into any enumeration or iterative loop that examines the MimeTypes array.
- Note that Netscape 6.0 does not enumerate this collection properly and the example does not yield the correct result, in fact it only seems to work with Netscape 4.

Example code:

```
// Inline this script fragment to display all mime types
// supported by your browser (except for NNav 6.0 which exhibits
// a strange bug).

for(myProp in navigator.mimeTypes)
{
   document.write(myProp);
   document.write("<BR>");
}
```

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	ReadOnly

MimeTypeArray.length (Property)

The number of discrete MIME types that the browser supports.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`navigator.mimeTypes.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

Minima-maxima (Definition)

Limits for values in the environment or script.

The ECMA standard defines some limits for numeric values and the conditions under which it should evaluate numeric values according to the IEEE 754 standard behavior.

The standard provides for the implementation to support some enquiry functions so you can determine these limits.

The IEEE 754 computation logic further provides for error conditions to be handled gracefully by supplying not a number (`NaN`) values, infinity and undefined values in cases where a computation would normally generate a domain error and possibly crash the application.

If JavaScript did not provide such a forgiving environment in which to execute scripts, it is likely that some of the most trivial script errors would result in the hosting environment crashing. In the context of a web browser you would lose the session and have to restart the browser. On a desktop platform, this could be fatal to the OS and you might have to reboot the machine.

See also:	Limits, Range error, Type conversion

Minus (-) (Operator/additive)

Subtract one operand from another.

Availability:	ECMAScript edition –2

See also:	Add (+), Additive operator, Subtract (-)

mocha: URL (Request method)

This is a pseudonym for the JavaScript: URL. It is relevant to Netscape and is probably not supported on other browsers.

See also:	URL, javascript: URL

ModElement object (Object/DOM)

A DOM level 1 object that describes a modification to a document.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
JavaScript syntax:	-	`myModElement = new ModeElement()`
Object properties:	`cite, dateTime`	

The MSIE browser implements deletions and insertions as separate object types (`DEL` and `INS` respectively). The DOM level 1 standard includes both in a single object class.

See also:	`DEL` object, `INS` object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`cite`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`dateTime`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

ModElement.cite (Property)

A URL that references a document that describes why the item was modified.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myModElement`*`.cite`

The URL of the document that describes why the text was marked as modified is noted in this property.

See also:	`DEL.cite`

ModElement.dateTime (Property)

The date and time that the modification occurred.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myModElement`*`.dateTime`

This is the date and time value for when the modification change occurred. If you are maintaining change control down to the sub-document level in a content management system, these values can be defined from change records in the database.

See also:	`DEL.dateTime`

Modulo (Operator/multiplicative)

Modulo operations are called remainder in JavaScript. They may also be called modulus.

See also:	Days in year, Multiplicative expression, Remainder (%)

Money (Definition)

A locale specific value.

See also:	Localization, Currency symbol

Month from time (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

In an ECMA compliant implementation, given a time measured in milliseconds from 01-January-1970 UTC, the month number can be calculated from the value.

The formula for calculating day number is shown here:

`Day(t) = floor(t/msPerDay)`, where:

t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.

```
msPerDay = 86400000
```

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non-leap years to adjust the day numbers and yield the day number of the first day of the given year and then use that to work out the time in milliseconds when the year started:

```
DayFromYear(y) =
365 * (y – 1970) +
floor((y – 1969) / 4) -
floor((y – 1901) / 100) +
floor((y – 1601) / 400)
TimeFromYear(y) = msPerDay * DayFromYear(y)
```

`YearFromTime(t)` = The largest integer `y` to make `TimeFromYear(y)` less than or equal to `t`.

```
DayWithinYear(t) = Day(t) – DayFromYear(YearFromTime(t))
```

The month value is worked out with this formulaic framework:

`MonthFromTime(t)` = lookup according to `DayWithinYear(t)` falling into a range according to the following table:

Greater than	Less than	Month	Name
000	031	0	January
031	059 + InLeapYear(t)	1	February
059 + InLeapYear(t)	090 + InLeapYear(t)	2	March
090 + InLeapYear(t)	120 + InLeapYear(t)	3	April
120 + InLeapYear(t)	151 + InLeapYear(t)	4	May
151 + InLeapYear(t)	181 + InLeapYear(t)	5	June
181 + InLeapYear(t)	212 + InLeapYear(t)	6	July
212 + InLeapYear(t)	243 + InLeapYear(t)	7	August
243 + InLeapYear(t)	273 + InLeapYear(t)	8	September
273 + InLeapYear(t)	304 + InLeapYear(t)	9	October
304 + InLeapYear(t)	334 + InLeapYear(t)	10	November
334 + InLeapYear(t)	365 + InLeapYear(t)	11	December

Note that `MonthFromTime(0)` is 0 which corresponds to Thursday, 01-January-1970.

Example code:

```
// Work out a month number from a time value
var msPerDay = 86400000;
var myMilliseconds = Number(new Date());
document.write(monthFromDayNumber(myMilliseconds));
// Month from day number
function monthFromDayNumber(aMillisecondTime)
{
   var myMonthLookup = new Array();

   var myDayWithinYear = dayWithinYear(aMillisecondTime);
   var myYearFromTime  = yearFromTime(aMillisecondTime);
   var myLeapNumber    = +inLeapYear(myYearFromTime);
   myMonthLookup[0]  =   0;
   myMonthLookup[1]  =  31;
   myMonthLookup[2]  =  59 + myLeapNumber;
   myMonthLookup[3]  =  90 + myLeapNumber;
   myMonthLookup[4]  = 120 + myLeapNumber;
   myMonthLookup[5]  = 151 + myLeapNumber;
   myMonthLookup[6]  = 181 + myLeapNumber;
   myMonthLookup[7]  = 212 + myLeapNumber;
   myMonthLookup[8]  = 243 + myLeapNumber;
   myMonthLookup[9]  = 273 + myLeapNumber;
   myMonthLookup[10] = 304 + myLeapNumber;
   myMonthLookup[11] = 334 + myLeapNumber;

   for(var ii=0; ii<12; ii++)
   {
      if(myDayWithinYear < myMonthLookup[ii])
      {
```

```
            return ii;
         }
      }
      return 12;
   }
   // Work out day number within year based on time value
   function dayWithinYear(aMilliseconds)
   {
      var myDayNumber     = dayNumber(aMilliseconds);
      var myYearFromTime  = yearFromTime(aMilliseconds);
      var myDayFromYear   = dayFromYear(myYearFromTime);
      var myDayWithinYear = myDayNumber - myDayFromYear;
      return myDayWithinYear;
   }
   // Return year number based on time value
   function yearFromTime(aMilliseconds)
   {
      var myStartYear = 1970;
      while(timeFromYear(myStartYear) < myMilliseconds)
      {
         myStartYear++
      }
      return myStartYear-1;
   }
   // Work out milliseconds at start of year
   function timeFromYear(aYear)
   {
      var myTime = msPerDay * dayFromYear(aYear);
      return myTime;
   }
   // Work out day number from milliseconds
   function dayNumber(aMillisecondTime)
   {
      var myDay = Math.floor(aMillisecondTime/msPerDay);
      return myDay;
   }
   // Day from year function
   function dayFromYear(aYear)
   {
      var myDay = 365 * (aYear - 1970)             +
      Math.floor((aYear - 1969) / 4)   -
      Math.floor((aYear - 1901) / 100) +
      Math.floor((aYear - 1601) / 400);
      return myDay;
   }
   // Flag a leap year with a Boolean value
   function inLeapYear(aYear)
   {
      if((aYear % 4) != 0)
      {
         return false;
      }
      if(((aYear % 100) != 0) ||
   ((aYear % 400) == 0))
      {
         return true;
      }
      return false;
   }
```

Month number (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

In ECMA compliant implementations, months are identified by an integer in the range 0 to 11, inclusive.

The month number is calculated by taking the number of the day at the target time and then taking the day number at the start of that year. The difference is the day number within the year, which can then be used via a compare and lookup mechanism to deduce the month. The `InLeapYear()` method comes into play to offset the day number by one when it is a leap year.

See also:	Day number, Day within year, Month from time, Time range

Cross-references:

ECMA 262 edition 2 –section –15.9.1.4

ECMA 262 edition 3 –section –15.9.1.4

MotionBlur() (Filter/visual)

An enhanced motion blur artefact that replaces the older `Blur()` filter functionality.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

filter – `MotionBlur()`

Mouse events (Definition)

Mouse events are part of the browser's event handling complex and are triggered by physical interaction with the mouse.

These events correspond to user actions as the mouse is moved over various elements on the screen or as the user clicks the mouse buttons.

Note that some of these events are triggered in multiples as a result of a single action.

For example, as a mouse button is pressed, a `mouse-down` event is fired. As it is released, a `mouse-up` and a `click` event are fired. A `click` event is only fired once for each `mouse-down` and `mouse-up` pair.

A `double-click` requires two `down-up` cycles within quick succession but the `mouse-down` and `mouse-up` events will also fire.

The DOM standard refines the event model and creates a specific object class to handle Mouse Events. The event model will evolve as more browsers take on the DOM specified model.

See also:	`onClick`, `onDblClick`, `onMouseDown`, `onMouseDrag`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`

MouseEvent object (Object/DOM)

This is part of the DOM level 2 mouse event set.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myMouseEvent* = new MouseEvent()
Object properties:	`altKey, bubbles, button, cancelable, clientX, clientY, cllientX, ctrlKey, currentTarget, detail, eventPhase, metaKey, relatedTarget, screenX, screenY, shiftKey, target, timeStamp, type, view`	
Object methods:	`initEvent(), initMouseEvent(), initUIEvent(), preventDefault(), stopPropagation()`	

The availability of the `MouseEvent` object handling can be determined with the `Implementation.hasFeature()` method call.

The available set of events is defined by HTML 4.0 and DOM level 0 with some additional events having been added. These event types are enumerated in the DOM level 2 specification and are:

- `click`
- `mousedown`
- `mouseup`
- `mouseover`
- `mousemove`
- `mouseout`

The contextual information is carried in the detail property which is inherited from the `UIEvent` object. This value is incremented for each complete mouse click cycle but is reset to zero if the mouse is moved, even if that happens between `mousedown` and `mouseup`.

This kind of event is a scenario where event bubbling is likely to be useful because the mouse may click on a pixel sized item which is a child of the object that is really receiving a higher level event.

See also:	`AbstractView object`, `Event` object, `Implementation.hasFeature()`, `onClick`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `UIEvent` object

Property	JavaScript	JScript	Nav	IE	Opera	DOM	Notes

MouseEvent.altKey (Property)

A Boolean value that represents the state of the `[alt]` key.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myMouseEvent`*`.altKey`

When an event is being processed, you may want to know the state of the `[alt]` key on the keyboard.

This Boolean property returns `true` when the `[`*`alt`*`]` key is pressed and `false` when it is not.

This property reflects the state of the `[`*`alt`*`]` key at the instant when the event was triggered. The user may have released the `[`*`alt`*`]` key in the meantime so you should not assume that if the `[`*`alt`*`]` key was pressed earlier on that it is still pressed when the event handler is being executed.

Warnings:

- The key may not always be labelled "ALT" on the keyboard.

See also:	`Event.altKey`

Property attributes:

`ReadOnly`.

MouseEvent.button (Property)

The mouse button that was pressed to trigger the event.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myMouseEvent`*`.button`

If you need to determine which mouse button was pressed to trigger the event, this property will contain a value to indicate the button.

Note that on a Macintosh, this value is meaningless as there is only one button on an Apple Macintosh mouse.

Third party mice can be added to Apple Macintosh systems to provide multiple (2 or 3) button functionality but they are by no means commonplace and it is probably safe to assume only a 1 button mouse on the Macintosh platform.

The values for the buttons are defined to cope with 1, 2 or 3 button mice.

The following values correspond with mouse buttons:

- 0 –No mouse button was pressed when the event was triggered
- 1 –The left button was pressed
- 2 –The right button was pressed
- 3 –The middle button was pressed

See also:	`Event.button`, `Event.which`

Property attributes:

`ReadOnly`.

MouseEvent.clientX (Property)

Mouse position relative to the web page.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myMouseEvent`*`.clientX`

This is the horizontal position of the mouse when the event was triggered. The position is calculated relative to the visible document area within the window or frame the mouse was positioned in when the event triggered.

See also:	`Event.clientX`

Property attributes:

`ReadOnly`.

MouseEvent.clientY (Property)

Mouse position relative to the web page.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myMouseEvent*`.clientY`

This is the vertical position of the mouse when the event was triggered. The position is calculated relative to the visible document area within the window or frame the mouse was positioned in when the event triggered.

See also:	`Event.clientY`

Property attributes:

`ReadOnly`.

MouseEvent.ctrlKey (Property)

A Boolean value that represents the state of the `[control]` key.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myMouseEvent*`.ctrlKey`

When an event is being processed, you may want to know the state of the `[`*control*`]` key on the keyboard.

This Boolean property returns `true` when the `[`*control*`]` key is pressed and `false` when it is not.

This property reflects the state of the `[`*control*`]` key at the instant when the event was triggered. The user may have released the key in the meantime so you should not assume that if the `[`*control*`]` key was pressed earlier on that it is still pressed when the event handler is being executed.

See also:	`Event.ctrlKey`

Property attributes:

`ReadOnly`.

MouseEvent.initMouseEvent() (Method)

After creating a `MouseEvent` object, it must be initialised with this method call.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myMouseEvent*.initMouseEvent(*aType*, *aBubble*, *aCancel*, *aView*, *aDetail*, *aScrnX*, *aScrnY*, *aClntX*, *aClntY*, *aCtrl*, *anAlt*, *aShift*, *aMeta*, *aButton*, *aRelTarg*)
Argument list:	*aType*	A string value describing the event type
	aBubble	A boolean flag indicating whether the event can bubble
	aCancel	A boolean flag indicating whether the event can be cancelled
	aView	A reference to an `AbstractView` object
	aDetail	A value describing the event detail
	aScrnX	A screen X coordinate value
	aScrnY	A screen Y coordinate value
	aClntX	A client X coordinate value
	aClntY	A client Y coordinate value
	aCtrl	A boolean value indicating the state of the control key
	anAlt	A boolean value indicating the state of the alt key
	aShift	A boolean value indicating the state of the shift key
	aMeta	A boolean value indicating the state of the meta key
	aButton	A numeric value indicating which button is being emulated
	aRelTarg	A reference to an `EventTarget` object

A new event object is manufactured by calling the `DocumentEvent.createEvent()` method. That event should have been defined with a type specified as "`MouseEvent`". If it was, then it will support an `initMouseEvent()` method. This must be called before the event is dispatched otherwise the event object will not contain enough information for the event dispatcher/handler to make sense of it and route it to the correct target objects.

Two boolean argument values define whether the event will be allowed to be cancelled and what type of propagation to use (`bubble` or `capture`).

The view argument refers to an `AbstractView` object which DOM level 2 describes and which may not yet be well supported by any browser.

The detail value can be used to pass context information into the event handling chain.

The screen and client coordinate values are measured in pixels and must be specified as numeric values.

Five boolean values then define the state of keyboard keys when the event was assumed to be triggered.

Finally a reference to a related target object is passed.

See also:	`AbstractView object`, `EventTarget` object, `UIEvent.initUIEvent()`

MouseEvent.metaKey (Property)

A Boolean value that represents the state of the [*meta*] key.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myMouseEvent*.metaKey

When an event is being processed, you may want to know the state of the [*meta*] key on the keyboard.

This Boolean property returns `true` when the [*meta*] key is pressed and `false` when it is not.

This property reflects the state of the [*meta*] key at the instant when the event was triggered. The user may have released the [*meta*] key in the meantime so you should not assume that if the [*meta*] key was pressed earlier on that it is still pressed when the event handler is being executed.

Warnings:

- The key may not always be labelled "META" on the keyboard.

Property attributes:

`ReadOnly`.

MouseEvent.relatedTarget (Property)

A related `EventTarget` object is referred to.

Availability:	DOM level –2 JavaScript –1.5 Netscape Navigator version –6.0	
Property/method value type:	`EventTarget object`	
JavaScript syntax:	N	`myMouseEvent.relatedTarget`

The particular `EventTarget` referred to depends on the event type and context. For example, the standard suggests this might be the object the mouse has just moved off when a `mouseOver` is being processed.

The `target` and `relatedTarget` property values would be exchanged vice versa if a `mouseOut` event were being processed.

See also:	`EventTarget` object

Property attributes:

`ReadOnly`.

MouseEvent.screenX (Property)

Mouse position relative to the screen display.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myMouseEvent*.screenX

You may need to know the position of the mouse relative to the screen display coordinates and not the browser window or objects within it. This property provides the horizontal coordinate of the mouse within the screen.

See also:	`Event.screenX`

Property attributes:

`ReadOnly`.

MouseEvent.screenY (Property)

Mouse position relative to the screen display.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myMouseEvent*.screenY

You may need to know the position of the mouse relative to the screen display coordinates and not the browser window or objects within it. This property provides the vertical coordinate of the mouse within the screen.

See also:	`Event.screenY`

Property attributes:

`ReadOnly`.

MouseEvent.shiftKey (Property)

A Boolean value that represents the state of the `[shift]` key.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myMouseEvent*`.shiftKey`

When an event is being processed, you may want to know the state of the `[`*shift*`]` key on the keyboard.

This Boolean property returns `true` when the `[`*shift*`]` key is pressed and `false` when it is not.

This property reflects the state of the `[`*shift*`]` key at the instant when the event was triggered. The user may have released the key in the meantime so you should not assume that if the `[`*shift*`]` key was pressed earlier on that it is still pressed when the event handler is being executed.

See also:	`Event.shiftKey`

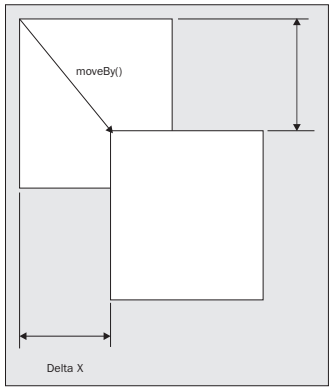
Property attributes:

`ReadOnly`.

moveBy() (Method)

An alias for the `window.moveBy()` method.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`moveBy(`*anOffsetX*`, `*anOffsetY*`)`
	-	*myWindow*`.moveBy(`*anOffsetX*`, `*anOffsetY*`)`
Argument list:	*anOffsetX*	A distance in pixels
	anOffsetY	A distance in pixels

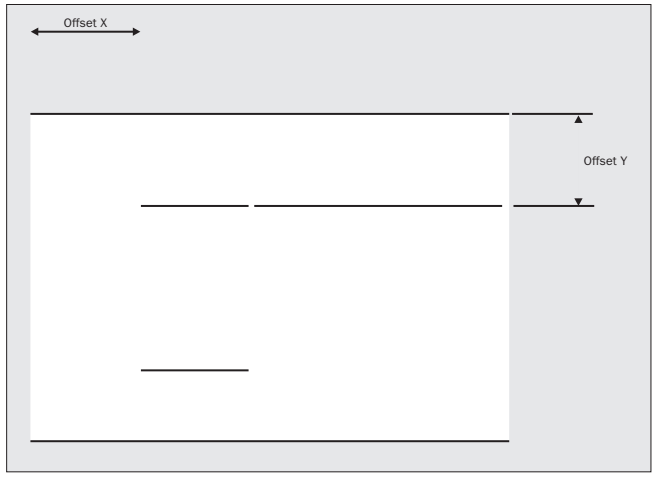


See also:	`Window.onmove`,`Window.moveBy()`

moveTo() (Method)

An alias for the `window.moveTo()` method.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`moveTo(`*`aCoordX`*`, `*`aCoordY`*`)`
	-	*`myWindow`*`.moveTo(`*`aCoordX`*`, `*`aCoordY`*`)`
Argument list:	*`aCoordX`*	A position in pixels
	`aCoordY`	A position in pixels



See also:	`Window.onmove`,`Window.moveTo()`

MSIE (Web browser)

An acronym for the Microsoft web browser.

See also:	JScript version, Undocumented features, Web browser, Internet Explorer

Multi-byte character (Definition)

Character sets using more than 8 bits to represent a code point.

JavaScript natively supports the Unicode character set. This means it is multi-byte character aware at the most fundamental level.

Unicode and localization issues are related to one other and the one depends on the other. You cannot effectively localize an environment properly without multi-byte character sets. The extensions to ASCII to make it an international character set were workable but somewhat inconvenient. All manner of escape sequences were required and ultimately, it consumes more space than a multi-byte character would have.

Unicode extended the width of the code points from 8 bits to 16. This allows the character set to increase from 256 to 65536 code points. To all intents and purposes, this is sufficient to encode every glyph and character share required by all languages world-wide.

However, there may still be some limitations in the encoding used for Far-Eastern language variants. These may be addressed in the Unicode version 3.0 standard.

See also:	Character set, Localization, Unicode

Multi-dimensional arrays (Definition)

Useful techniques for manipulating matrices for math problems.

Multi-dimensional arrays are not supported directly in JavaScript but you can construct them with arrays of arrays.

An array can refer to another array with one of its elements. This means you can build multi-dimensional arrays, which are useful for working out 3D transformations. You probably wouldn't implement a renderer or 3D modeller in JavaScript. However, you might have a Java applet that takes rotation values or perhaps a 3D viewing plugin of some sort that does the hard work.

Warnings:

- The arrays are not truly multi-dimensional and you must be careful to construct them properly and avoid damaging them inadvertently.

Example code:

```
// An example shamelessly stolen from Wrox Instant JavaSscript
// Create a 2x2 array and store an identity matrix in it.
var matrix = new Array(2);
matrix[0] = new Array(2);
matrix[1] = new Array(2);
matrix[0][0] = 1;
matrix[1][0] = 0;
matrix[0][1] = 0;
matrix[1][1] = 1;
```

See also:	Array index delimiter (`[]`), Copying objects

Cross-references:

Wrox *Instant JavaScript* –page –16

Multi-line comment (Definition)

Comment blocks that span several lines of script source text.

The character sequence `/*` introduces a multi-line comment. That comment block is terminated by the next occurrence of the `*/` character sequence. This means you cannot nest these comments within one another. That is arguably bad coding technique anyway.

If you are used to C language you will most likely have used conditional compilation blocks controlled via the pre-processor. Most implementations of JavaScript do not support this, however one or two recent implementations, especially those that operate outside the context of a web browser, are beginning to introduce many C language-like facilities. One of those is the pre-processor with its macro directives. This is particularly useful to developers even though it is somewhat non-standard.

Multiple line comments are replaced with a single line terminator during the interpretation phase. When the `/* ... */` does not have a line terminator inside, it is simply removed prior to interpretation of the remaining line content.

Everything between the start and end of a multi-line comment is ignored.

Warnings:

- You cannot nest these kinds of comment delimiters within one another.

Wrox *Instant JavaScript* –page –17

Multiplicative expression (Definition)

An expression containing a multiply or divide operator.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Multiplicative expressions use the multiplicative operators to yield a result by operating on two other values, which may themselves be nested.

See also:	Divide (/), Expression, Modulo, Multiplicative operator, Remainder (%)

Cross-references:

ECMA 262 edition 2 –section –11.5

ECMA 262 edition 3 –section –11.5

Multiplicative operator (Definition)

A multiply or divide operator.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Multiplicative operators are those that require multiplication or division to evaluate their result.

The following table lists all operators that are multiplicative and those, which are classified under other categories, which are also multiplicative, by implication:

Operator	Description
`%`	Remainder
`*`	Multiply
`/`	Divide
`*=`	Multiply and assign to an LValue
`/=`	Divide and assign to an LValue
`%=`	Remainder and assign to an LValue

Operands that are used with multiplicative operators must have numeric values or be convertible using the `valueOf()` method.

Warnings:

- The order of evaluation of the operands is described in the ECMA standard and a fully compliant implementation should evaluate from left to right. This means that the expression:
- *myFunctionA()* * *myFunctionB()*
- should evaluate *myFunctionA()* before *myFunctionB()* and any side effects of executing *myFunctionA()* will precede those for *myFunctionB()*.
- However, you should test this and not rely on it being portable across implementations.
- Beware of expressions like this:
  - `0 * myFunction()`
- Even though you may not have put the zero in as a constant, the operand on the left may evaluate to be zero. Some implementations may provide performance enhancements that depend on eliminating unnecessary computation. A zero multiplied by any other value will yield a zero. The function may never be executed.
- If you really want *myFunctionA()*, *myFunctionB()* or *myFunction()* to be executed reliably and in a portable manner, you should evaluate them outside of the expression and assign their results to variables, which you can then use in the expression in their place.
- There is a very marginal performance hit but the scripts will execute more reliably across a wider variety of platforms.

Cross-references:

ECMA 262 edition 2 –section –11.5

ECMA 262 edition 3 –section –11.5

Multiply (*) (Operator/multiplicative)

Multiply one operand by another.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*anOperand1 * anOperand2*
Argument list:	*anOperand1*	A value to be multiplied
	anOperand2	The multiplier value

The * operator performs multiplication, producing the product of its operands.

The multiplication is commutative. That means the operands being multiplied together can be arranged in any order without affecting the outcome as long as they are at the same precedence level. However, the multiplication may not always be associative in ECMAScript compliant interpreters due to finite precision in the evaluations. This means that placing parentheses around the operands may affect the outcome.

For example `(A * B) * C` may not evaluate identically to `A * (B * C)` to associative artifacts but `A * B * C` should be identical to `B * C * A` because of commutation.

The rules of floating point multiplication should be governed by the rules of IEEE 754 double-precision arithmetic.

If either operand is `NaN` then the result will be `NaN`.

The sign of the result is positive if both operands have the same sign, negative if the operands have different signs.

Multiplication of an infinite value by zero results in `NaN`.

Multiplication of infinity by infinity results in infinity. The sign is determined by the sign rules as normal.

Multiplying infinity by a finite non-zero value results in a signed infinity. The sign is determined as normal.

Otherwise, where neither an infinite value or `NaN` is involved, the product is computed and rounded to the nearest representable value. If the magnitude of the result is larger than the largest value the interpreter can cope with, an infinity of the appropriate sign is substituted. If the magnitude is too small to be represented, then a zero value is substituted.

Note that internally, zero values can be negative or positive and the sign may affect the result of subsequent computations.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

ECMA 262 edition 2 –section –11.5.1

ECMA 262 edition 2 –section –11.13

ECMA 262 edition 3 –section –11.5.1

Multiply then assign (*=) (Operator/assignment)

Multiply two operands storing the result in the first.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 *= anOperand2`*
Argument list:	*`anOperand1`*	A value to be multiplied and then assigned into
	`anOperand2`	A multiplier value

Multiply the left operand by the right operand and assign the result to the left operand.

This is functionally equivalent to the expression:

`anOperand1` = *`anOperand1`* * *`anOperand2`*;

Although this is classified as an assignment operator it is really a compound of an assignment and a multiplicative operator.

The associativity is right to left.

Refer to the operator precedence topic for details of execution order.

The new value of *`anOperand1`* is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an `LValue`. That is, it should be able to take an assignment and store the value.

ECMA 262 edition 2 –section –11.13

ECMA 262 edition 3 –section –11.13

MutationEvent object (Object/DOM)

A notification that the document content has changed should trigger a mutation event which is described in one of these objects.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myMutationEvent* = new MutationEvent()
Object properties:	attrChange, attrName, bubbles, cancelable, currentTarget, eventPhase, newValue, prevValue, relatedNode, target, timeStamp, type	
Class constants:	ADDITION, MODIFICATION, REMOVAL	
Object methods:	initEvent(), initMutationEvent(), preventDefault(), stopPropagation()	

The availability of the `MutationEvent` object handling can be determined with the `Implementation.hasFeature()` method call.

These event types are enumerated in the DOM level 2 specification and are:

- `DOMSubtreeModified`
- `DOMNodeInserted`
- `DOMNodeRemoved`
- `DOMNodeRemovedFromDocument`
- `DOMNodeInsertedIntoDocument`
- `DOMAttrModified`
- `DOMCharacterDataModified`

The DOM level 2 event module specification doesn't describe the binding of these events to event handlers so although this event model is implemented in Netscape 6.0, you may need to explore the event naming conventions to make effective use of it. Taking the event names and placing the 'on' prefix in front of them and using that as a property name to which you can attach a handler function may work. The DOM level 2 event module also provides an `EventListener` registration which allows you to register event types with `EventTarget` objects, using the `addEventListener()` method.

The contextual information is carried in the `detail` property, and when it is present, will usually describe a reference to a node object or an attribute value.

When the document content is modified, a `MutationEvent` object is instantiated to carry a description of that change to the event handler.

Mutation events cannot be cancelled. This is because the DOM interface would become unwieldy if the document changes were not properly completed. This may change later when the DOM standard introduces transaction handling, although the DOM level 2 event specification does not go to great lengths to explain in detail how that is likely to be implemented.

A cascading effect is very likely with a single DOM tree change causing a number of subsequent mutation events to be fired as lower portions of the tree are affected. The standard does not mandate any particular ordering of these events and leaves it to the implementation to control the sequence. This suggests that the cascaded mutations may occur in a different sequence depending on the browser. You should therefore design your event handler so that it can be called in a re-entrant and random orders and that there should be no dependency on things being traversed in a predictable sequence.

MutationEvent.attrChange (Property)

The value in this property describes the kind of change that has taken place when the mutation event was an attribute change.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myMutationEvent`*`.attrChange`

This value is meaningful for `DOMAttrModified` events.

The `MutationEvent` class provides the following constant values for testing attribute change property values:

Value	Symbolic name
1	MODIFICATION
2	ADDITION
3	REMOVAL

See also:	`Attribute` object, `MutationEvent.newValue`, `MutationEvent.prevValue`, `Node.attributes[]`

Property attributes:

`ReadOnly`.

MutationEvent.attrName (Property)

The name of a node attribute that has changed for a `DOMAttrChange` event.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myMutationEvent*`.attrName`

This is a string value containing the name of an attribute that has been changed. The old and new values are available in the `prevValue` and `newValue` properties of the `MutationEvent` if you need to inspect them.

See also:	`Attribute` object, `MutationEvent.newValue`, `MutationEvent.prevValue`, `Node.attributes[]`

Property attributes:

`ReadOnly`.

MutationEvent.initMutationEvent() (Method)

After creating a `MutationEvent` object, it must be initialized with this method call.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
JavaScript syntax:	N	*myMutationEvent*.initMutationEvent(*aType*, *aBubble*, *aCancel*, *aNode*, *aPrev*, *aNew*, *aName*)
Argument list:	*aType*	A string containing the event type
	aBubble	A boolean value indicating whether the event can bubble
	aCancel	A boolean value indicating whether the event can be cancelled
	aNode	A reference to a related `Node` object
	aPrev	A string containing the previous value
	aNew	A string containing the new value
	aName	A string containing the name of an attribute

A new event object is manufactured by calling the `DocumentEvent.createEvent()` method. That event should have been defined with a type specified as "`MutationEvent`". If it was, then it will support an `initMutationEvent()` method. This must be called before the event is dispatched otherwise the event object will not contain enough information for the event dispatcher/handler to make sense of it and route it to the correct target objects.

Two boolean argument values define whether the event will be allowed to be cancelled and what type of propagation to use (`bubble` or `capture`).

You can add a reference to a related node and can also define previous and new values if you are simulating an attribute change. Finally for an attribute change, the attribute name can be specified.

See also:	`Event.target`,`EventTarget object`,`Node object`

MutationEvent.newValue (Property)

When an attribute changes, the new attribute value is available here.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myMutationEvent*.newValue

You can use this value to check that the new attribute value is appropriate and if necessary modify it to ensure it falls within your require range. You can compare it with the previous value if need be.

See also:	`MutationEvent.attrChange`, `MutationEvent.attrName`, `MutationEvent.prevValue`

Property attributes:

`ReadOnly`.

MutationEvent.prevValue (Property)

When an attribute changes, the old attribute value is available here.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myMutationEvent*`.prevValue`

This value preserves the old attribute value so you can restore it into the attribute if you inspect the new value and find that it is inappropriate.

See also:	`MutationEvent.attrChange`, `MutationEvent.attrName`, `MutationEvent.newValue`

Property attributes:

`ReadOnly`.

MutationEvent.relatedNode (Property)

A `Node` object is referred to here which can be used to perform contextual examination of the event.

Availability:	DOM level –2 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Node object`	
JavaScript syntax:	N	*myMutationEvent*`.relatedNode`

For attribute changes, this should contain a reference to the node that owned the attribute that was changed. Other operations such as node addition or removal may contain parent nodes or indeed the node that has just been added during an insertion.

See also:	`Node` object, `Node.parentNode`

Property attributes:

`ReadOnly`.

name (Property)

An alias for the `window.name` property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`name`
	-	*`myWindow.name`*
HTML syntax:	`<FRAME NAME="...">Window.open(...)`	
Argument list:	*`aName`*	A name for the window
	`aString`	A string value containing the new name for the window
	`aURL`	A URL to load into the window

Refer to:

`Window.name`

NAME="..." (HTML Tag Attribute)

An HTML tag attribute that names an object.

Many objects are identified in the DOM hierarchy of the web browser by means of their `name` property. This value is defined as an HTML tag attribute.

Some objects can be accessed using an `ID="..."` HTML tag attribute instead of, or as well as, the `NAME="..."` HTML tag attribute. With browsers converging on the DOM specification and its Nodal structure, the `NAME="..."` HTML tag attribute is expected to become deprecated in favor of the `ID="..."` attribute.

See also:	`Anchor.name`, `Document.<form_name>`, `ID="..."`, `Object.name`, `OBJECT.name`, `Plugin.name`, `Window.name`

NamedNodeMap object (Object/DOM)

Where nodes have a `name` attribute, they can be presented as members of a NamedNodeMap collection object.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0
Inherits from:	`Array` object
JavaScript syntax:	- *`myNamedNodeMap`* `= new NamedNodeMap()`
Object properties:	`length`
Object methods:	`getNamedItem(), item(), removeNamedItem(), setNamedItem()`

A `NamedNodeMap` is a collection of nodes that can be accessed by name. It does not inherit from `NodeList`, and the DOM does not mandate any parentage. It will probably inherit from `Collection` or `Array` but this appears to be implementation dependant. A general purpose `Dictionary` class would be helpful as a starting point but these are not available in all implementations.

The nodes are not collated in any particular order and you can access them with a numeric index as well as by associative name.

This implies a namespacing issue and clearly there may be problems with your document if nodes share the same name and need to be collected into a `NamedNodeList` entity.

The DOM level 2 specification provides these new methods to cope with namespaces:

- `getNamedItemNS()`
- `setNamedItemNS()`
- `removeNamedItemNS()`

DOM 2 standardization is not quite stable and no browsers support it yet. At this time, browsers have reached DOM level 1 capabilities and we can expect support for these namespace extensions in the next round of browser upgrades.

See also:	`Collection` object, DOM, DOM –Level 1, `Node` object, `Node.attributes[]`, `NodeList` object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`length`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`getNamedItem``()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`item()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	Warning
`removeNamedItem()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`setNamedItem()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Inheritance chain:

`Array` Object

Web-references:

http://www.w3.org/TR/REC-DOM-Level-1/level-one-core.html#ID-1074577549

NamedNodeMap.getNamedItem() (Method)

Given the name of a node, it can be extracted from the collection by name.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*`myNamedNodeMap`*`.getNamedItem(`*`aName`*`)`
Argument list:	*`aName`*	The name of the node to be accessed

If a node having the specified name exists in the node map, the a reference to it will be returned. If there is no matching node, a `null` will be returned instead.

It isn't clear what happens if there are duplicate nodes with the same name. Some implementations may choose to return a collection of all nodes with a matching name.

NamedNodeMap.item() (Method)

The usual collection access by item number also applies to named node maps.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNamedNodeMap*`.item(`*anIndex*`)`
Argument list:	*anIndex*	A reference to an element in a collection

This accesses nodes by their position in the linear sequence of nodes within the map. The index value is zero-based so if the value specified is equal to or greater than the number of nodes in the map, a null value will be returned instead.

Warnings:

- Note that the `item()` method for a `NamedNodeMap` is spelled with a lower case i. The MSIE `Collection` class also has an `Item()` method that provides similar (but not identical) ways of accessing items in a collection. Note that `Collection.Item()` is spelled with a capital I.

See also:	`Collection.Item()`

NamedNodeMap.length (Property)

The number of members in the named node map is returned by this property.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myNamedNodeMap*`.length`

This is zero-based length of the NamedNodeMap collection/array. It allows you to enumerate through the collection with a `for(...)` loop, visiting each node in turn.

NamedNodeMap.removeNamedItem() (Method)

Given that you know the name of an item, you can locate and remove it from the collection. If necessary, the item is replaced by another containing the default attribute settings.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNamedNodeMap*`.removeNamedItem(`*aName*`)`
Argument list:	*aName*	An associative array reference

The value returned is a reference to the node that was removed. The same rules used for the *getNamedItem*`()` method apply. If no item is found then a null is returned instead. Multiple matching nodes may result in unpredictable and implementation-specific results.

If this node is not referred to by any other means and you do not assign the value to a variable, then the node will become detached and no longer has an owner. You will have no way to locate that node again without reconstructing the document. The object representing the node should in due course be garbage-collected automatically.

NamedNodeMap.setNamedItem() (Method)

A node is added to the collection having the specified node name. Any node already present with that name will be replaced.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNamedNodeMap*`.setNamedItem(`*aNode*`)`
Argument list:	*aNode*	The node to be set

If a replacement happens, the old node that occupied the same position in the document and which was displaced by the new node will be returned as a result of this method call.

If you need to access that node again, you must make sure a reference to it is retained otherwise you will need to reconstruct the document from scratch to manufacture another.

Namespace (Definition)

A table where identifiers are stored.

A namespace behaves like a dictionary table where lexically sorted items can be stored. There may be several namespaces. Each namespace is distinct from any other and so a particular value may be present in more than one namespace and may mean a different thing in each.

For example, the collection of properties belonging to an object class is referenced via a namespace. Each class maintains a separate namespace and so a property with a particular name can be added to several objects without any collisions.

The namespace where variable names and functions belong is also the same namespace where reserved words and keywords are accessed. Or at least this is the conceptual idea, when the standard recommends that you should not name your identifiers with the same value as a reserved word.

A namespace could be conceived as a particular directory within a file system or a set of object ID names within a document model. All of these operate with typical namespace behaviors regarding collisions between dissimilar objects having the same name.

Namespace pollution can be alleviated by prefixing the names of certain kinds of objects. You might have two functions that create named items in a namespace and to ensure they do not operate on each other's entities, they could each add a different prefixing letter to the entity names.

Style sheets use namespaces as well to indicate different functionality during the cascading process.

The scope-chain rules of execution contexts within a JavaScript allow for namespaces to be expanded and collapsed as functions are called and executed. Variables can be created with a scope that is local to within a specific function. However the scope-chain mechanism allows the namespace to be layered and cascaded so that a reference to an identifier that is not local to the function but exists higher up the scope chain is still reachable. This means that the namespace for variables in JavaScript operates in a tree-like manner.

You may find in some implementations that there are small variations in the namespace behavior. Historically, language developers have found this to be a contentious area. In particular, there was a stage during the development of the C language standard where members of all structures were considered to live within the same namespace. Fortunately, the standard rejects this model and members of structures live in separate namespaces, one per structure. So it should be for objects in JavaScript, given the caveat that prototype inheritance can cloud the issue and a prototype tree for objects operates essentially in the same way as the scope chain does for functions.

Typically the object, method and property names are spelled inconsistently for some items. There are wide spread inconsistencies in the JavaScript language implementations. Although the core language is specified reasonably consistently, the browser manufacturers have added a large number of extensions that do not follow consistent naming conventions.

NaN (Constant/static)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition –2 JavaScript –1.3 JScript –2.0 Internet Explorer –4.0 Netscape –4.06 Netscape Enterprise Server –2.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- `NaN`

The primitive value `NaN` represents the IEEE 754 "Not-a-Number" value. This is returned when the result of an evaluation is known to yield a numeric value but its magnitude and sign is uncertain. Because the value is numeric but uncertain, you cannot compare `NaN` with anything else (including itself). However you can test for its existence with the `isNaN()` function.

In IEEE 754, there are many millions of possible values for `NaN`. In ECMA-compliant JavaScript interpreters, they are all collected together and referred to as a single value. This means you cannot distinguish the reason for the `NaN` error as you may be able to in other languages that use IEEE 754 arithmetic.

It is possible in the hosting environment to provide additional facilities to determine what sort of `NaN` values you have. This is implementation dependant however and not part of the standard.

If you are in an environment that does not have the `NaN` value implemented, then you may be able to create one yourself like this:

```
var NaN = 0/0;
```

The value has existed since JavaScript 1.1 but it was given a property name in JavaScript 1.3. Therefore from scripting point of view, its availability is defined as JavaScript 1.3 and not 1.1.

Warnings:

- Be careful not to assign your own values to this variable. You can corrupt it in some implementations. In MSIE version 5 for Macintosh, assigning a value to the global `NaN` value changes its setting but leaves `Number.NaN` unaffected. You cannot modify `Number.NaN`.
- Version 3.02 of MSIE with JScript version 1.0 silently converts `NaN` values to zero. It does not know what `NaN` is.
- Netscape 2.02 cannot tell the difference between `null` and `undefined`.
- This constant is available as a property of the `Global` object in MSIE version 4 but not in Netscape 4.

See also:	Arithmetic constant, Exception, `Global` object, Global special variable, IEEE 754, Infinity, `isNaN()`, Not a Number, null, Number, `Number.NaN`, Range error, Special number values, `Value` property

Property attributes:

`DontEnum`.

native (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

Cross-references:

ECMA 262 edition 2 –section –7.4.3

ECMA 262 edition 3 –section –7.5.3

Native feature (Definition)

That which is supported in the base level of the language.

Native features are those that are defined in the ECMA-262 standard (ECMAScript). That is anything that is fundamentally and solely JavaScript.

Hooks to activate some piece of hardware or database loading facilities and document objects are not considered fundamental and are therefore not native features of the language.

Adding two numbers together, instantiating objects with a new operator, or concatenating strings are fundamental, even if the objects being instantiated are host objects. The functionality is native because the new operator is a native capability of the language. You can instantiate any object of any type with the new operator as long as there is a constructor function available.

However, some implementations may provide enhancements to the native features without them being classified as host environment capabilities. These might be additional operators or extra function in the `Math` object for example. Maybe you could do more sophisticated things with `String` objects. This all fits under the category of enhancements to the fundamental language.

See also:	ECMAScript, JavaScript language

Cross-references:

Wrox *Instant JavaScript* –page –12

Native object (Definition)

One of the built-in objects that the core implementation provides.

Availability:	ECMAScript edition –2

A native object is any object supplied by the interpreter that is not considered part of the hosting environment.

Some native objects are built into the core interpreter while others may be constructed by executing script code. These are sometimes called built-in objects.

Here is a list of native object types that all ECMA-compliant interpreters must support:

- `Array`
- `Boolean`
- `Date`
- `Function`
- `Math`
- `Number`
- `Object`
- `String`

The `Global` object is added to the scope chain of a program when it commences execution. Other built-in objects are accessible as initial properties of the `Global` object. Some of these are added as core functionality and are available in all implementations. Others are added as host objects defined differently for each implementation.

Many built-in objects are functions. They can be invoked with arguments. Some of these are constructors; most are associated with objects so that they can be used as methods. These are functions that are intended to be used with the new operator.

navigate() (Method)

Load a new URL into the window.

Availability:	JScript –1.0 Internet Explorer –3.02	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	*myWindow*`.navigate(`*aURL*`)`
	IE	`navigate(`*aURL*`)`
Argument list:	*aURL*	A new location to navigate the window to

Warnings:

- This is variously referred to as a `navigate()` method and a `Navigate()` method. Note the different capitalization.
- According to some (but not all) Microsoft documentation on this, it is also a shortcut to the `navigateFrame()` method. However, this is at variance with the coverage under DHTML, which does not mention `navigateFrame()` at all.

Refer to:

`Window.navigate()`

navigator (Property)

An alias for the `window.navigator` property.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera –3.0	
Property/method value type:	`Navigator` object	
JavaScript syntax:	-	*myWindow*`.navigator`
	-	`navigator`

See also:	Cross-platform compatibility, `Window.clientInformation`, `Window.navigator`

Property attributes:

`ReadOnly`.

Navigator object (Object/browser)

An object that contains properties that describe the browser (a.k.a. user agent or client).

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*myWindow*`.navigator`
	-	`navigator`
Object properties:	`appCodeName, appMinorVersion, `*`appName`*`, ` *`appVersion`*`, browserLanguage, constructor, cookieEnabled, cpuClass, language, onLine, opsProfile, platform, securityPolicy, systemLanguage, userAgent, userLanguage, userProfile`	
Object methods:	`javaEnabled(), plugins, preference(), savePreferences(), taintEnabled()`	
Collections:	`mimeTypes[], plugins[]`	

The `navigator` object is named after Netscape Navigator but is also present in other browsers since it has become the defacto standard way of enquiring as to a browser's provenance.

You can inspect the various properties belonging to the `navigator` object and establish the name and type of the browser, its version, and the platform it is running on.

The `navigator` object is available as a property of the `window` and also the `Global` object but it will be the same `navigator` object. There is only one and you cannot instantiate another.

As this object is persistent, you might add properties to it that can be passed from window to window. However this will only work on Netscape, because MSIE seems to initialize a new `navigator` object for each window. MSIE does allow you to add properties to the `navigator` object but they are private to that window. Netscape shares them across windows. The example shows how to make this work.

You can accomplish the same thing in a cross-browser portable manner by using a frameset and storing properties in the top-level frameset's `Global` object. You can also (if security allows) write scripts to communicate between windows, in which case you may need to make sure the scripts are aware of multiple `document` objects as well as windows. This can get tricky and you may need to make sure the scripts run in the correct windows and return a value to a caller. This should ensure they run in the correct scope.

Netscape 6.0 provides a sidebar, which you should expect to be persistent. There's a similar sidebar in MSIE too. Netscape clearly intends you to script its sidebar but right now the implementation is a bit buggy. It might be too much to hope for, but digging into the internals of these suggests that RDF is involved, which may point to some commonality. Maybe we will be able to use the sidebar in the browsers as a repository for session storage, or persistent values that we can access from script, but it's not there and working yet.

Warnings:

- You cannot enumerate the properties of the `navigator` (`clientInformation`) object in MSIE version 4.5 for Macintosh. This may apply to other platform implementations of MSIE version 4.5 as well.
- The `navigator` object is much better supported in version 5.0 of MSIE for Macintosh, which was released in the Spring of 2000.
- The example below was found not to work on Netscape 6, due to bugs.

Example code:

```
<!-- Save this in navigator.html -->

<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
navigator.myNewProperty = "session global value";
open("navigator1.html");
</SCRIPT>
</BODY>
</HTML>
-----------------------------------------------------------------
```

```
<!-- Save this in  navigator1.html -->
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
document.write(navigator.myNewProperty);
</SCRIPT>
</BODY>
</HTML>
```

See also:	Cross platform compatibility, `Window.navigator`

Navigator.appCodeName (Property)

The codename for the browser.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`navigator.appCodeName`

This is generally used for internal purposes and is often just another name for the browser. Because these properties are mostly evolved rather than thought out logically, there is a great deal of duplication and ambiguity in the `navigator` object.

Most browsers appear to report that their code name is `'Mozilla'`.

Property attributes:

`ReadOnly`.

Navigator.appMinorVersion (Property)

A version value supported by MSIE.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`navigator.appMinorVersion`

This is the version code following the dot. Thus version 5.0 of MSIE would yield the value 0. At least that is the theory. MSIE version 4.5 for Macintosh also yields the value 0 for this property.

Warnings:

- Be wary of the value returned by this property on MSIE. It may not be consistent with what you expect. Bug fixes and patches are normally not reflected in this value although you can parse `appVersion` or `userAgent` for further information and in the MSIE browser you can also get access to script engine version and build number values.

See also:	`ScriptEngine(),ScriptEngineBuildVersion(), ScriptEngineMajorVersion(), ScriptEngineMinorVersion()`

Property attributes:

`ReadOnly`.

Navigator.appName (Property)

The generic type or model name of the web browser.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*navigator*.appName

This is the name of the web browser with no version numbering information. It is not necessarily the same as the application code name property.

Here are some example values:

- `Netscape`
- `Microsoft Internet Explorer`

Property attributes:

`ReadOnly`.

Navigator.appVersion (Property)

The version and release information for the browser.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*navigator*.appVersion

This is the full version string for the browser.

Here are some typical values:

- `4.7 (Macintosh; I; PPC)`
- `4.0 (compatible; MSIE 4.5; Macintosh; U; PPC)`
- `4.0 (compatible; MSIE 5.0; Macintosh; I; PPC)`

Note that Netscape provides a version number in the form X.XX while MSIE only describes to X.X accuracy.

See also:	`Native` object

Property attributes:

`ReadOnly`.

Navigator.browserLanguage (Property)

The national language variant of the browser.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`navigator.browserLanguage`

This is a value you can check to ensure the user is operating a suitably configured browser for your pages. Nationality settings can affect many aspects of the script behavior such as:

- Font character sets
- Currency symbols
- Sort collation sequences
- Searching and comparing of strings

Refer to the Language codes topic for a list of the available codes.

This property is available in MSIE only. For scripts running in the Netscape browser, you should use the `Navigator.language` property.

See also:	Language codes, `Navigator.language`

Property attributes:

`ReadOnly`.

Navigator.browserLanguage (Property)

The national language version supported by the MSIE browser.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`navigator.language`

The value stored in this property will be the international standard code for languages. This may not be the same as the values specified in the ISO 3166 standard but it should conform to the ISO 639 standard, which allocates two and three letter codes to countries.

Refer to the Language codes topic for a list of the available codes.

This is equivalent to the `Navigator.language` property in the Netscape browser.

Warnings:

- Beware that use of this property name for some objects describes a scripting language and not an international language variant.
- On MSIE, this value is returned by the `browserLanguage` property of the `Navigator` object.

See also:	`Element.lang`, Language codes, `Navigator.browserLanguage`, `Navigator.language`, `Navigator.systemLanguage`, `Navigator.userLanguage`

Property attributes:

`ReadOnly`.

Navigator.constructor (Property)

A constructor for creating new `navigator` objects.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Navigator` object	
JavaScript syntax:	N	`navigator.constructor`

Netscape supports a `constructor` property for the `Navigator` object. You won't find very many circumstances where you will need to create a new instance of the `Navigator` object.

This is another example of where the generic approach to creating objects that Netscape employs may be less optimal than the special individually-coded objects support that MSIE employs (even though it leads to a more bulky implementation).

Warnings:

- Because Netscape supplies a constructor for virtually every object type that it supports, there is a constructor for the `Navigator` object class. However, trying to access the `navigator.constructor` value is quite hard. There seems to be a bug in its implementation that prevents it being converted to a primitive. However it still responds to a request for its `name` or `prototype` properties.

- Since this object behaves in this strange way, building general-purpose scripts that access constructors is quite hard. During our research, several general purpose inspector scripts were written. One that examined constructors worked on most objects but failed on the `Navigator` object.
- This may be a scope-chain problem, because if you pass a `Navigator` object to a function in one of its arguments, then accessing the constructor of that argument may yield the source text of the function. This problem is manifested in Netscape 4.7 for Macintosh and may be extant on other platforms.
- This doesn't seem to affect whether the other properties that the `Navigator` object supports can be enumerated in a `for( ... in ... )` loop.

Navigator.cookieEnabled (Property)

A flag value indicating whether cookies are available or not.

Availability:	JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`navigator.cookieEnabled`

You can use this property to check whether the user has enabled cookie support. The content of this property will be the Boolean `true` or `false` value. This may affect the way that you treat the user when they access your site.

Property attributes:

`ReadOnly`.

Navigator.cpuClass (Property)

An indication of what sort of processor is in the hardware.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`navigator.cpuClass`

This property reports the following types of CPU:

- `x86`
- `PPC`

The `x86` value would be yielded on systems running on an Intel processor such as a Pentium or when running a web browser inside a PC emulator on a Macintosh. The `PPC` value would be returned when running the browser as a native application in the Macintosh.

Property attributes:

`ReadOnly`.

Navigator.javaEnabled() (Method)

A method that tells you whether Java support is enabled in the browser or not.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`navigator.javaEnabled()`

You can use this property to check whether the user has enabled Java applet support. The value returned by this method will be the Boolean `true` or `false` primitive. This may affect the way that you treat the user when they access your site.

Navigator.language (Property)

The national language version supported by the browser.

Availability:	JavaScript –1.2 Netscape –4.0 Opera –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`navigator.language`

The value stored in this property will be the international standard code for languages. This may not be the same as the values specified in the ISO 3166 standard but it should conform to the ISO 639 standard, which allocates two and three letter codes to countries.

Refer to the Language codes topic for a list of the available codes.

Warnings:

- Beware that use of this property name for some objects describes a scripting language and not an international language variant.
- On MSIE, this value is returned by the `browserLanguage` property of the `Navigator` object.

See also:	`Element.lang`, Language codes, `Navigator.browserLanguage`, `Navigator.systemLanguage`, `Navigator.userLanguage`

Property attributes:

`ReadOnly`.

Navigator.mimeTypes[] (Collection)

This property returns an array of supported MIME types.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	-	`navigator.mimeTypes`

The MIME type array is a sub-class of the built-in `Array` class. It is called a `MimeTypeArray`.

Here is a list of MIME types supported in recent versions of MSIE and Netscape:

Type	Description
application/mac-binhex40	Macintosh BinHex Archive
application/macbinary	MacBinary application
application/msword	Microsoft Word Document
application/pdf	Adobe Portable Document Format (PDF)
application/postscript	PostScript File
application/rtf	Rich Text Format File
application/sdp	Session Description Protocol
application/smil	SMIL Document
application/streamingmedia	Standard Streaming Metafile
application/vnd.ms-excel	Microsoft Excel Worksheet

The example inspects the available MIME types. For each one, it will display these properties (note that only one is shown as an example):

```
type:audio/x-rmf

description:audio/x-rmf

suffixes:rmf

enabledPlugin:[object Plugin]
```

Warnings:

- In MSIE version 4.5 for Macintosh, this returns the `undefined` value and therefore you cannot establish the MIME types that the browser will support. In MSIE for other platforms a `null` value may be returned.
- In Netscape the array element property name values are the same as the type name. In MSIE version 5, the values are simply the numeric index. This may affect the way that you access the array. However, you can access the `type` property of each element in the array and if you check that, you should be able to build a portable script.
- MSIE and Netscape support different sets of MIME types. Some are supported on both and some only on one. They also differ somewhat in the textual description of the MIME type so it is really only safe to test the `type` property and ignore the `description` property.
- If you write an inspector script to dump the array values out to the screen, you may observe that some types do not have a descriptive name and in a couple of cases, a MIME-type exists with a name but no correctly defined type value. This may be version- and platform-specific. The values reported by this array may also be modified according to what you do in the preferences panels regarding the mapping of file types to helper applications.

- Many MIME types that are browser-specific may actually be similar to MIME types in other browsers. Because these are created and defined by different browser manufacturers there are always likely to be some browser-dependent differences.
- The associative array technique may not always work across browsers.

Example code:

```
<!-- Show all mime types installed -->
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
for (var myIndex=0; myIndex<navigator.mimeTypes.length; myIndex++)
{
   for (var myProperty in navigator.mimeTypes[myIndex])
   {
      document.write(myProperty);
      document.write(":");
      document.write(navigator.mimeTypes[myIndex][myProperty]);
      document.write("<BR>");
   }
   document.write("<HR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`MimeType` object, `MimeTypeArray` object

Property attributes:

`ReadOnly`.

Navigator.onLine (Property)

This property tells you whether the browser is online to a network.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`navigator.onLine`

If you select the work offline mode then this property will return `false`. It returns `true` when you go back online. This allows you to write scripts that will operate differently when they are being executed in an offline session.

Property attributes:

`ReadOnly`.

Navigator.opsProfile (Property)

An undocumented property of the `Navigator` object.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`Undefined`	
JavaScript syntax:	IE	`navigator.opsProfile`

This property is visible when the `Navigator` object is placed in a enumerating `for( ... in ... )` loop. However, there does not appear to be any documentation available on what it is used for. Its name suggests that it might be something to do with user preferences.

It seems to be available only on some versions and platforms. It shows up on MSIE version 5.0 for Macintosh but not on Windows.

Warnings:

- This yields the `undefined` value in MSIE and Netscape .

Property attributes:

`ReadOnly`.

Navigator.platform (Property)

The name of the hardware or operating system that the browser is running on.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`navigator.platform`

Using this property to optimize the page content for the platform can yield some benefits in performance at the expense of a little more work required to develop the site content.

Here are some possible values for this property:

- `Win16`
- `Win32`
- `MacPPC`
- `Mac68K`

Other values will be received by users of Unix systems.

This at least lets you distinguish between users running on one of the modern versions of Windows vs. a Macintosh user, or a user of an older platform. You can then opt to present simpler content with less client-side rendering effort on a lesser platform.

Property attributes:

`ReadOnly`.

Navigator.plugins.refresh() (Method)

Refresh all the plugins in the current page.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
JavaScript syntax:	-	`navigator.plugins.refresh()`

This is not strictly a direct method belonging to the `Navigator` object but it is helpful to remind you about it if you are looking at the `Navigator.plugins` property.

Calling this method is recommended if you suspect that a new plugin has been installed since the current browsing session was started. Actually, this is likely to happen quite rarely, but nevertheless, calling `Navigator.plugins.refresh()` as a matter of course at the start of your plugin access script will not cause any undue harm.

Navigator.plugins[] (Collection)

An array of the plugins currently installed into the browser.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	-	`navigator.plugins`

The object returned is a sub-class of the `Array` object. It is a `PluginArray`.

Here is a list of some plugins displayed by using JavaScript to unwrap the `plugins` array:

- Headspace Beatnik Helper Stub Plugin V1.0.1
- LiveAudio
- Shockwave for Director

- PDFViewer
- QuickTime Plug-in 4.1
- RealPlayer(tm) G2 LiveConnect-Enabled Plug-in (Mac)
- Shockwave Flash

The default plugin has been omitted since it is always there. However note that it is not always spelled the same in all browsers. If you are displaying a list of plugins to the user, then be careful how you eliminate unwanted items.

You may check for the existence of a plugin using the following logical expression:

```
(navigator.plugins["TheRequiredItem"] != null)
```

However, this may not always work due to the naming conventions.

The example enumerates some plugins and of course the output depends on the plugins you have installed. You might typically see something like this listed:

- Headspace Beatnik Helper Stub Plugin V1.0.1
- Default Plug-in
- LiveAudio
- Shockwave for Director
- PDFViewer
- QuickTime Plug-in 4.1
- RealPlayer(tm) G2 LiveConnect-Enabled Plug-in (Mac)
- Shockwave Flash

Warnings:

- This sometimes yields the `undefined` value and therefore it is impossible to determine which plugins are supported in MSIE version 4.5 for Macintosh and other browser/platform combinations that do not support the `plugins` array.
- If this is supported in a target browser you are writing scripts for, the exact results will depend on the user's configuration. There is enormous scope for users to install a variety of free and downloadable plugins from the web. There is no guarantee as to what plugins they will have installed. Their browser may only report a couple of plugins (theoretically the minimum is just the one default plugin) or they may have many plugins installed.
- The associative array technique may not always work across browsers.
- Netscape and MSIE encapsulate plugin/embedded objects in different ways. In MSIE they are objects of the `EMBED` class. In Netscape they are objects commonly referred to as belonging to the `Plugin` class although they are really implemented as `JavaObject` objects. In MSIE, this is an `ActiveX` object.

- There is additional confusion in that there is a `plugins[]` array that belongs to the document and another than belongs to the `navigator` object. They both contain collections of objects but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.
- To help clarify this confusing situation, the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` array. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and `Embed` objects will be an instance of a plugin that is alive and running in a document.

Example code:

```
<!-- Display all plugin names -->
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
for (var myIndex=0; myIndex<navigator.plugins.length; myIndex++)
{
   document.write(navigator.plugins[myIndex].name);
   document.write("<HR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Plugin` object, `PluginArray` object

Property attributes:

`ReadOnly`.

Navigator.preference() (Method)

A mechanism for allowing signed scripts to set a preference value in Netscape .

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
JavaScript syntax:	-	`navigator.preference()`
	-	`navigator.preference(`*`aName`*`)`
	-	`navigator.preference(`*`aName`*`, `*`aValue`*`)`
Argument list:	*`aName`*	The name of a preference
	`aValue`	A new value to store in a preference

This is not portable but may be necessary in some captive intranet situations where you know what the target client is going to be and have some control over it.

Although the method appears to be widely available, the values for specifying user preferences certainly have not been standardized and the security implications are also not common to all the platforms. You should be prepared to write some portability support code if you plan to deploy this functionality.

Warnings:

- You cannot access this method unless the script has the `UniversalPreferencesRead` privilege. Setting preferences requires the `UniversalPreferencesWrite` privilege.

See also:	`UniversalPreferencesRead`, `UniversalPreferencesWrite`

Web-references:

http://developer.netscape.com/library/documentation/deploymt/jsprefs.htm

Navigator.savePreferences() (Method)

Save the preference values for the current user.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	`navigator.savePreferences()`

Any access to the preferences mechanisms in a browser for any purpose other than reading them should be treated with some suspicion. It may be preferable to invite the user to adjust a preference setting rather than to modify it for them. You might affect the behavior of other pages inadvertently.

Warnings:

- In Netscape, your script needs to be granted the `UniversalPrefrencesWrite` privilege before this call can be executed successfully.

See also:	`UniversalPreferencesWrite`

Navigator.securityPolicy (Property)

An indication of the current security policy settings.

Availability:	JavaScript –1.4 Netscape –4.7	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`navigator.securityPolicy`

This property contains the current security policy settings. Examining this property in a browser session yields the value "`Export policy`".

Warnings:

- This yields the `undefined` value in MSIE for Macintosh.

Property attributes:

`ReadOnly`.

Navigator.systemLanguage (Property)

An MSIE-specific language property.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`navigator.systemLanguage`

This property describes the system-specified language and country code. It uses the same language values as the `navigator.language` property.

Refer to the Language codes topic for a list of the available codes.

The most likely default value you will encounter will be "en" which signifies English but does not make distinction between UK and US variants. The value is supposed to be case-insensitive.

Warnings:

- Note that some platforms will yield a language and country code while others may only yield a language code.

See also:	`Element.lang`, ISO 3166, Language codes, `Navigator.language`, `Navigator.userLanguage`

Property attributes:

`ReadOnly`.

Navigator.taintEnabled() (Method)

This feature is no longer recommended. It is part of a now defunct security mechanism.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0 Deprecated	
JavaScript syntax:	-	`navigator.taintEnabled()`

This method is only supported in order to prevent scripts from crashing. The data-tainting support was a short-lived means of sending data back to a server. The security implications became unworkable and the whole data-tainting idea was deprecated.

The functionality was removed in JavaScript version 1.2. If you encounter this method in a script you are maintaining, you should seek to remove it to prevent run-time errors in the future.

If a browser implements this at all, it should return the value `false` for this method. Some earlier Netscape browsers may not. This functionality is highly deprecated and you can expect it to cause run-time exceptions in future.

Warnings:

- DO NOT USE THIS FACILITY!

See also:	`taint(),untaint()`

Navigator.userAgent (Property)

The identifying string for this browser.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`navigator.userAgent`

This string is returned to a web server in the `USER-AGENT:` header of an HTTP request. This is often logged and processed to analyze the distribution of browser types across the user base for a site.

The `userAgent` string contains much useful information and generally includes everything the `appVersion` and `appName` properties would have told you as well.

Here are some typical values:

- `Mozilla/4.7 (Macintosh; I; PPC)`
- `Mozilla/4.0 (compatible; MSIE 4.5; Mac_PowerPC)`
- `Mozilla/4.0 (compatible; MSIE 5.0; Mac_PowerPC)`

Warnings:

- Beware that some customized browsers will encode a variety of strange textual values into their `userAgent` property.

- While this will only affect the user of the browser when they run your script, the nature of the `userAgent` string may cause your script to fail.
- The following unusual values have been encountered in `userAgent` strings:
  - - Null characters
  - - Control characters
  - - URL strings
  - - HTML
  - - C-Code
  - - JavaScript
  - - GIF image data
  - - Very large text blocks
- These appear to be intended to cause server difficulties and possibly malfunctions in logging analysis systems. They may, as a side effect, cause your script to crash and burn too.

Example code:

```
// A function to normalize the user agent string
function getBrowserType()
{
   var myUserAgent;
   var myMajor;
   myUserAgent   = navigator.userAgent.toLowerCase();
   myMajor       = parseInt(navigator.appVersion);
   if( (myUserAgent.indexOf('mozilla')    != -1) &&
      (myUserAgent.indexOf('spoofer')    == -1) &&
      (myUserAgent.indexOf('compatible') == -1) &&
      (myUserAgent.indexOf('opera')      == -1) &&
      (myUserAgent.indexOf('webtv')      == -1))
   {
      if (myMajor > 4)
      {
         return "nav6";
      }
      if (myMajor > 3)
      {
         return "nav4";
      }
      return "nav";
   }
   if (myUserAgent.indexOf("msie") != -1)
   {
      if (myMajor > 4)
      {
          return "ie5";
      }
      if (myMajor > 3)
      {
         return "ie4";
      }
```

```
        return "ie";
    }
    return "other";
}

alert(getBrowserType());
```

See also:	`server.agent`

Property attributes:

ReadOnly.

Navigator.userLanguage (Property)

An MSIE specific language property.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`navigator.userLanguage`

This property describes the user-selected language code. It uses the same language values as the `navigator.language` property.

Refer to the Language codes topic for a list of the available codes.

Warnings:

- Note that some platforms will yield a language and country code while others may only yield a language code.

See also:	`Element.lang`, ISO 3166, Language codes, `Navigator.language`, `Navigator.systemLanguage`

Property attributes:

`ReadOnly`.

Navigator.userProfile (Property)

This yields a user profile object in MSIE browsers.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`UserProfile object`	
JavaScript syntax:	IE	`navigator.userProfile`

User profiles are available only on MSIE. The same arguments regarding uninvited modification and possible knock-on effects apply here just as much as they do to Netscape. Even though the scripting techniques may be different, the consequences may be similar.

See also:	`vCard` object

Property attributes:

`ReadOnly`.

Negation operator (-) (Operator/unary)

Negate an operand's value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`-anOperand`*
Argument list:	*`anOperand`*	A numeric value that can be negated

The operand is evaluated and converted to a numeric value. The result is negated.

A positive value becomes negative and a negative value becomes positive.

This is functionally equivalent to:

```
anOperand *= -1
```

Which is equivalent to:

```
anOperand = anOperand * -1
```

And also:

```
anOperand = 0 - anOperand
```

Although this is classified as a unary operator, its functionality is really that of an additive operator.

The associativity is from right to left.

Refer to the Operator Precedence topic for details of execution order.

See also:	Add (+), Additive expression, Additive operator, Associativity, Decrement value (--), Operator Precedence, Subtract (-), Unary operator

ECMA 262 edition 2 –section –11.4.7

ECMA 262 edition 3 –section –11.4.7

NES (Product)

An abbreviation for Netscape Enterprise Server.

Refer to:

Netscape Enterprise Server

nethelp: URL (Request method)

A special URL access mode for Netscape help screens.

Availability:	JavaScript –1.2 Netscape –4.0

This is a special request method provided by the Netscape browser to gain access to local client-side help resources. The resources are loaded from files that live in a help folder within the folder containing the browser application. You can access the files with a text editor and study how they work. They are just plain HTML and JavaScript; however, they provide a quite helpful embedded help system. In a large enterprise where you control the deployment of the browsers, you may want to augment the browser help with some internal help pages. You might want to add details of your help desk and how to contact it for instance.

These special URLs are not present in MSIE although there will be some internal resources in that browser that may provide customization opportunities in a similar way. Indeed, Microsoft provides an administrator kit which you can use to customize the browser installation.

You may also be able to obtain admin tools from Netscape and Microsoft to carry out legitimate customizations on the browsers before deploying them throughout your organization.

This can be called from JavaScript by setting the `location.href` of a window to a valid `nethelp:` location.

Here are some examples:

URL	Description
nethelp:netscape/home:start_here	Front page of the help system
nethelp:netscape/collabra:HELP_SEC_CERTS_CRYPTOMODS	Security help
nethelp:netscape/collabra:HELP_SEC_CERTS_ISSUERS	Security help
nethelp:netscape/collabra:HELP_SEC_INFO	Security help
nethelp:netscape/collabra:HELP_SEC_PASS_UNSET	Security help
nethelp:netscape/collabra:HELP_SEC_PREFS_APPLET	Security help
nethelp:netscape/collabra:HELP_SEC_PREFS_MESSENGER	Security help
nethelp:netscape/collabra:HELP_SEC_PREFS_NAVIGATOR	Security help

Mostly, these special URLs will be useful for debugging. Getting details of the disk cache for example may be useful. Pulling up the JavaScript debugger page if you detect an error in your script might also be a cool trick.

This appears to have changed somewhat in Netscape 6.0, which is likely to provide a whole range of new possibilities. Once the browser is fully debugged and working we can spend many happy hours inspecting it to discover them.

Warnings:

- This is not present in MSIE at all. It displays help using a completely different mechanism altogether.

See also:	`about:` URL, `javascript:` URL, `mailbox:` URL, `mailto:` URL, URL

Netscape Enterprise Server (Product)

A web server that supports JavaScript on the server side.

Server-side scripting is accomplished by enclosing the JavaScript code inside `<SERVER>` tags in the HTML. These will be parsed out as the pages is processed and sent onwards. They will be replaced by the output of the script enclosed in the tags.

The main difference is that where you might have used a `document.write()` method in the client-side script, on the server side, you use a `write()` method.

If the `<SERVER>` tag remains intact and is forwarded in the document sent onwards to the browser, the browser should ignore it. However, this could give away much valuable information about the inside of the server and middle-ware. That could aid the wily hacker in an intrusion attack.

Netscape Navigator (Web browser)

One of the two major web browser platforms.

Netscape has made the source of the Communicator product available (which includes the Navigator browser). You can download this from the Netscape web site and participate in the development of the browser project. Netscape 6.0 is only just released for public use but is likely to contain some bugs.

We refer to this browser consistently as Netscape regardless of whether you are running Communicator or any other packaged version.

Here is a brief guide to versions of Netscape vs. JavaScript:

Version	JavaScript
2.0	JavaScript 1.0
3.0	JavaScript 1.1
4.0 to 4.05	JavaScript 1.2
4.06 to 4.75	JavaScript 1.3
5.0	JavaScript 1.4
6.0	JavaScript 1.5

Note that version 5.0 never shipped although if you search on the web you can find some installable binaries may satisfy your curiosity regarding browser history. Some reports suggest that those version 5.0 browsers only supported JavaScript 1.3. Because Mozilla is factored into components, it's feasible that you could build any version of the browser with whatever version of JavaScript you want.

Many values that Netscape exposes as JavaScript properties reflect the value of an HTML tag attribute. Likewise, many of its special objects are counterparts to the HTML tags. However it does not map objects so completely or consistently to HTML tags as the MSIE browser. Nor does it support the attributes and style mechanisms as elegantly.

Where the information is available, we have indicated the version number of JavaScript (or JScript) when HTML tags and attributes became accessible as objects or properties. In many cases, this may be a later version than when the instantiating HTML tag or attribute was first supported by the browser.

We constructed many scripts to inspect and enumerate the various properties of the objects in the MSIE and Netscape browsers. These uncovered many object types and properties that were hitherto undocumented. They might have been available in earlier versions of the browser. However, where language elements were discovered for the first time, they are initially documented as being available from version 4 of Netscape. A limited amount of further testing was applied where it was suspected that language elements may have been available in earlier releases and the availability modified accordingly.

Version 5 of Netscape was scrapped because its codebase became too unwieldy to work with. There seems little point in documenting its peculiarities. Netscape version 6.0 was in beta trials and until PR3 was so unstable and crash-prone that most of our testing bore little fruit. Right at the point where content was being finalized for publication Netscape 6.0 was released as a final product. It is clearly still a work in progress and there are quite a few non-working components. It looks good though. The potential for exercising the DOM standard document navigation is really exciting. There is a great deal yet to discover about the new browser and it will stabilize as bugs get fixed and new releases are shipped.

Perhaps browser versions may become less important as they converge on a single standard benchmark of functionality. For the time being, current practice suggests that version 4 browsers of both traditions are rapidly being taken over by version 5 MSIE browsers. Version 2 and 3 of MSIE and Netscape have declined to such small usage levels as to not require any further serious attempts to support them on new projects. Netscape 6.0 may win back some market share but only if its bugs are fixed quickly. Version 6.0 of MSIE is about to go to beta testers and the standards bodies are still some way ahead of the browser manufacturers so there is a long way to go yet.

Warnings:

- Netscape 2.02 does not cope gracefully with dollar signs in identifier names.

netscape (Java package)

A short-cut reference to the `Packages.netscape` object. It allows JavaScript to access the Java class hierarchy to instantiate Java objects.

Availability:	JavaScript –1.1 Netscape –3.0 Netscape Enterprise Server –2.0	
Property/method value type:	`JavaPackage netscape`	
JavaScript syntax:	N	*myWindow*`.netscape`
	N	*myWindow*`.Packages.netscape`
	N	`netscape`
	N	`Packages.netscape`

See also:	`Window.java`, `Window.netscape`, `Window.Packages`, `Packages.netscape`

netscape.applet (Java package)

The root node of the Java hierarchy where the applets are built. A shortcut to the `Packages.netscape.applet` package.

Availability:	JavaScript –1.1 Netscape –3.0

This property returns a Java package that is encapsulated inside a JavaScript object belonging to the `JavaPackage` class.

You need to know quite a lot about the underlying Java objects to make use of this because the properties and methods it supports are not exposed in an enumerable fashion. This means you would have difficulty in writing a JavaScript inspector to examine these objects.

See also:	`JavaPackage` object

netscape.cfg (Java package)

A new style configuration file for Netscape. Not to be confused with the `Packages.netscape` Java classes.

Availability:	JavaScript –1.1 Netscape –3.0

See also:	`netscape.lck`, Preferences

netscape.javascript (Java package)

A Java package for supporting JavaScript inside Java. A shortcut to the `Packages.netscape.javascript` package.

Availability:	JavaScript –1.1 Netscape –3.0

Refer to:

`JavaPackage` object

netscape.javascript.JSObject (Java class)

The full definition of the `JSObject` class for encapsulating JavaScript objects in Java. A shortcut to the `Packages.netscape.javascript.JSObject` class.

Availability:	JavaScript –1.1 Netscape –3.0
Class methods:	`getWindow()`

Values of this type are visible to JavaScript as the encapsulated object that was originally passed to Java. Effectively, the wrapper is removed.

Note that you cannot use this as a constructor. There wouldn't be any point anyway because you can create JavaScript objects within the JavaScript environment; there is no need to go through the Java bridge to accomplish that.

See also:	Java calling JavaScript, Java to JavaScript values, JavaScript to Java values, `JSObject` object

netscape.lck (Java package)

A configuration file as used in older versions of Netscape. Not to be confused with `Packages.netscape`.

Availability:	JavaScript –1.1 Netscape –3.0

This is provided as support for preference management in older versions of Netscape.

See also:	Preferences

Cross-references:

Wrox *Instant JavaScript* –page –59

netscape.plugin (Java package)

The top of a hierarchy of Java packages that support plugins. This is a shortcut to the `Packages.netscape.plugin` package.

Availability:	JavaScript –1.1 Netscape –3.0

Refer to:

`JavaPackage` object

netscape.plugin.Plugin (Java class)

A special class for encapsulating plugins so they present a common API. This is a shortcut to the `Packages.netscape.plugin.Plugin` class.

Availability:	JavaScript –1.1 Netscape –3.0
HTML syntax:	`<EMBED>`
Object methods:	`destroy(), equals(), getClass(), getPeer(), getWindow(), hashCode(), init(), isActive(), notify(), notifyAll(), toString(), wait()`

See also:	`<EMBED>`, LiveConnect, `Plugin` object

Method	JavaScript	JScript	N	IE	Opera	Notes
`destroy()`	1.1 +	-	3.0 +	-	-	-
`equals()`	1.1 +	-	3.0 +	-	-	-
`getClass()`	1.1 +	-	3.0 +	-	-	-
`getPeer()`	1.1 +	-	3.0 +	-	-	-
`getWindow()`	1.1 +	-	3.0 +	-	-	-
`hashCode()`	1.1 +	-	3.0 +	-	-	-
`init()`	1.1 +	-	3.0 +	-	-	-
`isActive()`	1.1 +	-	3.0 +	-	-	-
`notify()`	1.1 +	-	3.0 +	-	-	-
`notifyAll()`	1.1 +	-	3.0 +	-	-	-
`toString()`	1.1 +	-	3.0 +	-	-	-
`wait()`	1.1 +	-	3.0 +	-	-	-

netscape.security (Java package)

The top of a hierarchy of Java packages that provide security facilities. This is a shortcut to the `Packages.netscape.security` package.

Availability:	JavaScript –1.1 Netscape –3.0

See also:	Security policy, `JavaPackage` object

netscape.security.PrivilegeManager (Java class)

Part of the Netscape security model implemented with Java.

Availability:	JavaScript –1.1 Netscape –3.0
Class properties:	`EQUAL, NO_SUBSET, PROPER_SUBSET, SIGNED_APPLET_DBNAME, TEMP_FILENAME, theDebugLevel`
Class methods:	`checkPrivilegeEnabled(), checkPrivilegeGranted(), disablePrivilege(), enablePrivilege(), enableTarget(), getMyPrincipals(), getPrivilegeManager(), getSystemPrincipal(), revertPrivilege()`
Object methods:	`disablePrivilege(), enablePrivilege(), getPrivilegeTableFromStack()`

Because the Netscape security model is based on the Java security model, the Netscape browser requests its privileges through the Java mechanisms. These are encapsulated in a class that you can access from inside JavaScript.

The downside of this is that there is no meaningful value returned when the request is made. If the request for a privilege is denied, the error causes a Java exception, which is difficult to trap from JavaScript. It is possible that more recent browser versions will support an exception-handling mechanism.

See also:	`PrivilegeManager` object, Requesting privileges, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `UniversalFileRead`, `UniversalPreferencesRead`, `UniversalPreferencesWrite`, `UniversalSendMail`

Method	JavaScript	JScript	N	IE	Opera	Notes
`disablePrivilege()`	1.1 +	-	3.0 +	-	-	-
`enablePrivilege()`	1.1 +	-	3.0 +	-	-	-
`getPrivilegeTableFromStack()`	1.1 +	-	3.0 +	-	-	-

new (Operator/unary)

An object construction operator.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	An object whose type depends on the constructor	
JavaScript syntax:	-	*myObject* = new *aConstructor*
	-	*myObject* = new *anObject*(*someArguments*)
Argument list:	*aConstructor*	An object constructor function
	anObject	An object to clone
	someArguments	A collection of initial values for the new instance

The new operator creates a new instance of the object it is operating on.

As the object is created, the receiver's Construct method is called with no arguments passed to it. Any initialization is only carried out by the Construct method.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

Typically this would be used to instantiate core objects of the following types:

- `Array`
- `Boolean`
- `Date`
- `Function`
- `Number`
- `Object`
- `RegExp`
- `String`

This can also be used to instantiate some host objects.

See also:	`Array()`, Associativity, `Boolean()`, `Date()`, `Function()`, Left-Hand-Side expression, List type, `Number()`, `Object()`, Operator Precedence, `RegExp()`, `String()`

Newline (Escape sequence)

A means of introducing line breaks into string content texts.

Availability:	ECMAScript edition –2

The newline escape sequence `\n` can be placed in string literals if you want to break the output text over more than one line.

Warnings:

- Do not use a line terminator even with a backslash to escape it. In other words, don't think that placing a backslash as the last character of a line will hide the line terminator. While that may work in other languages, it won't work in JavaScript.

See also:	Escape sequence (\), Line terminator

ECMA 262 edition 3 –section –7.3

Newlines are not <BR> tags (Pitfall)

A newline in a script does not display a line break in HTML output.

Because HTML is fairly freely formatted, you have to explicitly tell it when a line break is to appear. You can do this a variety of block-level tags. Its most likely done with a `<BR>` or `<P>` tag.

When you use the `document.write()` method, you need to explicitly include the necessary `<BR>` or `<P>` tags otherwise the HTML output that gets displayed will all run onto a single line. Placing a `\n` newline escape into the output may make the HTML source look nice but it won't affect the displayed output.

A line break is also introduced when you use block structured elements in the HTML. Here is a list of common HTML tags that do this (there are others too):

- <BLOCKQUOTE>
- <BODY>
-
- <DD>
- <DL>
- <DIV>
- <DT>
- <H1> etc
- <HR>
- <HTML>
- <LI>
- <OBJECT>
- <OL>
- <P>
- <PRE>
- <UL>

Wrox *Instant JavaScript* –page –46

News posts containing JavaScript (Advice)

You can embed JavaScript into news postings composed using HTML.

When you compose and post a news message, you may use HTML as a way to improve the presentation. This means you can include some JavaScript to be executed in the client mail-reader application.

Not all news-reading clients can support HTML let alone JavaScript. However, if your recipient does (and that is likely if its a web browser), then you can do some creative things to link topics in threads and pre-format replies so that they associate correctly into the news topic tree. You simply construct your HTML document in the normal way.

Warnings:

- There are significant security and virus related risks with JavaScript enabled news. The possibilities are so catastrophic that the best reccomendation is to deactivate JavaScript and Java in any news-reading client application.
- Just because something is possible does not mean it is advisable or good to do.
- On the other hand, within the confines of a closely controlled intranet or workgroup, this could find many useful applications. Just so long as you know where the news posts came from and you can absolutely trust that they have not been compromised.
- Personally, I'd recommend that you turn it off. It might be useful for including the odd diagram but mostly you need to get the informational content and it doesn't really need to be very pretty.

See also:	E-mail containing JavaScript

Cross-references:

Wrox *Instant JavaScript* –page –60

news: URL (Request method)

A request from a web browser to a news server to send a document.

Use the browser to download and browse some news content.

Warnings:

- This is only allowed under script control if the script has the `UniversalSendMail` privilege.

See also:	`javascript:` URL, `UniversalSendMail`, URL

Node object (Object/DOM)

A node is the primary component from which documents are built (in the context of a DOM hierarchy).

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
JavaScript syntax:	-	*myNode* = *myMutationEvent*.relatedNode
Object properties:	`firstChild, lastChild, nextSibling, nodeName, nodeType, nodeValue, ownerDocument, parentNode, previousSibling`	

Class constants:	`ATTRIBUTE_NODE, CDATA_SECTION_NODE, COMMENT_NODE, DOCUMENT_FRAGMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, ELEMENT_NODE, ENTITY_NODE, ENTITY_REFERENCE_NODE, NOTATION_NODE, PROCESSING_INSTRUCTION_NODE, TEXT_NODE`
Object methods:	`appendChild(), cloneNode(), hasChildNodes(), insertBefore(), removeChild(), replaceChild()`
Collections:	`attributes[], childNodes[]`

Here is a list of the available node types:

Constant	Type	Description
`undefined`	null	A member of the attributes collection
`ELEMENT_NODE`	1	HTML element object node
`ATTRIBUTE_NODE`	2	HTML tag attribute object
`TEXT_NODE`	3	Text object node
`CDATA_SECTION_NODE`	4	CDATA section
`ENTITY_REFERENCE_NODE`	5	Entity reference
`ENTITY_NODE`	6	Entity node
`PROCESSING_INSTRUCTION_NODE`	7	Processing instruction node
`COMMENT_NODE`	8	Comment node
`DOCUMENT_NODE`	9	Document object
`DOCUMENT_TYPE_NODE`	10	Doctype object
`DOCUMENT_FRAGMENT_NODE`	11	Document fragment node
`NOTATION_NODE`	12	Notation node

The DOM level 2 specification adds the following methods:

- `supports()`
- `normalize()`

It also adds the following properties:

- `namespaceURI`
- `prefix`
- `localName`

At DOM level 3, the interface to the `Node` object is expected to evolve further to allow nodes to be compared and to be able to extract a serialized version of a DOM tree branch into a string primitive. This functionality is still under review as this is being written. The following additional properties are expected to be supported:

- `baseURI`
- `textContent`
- `key`

DOM level 3 is expected to add the following methods to the `Node` object:

- `compareDocumentOrder()`
- `compareTreePosition()`
- `isSameNode()`
- `lookupNamespacePrefix()`
- `lookupNamespaceURI`
- `normalizeNS()`
- `setUserData()`
- `getUserData()`

If the implementation supports the DOM level 2 event model (this is the case with Netscape 6.0), then the `Node` object should also support the methods and properties defined by the `EventTarget` object.

See also:	`Attribute.nodeType`, `Document` object, `DocumentFragment` object, `Element` object, `EventTarget` object, `MutationEvent.initMutationEvent()`, `MutationEvent.relatedNode`, `NamedNodeMap` object, `Node.firstChild`, `Node.insertBefore()`, `Node.lastChild`, `Node.nextSibling`, `Node.parentNode`, `Node.previousSibling`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`firstChild`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`lastChild`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nextSibling`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nodeName`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nodeType`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`nodeValue`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`ownerDocument`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`parentNode`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`previousSibling`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`appendChild()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`cloneNode()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`hasChildNodes()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`insertBefore()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`removeChild()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`replaceChild()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Node.appendChild() (Method)

A new child node object is added to the end of the list of immediate children of this node.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.appendChild(`*aNode*`)`
Argument list:	*aNode*	The node to be appended

Node.attributes[] (Collection)

A `NamedNodeMap` collection of attributes for this node.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`NamedNodeMap` object	
JavaScript syntax:	-	*myNode*`.attributes`
See also:	`Element.attributes[]`, `MutationEvent.attrChange`, `MutationEvent.attrName`, `NamedNodeMap` object	

Node.childNodes[] (Collection)

A `NodeList` containing the immediate children of this node.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`NodeList` object	
JavaScript syntax:	-	*myNode*`.childNodes`
See also:	`Element.childNodes[]`, `NodeList` object	

Node.cloneNode() (Method)

The `node` object is cloned but the new instance has no parent node defined.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.cloneNode(`*aSwitch*`)`
Argument list:	*aSwitch*	Indicates whether a deep or shallow clone is required

Node.firstChild (Property)

The first object in the collection of direct children of this element.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.firstChild`
See also:	`Element.firstChild`, `Node` object	

Node.hasChildNodes() (Method)

A convenience method to provide a flag indicating whether there are any children belonging to this node.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myNode*`.hasChildNodes()`
See also:	`Element.contains()`, `Element.firstChild`	

Node.insertBefore() (Method)

This method inserts a child element into the collection at the indicated position.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.insertBefore(`*aNode1, aNode2*`)`
Argument list:	*aNode1*	The node to be inserted
	aNode2	The node indicating the insertion point

See also:	`Element.insertAdjacentText()`, `Node` object

Node.lastChild (Property)

The last child object contained within the DOM hierarchy that descends from this element.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.lastChild`

See also:	`Element.lastChild`, `Node` object

Node.nextSibling (Property)

An HTML element at the same level within the document hierarchy.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.nextSibling`

See also:	`Element.nextSibling`, `Node` object

Node.nodeName (Property)

The name value for this `node` object. This is provided by the HTML tag attribute.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNode*`.nodeName`

See also:	`Element.nodeName`

Node.nodeType (Property)

The nodes are created for a variety of purposes. This property indicates what sort of node has been instantiated.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myNode*`.nodeType`

The values in this parameter correspond to the values of the Static Constants belonging to the Node Class.

Here is a list of the available node types:

Constant	Type	Description
`undefined`	null	A member of the attributes collection
`ELEMENT_NODE`	1	HTML element object node
`ATTRIBUTE_NODE`	2	HTML tag attribute object
`TEXT_NODE`	3	Text object node
`CDATA_SECTION_NODE`	4	CDATA section
`ENTITY_REFERENCE_NODE`	5	Entity reference
`ENTITY_NODE`	6	Entity node

Table continued on following page

Constant	Type	Description
PROCESSING_INSTRUCTION_NODE	7	Processing instruction node
COMMENT_NODE	8	Comment node
DOCUMENT_NODE	9	Document object
DOCUMENT_TYPE_NODE	10	Doctype object
DOCUMENT_FRAGMENT_NODE	11	Document fragment node
NOTATION_NODE	12	Notation node

See also:	Element.nodeType

Node.nodeValue (Property)

The value of the node depends on the kind of node that the object encapsulates. Some nodes have `null` values.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myNode*.nodeValue

See also:	Element.nodeValue

Node.ownerDocument (Property)

The document that the node belongs to can be accessed via this property.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	Document object	
JavaScript syntax:	-	*myNode*.ownerDocument

The `Node.ownerDocument` property is similar to the `document` property of an `Element` object. In this case, because we are considering only DOM nodes, whether the document is HTML or not is of no consequence. For now it probably is because the work centers around browser capabilities, but the DOM specification is far more than just a better way to describe a web page.

They have very cleverly separated the description of an abstract document and the 'HTMLness' of it into two layers. That way, implementors can superimpose other types of document content on top of a generic DOM foundation built on the Node structure.

This property is effectively provided by MSIE version 5 as a property of an `Element` object. Netscape 6.0 makes it available here in a more DOM-compliant manner.

It is a convenience property because accessing a containing `document` object in this way is far easier than walking down a `document.childNode` sequence to locate a contained document.

See also:	`Document` object, `Element.ownerDocument`

Node.parentNode (Property)

The direct parent node of the current object. This object will be a member of the `childNodes` collection for that object.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.parentNode`

See also:	`Element.parentNode`, `MutationEvent.relatedNode`, `Node` object

Node.previousSibling (Property)

The object immediately before this one in the `childNodes` collection of their joint parent node.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.previousSibling`

See also:	`Element.previousSibling`, `Node` object

Node.removeChild() (Method)

A method for removing child nodes from the collection.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.removeChild(`*aNode*`)`
Argument list:	*aNode*	The node object to be removed

Node.replaceChild() (Method)

A means of replacing child objects with new nodes and discarding the old ones.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	*myNode*`.replaceChild(`*newNode*`, `*oldNode*`)`
Argument list:	*newNode*	The node to be placed into the hierarchy
	oldNode	The node to be replaced

NodeList object (Object/DOM)

A generic collection of nodes, not presented in any particular order.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
JavaScript syntax:	-	*myNodeList* `= ` *myDocument*`.getElements ByTagName(`*aTagName*`)`
Argument list:	*aTagName*	The name of an HTML tag
Object properties:	`length`	
Object methods:	`item()`	

This object is based on an `Array` object and contains a set of `Node` items contained within a DOM hierarchy.

Do not confuse DOM `NodeList` arrays with `Enumerator` or `Collection` objects. The `NodeListitem()` method is subtly different to the `Enumerator.Item()` method.

See also:	`Collection` object, `Document.getElementsByTagName()`, `Element.getElementsByTagName()`, `Enumerator` object, `NamedNodeMap` object, `Node.childNodes[]`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`length`	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	1 +	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`item()`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

NodeList.item() (Method)

An item extractor to retrieve a `Node` from within a `NodeList` collection.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Node` object	
JavaScript syntax:	-	`myNodeList.item(anIndex)`
Argument list:	*`anIndex`*	A numeric index to a `Node` in the collection

You should node that in MSIE, the `Collection` object has an `Item()` method whereas DOM mandates that a `NodeList` should have an `item()` method. Note the difference in the case of the initial letter.

Even though an implementation may forgive an upper-lower case error when it parses the script source text, an `item()` call on `NodeList` can only return a `Node` object referenced using an integer index location within the collection.

Because the `NodeList` is based on an `Array`, `NodeList.item(`*`anIndex`*`)` is functionally equivalent to `NodeList[`*`anIndex`*`]` and one can enumerate through the set of `Node` objects using either technique.

NodeList.length (Property)

Returns the length of a collection array.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myNodeList*.length

The `NodeList` collection behaves exactly like an `Array` object and returns a number representing a count of all the `Node` objects in the collection.

Example code:

```
myCount = document.all.length;
```

See also:	`Array.length`, `Collection.length`

Property attributes:

`ReadOnly`.

NOFRAMES object (Object/HTML)

An object that represents the content of a `<NOFRAMES>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myNOFRAMES* = *myDocument*.all.*anElementID*
	IE	*myNOFRAMES* = *myDocument*.all.tags("NOFRAMES")[*anIndex*]
	IE	*myNOFRAMES* = *myDocument*.all[*aName*]
	-	*myNOFRAMES* = *myDocument*.getElementById(*anElementID*)
	-	*myNOFRAMES* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myNOFRAMES* = *myDocument*.getElementsByTagName("NOFRAMES")[anIndex]

HTML syntax:	`<NOFRAMES> ... </NOFRAMES>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey, tabIndex, dir`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

This was added to the MSIE browser at revision 4. It is a sub-class of the basic `Element` object and therefore shares many properties with other objects in the MSIE browser. Although it is implemented as an `Element`, it is not a DOM specified item.

See also:	`Element` object, `NOSCRIPT` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`accessKey`	-	3.0 +	-	4.0 +	-	-	-	-
`tabIndex`	-	3.0 +	-	4.0 +	-	-	-	-
`dir`	-	5.0 +	-	5.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onDblClick`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onKeyPress`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onKeyUp`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseDown`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseMove`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseOver`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
`onMouseUp`	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

NOFRAMES.dir (Property)

The direction of rendering of text contained within the block owned by the `<NOFRAMES>` tag.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myNOFRAMES*`.dir`

The `dir` property may be set to indicate a left-to-right or right-to-left parsing direction.

This is part of the localization support and represents the contents of the `DIR="..."` tag attribute.

If you assign a value to this property it is case-sensitive and must be either "`ltr`" or "`rtl`". Note that this is at variance with some documentation which says it is case-insensitive.

This property works in conjunction with the `lang` property to control the direction of text flow.

See also:	`BDO.dir,Element.dir,NOSCRIPT.dir`

Nombas ScriptEase (Product)

A standalone JavaScript interpreter.

This is an example of a JavaScript interpreter than can be used in several contexts.

The ScriptEase Web Server Edition (SEWSE) can be used in the backend of a server to accomplish much of what you might do with `<SERVER>` tags in the Netscape Enterprise Server or with Microsoft ASP. SEWSE is called as part of the CGI mechanism in the web server.

The Script Ease Desk Top implementation provides a way to use JavaScript to control desktop actions. This is available cross-platform and accomplishes the kind of things you might do with AppleScript on a Macintosh or Windows Script Host in the Microsoft Windows environment.

The SEWSE interpreter can also be used for general purpose scripting in the Unix environment in much the way you would use Bourne, Korn or C shells or the Perl interpreter.

You can also embed Script Ease into your own applications and add scriptability to them.

See also:	Standalone JavaScript

Nondigit (Definition)

A non-digit letter that can be used in an identifier.

In the context of creating identifier names, a non-digit character is a member of the following set:

```
a b c d e f g h i j k l m

n o p q r s t u v w x y z

A B C D E F G H I J K L M

N O P Q R S T U V W X Y Z
```

_ (Underscore)

See also:	Digit, Identifier

<NOSCRIPT> (HTML Tag)

A special tag that allows browsers that don't support scripting to display alternative content.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0

Browsers that support the `<SCRIPT>` tag should also support the `<NOSCRIPT>` tag. However, their support for the `<NOSCRIPT>` tag should be to hide or ignore anything between the `<NOSCRIPT>` tag and its corresponding `</NOSCRIPT>` closure.

Warnings:

- This is not supported by Netscape 2.

See also:	`<SCRIPT>`, Compatibility

NOSCRIPT object (Object/HTML)

An object representing the `<NOSCRIPT>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0
Inherits from:	`Element` object

JavaScript syntax:	IE	*myNOSCRIPT* = *myDocument*.all.*anElementID*
	IE	*myNOSCRIPT* = *myDocument*.all.tags("NOSCRIPT")[*anIndex*]
	IE	*myNOSCRIPT* = *myDocument*.all[*aName*]
	-	*myNOSCRIPT* = *myDocument*.getElementById(*anElementID*)
	-	*myNOSCRIPT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myNOSCRIPT* = *myDocument*.getElementsByTagName("NOSCRIPT")[*anIndex*]
HTML syntax:	<NOSCRIPT> ... </NOSCRIPT>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	accessKey, tabIndex, dir	
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

This was added to the MSIE browser at revision 4. It is a sub-class of the basic Element object and therefore shares many properties with other objects in the MSIE browser. Although it is implemented as an Element, it is not a DOM-specified item.

See also:	Element object, NOFRAMES object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
accessKey	-	3.0 +	-	4.0 +	-	-	-	-
tabIndex	-	3.0 +	-	4.0 +	-	-	-	-
dir	-	5.0 +	-	5.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

NOSCRIPT.dir (Property)

The direction of rendering of text contained within the block owned by the `<NOSCRIPT>` tag.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myNOSCRIPT*`.dir`

The `dir` property may be set to indicate a left-to-right or right-to-left parsing direction.

This is part of the localization support and represents the contents of the `DIR="..."` tag attribute.

If you assign a value to this property it is case-sensitive and must be either "`ltr`" or "`rtl`". Note that this is at variance with some documentation which says it is case-insensitive.

This property works in conjunction with the `lang` property to control the direction of text flow.

See also:	`BDO.dir`, `Element.dir`, `NOFRAMES.dir`

Not a number (Definition)

A special numeric value used to handle computational error conditions.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

IEEE 754 describes a numeric regime that includes the ability to flag exceptions when calculations generate invalid results. The result of such an expression may be signified by the `NaN` or Not a Number exception.

See also:	IEEE 754, `NaN`

Cross-references:

ECMA 262 edition 2 –section –4.3.23

ECMA 262 edition 3 –section –4.3.23

NOT Equal to (!=) (Operator/equality)

Compare two operands for inequality.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*anOperand1* `!=` *anOperand2*
Argument list:	*anOperand1*	A value to be compared
	anOperand2	Another value to be compared

The two operands are compared, and the Boolean `true` value is returned if they are not equal, otherwise `false` if they are equal. Note that JavaScript will attempt to convert both operands to the same type for comparison.

When testing for inequality, the following rule is invariant:

```
A != B
```

is equivalent to:

```
!(A == B)
```

Also, the rule of positioning allows that:

```
A == B
```

is identical to:

```
B == A
```

(Apart from the fact that exchanging the operands in this way alters the order in which they are evaluated.)

Exchanging the operands may have undesirable side effects if they are expressions. For example, they may call functions and test the results. If the functions are not totally independent of one another, you may get unexpected results.

The associativity is from left to right.

Refer to the Operator Precedence topic for details of execution order.

Refer to the Equality expression topic for a discussion on the ECMA standard definition of the equality testing rules.

See also:	ASCII, Associativity, Equal to (==), Equality expression, Equality operator, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), Logical expression, Logical NOT –complement (`!`), Logical operator, NOT Identically equal to (`!==`), Operator Precedence, Relational expression, Relational operator, typeof, Unicode

Cross-references:

ECMA 262 edition 2 –section –11.9.2

ECMA 262 edition 2 –section –11.9.3

ECMA 262 edition 3 –section –11.9.2

ECMA 262 edition 3 –section –11.9.3

NOT Identically equal to (!==) (Operator/identity)

Compare two values for non-equality and identical type.

Availability:	ECMAScript edition –3 JavaScript –1.3 JScript –1.0 Internet Explorer –3.02 Netscape –4.06	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`anOperand1`* `!==` *`anOperand2`*
Argument list:	*`anOperand1`*	A value to be compared
	`anOperand2`	Another value of the same type to be compared

The two operands are compared and Boolean `false` is returned if both values are equal, and of the same type, otherwise Boolean `true` is returned.

The associativity is from left to right.

Refer to the Operator Precedence topic for details of execution order.

Warnings:

- This is not available for use server-side with Netscape Enterprise Server 3.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
myObject1 = 100;
myObject2 = "100";
if(myObject1 != myObject2)
{
   document.write("Objects are NOT equal<BR>");
}
else
{
   document.write("Objects are equal<BR>");
}

if(myObject1 !== myObject2)
{
   document.write("Objects are NOT identical<BR>");
}
else
{
   document.write("Objects are identical<BR>");
}
</SCRIPT>
</BODY>
</HTML>
```

Notation object (Object/DOM)

Notations are decalred in the DTD and are encapsulated in these `Notation` objects.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Inherits from:	`Node` object	
JavaScript syntax:	-	*myNotation* = new Notation*()*
Object properties:	`publicId, systemId`	

See also:	`Doctype` object, `Doctype.notations[]`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`publicId`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly
`systemId`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly

Inheritance chain:

`Node` object

Notation.publicId (Property)

The public identifier (if one was defined) for this notation. The value may be `null` if no identifier was defined.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	myNotation.publicId

Property attributes:

`ReadOnly`.

Notation.systemId (Property)

The system identifier (if one was defined) for this notation. The value may be `null` if no identifier was defined.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNotation*.systemId

Property attributes:

`ReadOnly`.

null (Primitive value)

A built-in primitive value.

Availability:	ECMAScript edition –2 JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`Null primitive`	
JavaScript syntax:	IE	`null`

The `null` value is a primitive value that represents the `null`, empty, or non-existent reference.

This is equivalent to the Java `null` data type when passing values back and forth between JavaScript and Java.

If you don't have a `null` keyword, you may be able to simulate a `null` value like this:

```
var null = (void 0);
```

The `null` and `undefined` values are subtly different. An empty thing is not the same as a non-existent thing. However in a browser it is difficult to distinguish between them.

The `null` value is now provided in some browsers as a built-in keyword, but the `undefined` value is not.

See also:	Cast operator, JavaScript to Java values, LiveConnect, `NaN`, undefined

ECMA 262 edition 2 –section –4.3.11

ECMA 262 edition 3 –section –4.3.11

O'Reilly *JavaScript Definitive Guide* –page –47

null (Type)

A native built-in type.

Availability:	ECMAScript edition –2
Property/method value type:	`Null primitive`

The type `null` has exactly one value, called `null`.

You can use this value when testing for the undefined state of variables and objects in browsers that do not support an explicit `undefined` value, to test for in logical expressions.

See also:	Cast operator, Special type, Type

Cross-references:

ECMA 262 edition 2 –section –4.3.12

Wrox *Instant JavaScript* –page –14

Null literal (Primitive value)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition –2 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Null primitive`	
JavaScript syntax:	-	`null`

The `null` literal is a value that represents the `null` or undefined state. It only has one value.

Name:	null

The null value is sometimes used in place of other values. For example, in some browser-based interpreters, there is no specific value for the undefined condition. However, you can work around this by testing for null. Strictly speaking they are distinctly different values with different semantic meanings. Even so, the trick works well enough for most practical purposes.

Use null in place of undefined when testing for the existence of entities.

See also:	Literal, Range error, Token, undefined

ECMA 262 edition 2 –section –7.7.1

ECMA 262 edition 3 –section –7.8.1

Null statement (Definition)

An empty statement consisting of a semicolon on its own.

See also:	Empty statement (;), Semicolon (;)

Number (Primitive value)

A built-in primitive value.

Availability:	ECMAScript edition –2
Property/method value type:	Number primitive

A number value is a member of the type Number and is a direct representation of a number.

It is basically a floating-point number and there is no special integer number class. Integers are simply floating-point values with a zero fractional part.

Numbers can be expressed as integers or floating-point values. They can be expressed in decimal, octal, or hexadecimal notation. They can also be expressed in exponential form.

Typical limits for the number type allow for very large number values. You can find out what the maximum value is by requesting the MAX_VALUE property from the built-in Number object. It will probably give you a value in the region of 1 followed by some 300 or more zeros. The smallest value is some 300 decimal places past the decimal point.

Actually the limits are 1.79e308 down to 5e-324 and both can be positive or negative.

There are special constants for the values `Infinity` and `NaN`. The `Infinity` value can be positive or negative. The `NaN` value represents a quantity that is known to be numeric but is not a valid value for the implementation. It can be tested for with the `isNaN()` function.

See also:	Cast operator, Floating constant, `Infinity`, `isNaN()`, JavaScript to Java values, `Number.MAX_VALUE`, `Number.MIN_VALUE`, Primitive value

Wrox *Instant JavaScript* –page –14

Number (Type)

A native built-in type.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

The number type defines objects that represent numbers and include the IEEE 754 `NaN` values in the set if the implementation is fully ECMA-compliant.

The number range is huge, representing the double precision 64 bit IEEE 754 set of values.

The IEEE 754 standard defines a large number of values that are considered to be not an actual number, and should be represented as `NaN`. Some implementations of IEEE 754 allow you to tell the difference between an overflow error and a divide by zero error. In JavaScript, all of these values are represented by a single `NaN` value and you cannot distinguish between them. The JavaScript `NaN` value is globally defined as a variable.

The `Number` type includes the values positive and negative Infinity and, internally at least, positive and negative zero are represented as two distinct values.

See also:	Cast operator, Data Type, Floating point, Fundamental data type, Hexadecimal value, IEEE 754, Infinity, Integer, `NaN`, Octal value, Primitive value, `ToBoolean`, `ToInt32`, `ToNumber`, `ToObject`, `ToPrimitive`, `ToUint16`, `ToUint32`, Type, Type conversion, `valueOf()`

ECMA 262 edition 2 –section –7.7.3

ECMA 262 edition 3 –section –7.8.3

Number object (Object/core)

An object of the class "`Number`".

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
JavaScript syntax:	-	*myNumber* = new Number*()*
	-	*myNumber* = Number
Object properties:	`constructor, prototype`	
Class constants:	`MAX_VALUE, MIN_VALUE, NaN, NEGATIVE_INFINITY, POSITIVE_INFINITY`	
Object methods:	`toExponential(), toFixed(), toLocaleString(), toPrecision(), toSource(), toString(), valueOf()`	

An instance of the class `Number` is created by using the new operator on the `Number()` constructor. The new object adopts the behavior of the built-in `prototype` object through the prototype-inheritance mechanisms.

All properties and methods of the `prototype` are available as if they were part of the instance.

A `number` object is a member of the type `Object` and is an instance of the built-in `Number` object.

`Number` objects are created by cloning the built-in `Number` object. This is done by calling the `Number` constructor with the `new` operator being applied to an existing `Number` object. Thus:

```
myNumber = new Number(1000);
```

A `Number` object can be coerced to a number value and can be used anywhere where a number value would be expected.

Programmers familiar with object-oriented techniques may prefer to use the `Number` object while procedural language programmers may implement the same functionality with a number value instead.

This is an example of the flexibility of JavaScript in its ability to accommodate a variety of users from different backgrounds.

The prototype for the `Number prototype` object is the `Object prototype` object.

You might want to add useful methods to the `Number.prototype` to output numbers in unusual formats. For example you could implement a roman numeral conversion method. Adding that to the prototype would let you output year numbers in classical formats.

Warnings:

- The `Number` object provides a collection of static constant values by way of properties belonging to the integral `Number` object. Because the mathematical mechanisms of any application tend to be provided by the operating system, you should find that between different browsers on any particular platform, the values that these constants yield will be very consistent.
- The ECMA standard lays down strict values for these properties and in general the browser manufacturers try to comply, but there is always the possibility that an implementation may use a non-compliant calculation.
- However, it may not be quite so reliable across platforms. You might enumerate one of these constants as you are authoring and then hard code that value into your script. When that script is executed on another platform, even in the same browser, the internal numeric support may yield a different value.
- You should always refer to the static constants using their symbolic names and not define them yourself, unless you are certain that the script is running on a platform that does not already define the constant value.

Wrox *Instant JavaScript* –page –33

Number() (Constructor)

A `Number` object constructor.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
Property/method value type:	`Number` object	
JavaScript syntax:	-	`new Number()`
	-	`new Number(aValue)`
Argument list:	*`aValue`*	A value to be converted to a `Number` object

The `Number()` constructor is used to manufacture a new instance of the built-in `Number` object converting the input value to a number as it instantiates the new object.

The value of the `Number` object when the constructor is called in a new expression is the same as value yielded by the type conversion function call.

Refer to the `Number()` Function topic for a table of rules for converting non-number values to `Number` objects.

The result is a `Number` object whose value is equivalent to the that of the passed-in argument. If the value is omitted, the `Number` object will assume a value of 0.

Warnings:

- Note that unlike the `Object()` constructor, which can be called without its parentheses, calling the `Number()` constructor without them yields an uninitialized object.

See also:	Constructor function, `constructor` property, `Global` object, new, `Number.prototype`, Object constant, `Object()`

Cross-references:

ECMA 262 edition 2 –section –15.1.3.6

ECMA 262 edition 2 –section –15.7.3.1

ECMA 262 edition 3 –section –15.7.2

Number() (Function)

A Number type convertor.

Availability:	ECMAScript edition –2 JavaScript –1.2 JScript –1.0 Internet Explorer –3.02 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number()`
	-	`Number(aValue)`
Argument list:	*aValue*	A value to be converted to a number.

When the `Number()` constructor is called as a function, it will perform a type conversion.

The following values are yielded as a result of calling `Number()` as a function:

Value	Result
No value	`0`
Undefined	Returns `NaN`
Null	`0`
Boolean `false`	`0`
Boolean `true`	`1`
Number	No conversion, the input value is returned unchanged.
Non numeric string	`NaN`
Numeric string	The numeric value rounded down if the number of digits exceeds the numeric accuracy specified by `Number.MAX_VALUE`.

Table continued on following page

Value	Result
Object	Internally, a conversion to one of the primitive types happens followed by a conversion from that type to a number. Some objects will return a number that is readily usable; others will return something that cannot be converted and `NaN` will result.

The result is a number value that is equivalent to the value of the passed in argument. If the argument is omitted the value `0` is returned.

Warnings:

- When converting strings to numbers, the number of digits in the numeric string is significant. If it exceeds the accuracy that the numeric storage can cope with, the value needs to be rounded before conversion. This is an area where the implementations are notoriously weak. MSIE apparently does a better job than Netscape. However, both are undergoing revision and its possible that the new versions of each will cope better than the older ones did.

Number.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition –2

This is an internal property that describes the class that a `Number` object instance is a member of. The reserved words suggest that in the future, this property may be externalized.

See also:	Class, `Number` object

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 –section –8.6.2

ECMA 262 edition 2 –section –15.7.2.1

ECMA 262 edition 3 –section –8.6.2

Number.constructor (Property)

A reference to a `constructor` object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
Property/method value type:	`Number` object	
JavaScript syntax:	-	*myNumber*`.constructor`

The initial value of the `Number` constructor is the built in `Number` object.

You can use this as one way of creating number objects although it is more popular to use the new `Number()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective, and there are some occasions when you might wish for a constructor that is not available in MSIE.

See also:	`Number.MAX_VALUE`, `Number.MIN_VALUE`, `Number.NaN`, `Number.NEGATIVE_INFINITY`, `Number.POSITIVE_INFINITY`, `Number.prototype`

Cross-references:

ECMA 262 edition 2 –section –15.7.2

ECMA 262 edition 3 –section –15.7.2

Number.MAX_VALUE (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number.MAX_VALUE`

This is a constant value representing the largest realizable positive finite value of the `Number` type.

The value is approximately 1.7976931348623157e+308.

Warnings:

- The word approximately is used when describing the result, because the mathematical accuracy of JavaScript implementations leaves something to be desired and there are some strange artifacts in some of the calculations.

See also:	Arithmetic constant, Floating point constant, Number, `Number.constructor`, Special number values

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Number.MIN_VALUE (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number.MIN_VALUE`

This is a constant value representing the smallest realizable non-zero positive value of the number type.

The resulting value is approximately 5e-324

Warnings:

- Although the `MAX_VALUE` is generally correct across implementations there are variations in the value of the `MIN_VALUE` constant.

See also:	Arithmetic constant, Floating point constant, Number, `Number.constructor`, Special number values

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.7.3.3

ECMA 262 edition 3 –section –15.7.3.3

O'Reilly *JavaScript Definitive Guide* –page –37

Number.NaN (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number.NaN`

This is a value representing invalid numeric values. It should be identical to the `NaN` value provided by the `Global` object in an ECMA-compliant implementation. Refer to the coverage of the `NaN` topic for full details.

However, it is generally considered unreliable to compare against `NaN` values with a simple equality test. To reliably test whether a numeric value is `NaN` or a good numeric value, use the `isNaN()` function and select an appropriate action according to its result.

See also:	Arithmetic constant, `NaN`, `Number.constructor`, Special number values

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.7.3.4

ECMA 262 edition 3 –section –15.7.3.4

Number.NEGATIVE_INFINITY (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number.NEGATIVE_INFINITY`

This is a constant representing the value negative infinity. It should be identical to a negative sign placed in front of the Infinity value provided as a property of the `Global` object in an ECMA-compliant implementation. Refer to the Infinity topic for further discussion.

Warnings:

- Netscape 2.02 does not understand what `Number.NEGATIVE_INFINITY` is.

See also:	Arithmetic constant, Infinity, `Number.constructor`, Special number values

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.7.3.5

ECMA 262 edition 3 –section –15.7.3.5

Number.POSITIVE_INFINITY (Constant/static)

A mathematical constant value.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`Number.POSITIVE_INFINITY`

This is a constant value representing positive infinity. It should be identical to the Infinity value provided as a property of the `Global` object in an ECMA-compliant implementation. Refer to the Infinity topic for further discussion.

Warnings:

- Netscape 2.02 does not understand what `Number.POSITIVE_INFINITY` is.

See also:	Arithmetic constant, Infinity, `Number.constructor`, Special number values

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Number.prototype (Property)

The prototype for the `Number` object that can be used to extend the interface for all `Number` objects.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number` object	
JavaScript syntax:	-	`Number.prototype`
	-	*`myNumber`*`.constructor.prototype`

The `prototype` property refers to the built-in `Number` `prototype` object.

The example demonstrates how to provide extensions to all instances of this class by adding a function to the `prototype` object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the capabilities of the Number object
function pythag(aValue1, aValue2)
{
   return Math.sqrt((aValue1*aValue1) + (aValue2*aValue2));
}

// Register the new function
Number.prototype.pythag = pythag;

// Create a number object and test the Number.pythag() method
myNumber = new Number();
document.write(myNumber.pythag(3, 4));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Number` object, `Number()`, `Number()`, `Number.constructor`, `Number.toString()`, `Number.valueOf()`, `prototype` property

Property attributes:

`DontDelete`, `DontEnum`.

Cross-references:

Number.toExponential() (Method)

Converts the number to an exponential format representation.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toExponential(`*aNumber*`)`
Argument list:	*aNumber*	The number of digits after the decimal point

This method is useful for formatting number values. This is especially helpful when presenting tables of scientific data, which may require values of a wide range of magnitudes to be presented in a similar way.

The argument value indicates the precision or decimal places of accuracy to the right of the decimal point character. If the argument is undefined, then as many digits as are necessary to completely distinguish the value are presented (up to the mathematical accuracy of the implementation).

See also:	`Number.toFixed(),Number.toPrecision(), Number.toString()`

Cross-references:

ECMA 262 edition 3 –section –15.7.4.6

Number.toFixed() (Method)

Converts the number to a fixed format representation.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toFixed(`*aNumber*`)`
Argument list:	*aNumber*	The number of digits after the decimal point

This method is useful for truncate formatting number values. This is especially helpful when presenting tables of financial data that needs to be justified and padded to the same number of digits after the decimal point.

The argument value indicates the precision or decimal places of accuracy to the right of the decimal point character. If the argument is undefined, then zero is assumed and the value will be presented as an integer.

This method may be useful for performing truncations from floating point to integer value. The output of this method may also be more precise when a large number of integer digits are required to present the number. According to the ECMA standard, the alternative `toString()` method loses some accuracy for numbers having 19 digits for example.

See also:	`Number.toExponential(),Number.toPrecision(), Number.toString()`

Cross-references:

ECMA 262 edition 3 –section –15.7.4.5

Number.toLocaleString() (Method)

Converts a number to a string taking locale-specific settings into account.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toLocaleString()`

Locale conventions may include special formatting of numbers such as thousands separators and decimal point symbols. The number will be converted according to the rules defined by the implementation's locale setting.

Warnings:

- ECMA warns that the first argument of this method is reserved for future use. Beware if your implementation makes use of an argument in this method as it may be non-compliant with a later version of the ECMA standard.

Cross-references:

ECMA 262 edition 3 –section –15.7.4.3

Number.toPrecision() (Method)

Convert a number to a string automatically selecting fixed or exponential notation.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toPrecision(`*aNumber*`)`
Argument list:	*aNumber*	The number of digits after the decimal point

This method will convert a number to a string and will select either a fixed or exponential notation according to the magnitude of the value being converted.

This would be useful where you have an arbitrary collection of values and don't want them presented in a ragged looking column.

See also:	`Number.toExponential(),Number.toFixed()`

Cross-references:

ECMA 262 edition 3 –section –15.7.4.7

Number.toSource() (Method)

Output a number formatted as a Number literal contained in a string.

Availability:	ECMAScript edition –3 JavaScript –1.3 Netscape –4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toSource()`

This is an alternative way to deliver a string version of a number value. In this case, it is formatted as a Number literal and can then be used in an `eval()` function to assign another number.

If you run the example below, it should yield this as a result:

```
(new Number(1000))
```

The result of calling this method is a string version of the number formatted as a Number literal.

Example code:

```
// Create a number and then examine its source
myNumber = new Number(1000);
document.write(myNumber.toSource());
```

Number.toString() (Method)

Return a string primitive version of an object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myNumber*`.toString(`*aRadix*`)`
Argument list:	*aRadix*	A radix to base the string conversion of the value on

The result of this method is a String primitive representation of the numeric value of the receiving object, rendered according to the passed-in radix value.

A radix is the number of discrete values in the counting sequence before a carry over digit is generated. Thus, the radix of decimal numbers is 10. With this mechanism, you can generate values to any radix. The radix is also called the base of the number system.

The radix value is in the range 2 to 36 and allows the numeric value to be reproduced in a variety of number bases.

- A missing radix is assumed to be base 10.
- Octal numbers use a radix value of 8.
- Hexadecimal numbers use a radix value of 16.
- Binary numbers use a radix value of 2.

For an example, refer to the Decimal value topic where this is used to generate a lookup table.

Before the radix conversion was available, this method simply converted to a string, which most commentators considered was unnecessary since JavaScript did this naturally without any need to add special scripting support. However, now that we can convert numeric values from one base to another, this function becomes far more useful.

Number.valueOf() (Method)

Return the primitive numeric value of the object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myNumber*`.valueOf()`

A `Number` object is converted to a simple Number primitive. You probably won't need to do this very often yourself because JavaScript is smart enough to convert Number primitives to `Number` objects and vice versa whenever it needs to. This is a whole lot better than having to cast data types to get expressions to work, as you would have to in other programming languages. This help makes JavaScript very accessible to non-programmers.

See also:	Cast operator, `Number.prototype`, `valueOf()`

ECMA 262 edition 3 –section –15.7.4.4

Numeric literal (Primitive value)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Numeric literals are constant numeric values expressed in Decimal, Hexadecimal, or Octal notation.

Numeric values can be integer or floating-point.

Floating-point values can be specified with exponential notation.

Hexadecimal values must always be integers, thus:

- `0xFF`
- `0XABCD`

Octal values must always be integers, must start with a zero and contain only the characters 0-7.

The standard does not mandate any particular rounding technique but recommends the use of IEEE 754 standard numeric computation. This standard has been in existence for some time now and is likely to be the foundation numeric computation standard in most platforms.

Numerical limits (Definition)

Limiting conditions for arithmetic values.

Refer to:

Limits

Obfuscation (Advice)

Needless complexity in the arrangement of tokens in a line of executable script.

There are competitions on the Internet to write the most egregious and highly functional code fragment in the fewest lines of code. This is particularly easy to do in C language. Certain operators lend themselves to the construction of extremely terse code, which, although functionally very clever, is also very hard to understand when diagnosing faults or carrying out maintenance.

This entry is not to recommend against the use of such operators, but to urge a word of caution on the basis that modern language parsing and execution engines may be smart enough to highly optimize the code, making any performance gains negligible anyway.

These days, it is quite difficult to yield any noticeable performance gains by epitomizing the code at the source level with compiled systems. There may still be some gains to be won with interpreted code. A badly designed algorithm may continue to perform badly in an interpreter where there is a possibility it might get corrected in an optimizing compiler.

The operators to be particularly cautious about are the assignment operators and the prefix/postfix operators. The ternary conditional operator is also hard to read in source and may offer little advantage over an `if(...) ...else` construct. These are equivalent but intent is much more obvious withthe `if(...) ... else` form:

```
// Conditional ternary operator

myResult = (mySwitch) ? "TRUE VALUE" : "FALSE VALUE" ;

// Conditional block

if(mySwitch)

{ myResult = "TRUE VALUE";}

else

{ myResult = "FALSE VALUE";}
```

Where this causes particular problems is in the maintenance phase where you might perhaps be adding another line of code. In cutting and pasting an existing line, it can be easy to overlook an operator and accidentally increment something twice or assign a value inadvertently.

Special care is necessary with iterators and conditional execution blocks. A particularly nasty habit is to have a condition that when `true`, executes one statement. This is frequently written into the source text without any enclosing braces. Those braces are important because they group the block of code into a single syntactical unit. When you later try to unpick someone else's script, the indentation may fool you into seeing several lines that appear to be conditionally executed when in fact only one is. The same applies to iterators as well. It is highly recommended that you put in the braces where they are required for multiple line conditional code and iterator blocks even when there is only one line of code being executed. This safeguards against errors when more lines are added to the conditional or iterated code block later on.

This is not recommended practice:

```
if(aCondition)

someCode;

while(aCondition)

someCode;

for( ... )

someCode;
```

This is slightly better but requires more effort when adding lines to the code block:

```
if(aCondition) someCode;

while(aCondition) someCode;

for( ... ) someCode;
```

This is less dangerous than having no braces but makes the line long and twice as hard to scan visually:

```
if(Condition) { someCode }
```

This is fashionable, but the braces are hard to balance visually:

```
if(aCondition) {

someCode

}
```

This is good because it thinks ahead to the possibility of maintenance and tends towards fewer editing errors:

```
if(aCondition)

{
someCode

}

while(aCondition)

{

someCode

}

for( ... )

{

someCode

}
```

If there is any downside to this it is that every balanced pair of braces will create a new execution context. This may slow performance, but on the other hand it can allow locally scoped variables to be created and destroyed at a level that is more granular than a function body.

There is also scope for a religious debate on indentation. Three space characters works great (for me). I don't like tabs because if you move the source code to another editor, the indentation can go awry. Space characters for indentation ensure that the source code looks the same in any monospaced editing window and probably looks OK in a word processor too.

See also:	Flow control, `if( ... ) ..., while( ... ) ...`

Object (Definition)

There is a distinct difference between an object and an Object.

We refer to the built-in `Object` class with a capitalised name. When referring generically to objects of other classes, the word object is all lower case. Therefore we can have an `Object` object and a `String` object. Native objects are built-in, host objects are also built in but created outside of the JavaScript core functionality. User-defined objects are not covered here.

Here is a list of object classes with a note about what sort of object they are and when how they are managed:

Class	Category	Description
`Array`	Native	A collection of objects in a sequence
`Boolean`	Native	A logical value container
`Date`	Native	A date value container
`Function`	Native	A function code container
`Global`	Built-in	A container for global properties, methods, and functions
`Image`	Hosted	Web browser image wrapper
`Math`	Built-in	A container for math functions
`Number`	Native	A numeric value
`Object`	Native	A generic object
`String`	Native	A sequence of characters

Because you might refer to documents in many ways, possibly by means of object properties or as a property belonging to another window, it is not safe to assume that the document property belonging to the `Global` object the script is attached to is always the document object you are trying to access. Because of this, the object references in the syntax examples assume the object is being referred to via a variable called *`myDocument`* or *`myObject`* etc. For example, the value *`myDocument`* is shown being assigned as a variable from the many alternative sources from which you can obtain a document object reference.

Object (Type)

A native built-in type.

Availability:	ECMAScript edition –2

An Object is an unordered collection of properties. Each property consists of a name, a value and a set of attributes.

See also:	Alias, Data Type, Definition, Internal Method, Internal Property, Object object, Property, Property attribute, Type

ECMA 262 edition 2 –section 8.6

ECMA 262 edition 3 –section 8.6

Wrox *Instant JavaScript* –page 28

Object constant (Definition)

Constant objects.

There are some constant objects defined by the standard. A host implementation may provide a few more.

Here is a summary of the basic set of constant objects:

- `Array` constructor
- `Boolean` constructor
- `Date` constructor
- `Function` constructor
- `Global` object
- `Math` object
- `Number` constructor
- `Object` constructor
- `RegExp` constructor

See also:	`Array()`, `Boolean()`, `Closure()`, Constant expression, `Date()`, `Function()`, `Global` object, `Math` object, `Number()`, Object literal, Object`()`

Cross-references:

Wrox *Instant JavaScript* –page 28

Object inspector (Useful tip)

A debugging tool for inspecting object properties and classes.

Here is a small debugging utility that breaks an object down and displays some of its properties.

Example code:

```
<!-- An example for use on Netscape only -->
<HTML>
<HEAD>
<SCRIPT>
function object_dump(anObject)
{
   document.write("<HR>");
   document.write("<TABLE BORDER=1>");
   table_row("<B>Item</B>", "<B>Value</B>");

   if(typeof anObject != "object")
   {
```

```
      table_row("Value", anObject);
      table_row("Typeof", typeof(anObject));
   }
   else
   {
      table_row("Value", anObject.valueOf());
      table_row("String equiv", anObject.toString());
      table_row("Typeof", typeof(anObject));
      table_row("Class", anObject.constructor.name);
      table_row("Prototype", anObject.prototype);
   }

   document.write("</TABLE>");
   document.write("<HR>");
}

function table_row(anItem, aName)
{
   document.write("<TR>");
   document.write("<TD>");
   document.write(anItem);
   document.write("</TD>");
   document.write("<TD>");
   document.write(aName);
   document.write("</TD>");
   document.write("</TR>");
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT>
function nest(abc)
{
   test("aa", bb, 100);
}
function test(aa, bb, cc, dd)
{
   object_dump(aa);
   object_dump(bb);
   object_dump(cc);
   object_dump(arguments.caller.callee.name);
   object_dump(arguments.callee.constructor.name);
}
var bb;
nest("aa", bb, 100);
object_dump(document);
</SCRIPT>
</BODY>
</HTML>
```

See also:	Arguments object, Debugging –client side, typeof

Object literal (Definition)

An object initialiser that creates the object as well.

Availability:	ECMAScript edition –3
Property/method value type:	`Object` object

JavaScript version 1.2 introduces Object literals.

The object is created and returned by the expression. This would normally be assigned to a variable, which effectively names the object. It isn't the object class but it can be copied. Its class is still "`Object`".

Object literals can be nested so that the properties of the topmost object can in fact be object literals themselves.

The values assigned to the properties as the object is created can be derived by evaluating a JavaScript expression.

You can add as many properties as you care to but you must be careful to keep the nesting properly balanced.

The result is an object with the properties containing the values described in the literal expression.

Example code:

```
// Create a simple object literal
var simple = { prop:100 };
// Create a nested object literal
var nested = { reference: { prop:100 } };
// Create a nested object literal with expression derived value
var evaluated = { reference: { prop:(Math.random()*100) } };
```

See also:	Object constant, `Object.constructor`

ECMA 262 edition 3 –section –11.1.5

O'Reilly *JavaScript Definitive Guide* –page –45

Object model (Definition)

There are several different object models that are realized in JavaScript implementations.

In the Netscape and MSIE web browsers, the object models are provided as representations of the document, the browser, event capturing mechanisms, and the style sheet. In addition, some implementations model the environs, the operating system, and the file system. Each of these object models interacts with the others and is a way of representing the tangible real-world objects.

Although these are generally arranged in a tree-like structure, there are many short cut references that mean you can refer to the same object in a variety of ways. For example the Netscape `JavaPackage` object can be referred to with the following properties in a Netscape browser:

- `Netscape`
- `Packages.netscape`
- `window.Packages.netscape`

Each one refers to an identical object but from the script writer's point of view, some time can be saved by using the short cuts. Scripts also appear simpler to read.

However, the downside is that the object model hierarchy becomes confusing unless you know about the short-cuts. These shortcuts provided for 'so-called' convenience may in fact be exactly the opposite if they are only available on one platform. Using them immediately renders your script non-portable.

Object object (Object/core)

An object of the class "`Object`".

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Netscape Enterprise Server 2.0 Opera 3.0	
JavaScript syntax:	-	*myObject* = new Object()
	-	*myObject* = Object
Object properties:	`__parent__, __proto__, constructor, name, prototype`	
Object methods:	`assign(), eval(), hasOwnProperty(), isPrototypeOf(), propertyIsEnumerable(), toLocaleString(), toSource(), toString(), unwatch(), valueOf(), watch()`	

An instance of the class "`Object`" is created by using the new operator on the `Object()` constructor. The new object adopts the behavior of the built-in prototype object through the prototype-inheritance mechanisms.

All properties and methods of the prototype are available as if they were part of the instance.

An Object is a member of the type `Object`. It is an unordered collection of properties, each of which may contain a primitive value, another object, or a function.

The constructor is invoked by the `new` operator or by calling it as a Constructor function. For example:

```
new String("Some Text");
```

This will create a new object of the `String` type. You can invoke the constructor without the new operator but the consequences will depend on the constructor as to what it will yield as a result. In the case of the `String` data type, the constructor could be invoked like this:

```
String("Some Text");
```

However, you would get a primitive string as a result from this and not a `String` object. JavaScript is somewhat forgiving and you may not notice this happening until later on when it becomes important that you have a `String` object and not a simple string.

Because this object is the topmost parent object in the prototype inheritance hierarchy, all other object classes inherit its methods and properties. However, in some cases they will get overridden or nulled out.

DOM level 2 adds the following properties:

`contentDocument`

Although JavaScript is object-based, it does not support true object-oriented classes such as the ones you find in C++, Smalltalk, Java or Objective C. Instead, it provides Constructor mechanisms, which create objects by allocating space for them in memory and assigning initial values to their properties.

All functions, including constructors are themselves objects; however, not all objects are constructors. Each constructor has a Prototype property that is used to facilitate inheritance based on the prototype. It also provides for shared properties, which is similar to but not the same as the Class properties that you find in true object-oriented languages.

Externally, the objects in JavaScript exhibit most of the attributes of a class based object oriented system and some commentators argue that this qualifies JavaScript as being a genuine object oriented system. However I think the following points declassify it as a truly object oriented system, meaning that it is an "object like" system:

- Global variables and the scope chain mechanism
- Prototype based inheritance
- Creation of multiple objects and calling them within a single script
- Object data is not truly private

It's a close enough call that JavaScript 2.0 may well move it into the class-based object-oriented category at which time the prototype inheritance would be replaced with super-class/sub-class mechanisms and the arguments become null and void.

Warnings:

- Be very careful not to confuse this generic top-level core object with the object that MSIE instantiates to represent an `<OBJECT>` tag. MSIE creates `OBJECT` objects for that purpose but also supports `Object` objects. For this reason, it may be the case that interpreters cannot become case-insensitive when matching class names. If they did, then it would be impossible to distinguish between Object and OBJECT class names.

O'Reilly *JavaScript Definitive Guide* –page 44

Wrox *Instant JavaScript* –page 28

Object() (Constructor)

An `Object` object constructor.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Netscape Enterprise Server 2.0 Opera 3.0	
Property/method value type:	`Object` object	
JavaScript syntax:	-	`new Object`
	-	`new Object()`
	-	`new Object(aValue)`
Argument list:	*aValue*	An initial value for the new object

When `Object` is called as part of a new expression, it is a constructor that may create an object instance.

There are limitations what is sensible for the `new` operator to be able to do with the `Object` constructor. Since the `Object` is considered to be the highest ancestor of all objects in the prototype inheritance chain, you cannot logically have more than one `Object` object. Passing other native objects to the `Object` Constructor implies a type casting from their native object type to the `Object` type. That's not logical either. The main use of the `Object` Constructor then is to manufacturer object instantiations from non-object data types.

The table summarizes the resulting values from using the `Object()` constructor with the `new` operator.

Value	Result
No argument	Creates a new empty object
null	Creates a new empty object
undefined	Creates a new empty object
Boolean	Create a new boolean object whose default value is the input value
Number	Create a new number object whose default value is the input value
String	Create a new string object whose default value is the input value
Native object	Return the native object itself
Host object	Host implementation dependant behavior. Objects are cloned if necessary but some may not be

Unless you assign the result of the new operation, an object will simply consume memory. You need to store a reference to it at the time it is instantiated. You can do this by assigning it to a variable or a property of another object, passing it in to a function and making sure it gets retained in there, or storing it as an element in an array.

Warnings:

- You can refer to objects without the parentheses but then you are not referring to a constructor function but to the object itself. The behavior varies between browsers and depends on the kind of object being instantiated and probably depends on whether it is a wrapper for a primitive data type or a more complex aggregated type.
- These all appear to create the same kind of object in both MSIE and Netscape

```
myObject = Object();

myNewObject = new Object();

myOtherObject = new Object;
```

  These do not:

```
myBoolean = Boolean();

myNewBoolean = new Boolean();

myOtherBoolean = new Boolean;
```

- In the case of the Boolean, Number, and String object types, only the first form will initialize the new object with a value. Placing the result of these examples in `document.write()` statements illustrates the behavior. You may want to examine the objects returned in more detail by developing an object inspector script.

Object() (Function)

An `Object` object constructor.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0	
Property/method value type:	An object of a type that depends on the passed in argument	
JavaScript syntax:	-	`Object()`
	-	`Object(aValue)`
Argument list:	*aValue*	A value to be stored in the new object.

The Object Constructor can be called as a function. When this happens, the value passed in undergoes a type conversion.

In an ECMA-compliant implementation, the Object constructor function uses the `ToObject` conversion. However it handles input values `undefined` and `null` as special cases and creates a new object as if the constructor had been used with the `new` operator.

The table summarizes the results based on the input value data types.

Value	Result
No argument	Creates a new empty object as if new `Object()` had been called.
`null`	Creates a new empty object as if new `Object(null)` had been called.
`undefined`	Creates a new empty object as if new `Object(undefined)` had been called.
`Boolean`	Create a new boolean object whose default value is the input value.
`Number`	Create a new number object whose default value is the input value.
`String`	Create a new string object whose default value is the input value.
`Object`	No conversion, the input value is returned unchanged.

ECMA 262 edition 3 –section 15.2

Object.__parent__ (Property)

A special property in which to access the scope chain during function execution.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`ScopeChain object`	
JavaScript syntax:	N	*myObject*`.__parent__`

See also:	Lexical scoping, `__parent__`

Object.__proto__ (Property)

A special property in which to access the prototype inheritance chain during construction.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Function` object	
JavaScript syntax:	N	*myObject*`.__proto__`

See also:	Lexical scoping, Prototype Based Inheritance, Prototype chain, `__proto__`

Object.assign() (Method)

A deprecated mechanism for intercepting messages sent to objects.

Availability:	JavaScript –1.1 Netscape –3.0 Deprecated	
JavaScript syntax:	N	*myObject*`.assign()`

Warnings:

- This method is deprecated in favor of the `Object.watch()` and `Object.unwatch()` methods.

See also:	`Object.unwatch(), Object.watch()`

Object.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition –2

This is an internal property that describes the class that an `Object` object instance is a member of. The reserved words suggest that in the future, this property may be externalized.

See also:	Class, `Object` object

Property attributes:

`DontEnum, Internal.`

Cross-references:

ECMA 262 edition 2 –section –8.6.2

ECMA 262 edition 2 –section –15.2.2.1

ECMA 262 edition 3 –section –8.6.2

Object.constructor (Property)

A reference to a constructor object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Object` object	
JavaScript syntax:	-	*myObject*`.constructor`

The initial value of the `Object.prototype.constructor` is the built-in Object constructor.

You can use this as one way of creating objects although it is more popular to use the new `Object()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	Object literal, `Object.prototype`

Cross-references:

ECMA 262 edition 2 –section –15.2.4.1

ECMA 262 edition 3 –section –15.2.2

Object.eval() (Method)

Evaluate the JavaScript source text passed in a string argument.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Netscape Enterprise Server version –2.0 Opera browser –3.0 Deprecated	
Property/method value type:	Function result	
JavaScript syntax:	-	*myObject*.eval()

Warnings:

- This is now deprecated and may even be unavailable in recent versions of Netscape and JScript. You should use the `eval()` function available from the `global` object.

See also:	`eval()`

Object.hasOwnProperty() (Method)

A method that can be used to test whether a property exists and belongs to the receiving object.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.hasOwnProperty(*aName*)
Argument list:	*aName*	The name of a property to test for

For this method to yield a Boolean `true` value, the property named in the argument must exist and must belong to the receiving object. If the property is inherited from a prototype or earlier ancestor then this method returns `false`.

This method would be useful if it could test for the existence of a property in the inheritance chain. There is an internal `HasProperty()` method but the ECMA standard indicate that it is not exposed to the script interface.

See also:	`HasProperty()`

Cross-references:

ECMA 262 edition 3 –section –15.2.4.5

Object.isPrototypeOf() (Method)

A test for the relationship between two objects to ascertain direct parentage.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.isPrototypeOf(*anObject*)
Argument list:	*anObject*	The object whose prototype is to be tested

The receiving object is tested for identity against the object referred to by the prototype property of the object passed as an argument. If the object in the argument is a direct child object through the prototype chain, then this method returns a `true` value.

See also:	`HasInstance()`

Cross-references:

ECMA 262 edition 3 –section –15.2.4.6

Object.name (Property)

This corresponds to the NAME attribute of the tag that creates the object.

Availability:	JScript –5.5 Internet Explorer –5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myObject*.name

Objects are identified either by the `NAME="..."` HTML tag attribute or by the `ID="..."` HTML tag attribute.

Netscape shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However in many cases, both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`NAME="..."`

Object.propertyIsEnumerable() (Method)

A test for whether a property has the don't enumerate flag set or not.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.propertyIsEnumerable(`*aName*`)`
Argument list:	*aName*	The name of the object property to test

If the receiving object has a member property of the name that is passed in the argument, and if the `DontEnum` attribute of that property is `false`, then this method returns the Boolean `true` value.

Cross-references:

ECMA 262 edition 3 –section 15.2.4.7

Object.prototype (Property)

The prototype for the `Object` object, which can be used to extend the interface for all `Object` objects.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Object` object	
JavaScript syntax:	-	`Object.prototype`
	-	*myObject*`.constructor.prototype`

The initial value of the prototype property of an `Object` object is the built in `Object` prototype object.

`Object` objects inherit the following properties from the `Object.prototype`:

- `Object.constructor`
- `Object.prototype`

`Object` objects inherit the following methods from their prototype:

- `Object.toString()`
- `Object.valueOf()`

The prototype property for the `Object` prototype object is `null`.

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Warnings:

- This is not supported on the WebTV platform.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the output capabilities of Object objects
function init()
{
   this.width  = 100;
   this.height = 200;
   this.depth  = 300;
   return "";
}
// Register the new function
Object.prototype.init = init;
// Create a new object
myObject = new Object();
myObject.init();
document.write(myObject.width  + "<BR>");
document.write(myObject.height + "<BR>");
document.write(myObject.depth  + "<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also: `Arguments` object, `Function.arguments[]`, JellyScript, `Object` object, `Object()`, `Object.constructor`, `Object.toString()`, `Object.valueOf()`, `prototype` property

Property attributes:

`ReadOnly, DontDelete, DontEnum.`

Cross-references:

ECMA 262 edition 2 –section 15.2.3.1

ECMA 262 edition 2 –section 15.2.4

ECMA 262 edition 3 –section 15.2.3.1

Object.toLocaleString() (Method)

Returns a string primitive version of the object taking the present locale into account during the translation.

Availability:	ECMAScript edition –3 JavaScript –1.5 JScript –5.5 Internet Explorer –5.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myObject`*`.toLocaleString()`

The locale context supplies some special conversion rules for strings. Depending on the locale, this might include special characters or a means of using double byte characters. It may also affect the direction of the text, for certain Asian locales for example.

Warnings:

- The ECMA standard reserves the first argument of this method for future use. It does not specify what that is but warns against implementations extending the syntax to include its use.

Cross-references:

ECMA 262 edition 3 –section –15.2.4.3

Object.toSource() (Method)

Output a string describing the object contents.

Availability:	JavaScript –1.3 JScript –3.0 Internet Explorer –4.0 Netscape –4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myObject`*`.toSource()`

This is an alternative way to deliver a string version of an object's internal values. In this case, it is formatted as an Object literal and can then be used in an `eval()` function to assign another object.

The exact format of what you see depends on the object being examined.

The result of calling this method is string version of the object formatted as an Object literal.

Warnings:

- Note that this is not available in the MSIE browser but can be useful when constructing an Object inspector for use in Netscape.

Object.toString() (Method)

Return a string primitive version of an object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myObject*`.toString()`

When the `toString()` method of an `Object.prototype` is invoked, the class name of the object is returned as a string.

The result of calling this method will be the string:

```
[object "Object"]
```

See also:	Cast operator, `Object.prototype, toString()`

Cross-references:

ECMA 262 edition 2 –section –15.2.4.2

ECMA 262 edition 3 –section –15.2.4.2

Object.unwatch() (Method)

A method to disable a watch that was set up on a property change.

Availability:	JavaScript –1.2 Netscape –4.0 Netscape Enterprise Server –3.0	
JavaScript syntax:	N	*myObject*.unwatch()

This is inherited by most object classes in Netscape.

Warnings:

- Because of the scoping rules, you cannot actually examine the value of the variable that has changed since the event handler is running in a completely different scope chain.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
function watchFunct()
{
  alert("Variable changed");
}
watch("myVariable", watchFunct)
myVariable = 100;
myVariable = 200;
unwatch("myVariable")
myVariable = 300;
</SCRIPT>
</BODY>
</HTML>
```

See also:	Object.assign(), Object.watch()

Object.valueOf() (Method)

The primitive numeric value of the object.

Availability:	ECMAScript edition –2 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	Depends on the object value	
JavaScript syntax:	-	*myObject*.valueOf()

As a general rule, the `valueOf()` method for an object simply returns the this property of the object itself. However, the object may be a wrapper for a host object some kind. It may therefore have been created by invoking the Object constructor. In that case, the host object should be returned in an ECMA-compliant implementation.

Implementations may choose to return the this property of an object or some other value if they choose.

The result of this method will be implementation-and object-dependant. The native core objects are well defined and will return predictable value types. Generally these will be defined by ECMA or W3C standards. It is up to the hosting environment to provide the `valueOf()` interface to its own suite of objects.

See also:	Cast operator, `Object.prototype, valueOf()`

Cross-references:

ECMA 262 edition 2 –section –15.2.2.1

ECMA 262 edition 2 –section –15.2.4.3

ECMA 262 edition 3 –section –15.2.4.4

Object.watch() (Method)

A means of establishing a call back when a property value changes.

Availability:	JavaScript –1.2 Netscape –4.0 Netscape Enterprise Server version –3.0	
JavaScript syntax:	N	*myObject*`.watch()`

This is inherited by most object classes in Netscape.

Warnings:

- Because of the scoping rules, you cannot actually examine the value of the variable that has changed since the event handler is running in a completely different scope chain.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
document.watch("myVariable", alert("Watch point triggered"))
document.myVariable = 100;
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Object.assign(), Object.unwatch(), unwatch(), watch()`

Object property delimiter (.) (Delimiter)

A token to delimit object properties from their object.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.0 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
JavaScript syntax:	-	`myObject.aProperty`
	-	`myObject.aProperty.aProperty`
Argument list:	`aProperty`	The identifier name of property to be accessed

The dot delimits properties and objects. It can find properties of properties of objects too.

The associativity is left to right.

Refer to the Operator Precedence topic for details of execution order.

You can also access the property values as if the object were an array. This:

```
anObject.aProperty
```

is equivalent to:

```
anObject["aProperty"]
```

The result will be the value of the property when it is an RValue or a reference to the property when it is an LValue.

See also:	Associativity, Decimal point (.), Operator Precedence, Postfix operator

OBJECT object (Object/HTML)

This is an object that encapsulates an ActiveX plugin. Do not confuse it with the `Object` object that is the super-class of all objects in JavaScript.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myOBJECT* = *myDocument*.all.*anElementID*
	IE	*myOBJECT* = *myDocument*.all.tags("OBJECT")[*anIndex*]
	IE	*myOBJECT* = *myDocument*.all[*aName*]
	-	*myOBJECT* = *myDocument*.applets[*anIndex*]
	-	*myOBJECT* = *myDocument*.getElementById(*anElementID*)
	-	*myOBJECT* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myOBJECT* = *myDocument*.getElementsByTagName ("OBJECT")[anIndex]
HTML syntax:	`<OBJECT> ... </OBJECT>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	`accessKey, align, altHtml, archive, border, classid, code, codeBase, codeType, data, dataFld, dataSrc, declare, form, height, hspace, name, object, readyState, standby, tabIndex, type, useMap, vspace, width`	
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDataAvailable, onDataSetChanged, onDataSetComplete, onDblClick, onDragStart, onError, onErrorUpdate, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReadyStateChange, onRowEnter, onRowExit, onSelectStart`	

This is an object representing an `<OBJECT>` HTML tag.

The `<OBJECT>` tag is a block-level tag. That means that it forces a line break before and after itself.

This object is specific to the MSIE browser when it runs on the Windows operating system. No other browser supports ActiveX as well as MSIE and no other operating system properly or completely supports the ActiveX infrastructure.

The events handled, and the properties and the methods of this object will depend on the kind of ActiveX object that is created.

The DOM level 1 specification refers to this as an `ObjectElement` object.

Warnings:

- Be very careful not to confuse this object with the generic top level core Object object that is the super-class of all objects in the interpreter.
- This is the object that MSIE instantiates to represent an <OBJECT> tag. MSIE creates OBJECT objects for that purpose but also supports Object objects. For this reason, it may be the case that interpreters cannot become case insensitive when matching class names. If they did, then it would be impossible to distinguish between Object and OBJECT class names.
- Creating an OBJECT class when an Object class already exists must have been a moment of insanity in an otherwise mostly excellent browser implementation project.

onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onReadyStateChange	-	3.0 +	-	4.0 +	-	-	-	-
onRowEnter	-	3.0 +	-	4.0 +	-	-	-	-
onRowExit	-	3.0 +	-	4.0 +	-	-	-	-
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Web-references:

http://www.w3.org/pub/WWW/TR/WD-object.htm

OBJECT.align (Property)

An alignment control for an <OBJECT> tag's position with respect to its parent object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myOBJECT*.align

The alignment of the ActiveX OBJECT object with respect to its containing parent object is defined in this property. The expected and widely available set of alignment specifiers are available:

- absbottom
- absmiddle
- baseline
- bottom
- center
- left
- middle
- right
- texttop
- top

OBJECT.altHtml (Property)

A block of alternative HTML to be used if the <OBJECT> tag fails to load its plugin correctly.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myOBJECT*.altHtml

The alternative HTML is used in case the base <OBJECT> tag experiences a problem when loading or the browser cannot use ActiveX objects as embeds. Of course if this property is accessible from the OBJECT object during scripting, the browser must have parsed the <OBJECT> tag, although it may still have had problems with the component.

This HTML is enclosed between the <OBJECT> and </OBJECT> tags in the HTML document source.

Certain tags are likely to be omitted from the `altHTML` property value. `<OBJECT>` blocks contain `<PARAMETER>` tags for passing values to the embedded ActiveX component. Clearly you won't want these appearing in the display if the component fails to load. The `<PARAMETER>` tags are considered integral to the `<OBJECT>` and it's smart enough to disregard them as it constructs its alternative HTML block.

Browsers that cannot understand and render `<OBJECT>` tags should also ignore the `<PARAMETER>` tags too.

OBJECT.archive (Property)

A space-separated archive list. This enumerates a set of classes that must be pre-loaded before the object can execute.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myOBJECT*`.archive`

This is a new attribute of the DOM `HTMLObjectElement` but is shown here as this is the existing object type it is to be added to.

OBJECT.border (Property)

The width of the border around the object when it is rendered into the display.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.border`

This property can be set from script and although its type is a String primitive, it will expect a numeric value. JavaScript will coerce as necessary during the assignment.

OBJECT.classid (Property)

The URL that locates the registered ActiveX control within the local file system when MSIE is used on the Windows platform.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myOBJECT*`.classid`

This is a special URL value used to locate ActiveX objects within the file system of the PC running the client browser. This is likely only available in Windows versions of the MSIE browser because that is the only platform that supports ActiveX objects. It is not supported on the Macintosh version of MSIE because ActiveX objects aren't available there. This is because they are compiled x86 micro-code and therefore cannot run in a non-Intel environment (unless the x86 CPU is being emulated).

The ActiveX control needs to have been registered and installed already. It is possible to construct an `<OBJECT>` tag that conveys sufficient information to locate and install a missing ActiveX control but this can be a quite involved process.

See also:	clsid: URL, URL

Property attributes:

`ReadOnly`.

OBJECT.code (Property)

The name of a Java applet to be used with the `<OBJECT>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.code`

This specifies the main code class to be loaded when the object is instantiated. This value is added to the codebase property to form a fully qualified URL.

There is conflicting information in the reference sources regarding the read/write ability of this property. Some suggest it is `ReadOnly` and others suggest you can assign a value to it. It may be that you can assign a value to it without the JavaScript interpreter complaining but that any value you assign is ignored.

OBJECT.codeBase (Property)

The path to the directory where the Java applet denoted by the `CLASS="…"` HTML tag attribute is to be found.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.codebase`

The codebase is the path to the directory where the classes specified in the code property are located. The actual path to the required files is generated by a string concatenation of codebase+code to generate a fully specified URL.

Due to security limitations it is not permitted to access a codebase value that is outside the domain specified by the containing document.

There is conflicting information in the reference sources regarding the read/write ability of this property. Some suggest it is `ReadOnly` and others suggest you can assign a value to it. It may be that you can assign a value to it without the JavaScript interpreter complaining but that any value you assign is ignored.

OBJECT.codeType (Property)

A description of the type of code in the object referred to by the `CLASSID="…"` HTML tag attribute.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.codeType`

This is a MIME type value that describes the kind of code being embedded by the `<OBJECT>` tag.

There is conflicting information in the reference sources regarding the read/write ability of this property. Some suggest it is `ReadOnly` and other suggest you can assign a value to it. It may be that you can assign a value to it without the JavaScript interpreter complaining but that any value you assign is ignored.

See also:	MIME types

OBJECT.data (Property)

A URL that points at a file containing data that the `OBJECT` element can access.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.data`

This is intended for passing in a URL that the ActiveX object can use to access some data service that is online and available for access via the network. It is not the URL of the ActiveX object itself.

Property attributes:

`ReadOnly`.

OBJECT.declare (Property)

A means of defining the object without activating it.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myOBJECT*`.declare`

Declaring an `OBJECT` in this way may be useful when referring to the object from elsewhere in the page or from within another object. Sometimes you simply want to know something about it, perhaps one of its parameters. For video players, sometimes its useful to instantiate the `OBJECT` into the display without playing the video right away.

OBJECT.form (Property)

The form that an object belongs to if it is used for form input.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Form` object	
JavaScript syntax:	-	*myOBJECT*`.form`

Property attributes:

`ReadOnly`.

OBJECT.height (Property)

The height of an area reserved for displaying the contents of the `<OBJECT>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myOBJECT*`.height`

The object space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is the smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

OBJECT.hspace (Property)

A horizontal margin space either side of the `<OBJECT>` tag with respect to its surrounding objects.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myOBJECT*`.hspace`

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The `hspace` property controls the margin to the left and right of the object.

OBJECT.name (Property)

The value of the `NAME="…"` HTML tag attribute.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.name`

Objects are identified either by the `NAME="…"` HTML tag attribute or by the `ID="…"` HTML tag attribute.

Netscape shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However in many cases, both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`NAME="…"`, Namespace

OBJECT.object (Property)

An accessor that yields a reference to the containing JavaScript object when there is a possibility of naming conflicts between internally visible and externally visible property names.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Object` object	
JavaScript syntax:	IE	*myOBJECT*`.object`

If a property is a public property of the ActiveX object, and that name coincides with a property of the JavaScript object that is instantiated by the `<OBJECT>` HTML tag, then access to the property belonging to the containing object is difficult. This is because the search order will see the public property of the ActiveX object first. By using the `object` property, once can access the containing object explicitly and retrieve a property of that object even if there is an identically named property belonging to the enclosed ActiveX object.

This access mechanism applies to method invocations as well.

See also:	`Applet.object`

Property attributes:

`ReadOnly`.

OBJECT.readyState (Property)

The current status disposition of the <OBJECT> tag as it is being loaded.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myOBJECT*.readyState

This property reflects the loading status of an <OBJECT> tag and its corresponding OBJECT object instantiation.

Sometimes, you can design scripts to execute while the document is downloading. Inline scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

If it is important that the document has completed loading, you can check this property for one of the following values:

State	Value
uninitialized	The object is first instantiated but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed but is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an OBJECT object that represents an <OBJECT> tag until the <BODY> has completed loading. This is because the ActiveX object construction requires a complete document body structure to attach itself to.

Every time this readyState value changes, it triggers an onReadyStateChange event call-back.

See also:	onReadyStateChange

Property attributes:

ReadOnly.

OBJECT.standby (Property)

Sets or resets the message text displayed while the object is loading.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myOBJECT*`.standby`

OBJECT.tabIndex (Property)

A control of where the `OBJECT` object appears in the tabbing order of the page.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myOBJECT*`.tabIndex`

This value indicates where in the tabbing sequence this object and any of its children will be placed. The tabbing order is used when filling in forms or moving focus. Pressing the `[`*tab*`]` key moves from one form element to the next according to the cascaded tabbing order defined by building a tree-like structure with the tab index values.

OBJECT.type (Property)

An indication of the MIME type of the object if its `codeType` property is undefined.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOBJECT*`.type`

The MIME type of the object is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

See also:	MIME types

OBJECT.useMap (Property)

The URL of a <MAP> defined hash element that defines a client-side image map.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	N	*myOBJECT*.useMap

This property reflects the value of the USEMAP="…" HTML tag attribute, which should refer to the named <MAP> tag containing an image map. The reference is by means of a "#NAME" value in this property that corresponds to the NAME="…" HTML tag attribute of the <MAP> tag describing the image map to use with the object.

OBJECT.vspace (Property)

A vertical spacing above and below the <OBJECT> with respect to its adjacent objects.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myOBJECT*.vspace

Margins placed around objects are either modified separately with all four margin sides having a different property or by adjusting the horizontal margins and vertical margins using just two values.

The vspace property controls the margin at the top and bottom of the object.

OBJECT.width (Property)

The height of an area reserved for displaying the contents of the <OBJECT> tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myOBJECT*.width

The object space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is the smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

Obsolescent (Definition)

A feature of the language that is no longer supported.

Warnings:

- If you use obsolescent functionality, your script may fail when it is deployed on other platforms.

See also:	Deprecated functionality

Octal value (Definition)

A numeric value based on a radix of 8.

Availability:	ECMAScript edition –3

An octal value is an integer composed of only the following characters:

0 1 2 3 4 5 6 7

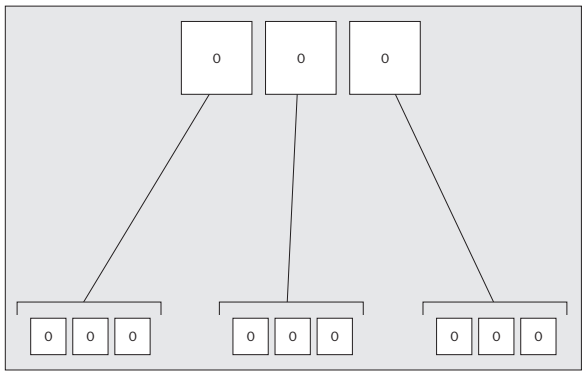
Octal values are always prefixed by a zero character.

The sequence carries over for the next increment when each column reaches the value 7. Thus:

00 01 02 03 04 05 06 07 010 011 012

Octal values have a historical significance from having been used in the earliest computer systems. However these days, they are particularly useful since they map quite conveniently to the binary system. Each octal digit corresponds to three binary digits.

The most significant of the three octal digits does not have a full range since it contains a carry over bit and a three digit octal number actually represents a 9 bit value. However, an 8 bit value can be encoded conveniently if the range is limited to 0377 as a maximum. Hexadecimal values map far more conveniently although they are harder to compute mentally.



Warnings:

- Beware when you prefix decimal values with a zero character. You may want to justify a column of figures. If you add leading zero characters to a numeric string, if that string is subsequently parsed back to a numeric value, you may inadvertently export the value as a decimal but import it as an octal value. This can lead to an extremely difficult-to-diagnose fault in your software because the parsers sometimes add some intelligence and will correctly interpret the value as decimal if the characters 8 or 9 are present, but otherwise interpret it as octal notation.
- This may be implementation-dependant behavior to some extent.
- Be careful that you remove any leading zero characters from the text strings that you plan to convert using the numeric parser. The example shows a simple function for doing this.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString = "00123";
document.write(stripLeadingZeros(myString));
// Strip leading zero characters off a numeric string
function stripLeadingZeros(aString)
{
   return aString.substr(aString.search(/[1-9]/));
}
</SCRIPT>
</BODY>
</HTML>
```

Off by one errors (Pitfall)

An error caused by missing the target value by one.

This kind of errors are caused by the following:

- Forgetting than an index is zero-based and assuming it begins at 1. This typically affects arrays and strings.
- Enumerating through a range of values and testing for equality with the target value rather than testing that you are still less than the target value. This is typically a problem when you build for loops.

See also: Array index delimiter ([ ]), `Array.slice()`, `do ... while( ... )`, `for( ... ) ...`, Pitfalls, `while( ... ) ...`

Off-screen image caching (Useful tip)

A technique for caching images locally in readiness for an animation.

Refer to:

Image preloading

offscreenBuffering (Property)

An alias for the `window.offScreenBuffering` property.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`Boolean` or `String primitive`	
JavaScript syntax:	-	*myWindow*`.offScreenBuffering`
	-	*myWindow*`.offScreenBuffering = `*aSetting*
	-	`offScreenBuffering`
	-	`offScreenBuffering = `*aSetting*
Argument list:	*aSetting*	A new value to control this functionality

Refer to:

`Window.offScreenBuffering`

OL object (Object/HTML)

An object that represents the ordered list contained in an `<OL>` tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myOL = `*myDocument*`.all.`*anElementID*
	IE	*myOL* `= `*myDocument*`.all.tags("OL")[`*anIndex*`]`
	IE	*myOL* `= `*myDocument*`.all[`*aName*`]`
	-	*myOL* `= `*myDocument*`.getElementById (`*anElementID*`)`
	-	*myOL* `= `*myDocument*`.getElementsByName(`*aName*`)[`*anIndex*`]`
	-	*myOL* `= `*myDocument*`.getElementsByTagName ("OL")[`*anIndex*`]`

HTML syntax:	`<OL> ... </OL>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`compact, start, type`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The `<OL>` tag is a block-level tag. That means that it forces a line break before and after itself.

The DOM level 1 standard describes this as a `HTMLOListElement` object.

See also:	Element object, `UL` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`compact`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`start`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`type`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseOver`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

OL.compact (Property)

A switching attribute that condenses the space required to display the ordered list on the screen.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myOL*`.compact`

The collection of `LI` objects are presented in the normal spaced out style when the compact property belonging to their owner `OL` object is set to `false`.

Setting the property to `true` should result in the list items being squeezed closer together. however the functionality is rarely supported on web browsers.

Its more likely that you'll apply CSS style attributes to the list to achieve the same effect.

Warnings:

- Setting the property in MSIE and Netscape is quietly ignored by both browsers. No visible effect, no error message.

See also:	`LI` object

OL.start (Property)

The starting index of items in the ordered list. The enumerator can be set to a predetermined value with this property.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myOL*`.start`

Ordered lists can start at any value. This is somewhat related to the `LI.value` property, which allows the list items to begin sequencing from any value you care to define. The value you specify here must be a positive integer.

Warnings:

- This exhibits some bugs in Netscape 6.0. Setting a start value seems to be applied inconsistently to the items in the list. They are renumbered but not correctly. For now, the best work around is to construct the list and use the `innerHTML` trick to store it into the page. This will likely get fixed as soon as people really get to grips with Netscape 6.0 and it does work fine in MSIE.

See also:	LI.value

OL.type (Property)

The presentation style of the ordered list.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOL*`.type`

Although the sequence numbers are incrementing in an ordered list, they may be displayed in a variety of different formats selected by this property.

You can override this on an item-by-item basis and so this property is related to the `LI.type` property.

The following type values are appropriate for this list type:

- `1` - Numeric
- `a` –Alphabetical –lower case
- `A` –Alphabetical –upper case
- `i` –Roman numerals –lower case
- `I` –Roman numerals –upper case

See also:	`LI.type, style.listStyleType, UL.type`

on ... (Event handler)

All event handlers begin with the word on.

The event handlers are many and various in their support across the browsers and in the way that they are triggered. There is no one object that supports them all and even when an object does not support them by default, the event-management capabilities of MSIE or Netscape can sometimes set objects up to support them anyway.

Here is a summary of the available supported events:

Event	Handler	Usage
Abort	`onabort`	When image loading is aborted.
AfterPrint	`onafterprint`	When printing has just finished.
AfterUpdate	`onafterupdate`	When an update is completed.
Back	`onback`	The user has clicked on the `[BACK]` button in the toolbar.
BeforeCopy	`onbeforecopy`	Immediately before a copy to the clipboard.
BeforeCut	`onbeforecut`	Immediately before a cut to the clipboard.
BeforeEditFocus	`onbeforeeditfocus`	Immediately before the edit focus is directed to an element.
BeforePaste	`onbeforepaste`	Immediately before the clipboard is pasted.
BeforePrint	`onbeforeprint`	Immediately before printing begins.
BeforeUnload	`onbeforeunload`	Called immediately prior to the window being unloaded.
BeforeUpdate	`onbeforeupdate`	Called immediately before an update commences.
Blur	`onblur`	When an input element loses input focus.
Bounce	`onbounce`	Triggered when a marquee element hits the edge of its element area.
Change	`onchange`	When edit fields have new values entered or a popup has a new selection, this event's handler can check the new value.
Click	`onclick`	When the user clicks the mouse button on the `Element` object that represents the object on screen.
ContextMenu	`oncontextmenu`	Special handling for contextual menus.
Copy	`oncopy`	When a copy operation happens.
Cut	`oncut`	When a cut operation happens.
DataAvailable	`ondataavailable`	Some data has arrived asynchronously from an applet or data source.
DataSetChanged	`ondatasetchanged`	A data source has changed the content or some initial data is now ready for collection.
DataSetComplete	`ondatasetcomplete`	There is no more data to be transmitted from the data source.
DblClick	`ondblclick`	When the user double-clicks on an object.
Drag	`ondrag`	When a drag operation happens.
DragDrop	`ondragdrop`	Some data has been dropped onto a window.
DragEnd	`ondragend`	When a drag ends.
DragEnter	`ondragenter`	When a dragged item enters the element.
DragLeave	`ondragleave`	When a dragged item leaves the element.
DragOver	`ondragover`	While the dragged item is over the element.
DragStart	`ondragstart`	The user has commenced some data selection with a mouse drag.
Drop	`ondrop`	When a dragged item is dropped.
Error	`onerror`	Triggered if an error occurs when loading an image.

Table continued on following page

Event	Handler	Usage
ErrorUpdate	`onerrorupdate`	An error has occurred in the transfer of some data from a data source.
FilterChange	`onfilterchange`	A filter has changed the state of an element or a transition has just been completed.
Finish	`onfinish`	A marquee object has finished looping.
Focus	`onfocus`	When the form element is selected for entry.
Forward	`onforward`	The user has clicked on the `[FORWARD]` button in the toolbar.
Help	`onhelp`	The user has pressed the `[F1]` key or selected `[help]` from the toolbar or menu.
KeyDown	`onkeydown`	When a key is pressed.
KeyPress	`onkeypress`	Pressing the key down and releasing it again elicits this event.
KeyUp	`onkeyup`	When a key is released.
Load	`onload`	When an object has completed loading.
LoseCapture	`onlosecapture`	When an element loses event capturing permission.
MouseDown	`onmousedown`	When the mouse button is pressed.
MouseDrag	`onmousedrag`	An event handler for mouse drag operations.
MouseMove	`onmousemove`	When the mouse pointer is moved.
MouseOut	`onmouseout`	When the mouse pointer leaves the active area occupied by the `Element` object that represents the object on screen.
MouseOver	`onmouseover`	When the mouse pointer enters the active area owned by the object.
MouseUp	`onmouseup`	When the mouse button is released.
Move	`onmove`	The browser window has been moved..
Paste	`onpaste`	When a paste operation happens.
PropertyChange	`onpropertychange`	When an object property is modified (similar to the Netscape `watch()` method).
ReadyStateChange	`onreadystatechange`	An object in the window has changed its ready state.
Reset	`onreset`	The user has clicked a reset button in a form.
Resize	`onresize`	As the window is resized, this event is triggered.
RowEnter	`onrowenter`	The data in a field bound to a data source is about to be changed.
RowExit	`onrowexit`	The data in a field bound to a data source has been changed
Scroll	`onscroll`	The window has been scrolled.
Select	`onselect`	Some textual content in the window has been selected.
SelectStart	`onselectstart`	A select action is beginning.
Start	`onstart`	A marquee element is beginning its loop.
Stop	`onstop`	When a stop action occurs.
Submit	`onsubmit`	The user has clicked on the submit button in a form
Unload	`onunload`	Triggered when the document is unloaded.

Events are associated with HTML tags by means of the `onEvent="..."` tag attribute. This assigns a function object to the onevent property of the `Element` object that represents a tag. Event handlers can be associated with objects by assigning function object references to the event-handler properties of the objects. However, this is also not consistently supported across the browsers.

Netscape supports event routing calls that can send events to objects by passing the `Event` object to them. The objects then map the events to an appropriate handler according to their set-up.

The initial value of this property will be an anonymous function whose body contains the contents of the `onEvent="..."` HTML tag attribute.

When the event is triggered and called, it will execute in the context of the `Element` object and not the window. This means the execution scope will be that of the `Element` object.

In Netscape prior to version 6.0, event handlers are passed an event object as an argument when they are called. In MSIE, no object is passed but the equivalent event object is available as the event property of the window that contains the `Element` object that receives the event trigger.

On the return from a handler, other processing may take place. In pre-version 6.0 Netscape browsers, the general technique for this is to return a `false` value. Returning nothing is equivalent to returning `true` which may allow some default processing in the browser to be called. In MSIE, this flag value is also supported, at least on later browser versions. In addition, the `returnValue` property of the event object can be set to `false`.

Now with the version 6.0 release of Netscape the DOM level 2 event model has been introduced. The event model is still undergoing some development at the W3C standards organisation and a level 3 update is available for review. This at least is a turning point for event handling because all browser manufacturers have stated that it is their goal to be standards-compliant. The new event model is mainly based on the MSIE way of doing things but it is a slightly hybrid and takes some ideas from the Netscape tradition too.

Warnings:

- Prior to version 6.0 of Netscape, anything more than simple event handling is managed differently between the Netscape and MSIE browsers.
- Properties that can be assigned with a function handler vary between Netscape and MSIE. Generally, MSIE allows this property assigning technique more completely and consistently across all its event handlers and objects that own them.
- Be aware that you don't always get a meaningful `event` object passed as an argument to the event handler in Netscape. On some platforms, the `event` object may have some useful properties, on others it may have none. The MSIE `event` object is more complete but less flexible as it needs to be shared between all events.
- Event handling support has radically changed in Netscape 6.0, and because it is a new code base and a new standard, there are likely to be bugs and limitations in its support for a while yet.

See also:	`Element.onevent`, `Event` object

onAbort (Event handler)

An event that happens when loading is interrupted.

Availability:	JavaScript –1.1 JScript –1.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onabort = *aHandler*
HTML syntax:	`<HTMLTag onAbort="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`IMG`	

This event is only supported by `IMG` objects. It is triggered if a page load is aborted partway through the loading of an image.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onError, onLoad`, Semantic event

onAfterPrint (Event handler)

Called when printing is completed.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*.onafterprint = *aHandler*

This provides a hook for cleaning up after printing a page.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBeforePrint`, Semantic event

onAfterUpdate (Event handler)

An event that happens after an update.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onafterupdate = `*aHandler*
HTML syntax:	`<HTMLTag onAfterUpdate="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`APPLET, Checkbox, Input, TABLE, AREA, DIV, MARQUEE,TD, BODY, Document, OBJECT, TEXTAREA, BUTTON, FIELDSET, RadioButton, TH, CAPTION, IMG, Select`	

If the contents of a page are database driven, this will be called after the database has been updated.

See also:	Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, onBeforeUpdate, Semantic event

onBack (Event handler)

Triggered by the back button.

Availability:	JavaScript –1.3 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myObject*`.onback = `*aHandler*
HTML syntax:	`<HTMLTag onBack="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event

This event is called when the user interacts with the browser. Some events like this are helpful for blocking the operation of certain browser UI elements.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onForward`, Semantic event, Window events

onBeforeCopy (Event handler)

Called immediately before a copy operation.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.onbeforecopy = aHandler`

If a selected area of the page is about to be copied to the clipboard, this allows the event to be intercepted and blocked if necessary.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBeforeCut`, `onBeforePaste`, Semantic event

onBeforeCut (Event handler)

Called immediately before a cut operation.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.onbeforecut = aHandler`

If a selected area of the page is about to be cut to the clipboard, this allows the event to be intercepted and blocked if necessary.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBeforeCopy`, `onBeforePaste`, Semantic event

onBeforeEditFocus (Event handler)

Called immediately before focus is relocated to another object.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.onbeforeeditfocus = aHandler`

If a field within a form is about to be edited, this allows the event to be intercepted and blocked if necessary.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Semantic event

onBeforePaste (Event handler)

Called immediately before a paste operation.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.onbeforepaste = aHandler`

If a form elements is about to have its contents pasted from the clipboard, this allows the event to be intercepted and blocked if necessary.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBeforeCopy`, `onBeforeCut`, Semantic event

onBeforePrint (Event handler)

Called immediately before printing commences.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.onbeforeprint = aHandler`

This provides a hook to set the page up before printing. This may be necessary to change the content of some items in the page so that they print more attractively.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onAfterPrint`, Semantic event

onBeforeUnload (Event handler)

An event before an unload happens.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`myObject.onbeforeunload = aHandler`
HTML syntax:	`<HTMLTag onBeforeUnload="...">`	
Argument list:	`aHandler`	A reference to a function object to handle the event
Supported by objects:	BODY, Layer, SCRIPT, Window FRAMESET, LINK, STYLE,	

This event is triggered immediately before an unload event. It provides a hook for cleaning up immediately before a page is unloaded.

It is bad User Interface design to call an alert box at this point in the proceedings.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onUnload`, Semantic event

onBeforeUpdate (Event handler)

An event called before an update happens.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onbeforeupdate = `*aHandler*
HTML syntax:	`<HTMLTag onBeforeUpdate="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`APPLET, Checkbox, Input, TD,AREA, DIV, OBJECT, TEXTAREA, BODY, Document, RadioButton, TH, BUTTON, FIELDSET, Select, CAPTION, IMG, TABLE,`	

Database updates my require some data-integrity checks to be carried out. This event trigger allows some checking to take place at an opportune moment, immedately before the update happens.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onAfterUpdate`, Semantic event

onBlur (Event handler)

Triggered when the user selects another form element for input and the current one loses focus.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –3.0 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.onblur = `*aHandler*
HTML syntax:	`<BODY onBlur="`*aHandler*`"> <FRAMESET onBlur="`*aHandler*`"> <HTMLTag onBlur="`*aHandler*`"> <INPUT onBlur="`*aHandler*`">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.

Supported by objects:	A, Embed, OBJECT, TD, Anchor, FIELDSET, Password, TEXTAREA, APPLET, FileUpload, RadioButton, TextCell, AREA, IMG, ResetButton, TH, BUTTON, Input, Select, TR, CAPTION, Layer, SPAN, Url, Checkbox, LEGEND, SubmitButton, DIV, MARQUEE, TABLE,

A blur event is caused by the user clicking on another window or frame or the `blur()` method being called for an object. When this event is triggered, an `onBlur` event handler will be invoked.

The `onblur` event handler is a function which is represented by an object that is referred to by this property. Because it is stored in a property, you can change the handler by storing a reference to a different function object in this property. At least, you can on MSIE.

You cannot redefine the value of the `window.onblur` property from inside the `onblur` function handler. This means you can't modify the `onblur` behavior while a blur event is in progress.

Netscape will pass an `event` object as an argument when it calls this event handler function. MSIE does not pass an object but makes the event data available via the `Event` object that is stored and accessed globally for all events.

DOM level 2 events refers to this as a `DOMFocusOut` event, which employs event bubbling for its propagation and cannot be canceled.

Warnings:

- It is somewhat easy to create an `onBlur/onFocus` recursion which leads to an endless loop with objects exchanging focus backwards and forwards. Focus on *`object A`* triggers a blur event on *`object B`*, which tries to wrest back the focus again because it believes its content is incomplete. Meanwhile *`object A`* isn't happy with its content either and so they play 'Tug-of-War' with one another. This continues until the browser has a race hazard attack and GPFs –that is if it hasn't already fallen over due to a stack overflow. If you're lucky only the browser will crash, but it could bring down the OS as well.

See also:	Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, Input.blur(), Input.focus(), onFocus, Password object, Semantic event, UIEvent object, Window.onblur

onBounce (Event handler)

Triggered when a marquee element hits the edge of its element area.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myObject`*`.onbounce = `*`aHandler`
HTML syntax:	`<HTMLTag onBounce="...">`	
Argument list:	*`aHandler`*	A reference to a function object to handle the event
Supported by objects:	`MARQUEE`	

You may want to change the MARQUEE content or do some wizzy animation effect when the bounce occurs.

Now that we can do pretty much the same things with dynamic HTML and style-driven positioning, this could become deprecated.

Its still quite useful though, because it knows how big the marquee content is and it triggers the bounces automatically. That's possible with CSS scripting but its not completely trivial because you need to measure the extent rectangle of an object, which could involve some very messy font metric calculations.

See also:	Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, onStart, onStop, Semantic event

onChange (Event handler)

Triggered when the value belonging to an input element is changed.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera browser –3.0
Property/method value type:	Boolean primitive
JavaScript syntax:	- *myObject*.onchange = *aHandler*
HTML syntax:	<HTMLTag onChange="..."> <INPUT onChange="...">
Argument list:	*aHandler* A reference to a function object to handle the event
Supported by objects:	BODY, FIELDSET, LEGEND, TEXTAREA, CAPTION, FileUpload, Password, TextCell, Checkbox, IMG, RadioButton, DIV, Input, Select,

When the data in the input element is modified, the ONCHANGE event handler is called.

You can place some script code directly into this handler like this:

```
<INPUT TYPE="TEXT" ONCHANGE="alert('Changed');">
```

In this context, you can refer to the input element itself using the 'this' keyword. Thus:

```
<INPUT TYPE="TEXT" ONCHANGE="this.value=checkValue(this.value);">
```

This will check the value and reset it to an allowed value. That may be to force it to be all lower case for example or to remove weird characters.

Actually, you don't need to pass *this.value* because it's accessible from within the function. Functions inherit some scope according to how they are called so this would be better:

```
<INPUT TYPE="TEXT" ONCHANGE="this.value=checkValue();">

<SCRIPT>

function checkValue(anObject)

{

this.value = this.value + "XXX";

return true;

}

</SCRIPT>
```

This is also a particularly useful event to handle on behalf of a `<SELECT>/<OPTION>` control although it is not supported fully in all browsers.

Because the MSIE version 3.0 browser doesn't trigger this event, it has become popular to place a small input button beside the selector so the user can select and then trigger. If you do that, you really should make that technique browser-version sensitive and 'do the automatic thing' when you can.

Cross-references:

Wrox *Instant JavaScript* –page –53

onClick (Event handler)

This event is triggered when the user clicks the mouse button with the pointer over the `Element` object that represents the object on screen.

Availability:	HTML version –4.0 JavaScript –1.0 JScript –1.0 Internet Explorer –3.0 Netscape –2.0 Opera browser –3.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myObject*.onclick = *aHandler*
HTML syntax:	`<A onClick="..."> <AREA onClick="..."> <HTMLTag onClick="..."> <INPUT onClick="...">`

Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	A, Checkbox, FileUpload, LISTING, S, TEXTAREA, ACRONYM, CITE, FONT, MAP, SAMP, TextCell, ADDRESS, CODE, FORM, MARQUEE, Select, TFOOT Anchor, DD, H1, MENU, SMALL, TH, APPLET, DEL, HR, OBJECT, SPAN, THEAD, AREA, DFN, I, OL, STRIKE, TR, B, DIR, IMG, P, STRONG, TT, BIG, DIV, Input, Password, SUB, U, BLOCKQUOTE, DL, INS, PLAINTEXT, SubmitButton, UL, BODY, Document, KBD, PRE, SUP, Url, BUTTON, DT, LABEL, Q, TABLE, VAR, CAPTION, EM, LEGEND, RadioButton, TBODY, CENTER, FIELDSET, LI, ResetButton, TD,		

The `onClick` event handler is invoked when the user clicks once on the object that it belongs to. This might normally be a hypertext link. As of version 1.1 of JavaScript, if the handler returns the Boolean false value then the browser will not follow the link to its HREF. If a true value is returned then it will.

This event applies to anchors, reset buttons, and submit buttons. A `false` return value inhibits the browser from taking any default actions once your handler is completed.

Netscape indicates which mouse button was pressed in the `which` property of the `Event` object that is passed as an argument to the event handler function. MSIE makes the value available in the `button` property of the `event` object referenced by the `window.event` property.

DOM level 2 refers to this as a `DOMActivate` event, which employs event bubbling for its propagation and can be canceled. The context info provides detail about whether its was a single or double click.

DOM level 2 also classifies this as a `MouseEvent` and specifies that it must follow a matching pair of `mousedown` and `mouseup` events without any intervening mouse movement. As a `MouseEvent` it uses bubbling propagation and can be canceled.

Warnings:

- When you add an `onClick` handler to an `<A>` tag object, MSIE and Netscape execute the click in the same way but modify the browser history differently.
- An `onClick` event will also generate an `onMouseDown` event and an `onMouseUp` event. The `onClick` will not be triggered until the `onMouseUp` event. There is no guarantee that the `onClick` event will arrive after the `onMouseUp` event although that is the logical order.

onContentReady (Event handler)

A special event handler provided to facilitate the loading of behavior controls.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.oncontentready = aHandler`

This event is notified to the behavior handler when the content of the element that the behavior is associated with has been loaded and parsed. This does not mean that the document is complete yet. That is signified by the `onDocumentReady` event being notified to the behavior script.

See also:	`onDocumentReady`

onContextMenu (Event handler)

Called when a context menu is requested by the user.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.oncontextmenu = aHandler`

Contextual menus can trigger this event as an item is selected. This allows you you to activate some context specific code at that time.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Semantic event

onCopy (Event handler)

Called when a copy operation is requested by the user.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.oncopy = aHandler`

If the user copies some page content to the clipboard, you may want to know that it has happened and do something about it or perhaps even block the action.

See also:	`dataTransfer.getData()`, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onCut`, `onPaste`, Semantic event

onCut (Event handler)

Called when a Cut operation is requested by the user.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*.oncut = *aHandler*

If the user cuts some page content to the clipboard, you may want to know that it has happened and do something about it or perhaps even block the action.

See also:	dataTransfer.getData(), Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, onCopy, onPaste, Semantic event

onDataAvailable (Event handler)

Some data has arrived asynchronously from an applet or data source.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myObject*.ondataavailable = *aHandler*
HTML syntax:	<HTMLTag onDataAvailable="...">	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	APPLET, AREA, BODY, IMG, OBJECT	

This event fires periodically as data arrives from data source objects that asynchronously transmit their data.

In a data-driven system, occasionally you will need to wait for the arrival of some data. This event triggers when the data has arrived, and you can build a script that works with the data that is triggered from this event, rather than build some polling code that sits there busily waiting for things to arrive.

See also:	Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, onDataSetChanged, onDataSetComplete, Semantic event, XML.event

onDataSetChanged (Event handler)

A data source has changed the content or some initial data is now ready for collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.ondatasetchanged = `*aHandler*
HTML syntax:	`<HTMLTag onDataSetChanged="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, AREA, BODY, IMG, OBJECT`	

This event fires when the data set exposed by a data source object changes.

When sharing data out of a database, it is possible that there are contentions or users trying to access and change the same data. You may need to watch a piece of data and perform some operation when it changes. This trigger is activated when that happens.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDataAvailable`, Semantic event, `XML.event`

onDataSetComplete (Event handler)

There is no more data to be transmitted from the data source.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.ondatasetcomplete = `*aHandler*
HTML syntax:	`<HTMLTag onDataSetComplete="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`APPLET, AREA, BODY, IMG, OBJECT`	

This event fires to indicate that all data is available from the data source object.

In a data-driven loop, you may want to perform some processing at closure when the data has been completely retrieved from the database. This event is triggered when that happens.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.reason`, `Event.returnValue`, Handler, `onDataAvailable`, Semantic event, `XML.event`

onDblClick (Event handler)

Triggered when the user double-clicks on an object.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.ondblclick = *aHandler*
HTML syntax:	`<A onDblClick="..."> <AREA onDblClick="..."> <BODY onDblClick="..."> <HTMLTag onDblClick="..."> <IMG onDblClick="..."> <INPUT onDblClick="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`A, DIR, LI, STRIKE,ACRONYM, DIV, LISTING, STRONG,ADDRESS, DL, MAP, SUB,Anchor, Document, MARQUEE, SubmitButton,APPLET, DT, MENU, SUP,AREA, EM, OBJECT, TABLE,B, FIELDSET, OL, TBODY,BIG, FileUpload, P, TD,BLOCKQUOTE, FONT, Password, TEXTAREA,BODY, FORM, PLAINTEXT, TextCell,BUTTON, H1, PRE, TFOOT,CAPTION, HR, Q, TH,CENTER, I, RadioButton, THEAD,Checkbox, IMG, ResetButton, TR,CITE, Input, S, TT,CODE, INS, SAMP, U,DD, KBD, Select, UL,DEL, LABEL, SMALL, Url,DFN, LEGEND, SPAN, VAR,`	

This event is generated when the user clicks on the receiving object twice.

Netscape indicates which mouse button was pressed in the `which` property of the `event` object that is passed as an argument to the event handler function. MSIE makes the value available in the `button` property of the event object referenced by the `window.event` property.

Warnings:

- This is not supported by Netscape 4.0 on Unix or Macintosh platforms.
- An `onDblClick` event will also trigger `onMouseDown` and `onMouseUp` events. There will also be a possibility of `onClick` event triggering in some implementations, although a single click and double click should be distinguishable from one another. There is no guarantee that the `onDblClick` will arrive after the second `onMouseUp` although that is the logical order.

See also:	Element object, Event, Event handler, Event model, Event names, `Event` object, `Event.button`, `Event.returnValue`, `Event.which`, Handler, Mouse events, `onClick`, `onMouseDown`, `onMouseUp`, Semantic event

onDocumentReady (Event handler)

A special event to signify that a document is loaded and ready for use.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*`.ondocumentready = `*aHandler*

This event is notified to the behavior handler when the document has been downloaded and completely parsed. The handler needs to be able to distinguish between different events that may trigger it and lock out any user interaction until after this notification has been received.

See also:	`onContentReady`

onDrag (Event handler)

Called when a Drag is activated by the user.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*`.ondrag = `*aHandler*

Drag and drop code is notoriously non-portable and hard to manage. This family of event triggers greatly facilitate that process although they are not widely supported on all browsers.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDragDrop`, `onDragEnd`, `onDragEnter`, `onDragLeave`, `onDragOver`, `onDragStart`, `onDrop`, Semantic event

onDragDrop (Event handler)

Some data has been dropped onto a window.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.ondragdrop = `*aHandler*

HTML syntax:	<BODY onDragDrop="*aHandler*"> <FRAMESET onDragDrop="*aHandler*"> <HTMLTag onDragDrop="*aHandler*">	
Argument list:	*aHandler*	A reference to a function object to handle the event

This is triggered when some data is dropped onto an object in the window. You can then access the data and decide what to do with it.

This event handler is most likely to be invoked when the user drags an item onto a window in Netscape.

To access the details of the entity that has been dragged into and dropped on the window, you need to inspect the `data` property of the `event` object that is passed as an argument to the handler when it is called.

The data is a single URL when a single entity is dropped into the window or an array of strings, each containing a URL when a collection of entities are dropped onto a window. What you can then do with those entity references really depends on your platform and browser capabilities and what you can do to files on your client system given the security implications of browser access to the filesystem.

You will need `UniversalBrowserRead` privilege to access this data in Netscape.

The handler is registered either by assigning a function to the `ondragdrop` property or by defining it with an HTML tag attribute.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragEnd`, `onDragEnter`, `onDragLeave`, `onDragOver`, `onDragStart`, `onDrop`, Semantic event, `UniversalBrowserAccess`, `UniversalBrowserRead`, `Window.ondragdrop`

onDragEnd (Event handler)

Called when the drag finishes and the dragged object is dropped and released.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*.ondragend = *aHandler*

This provides a more fine-grain approach to drag-drop management. It may be that you want to display some active animated effect while the drag is in progress. This tells you the dragging is now finished.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnter`, `onDragLeave`, `onDragOver`, `onDragStart`, `onDrop`, Semantic event

onDragEnter (Event handler)

Called when a dragged object enters the receiving object.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.ondragenter = aHandler`

Drag and drop may be fine-tuned to apply to only parts of the page. With this, you can do some artful rollover effects to highlight locations on the page where drags and drop is OK and where its not.

See also:	`dataTransfer.dropEffect`, Event, Event handler, Event model, Event names, Event object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnd`, `onDragLeave`, `onDragOver`, `onDragStart`, `onDrop`, Semantic event

onDragLeave (Event handler)

Called when a dragged object leaves the receiving object.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.ondragleave = aHandler`

Rolling off of a dragged 'hot' item triggers this event. This is like a rollover effect but it is active only while dragging.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnd`, `onDragEnter`, `onDragOver`, `onDragStart`, `onDrop`, Semantic event

onDragOver (Event handler)

Called repeatedly while the dragged object is over the receiving object.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	`myObject.ondragover = aHandler`

Drag over effects to highlight objects while dragging can be achieved with this trigger. When it happens, the mouse will have just crossed the boundary of an object while dragging some content with it.

See also:	`dataTransfer.dropEffect`, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnd`, `onDragEnter`, `onDragLeave`, `onDragStart`, `onDrop`, Semantic event

onDragStart (Event handler)

The user has commenced some data selection with a mouse drag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myObject`*`.ondragstart = `*`aHandler`*
HTML syntax:	`<HTMLTag onDragStart="...">`	
Argument list:	*`aHandler`*	A reference to a function object to handle the event.
Supported by objects:	`ACRONYM, DL, LI, STRONG, ADDRESS, Document, LISTING, SUB, B, DT, MARQUEE, SUP, BIG, EM, MENU, TABLE, BLOCKQUOTE, FIELDSET, OBJECT, TBODY, BODY, FONT, OL, TD, BUTTON, FORM, P, TEXTAREA, CAPTION, H1, PLAINTEXT, TFOOT, CENTER, HR, PRE, TH, CITE, I, Q, THEAD, CODE, IMG, S, TR, DD, Input, SAMP, TT, DEL, INS, Select, U, DFN, KBD, SMALL, UL, DIR, LABEL, SPAN, VAR, DIV, LEGEND, STRIKE,`	

At the commencement of a drag, this event trigger can be used to initiate some kind of feedback animation effect to tell the user where the dragged items can be deposited.

See also:	`dataTransfer.clearData()`, `dataTransfer.effectAllowed`, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnd`, `onDragEnter`, `onDragLeave`, `onDragOver`, `onDrop`, Semantic event

onDrop (Event handler)

Called when a dragged object is dropped into a receiving window.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*`myObject`*`.ondrop = `*`aHandler`*

This is the complement of the `onDrag` event. It provides a means to hook into the object drop when it is deposited in the page.

See also:	`dataTransfer.clearData()`, `dataTransfer.dropEffect`, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onDrag`, `onDragDrop`, `onDragEnd`, `onDragEnter`, `onDragLeave`, `onDragOver`, `onDragStart`, Semantic event

onError (Event handler)

Triggered if an error occurs when loading an image.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onerror = *aHandler*
HTML syntax:	`<HTMLTag onError="..."><IMG onError="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`IMG, LINK, OBJECT, SCRIPT, STYLE`	

There is an `onError` event defined as part of the set of events supported by JavaScript. However, the `onError` event is actually only supported by `Image` objects when defined in HTML tag attributes. You can add an error handler to a `window` object with the `onerror` property.

The `<IMG onError="...">` tag attribute allows an error during image loading to be handled gracefully.

Attaching an error handler to a window with the `window.onerror` property allows JavaScript errors to be intercepted.

Error events have a slightly different parameter passing API so although they are events, they are slightly different from the rest of the event model.

The API for the function that is associated with this event should take three parameters.

Warnings:

- This event handler cannot be set in HTML using the tag attribute technique apart from when it applies to an `<IMG>` tag. However, it also applies to windows and frames although there is no tag attribute to connect it to. You can only associate it with a window or frame by using the script-driven property assignment.
- Beware of the return values. Returning `true` from an error handler inhibits the browser form carrying out any further action. This is exactly opposite to the return value from a form element event handler, which requires that a `false` value be returned to inhibit any further action by the browser.
- The range of objects you can register an `onError` handler with is platform and browser version dependent and you should experiment with your target client base if you plan to use this other than for debugging help.

See also:	Error events, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onAbort`, `onErrorUpdate`, `onLoad`, Semantic event, `Window.onerror`

Cross-references:

Wrox *Instant JavaScript* –page –55

onErrorUpdate (Event handler)

An error has occurred in the transfer of some data from a data source.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onerrorupdate = `*aHandler*
HTML syntax:	`<HTMLTag onErrorUpdate="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`APPLET, CAPTION, FIELDSET, RadioButton, AREA, Checkbox, Input, Select, BODY, Document, OBJECT, TEXTAREA`	

Data-driven systems may generate errors. This event is triggered when the error status of a database connection changes.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onError`, Semantic event

onFilterChange (Event handler)

A filter has changed the state of an element or a transition has just been completed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onfilterchange = `*aHandler*
HTML syntax:	`<HTMLTag onFilterChange="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.

Supported by objects:	ACRONYM, DL, LISTING, STRONG, ADDRESS, DT, MENU, SUB, B, EM, OBJECT, SubmitButton, BIG, FIELDSET, OL, SUP, BLOCKQUOTE, FileUpload, P, TBODY, BODY, FONT, PLAINTEXT, TD, BUTTON, FORM, PRE, TEXTAREA, CAPTION, H1, Q, TFOOT, CENTER, HR, RadioButton, TH, Checkbox, I, ResetButton, THEAD,CITE, IMG, S, TR, CODE, Input, SAMP, TT, DD, INS, Select, U, DEL, KBD, SMALL, UL, DFN, LABEL, SPAN, VAR, DIR, LI, STRIKE,

Changing a filter will trigger this event. It is also triggered when a transition has just been completed. Filters are a MSIE-specific means of providing more attractive on-screen effects when things change.

Calling a function that changes a filter and executes a transition results in a further trigger for this event handler. Thus, you can set up an animation loop with this handler but, be careful to avoid stacking recursions or the browser will crash.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, `Filter` object, Handler, Semantic event, `style.filter`

onFinish (Event handler)

Triggered when a marquee object has finished looping.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onfinish = `*aHandler*
HTML syntax:	`<HTMLTag onFinish="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`MARQUEE`	

When the `MARQUEE` has completed its anticipated number of loops, this event is triggered so that you can set up some new animation if necessary.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onStart, onStop`, Semantic event

onFocus (Event handler)

When the form element is selected for entry.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –3.0 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onfocus = *aHandler*
HTML syntax:	`<BODY onFocus="`*aHandler*`"> <FRAMESET onFocus="`*aHandler*`"> <HTMLTag onFocus="`*aHandler*`"> <INPUT onFocus="`*aHandler*`">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`A, DIV, LEGEND, TABLE, Anchor, Embed, MARQUEE, TEXTAREA, APPLET, FIELDSET, OBJECT, TextCell, AREA, FileUpload, Password, Url, BUTTON, IMG, RadioButton, CAPTION, Input, ResetButton, Checkbox, Layer, SubmitButton,`	

When the input focus is directed onto a control, the browser will generally highlight the item to indicate that the cursor is localized there and that any keyboard input will affect that `<INPUT>` item.

DOM level 2 events refers to this as a `DOMFocusIn` event, which employs event bubbling for its propagation and cannot be canceled.

In MSIE, you can hide the visible effect of an object acquiring focus by means of the `hideFocus` property on HTML elements.

Warnings:

- It is somewhat easy to create an `onBlur/onFocus` recursion, which leads to an endless loop with objects exchanging focus backwards and forwards. Focus on *`object A`* triggers a `blur` event on *`object B`*, which tries to wrest back the focus again because it believes its content is incomplete. Meanwhile *`object A`* isn't happy with its content either and so they play 'Tug-of-War' with one another. This continues until the browser has a race hazard attack and GPFs –that is, if it hasn't already fallen over due to a stack overflow. If you're lucky, only the browser will crash, but it could bring down the OS as well.

See also:	`Element.hideFocus`, Event, Event handler, Event model, Event names, Event object, `Event.returnValue`, Handler, `Input.blur(), Input.focus(), onBlur`, Password object, Semantic event, `UIEvent` object, `Window.onfocus`

onForward (Event handler)

When the forward button is clicked.

Availability:	JavaScript –1.3 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myObject*.onforward = *aHandler*
HTML syntax:	`<HTMLTag onForward="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event

This event is called when the user interacts with the browser. Some events like this are helpful for blocking the operation of certain browser `UI` elements.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBack`, Semantic event, Window events

onHelp (Event handler)

The user has pressed the `[F1]` key or selected `[help]` from the toolbar or menu.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*.onhelp = *aHandler*
HTML syntax:	`<BODY onHelp="..."> <FRAMESET onHelp="...">` `<HTMLTag onHelp="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`A, DIR, LI, STRIKE, ACRONYM, DIV, LISTING, STRONG, ADDRESS, DL, MAP, SUB, Anchor, Document, MARQUEE, SubmitButton, APPLET, DT, MENU, SUP, AREA, EM, OBJECT, TABLE, B, FIELDSET, OL, TBODY, BIG, FileUpload, P, TD, BLOCKQUOTE, FONT, Password, TEXTAREA, BODY, FORM, PLAINTEXT, TextCell, BUTTON, H1, PRE, TFOOT, CAPTION, HR, Q, TH, CENTER, I, RadioButton, THEAD, Checkbox, IMG, ResetButton, TR, CITE, Input, S, TT, CODE, INS, SAMP, U, DD, KBD, Select, UL, DEL, LABEL, SMALL, Url, DFN, LEGEND, SPAN, VAR`	

This handler is invoked if the `[F1]` key is pressed or the `[help]` item is selected from the menu while the `Element` object has the input focus.

This handler is particularly applicable to the <BODY> and <FRAMESET> tags and will be defined for Element objects that correspond to them.

In MSIE, after this event has been handled, the built-in help window will be displayed. This can be suppressed by passing the value false back rather than true. Passing no value back defaults to true.

Warnings:

- On the Macintosh platform, this event is triggered by the [HELP] key and not the [F1] key.

See also:	Element object, Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, Semantic event

onKeyDown (Event handler)

Triggered when a key is pressed.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	-	*myObject*.onkeydown = *aHandler*
HTML syntax:	<A onKeyDown="..."><AREA onKeyDown="..."><BODY onKeyDown="..."><HTMLTag onKeyDown="..."><IMG onKeyDown="..."><INPUT onKeyDown="...">	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	A, DIR, LI, STRONG, ACRONYM, DIV, LISTING, SUB, ADDRESS, DL, MAP, SubmitButton, Anchor, Document, MARQUEE, SUP, APPLET, DT, MENU, TABLE, AREA, EM, OL, TBODY, B, FIELDSET, P, TD,BIG, FileUpload, Password, TEXTAREA, BLOCKQUOTE, FONT, PLAINTEXT, TextCell, BODY, FORM, PRE, TFOOT, BUTTON, H1, Q, TH, CAPTION, HR, RadioButton, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U, CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, LEGEND, STRIKE,	

As the key is pressed down, this event is triggered. If you return the value true, the event will be passed to the browser for further processing. Returning false inhibits this action and discards the message.

In Netscape, the key code of the key that triggered the event is available in the which property of the event object that is passed to the event handler as an argument. The equivalent value in MSIE is available in the keyCode property of the event object referenced by the window.event property.

The key value is the Unicode character code point value which, is a numeric value. This may need to be converted to a character if you want to display it. You can do that with the `String.fromCharCode()` static method which will create a one character string for you.

You may need to determine whether any of the modifier keys were pressed. In Netscape, you retrieve a bitmask value from the `modifiers` property of the `event` object. This can then be masked against the various bit flags available as static properties of the `Event` class.

In MSIE, modifier keys are available with a set of properties, which return the state of each modifier key individually.

In MSIE, you can modify the value of the key that is passed back to the browser by storing a different Unicode code point value in the `returnValue` property of the `Event` object.

Warnings:

- To use key-codes and modifier keys in a portable way, you will need to implement some browser-specific support and then call an appropriate routine according to the browser the script is executing in.
- This is not supported on the WebTV platform.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.altKey, Event.ctrlKey, Event.keyCode, Event.modifiers, Event.returnValue, Event.shiftKey, Event.which`, Handler, JellyScript, Keyboard events, `onKeyPress, onKeyUp`, Semantic event, `String.fromCharCode(),TEXTAREA` object, `TextCell` object

onKeyPress (Event handler)

Pressing the key down and releasing it again triggers this event.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onkeypress = *aHandler*
HTML syntax:	`<A onKeyPress="..."> <AREA onKeyPress="..."> <BODY onKeyPress="..."> <HTMLTag onKeyPress="..."> <IMG onKeyPress="..."> <INPUT onKeyPress="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event

Supported by objects:	A, DIR, LI, STRONG, ACRONYM, DIV, LISTING, SUB, ADDRESS, DL, MAP, SubmitButton, Anchor, Document, MARQUEE, SUP, APPLET, DT, MENU, TABLE, AREA, EM, OL, TBODY, B, FIELDSET, P, TD, BIG, FileUpload, Password, TEXTAREA, BLOCKQUOTE, FONT, PLAINTEXT, TextCell, BODY, FORM, PRE, TFOOT, BUTTON, H1, Q, TH, CAPTION, HR, RadioButton, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U, CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, LEGEND, STRIKE,

This handler is sometimes more appropriate than the `onKeyDown` and `onKeyUp` handlers. They should be used if you want some action to occur on each transition and to indicate by some feedback mechanism to the user that the key is still down.

As the key is pressed down and then released again, this event is triggered. If you return the value `true`, the event will be passed to the browser for further processing. Returning `false` inhibits this action and discards the message.

In Netscape, the key code of the key that triggered the event is available in the `which` property of the `event` object that is passed to the event handler as an argument. The equivalent value in MSIE is available in the `keyCode` property of the event object referenced by the `window.event` property.

The key value is the Unicode character code point value, which is a numeric value. This may need to be converted to a character if you want to display it. You can do that with the `String.fromCharCode()` static method, which will create a one character string for you.

You may need to determine whether any of the modifier keys were pressed. In Netscape, you retrieve a bitmask value from the `modifiers` property of the `event` object. This can then be masked against the various bit flags available as static properties of the `Event` class.

In MSIE, modifier keys are available with a set of properties that return the state of each modifier key individually.

In MSIE, you can modify the value of the key that is passed back to the browser by storing a different Unicode code point value in the `returnValue` property of the `Event` object.

This event was only supported by `TextCell` objects in the WebTV platform from the Summer 2000 release onwards.

Warnings:

- An `onKeyPress` event will also trigger an `onKeyDown` event and an `onKeyUp` event. The `onKeyPress` will not be triggered until the `onKeyUp` occurs. There is no guarantee that the `onKeyUp` will happen before the `onKeyPress` although that is the logical sequence.
- You do not receive a message when a modifier key is held down on its own. However you could sense the state of that as keys are processed. It isn't ideal but may be sufficient.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, JellyScript, Keyboard events, `onKeyDown`, `onKeyUp`, Semantic event, `TEXTAREA` object, `TextCell` object

onKeyUp (Event handler)

Triggered when a key is released.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myObject*.onkeyup = *aHandler*

HTML syntax:	`<AREA onKeyUp="..."> <BODY onKeyUp="...">`
	`<HTMLTag onKeyUp="..."> <IMG onKeyUp="...">`
	`<INPUT onKeyUp="...">`

Argument list:	*aHandler* A reference to a function object to handle the event
Supported by objects:	`A, DIR, LI, STRONG, ACRONYM, DIV, LISTING, SUB, ADDRESS, DL, MAP, SubmitButton, Anchor, Document, MARQUEE, SUP, APPLET, DT, MENU, TABLE, AREA, EM, OL, TBODY, B, FIELDSET, P, TD, BIG, FileUpload, Password, TEXTAREA, BLOCKQUOTE, FONT, PLAINTEXT, TextCell, BODY, FORM, PRE, TFOOT, BUTTON, H1, Q, TH, CAPTION, HR, RadioButton, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U, CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, LEGEND, STRIKE,`

As the key is released, this event is triggered.

In Netscape, the key code of the key that triggered the event is available in the `which` property of the `event` object that is passed to the event handler as an argument. The equivalent value in MSIE is available in the `keyCode` property of the event object referenced by the `window.event` property.

The key value is the Unicode character code point value, which is a numeric value. This may need to be converted to a character if you want to display it. You can do that with the `String.fromCharCode()` static method, which will create a one character string for you.

You may need to determine whether any of the modifier keys were pressed. In Netscape, you retrieve a bitmask value from the `modifiers` property of the `event` object. This can then be masked against the various bit flags available as static properties of the Event class.

In MSIE, modifier keys are available with a set of properties that return the state of each modifier key individually.

In MSIE, you can modify the value of the key that is passed back to the browser by storing a different Unicode code point value in the `returnValue` property of the `Event` object.

Warnings:

- This is not supported on the WebTV platform.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, JellyScript, Keyboard events, `onKeyDown`, `onKeyPress`, Semantic event, `TEXTAREA` object, `TextCell` object

onLoad (Event handler)

Triggered when an object has completed loading.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onload = *aHandler*
HTML syntax:	`<BODY onLoad="aHandler"> <BODY onUnload="aHandler"> <FRAMESET onLoad="aHandler"> <FRAMESET onUnload="aHandler"> <HTMLTag onUnload="aHandler"> <IMG onUnload="aHandler">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, BODY, IMG, LINK, STYLE, AREA, FRAMESET, Layer, SCRIPT, Window`	

This event is associated with `<BODY>` and `<FRAMESET>` tags. It is triggered when either have finished loading.

In the case of a `<BODY>` tag, that is when all images are loaded and any `<APPLET>` or plugin items have started running.

In the case of the `<FRAMESET>` tag, it is when all frames have loaded and arguably should be after all `<BODY>` tags have triggered their `onLoad` events. However, you probably should not rely on the last `<BODY>` `onLoad` event occurring before the `<FRAMESET>` `onLoad` event.

In any case, it would probably be bad form to have too many `onLoad` handlers activated during a page load.

Although it is associated with `<BODY>` and `<FRAMESET>`, the event is owned by the `window` object in the document object model.

Warnings:

- This fails to trigger on images when they are loaded into version 4.0 of MSIE. If you need an `onLoad` trigger for the page then you can trigger from the `<BODY onLoad="...">` HTML tag attribute. At least when the whole page is loaded your image should have loaded. However, even that isn't always reliable.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onAbort, onError, onUnload`, Semantic event, Window events, `Window.onload`, `Window.onunload`

onLoseCapture (Event handler)

Called when capturing is deactivated for an object.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myObject*.onlosecapture = *aHandler*

External event capture control may leave an object in some strange state. You may want to know when event capturing has been removed. This event is triggered when that happens.

See also:	`captureEvents`(), Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Semantic event

onMouseDown (Event handler)

Triggered when the mouse button is pressed.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onmousedown = *aHandler*
HTML syntax:	`<A onMouseDown="..."> <AREA onMouseDown="..."> <BODY onMouseDown="..."><HTMLTag onMouseDown="..."> <IMG onMouseDown="..."> <INPUT onMouseDown="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.

Supported by objects:	A, DIR, LI, STRONG, ACRONYM, DIV, LISTING, SUB, ADDRESS, DL, MAP, SubmitButton, Anchor, Document, MARQUEE, SUP, APPLET, DT, MENU, TABLE, AREA, EM, OL, TBODY, B, FIELDSET, P, TD, BIG, FileUpload, Password, TEXTAREA, BLOCKQUOTE, FONT, PLAINTEXT, TextCell, BODY, FORM, PRE, TFOOT, BUTTON, H1, Q, TH, CAPTION, HR, RadioButton, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U,CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, LEGEND, STRIKE,

As the mouse button is pressed down, this event is triggered. If you return the value `true`, the event will be passed to the browser for further processing. Returning `false` inhibits this action and discards the message.

Netscape indicates which mouse button was pressed in the `which` property of the `event` object that is passed as an argument to the event handler function. MSIE makes the value available in the `button` property of the event object referenced by the `window.event` property.

DOM level 2 classifies this as a `MouseEvent` and specifies that it uses bubbling propagation and can be canceled.

Warnings:

- This is not supported on the WebTV platform.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.button`, `Event.returnValue`, `Event.which`, Handler, JellyScript, Mouse events, `MouseEvent` object, `onClick`, `onDblClick`, `onMouseUp`, `onReset`, `onSelect`, `onSubmit`, Semantic event

onMouseDrag (Event handler)

An event handler for mouse drag operations.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onmousedrag = `*aHandler*
HTML syntax:	`<HTMLTag onMouseDrag="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event

Holding down the mouse button and then moving the mouse across the window will initiate this event.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Mouse events, Semantic event

onMouseMove (Event handler)

Triggered when the mouse pointer is moved.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myObject*.onmousemove = *aHandler*
HTML syntax:	`<HTMLTag onMouseMove="...">`
Argument list:	*aHandler* A reference to a function object to handle the event.
Supported by objects:	`A, DIR, LI, STRONG, ACRONYM, DIV, LISTING, SUB, ADDRESS, DL, MAP, SubmitButton, Anchor, Document, MARQUEE, SUP, APPLET, DT, MENU, TABLE, AREA, EM, OL, TBODY, B, FIELDSET, P, TD, BIG, FileUpload, Password, TEXTAREA, BLOCKQUOTE, FONT, PLAINTEXT, TextCell, BODY, FORM, PRE, TFOOT, BUTTON, H1, Q, TH, CAPTION, HR, RadioButton, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U, CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, LEGEND, STRIKE,`

When you move the mouse, the browser generates mouse move events and sends them to the `Element` object that is under the mouse at that moment. As the mouse reaches the boundary of an element a mouse event out and a mouse over event are generated and directed to the appropriate elements for them to handle.

Netscape does not support this event handler on individual elements. You have to use the `captureEvents()` method that belongs to a window or layer object and then delegate the handling to the handler as you need to.

DOM level 2 classifies this as a `MouseEvent` and specifies that it uses bubbling propagation and can be canceled.

Warnings:

- As a mouse is moved within an element, a large number of mouse move events will be triggered. This can cause problems if your handler carries out a lot of lengthy computation. It can cause severe browser crashing problems if you are creating and destroying objects under the mouse while it is moving.

See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `Layer.captureEvents()`, `Layer.releaseEvents()`, Mouse events, `MouseEvent` object, Semantic event, `Window.captureEvents()`, `Window.releaseEvents()`

onMouseOut (Event handler)

Triggered when the mouse pointer leaves the active area occupied by the `Element` object that represents the object on screen.

Availability:	HTML version –4.0 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onmouseout = *aHandler*
HTML syntax:	`<A onMouseOut="..."> <AREA onMouseOut="..."> <HTMLTag onMouseOut="..."><IMG onMouseOut="..."> <LAYER onMouseOut="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`A, DIR, LEGEND, STRIKE, ACRONYM, DIV, LI, STRONG, ADDRESS, DL, LISTING, SUB, Anchor, Document, MAP, SubmitButton, APPLET, DT, MARQUEE, SUP,AREA, EM, MENU, TABLE, B, FIELDSET, OL, TBODY, BIG, FileUpload, P, TD, BLOCKQUOTE, FONT, Password, TEXTAREA, BODY, FORM, PLAINTEXT, TextCell, BUTTON, H1, PRE, TFOOT, CAPTION, HR, Q, TH, CENTER, I, RadioButton, THEAD, Checkbox, IMG, ResetButton, TR, CITE, Input, S, TT, CODE, INS, SAMP, U,DD, KBD, Select, UL, DEL, LABEL, SMALL, Url, DFN, Layer, SPAN, VAR`	

When you move the mouse, the browser generates mouse move events and sends them to the `Element` object that is under the mouse at that moment. As the mouse reaches the boundary of an element a mouse out event and a mouse over event are generated and directed to the appropriate elements for them to handle.

DOM level 2 classifies this as a `MouseEvent` and specifies that it uses bubbling propagation and can be canceled.

Warnings:

- You may need to implement some code for this handler to reset the status line after changing it with an `onMouseOver` event handler. That would be necessary for Netscape 2.0 and 3.0 on the Windows platform.
- As a mouse is moved over an element, an entry event is triggered. It can cause severe browser crashing problems if you are creating and destroying objects under the mouse while it is moving. In particular, the destruction of an object can mean that the mouse out has no logical destination since it must somehow leave the element it entered.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Mouse events, `MouseEvent` object, `onMouseOver`, Semantic event, Status line, `Window.defaultStatus`, `Window.status`

onMouseOver (Event handler)

Triggered when the mouse pointer enters the active area owned by the object.

Availability:	HTML version –4.0 JavaScript –1.0 JScript –1.0 Internet Explorer –3.0 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.onmouseover = `*aHandler*
HTML syntax:	`<A onMouseOver="..."> <AREA onMouseOver="..."> <HTMLTag onMouseOver="..."> <IMG onMouseOver="..."> <LAYER onMouseOver="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`A, DIR, LEGEND, STRIKE, ACRONYM, DIV, LI, STRONG, ADDRESS, DL, LISTING, SUB, Anchor, Document, MAP, SubmitButton, APPLET, DT, MARQUEE, SUP, AREA, EM, MENU, TABLE, B, FIELDSET, OL, TBODY, BIG, FileUpload, P, TD, BLOCKQUOTE, FONT, Password, TEXTAREA, BODY, FORM, PLAINTEXT, TextCell, BUTTON, H1, PRE, TFOOT, CAPTION, HR, Q, TH, CENTER, I, RadioButton, THEAD, Checkbox, IMG, ResetButton, TR, CITE, Input, S, TT, CODE, INS, SAMP, U, DD, KBD, Select, UL, DEL, LABEL, SMALL, Url, DFN, Layer, SPAN, VAR`	

As the mouse moves over the object, this event is triggered. Normally, passing over a link will display its value in the status bar. You can inhibit this behavior by returning the Boolean `true` value leaving the status line unchanged. Returning `false` allows the browser to overwrite the status line with the URL value of the link.

DOM level 2 classifies this as a `MouseEvent` and specifies that it uses bubbling propagation and can be canceled.

Warnings:

- You may need to implement an `onMouseOut` handler to clear the status line again if you used this event handler to display a message in the status line. That would be necessary in particular for Netscape 2.0 and 3.0 on the Windows platform.
- Be sure to set the Boolean return value correctly to either allow or deny the browser permission to perform its normal default behavior on return from the event handler.
- As a mouse is moved over an element, an entry event is triggered. It can cause severe browser crashing problems if you are creating and destroying objects under the mouse while it is moving. In particular, the destruction of an object can mean that the mouse out has no logical destination since it must somehow leave the element it entered.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Mouse events, `MouseEvent` object, `onMouseOut`, Semantic event, Status line, `Window.defaultStatus, Window.status`

onMouseUp (Event handler)

Triggered when the mouse button is released.

Availability:	HTML version –4.0 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera browser –3.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myObject*.onmouseup = *aHandler*
HTML syntax:	`<A onMouseUp="..."> <AREA onMouseUp="..."> <BODY onMouseUp="..."> <HTMLTag onMouseUp="..."> <IMG onMouseUp="..."> <INPUT onMouseUp="...">`
Argument list:	*aHandler* A reference to a function object to handle the event.
Supported by objects:	`A, DIR, LEGEND, STRONG, ACRONYM, DIV, LI, SUB, ADDRESS, DL, LISTING, SubmitButton, Anchor, Document, MAP, SUP, APPLET, DT, MARQUEE, TABLE, AREA, EM, MENU, TBODY, B, FIELDSET, OL, TD,BIG, FileUpload, P, TEXTAREA, BLOCKQUOTE, FONT, Password, TextCell, BODY, FORM, PLAINTEXT, TFOOT, BUTTON, H1, PRE, TH, CAPTION, HR, Q, THEAD, CENTER, I, ResetButton, TR, Checkbox, IMG, S, TT, CITE, Input, SAMP, U,CODE, INS, Select, UL, DD, KBD, SMALL, Url, DEL, LABEL, SPAN, VAR, DFN, Layer, STRIKE,`

As the mouse button is released, this event is triggered. If you return the value `true`, the event will be passed to the browser for further processing. Returning `false` inhibits this action and discards the message.

Netscape indicates which mouse button was pressed in the `which` property of the `event` object that is passed as an argument to the event handler function. MSIE makes the value available in the `button` property of the event object referenced by the `window.event` property.

DOM level 2 classifies this as a `MouseEvent` and specifies that it uses bubbling propagation and can be canceled.

Warnings:

- When you release the mouse button, you get a `MouseUp` raw event and a `Click` semantic event. Be careful that you know you are only calling event handlers once.
- This is not supported on the WebTV platform.

See also:	`Element` object, Event, Event handler, Event model, Event names, `Event` object, `Event.button, Event.returnValue, Event.which`, Handler, JellyScript, Mouse events, `MouseEvent` object, `onClick, onDblClick, onMouseDown, onReset, onSelect, onSubmit`, Semantic event

onMove (Event handler)

The browser window has been moved.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.onmove = `*aHandler*
HTML syntax:	`<BODY onMove="`*aHandler*`"> <FRAMESET onMove="`*aHandler*`"> <HTMLTag onMove="`*aHandler*`">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`Window`	

Moving the browser window usually won't cause any problems. However, if you have some window content that you want to position relative to the screen, or if you want to locate the window at a specific location, perhaps locating it on a grid, this event may be useful.

The event is triggered when a window is moved on the screen to another location.

The handler is registered by defining it with an HTML tag attribute or by assigning a handler function to the property.

The event is also triggered when a window is moved under control of a script with the `moveTo()` or `moveBy()` methods.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Semantic event, Window events, `Window.onmove`

onPaste (Event handler)

Called when a Paste operation is requested by the user.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*`.onpaste = `*aHandler*

This is useful if you want to intercept and possibly block a paste operation where the user may be attempting to paste some external content into a text field. Perhaps you do want to let them do it but you want to be sure the contents are checked for data integrity.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onCopy, onCut`, Semantic event

onPropertyChange (Event handler)

Called when a property belonging to the receiving object is changed.

Availability:	JScript –5.0 Internet Explorer –5.0	
JavaScript syntax:	IE	*myObject*.onpropertychange = *aHandler*

This is part of the property monitoring facilities. It can be used as an alternative to the `watch()/unwatch()` facilities in Netscape.

When this event is triggered, the handler can inspect the `event` object to determine what property was changed and on what object.

The object affected is returned in the `srcElement` property and the property in its `propertyName` property.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.propertyName`, `Event.returnValue`, `Event.srcElement`, Handler, Semantic event, `unwatch()`, `watch()`

onReadyStateChange (Event handler)

An object in the window has changed its ready state.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*.onreadystatechange = *aHandler*
HTML syntax:	`<HTMLTag onReadyStateChange="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, Document, OBJECT, STYLE, AREA, LINK, SCRIPT,`	

This event fires when the state of the object has changed.

Some objects may need to be completely loaded before you can properly interact with them. This is a means of getting a call-back when the ready state of an object changes. It saves the need for watching the `readyState` in a polling loop, which is wasteful of resources and a generally deprecated technique.

See also:	`Document.readyState`, `Element.readyState`, `Embed.readyState`, Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `IMG.readyState`, `LINK.readyState`, `OBJECT.readyState`, `SCRIPT.readyState`, Semantic event, `STYLE.readyState`, `XML.event`

onReset (Event handler)

The user has clicked a reset button in a form.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onreset = *aHandler*
HTML syntax:	`<FORM onReset="..."> <HTMLTag onReset="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`FORM`	

As the `<FORM>` reset button is clicked, this event is triggered. If you return the value `true`, the event will be passed to the browser for further processing and the form will be reset. Returning `false` inhibits this action and discards the message, and the form will not be reset. This provides a means of inhibiting `<FORM>` resets altogether.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onClick, onMouseDown, onMouseUp, onSubmit`, Semantic event

onResize (Event handler)

As the window is resized, this event is triggered.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onresize = *aHandler*
HTML syntax:	`<BODY onResize="`*aHandler*`"> <FRAMESET onResize="`*aHandler*`"> <HTMLTag onResize="`*aHandler*`">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, FIELDSET, MARQUEE, Input, AREA, FRAMESET, Select, TD, BUTTON, IMG, TABLE, Window, DIV, , ,`	

Moving or resizing windows may be something your scripts will need to know about. A move is generally harmless, but a resize may not be so benign to your page content. This event trigger provides a means to fix up the display if the window aspect ration or size is changed.

This event is triggered when a window is enlarged or reduced in size.

The handler is registered by defining it with an HTML tag attribute. The handler can also be registered by assigning the `function` object to the `onresize` property of the window.

The event is also triggered when a window is resized under control of a script with the `resizeTo()` or `moveBy()` methods.

Warnings:

- There are numerous issues with `onResize` events in Netscape 4.0. In particular, an `onResize` causes Netscape to "forget" positioning information for `<LAYER>` objects and absolutely positioned `<DIV>` blocks.
- This could be fixed by simply making this assignment:

```
self.onresize = self.reload;
```

- This attaches a reload call to the resize event handler. However registering event handlers in this way on Netscape prior to version 6.0 has proven to be inconsistent. In this particular case it will cause a browser-crashing endless loop.
- The crashing only happens on some versions of Netscape 4.0. The problem is caused because the `resize` event handler will fire a second `Resize` event when the window scrollbars are drawn once the page is loaded –odd behavior. We've sat in front these browsers for years now and watched Netscape draw a page, then realize it can't fit all the content in and so decide it needs scroll bars and draw it all again. However, up until recently we never realized that an `onResize` was being triggered as well –if only we had a generic event watcher of some kind so we could see what is going on behind the scenes!
- Anyway, the example suggests a fix and was provided by Jon Stephens. This demonstrates other subtle and neat tricks such as storing persistent values as member properties of the function object itself.

Example code:

```
// This checks to see if the window's dimensions have
// actually changed (because Netscape often fires a
// false onResize event when it forms scrollbars);
// if the dimensions have changed, the document is
// reloaded.
// Note that document.location is not supposed to be
// settable, but here's another case where the
// implementation does not match the specs.
function resizeFix()
{
   if((document.resizeFix.initWidth  != window.innerWidth)
||(document.resizeFix.initHeight != window.innerHeight))
   {
      document.location = document.location;
   }
}

// This function checks to see if the browser supports the
// Layer object (i.e., Netscape 4.X);
// If it does, then it creates a new object with properties
// to hold the current window width & height and assigns
// the resizeFix() function to the window's onResize event.
function checkBrowser()
```

```
{
   if(document.layers)
   {   if(typeof document.fix == "undefined")
       {
           document.resizeFix = new Object();
           document.resizeFix.initWidth  = window.innerWidth;
document.resizeFix.initHeight = window.innerHeight;
       }
       window.onresize = resizeFix;
   }
}

// This calls the browser check function above
checkBrowser();
```

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, Semantic event, Window events, `Window.onresize`

onRowEnter (Event handler)

The data in a field bound to a data source is about to be changed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onrowenter = `*aHandler*
HTML syntax:	`<HTMLTag onRowEnter="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, DIV, MARQUEE, TD, AREA, Document, OBJECT, TEXTAREA, BODY, IMG, Select, TH, BUTTON, Input, TABLE,`	

This event is triggered for those data driven systems that need to track row and column changes to the data containers that are associated with a database. It fires to indicate that the current row has changed in the data source and new data values are available on the object.

See also:	Event, Event handler, Event model, Event names, Event object, `Event.returnValue`, Handler, `onRowExit`, Semantic event, `XML` object, `XML.event`

onRowExit (Event handler)

The data in a field bound to a data source has been changed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onrowexit = `*aHandler*
HTML syntax:	`<HTMLTag onRowExit="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`APPLET, DIV, MARQUEE, TD, AREA, Document, OBJECT, TEXTAREA, BODY, IMG, Select, TH, BUTTON, Input, TABLE,`	

This event fires just before the data source control changes the current row in the object.

On exiting from a row, you may want to check the contents and possibly update the database with the changes.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onRowEnter`, Semantic event, `XML` object, `XML.event`

onRowsDelete (Event handler)

Some rows are about to be deleted from the database.

Availability:	JScript –3.0 Internet Explorer –4.0
Property/method value type:	`Boolean primitive`

This event fires when rows are about to be deleted from the recordset. You may want to intercept this event and check whether you really do want to delete these rows.

See also:	`XML.event`

onRowsInserted (Event handler)

Some new data is being inserted into the database.

Availability:	JScript –3.0 Internet Explorer –4.0
Property/method value type:	`Boolean primitive`

This event fires just after new rows are inserted in the current recordset. You may want to intercept this event to fix up some relationships in the database to maintain data integrity.

See also:	XML.event

onScroll (Event handler)

The window has been scrolled.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	IE	*myObject*.onscroll = *aHandler*
HTML syntax:	<HTMLTag onScroll="...">	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	BODY, FIELDSET, MARQUEE, Window, CAPTION, IMG, TABLE, DIV, LEGEND, TEXTAREA,	

Scrolling windows is usually harmless. However, you might have some window content that want to remain visible after the window has scrolled. Perhaps you have some navigation objects placed in a layer that you want to leave positioned where it was regardless of the window scroll position.

See also:	Event, Event handler, Event model, Event names, Event object, Event.returnValue, Handler, Semantic event, Window events

onSelect (Event handler)

Some textual content in the window has been selected.

Availability:	JavaScript –1.0 JScript –3.0 Internet Explorer –4.0 Netscape –2.0 Opera browser –3.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	-	*myObject*.onselect = *aHandler*
HTML syntax:	<HTMLTag onSelect="...">	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	CAPTION, FileUpload, RadioButton, TEXTAREA, Checkbox, Input, ResetButton, TextCell, FIELDSET, Password, SubmitButton,	

Selecting text in the window may be a precursor to a cut or paste operation. If the elements are able to support TextRanges, then you may want to receive a trigger when a text selection occurs.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onClick, onMouseDown, onMouseUp, onSelectStart`, Semantic event

onSelectStart (Event handler)

A select action is beginning.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onselectstart = `*aHandler*
HTML syntax:	`<HTMLTag onSelectStart="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event.
Supported by objects:	`A, DIV, LI, SUB, ACRONYM, DL, LISTING, SUP, ADDRESS, Document, MARQUEE, TABLE, Anchor, DT, MENU, TBODY, B, EM, OBJECT, TD, BIG, FIELDSET, OL, TEXTAREA, BLOCKQUOTE, FONT, P, TFOOT, BODY, FORM, PLAINTEXT, TH, BUTTON, H1, PRE, THEAD, CAPTION, HR, Q, TR, CENTER, I, S, TT, CITE, IMG, SAMP, U, CODE, Input, Select, UL, DD, INS, SMALL, Url, DEL, KBD, SPAN, VAR, DFN, LABEL, STRIKE, , DIR, LEGEND, STRONG,`	

At the commencement of a selection, this event is triggered. This allows you to do some animation or perhaps draw a bounding rectangle while the selection takes place.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onSelect,` Semantic event

onStart (Event handler)

Fires when a `MARQUEE` element is beginning its loop.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myObject*`.onstart = `*aHandler*
HTML syntax:	`<HTMLTag onStart="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`MARQUEE`	

A `MARQUEE` element provides a suite of events that allow you to attach all manner of event driven animations and wizzy effects to them. This event is triggered when the `MARQUEE` starts its loop.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBounce, onFinish, onStop`, Semantic event

onStop (Event handler)

Called when the user stops a page loading.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myObject*`.onstop = `*aHandler*

This event is called when the user halts the page loading with the stop button on the toolbar.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onBounce, onFinish, onStart`, Semantic event

onSubmit (Event handler)

The user has clicked on the submit button in a form.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –3.0 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*`.onsubmit = `*aHandler*
HTML syntax:	`<FORM onSubmit="..."> <HTMLTag onSubmit="...">`	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`FORM`	

As the `<FORM>` submit button is clicked, this event is triggered. If you return the value `true`, the event will be passed to the browser for further processing and the form will be submitted. Returning `false` inhibits this action and discards the message, the form will not be submitted. This provides a means of inhibiting `<FORM>` submits when the form data is bad.

You can later on call the `submit()` method to send the form content back to the server.

Note that the `submit()` method will not trigger an `onSubmit` event.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, `onClick, onMouseDown, onMouseUp, onReset`, Semantic event

onUnload (Event handler)

Triggered when the document is unloaded.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myObject*.onunload = *aHandler*
HTML syntax:	<BODY onUnload="*aHandler*"> <FRAMESET onUnload="*aHandler*"> <HTMLTag onUnload="*aHandler*">	
Argument list:	*aHandler*	A reference to a function object to handle the event
Supported by objects:	`BODY, Layer, SCRIPT, Window, FRAMESET, LINK, STYLE,`	

The `onUnload` event is triggered for a `<BODY>` or `<FRAMESET>` tag when the page is about to disappear and be replaced with another. You should avoid doing anything lengthy or complex here –it should just be used to do some cleaning up.

It is considered bad technique to place an alert or any other dialog in the `onUnload` handler. It is also bad manners to tie the processing up in a lengthy piece of script execution at this stage.

You might use the `unLoad` handler to remove any values you put into the window status bar.

Although this is a tag attribute that is applied to the `<BODY>` tag, it is really associated with the `Window` object in which the document body is loaded.

Warnings:

- This is not supported on the WebTV platform.

See also:	Event, Event handler, Event model, Event names, `Event` object, `Event.returnValue`, Handler, JellyScript, `onBeforeUnload`, `onLoad`, Semantic event, Window events, `Window.onunload`

open() (Method)

An alias for the `window.open()` method.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Window` object	
JavaScript syntax:	-	*myWindow*.open()
	-	*myWindow*.open(*aURL*)
	-	*myWindow*.open(*aURL*, *aName*)
	-	*myWindow*.open(*aURL*, *aName*, *aFeatureList*)
	-	*myWindow*.open(*aURL*, *aName*, *aFeatureList*, *aFlag*)
	-	open()
	-	open(*aURL*)
	-	open(*aURL*, *aName*)
	-	open(*aURL*, *aName*, *aFeatureList*)
	-	open(aURL, *aName*, *aFeatureList*, *aFlag*)
Argument list:	*aFeatureList*	A list of attributes for the new window
	aFlag	A flag to indicate how the history list is to be modified
	aName	The name of a new or existing target window
	aURL	A URL to load into the window

Refer to:

`Window.open()`

opener (Property)

An alias for the `window.opener` property.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera browser –3.0	
Property/method value type:	`Window` object	
JavaScript syntax:	-	*myWindow*.opener
	-	opener

Property attributes:

`ReadOnly.`

Refer to:

`Window.opener`

OpenTV (TV Set-top Box)

An interactive TV set-top box environment.

At present this system does not support HTML or JavaScript. However, there is a growing trend among TV set-topbox manufacturers to provide integrated web browsing.

Because the developer environment for this system is based on the C language, it is theoretically possible to download a minimal HTML and JavaScript browser into the set-top box. There would be major considerations regarding bandwidth requirements for such an application but it could be done.

As the set-top boxes become more sophisticated, expect this kind of functionality to become commonplace. It becomes even more likely with the advent of large hard disk caches and more powerful CPUs driving the set-top box.

See also:	Interpret, Platform, Script execution, TV Set-top boxes, Web browser

Opera (Web browser)

A web browser alternative to MSIE and Netscape.

The Opera web browser is an alternative browser to the Netscape and MSIE browsers on the Windows platform. It is highly standards-based, and as a result has gained much respect. However, because many pages do not contain strictly standard content, you should quality-check your site on this browser to ensure its compliance. Using Opera as a reference browser can significantly improve the likelihood of your site continuing to work in the future as all browsers are likely to converge on the functionality embodied in the standards.

Details of what is supported in version 5 can be found at the web reference below.

See also:	ECMA, ECMAScript, Platform, Script execution, Web browser

Web-references:

http:www.opera.com/opera5/

Operator (Definition)

A special symbolic token that when placed adjacent to or between values creates an expression.

Availability:	ECMAScript edition –2

An operator is a token that represents a particular operation to be performed on one or two operands. The combination of operands and operator is called an expression. The operation yields a result, which can be used as an operand in subsequent expressions. Expressions can be nested implicitly according to the precedence rules of the operators, or explicitly by using using the parentheses grouping operator.

Depending on the operators and operands used, side effects may occur. This is particularly likely when function calls are used as operands since a function call can invoke many lines of code.

For example, an expression calling two functions, each of which opens a pop-up browser window would cause two new windows to appear as a side effect every time the expression was evaluated.

Here is a list of all the operators supported by JavaScript:

Operator	Description
!	Logical NOT
!=	NOT equal to
%	Remainder
%=	Remainder and assign to an LValue
&	Bitwise AND
&&	Logical AND
&=	Bitwise AND and assign to an LValue
(	Function argument delimiter and precedence control
)	Function argument delimiter and precedence control
*	Multiply
*=	Multiply and assign to an LValue
+	Add
+	Concatenate string
+	Unary convert the operand to a numeric value.
++	Increment LValue
+=	Add and assign to an LValue
,	Argument delimiter
-	Subtract
-	Unary negate the value
--	Decrement LValue

Table continued on following page

Operator	Description
`-=`	Subtract and assign to an LValue
`.`	Property accessor
`/`	Divide
`/=`	Divide and assign to an LValue
`:`	Part of conditional operator
`;`	Empty statement
`<`	Less than
`<<`	Bitwise left shift
`<<=`	Bitwise shift left and assign to an LValue
`<=`	Less than or equal to
`=`	Simple assignment to an LValue
`==`	Equal to
`===`	Identity
`>`	Greater than
`>=`	Greater than or equal to
`>>`	Bitwise shift right
`>>=`	Bitwise shift right and assign to an LValue
`>>>`	Bitwise shift right (unsigned)
`>>>=`	Bitwise shift right (unsigned) and assign to an LValue
`?`	Conditional operator
`[`	Array index delimiter
`]`	Array index delimiter
`^`	Bitwise XOR (exclusive OR)
`^=`	Bitwise exclusive XOR and assign to an LValue
`delete`	Used to delete a property from an object if it can be deleted
`false`	Boolean constant
`new`	Invokes an object constructor
`true`	Boolean constant
`typeof`	Determines the type of an evaluation or value
`void`	Regardless of the result of evaluating the expression that may be operated on, this will always yield the undefined value
`{`	Start code block
`|`	Bitwise inclusive OR
`|=`	Bitwise inclusive OR and assign to an LValue
`||`	Logical OR
`}`	End code block
`~`	Bitwise complement (NOT)

Refer to the Operator Precedence topic for details of the order in which operators and their expressions are evaluated in complex lines of code. This is sometimes light-heartedly referred to as "who's on first".

See also:	Additive operator, Assignment operator, Associativity, Binary operator, Bitwise operator, Cast operator, Equality operator, Expression, Grouping operator ( ), Lexical element, Logical operator, Mathematics, Multiplicative operator, Operator Precedence, Postfix operator, Prefix operator, Punctuator, `typeof`, Unary operator, `void`

Cross-references:

Operator Precedence (Definition)

A means of controlling execution priority in expressions.

Availability:	ECMAScript edition –2

The operators below are listed in decending order of precedence. The associativity colum indicates the direction in which items are evaluated.

Operator	Description	Assoc
`()`	Grouping operator	L-R
`[]`	Array index delimiter	L-R
`.`	Property accessor	L-R
`++`	Postfix increment	L-R
`--`	Postfix decrement	L-R
`!`	Logical NOT	R-L
`~`	Bitwise NOT	R-L
`++`	Prefix increment	R-L
`--`	Prefix decrement	R-L
`-`	Negate operand	L-R
`delete`	Delete a property from an object	R-L
`new`	Invokes an object constructor	R-L
`typeof`	Determines the type of a value	R-L
`void`	Always yields the undefined value	R-L
`*`	Multiply	L-R
`/`	Divide	L-R
`%`	Remainder	L-R
`+`	Convert the operand to a numeric value	L-R
`+`	Add	L-R
`-`	Subtract	L-R

Table continued on following page

Operator	Description	Assoc
`+`	Concatenate string	L-R
`<<`	Bitwise shift left	L-R
`>>`	Bitwise shift right	L-R
`>>>`	Bitwise shift right (unsigned)	L-R
`<`	Compare less than	L-R
`<=`	Compare less than or equal to	L-R
`>`	Compare greater than	L-R
`>=`	Compare greater than or equal to	L-R
`in`	Property is in object	L-R
`instanceof`	Object is instance of another object	L-R
`==`	Compare equal to	L-R
`!=`	Compare NOT equal to	L-R
`===`	Compare identically equal to	L-R
`!==`	Compare identically NOT equal to	L-R
`&`	Bitwise AND	L-R
`^`	Bitwise XOR	L-R
`|`	Bitwise OR	L-R
`&&`	Logical AND	L-R
`||`	Logical OR	L-R
`?:`	Conditional execution	R-L
`=`	Assign	R-L
`*=`	Multiply and assign	R-L
`/=`	Divide and assign	R-L
`%=`	Remainder and assign	R-L
`+=`	Add and assign	R-L
`-=`	Subtract and assign	R-L
`<<=`	Bitwise shift left and assign	R-L
`>>=`	Bitwise shift right and assign	R-L
`>>>=`	Bitwise shift right (unsigned) and assign	R-L
`&=`	Bitwise AND and assign	R-L
`|=`	Bitwise inclusive OR and assign	R-L
`^=`	Bitwise XOR and assign	R-L
`,`	Argument delimiter	L-R
`;`	Empty statement	L-R
`{ }`	Delimit code block	L-R

OptGroupElement object (Object/HTML)

A means of grouping options together into logical sets.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myOPTGROUP = myDocument.all.anElementID`
	IE	`myOPTGROUP = myDocument.all.tags("OPTGROUP")[anIndex]`
	IE	`myOPTGROUP = myDocument.all[aName]`
	-	`myOPTGROUP = myDocument.getElementById(anElementID)`
	-	`myOPTGROUP = myDocument.getElementsByName(aName)[anIndex]`
	-	`myOPTGROUP = myDocument.getElementsByTagName("OPTGROUP")[anIndex]`
HTML syntax:	`<OPTGROUP> ... </OPTGROUP>`	
Argument list:	*anElementID*	The `ID` value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Object properties:	`disabled, label`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`disabled`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`label`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onHelp	-	5.0 +	-	5.0 +	-	-	-	Warning
onKeyDown	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onKeyPress	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onKeyUp	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onMouseDown	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onMouseMove	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.5 +	5.0 +	6.0 +	5.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

OptGroupElement.disabled (Property)

A switch for activating or deactivating a grouped option set.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`.myOptGroupElement`*`.disabled`

OptGroupElement.label (Property)

A label that is applied to a group of options.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myOptGroupElement`*`.label`

Option object (Object/HTML)

One of a set of objects belonging to a select object in a form.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
Inherits from:	`Element` object	
JavaScript syntax:	-	*myOption* = *myDocument*.*aFormName*.*aSelectorName*.options[*anIndex*]
	-	*myOption* = *myDocument*.*aFormName*.elements[*anItem*Index].options[*anIndex*]
	IE	*myOption* = *myDocument*.all.*anElementID*
	IE	*myOption* = *myDocument*.all.*anElementID*.elements[*anIndex*].options[*anIndex*]
	IE	*myOption* = *myDocument*.all.*anElementID*.options[*anIndex*]
	IE	*myOption* = *myDocument*.all.tags("OPTION")[*anIndex*]
	IE	*myOption* = *myDocument*.all[*aName*]
	-	*myOption* = *myDocument*.forms[*aFormIndex*].*aSelectorName*.options[*anIndex*]
	-	*myOption* = *myDocument*.forms[*aFormIndex*].elements[*anIndex*].options[*anIndex*]
	-	*myOption* = *myDocument*.getElementById(*anElementID*)
	-	*myOption* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myOption* = *myForm*.*aSelectorName*.options[*anIndex*]
	-	*myOption* = *myForm*.*elements*[*anItem*Index].options[*anIndex*]
	-	*myOption* = *myOptionsArray*[*anIndex*]
	-	*myOption* = *mySelector*.options[*anIndex*]
	-	*myOption* = *myDocument*.getElementsByTagName("OPTION")[*anIndex*]
HTML syntax:	`<OPTION> ... </OPTION>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	anItemIndex	A valid reference to an item in the collection
	aName	The name attribute of an element
	aFormIndex	A reference to a particular form in the forms collection
	anElementID	The `ID` attribute of an element
Object properties:	`defaultSelected, form, index, label, prototype, selected, text, value`	

Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`

In Netscape, this sub-class of the Input object supports a couple of properties that may not be available on other platforms.

The DOM level 1 specification calls this object type an `OptionElement` object.

Warnings:

- In Netscape, this object is easy to confuse with the `Select` object to which the options belong. Be careful to maintain the correct structural relationship between `Select` popup menus and their option sets.
- Netscape 6.0 PR3 exhibited some instabilities in the support of this object; however, it is not certain whether the bug is still outstanding on the final release as well. The problem seemed related to the creation of new `Option` objects by means of the constructor. This is not something that everyone is going to be doing on all their pages so its not likely to be a show stopper unless its just that one thing you need to use.

See also:	`Form.elements[]`, Input object, `OptionsArray` object, `response.getOptionValue()`, `response.getOptionValueCount()`, `Select` object

Property	JavaScript	JScript	N	IE	Opera	NES	DOM	HTML	Notes
`defaultSelected`	1.1 +	1.0 +	3.0 +	3.02 +	3.0 +	2.0 +	1 +	-	-
`form`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	2.0 +	1 +	-	Warning
`index`	1.0 +	1.0 +	2.0 +	3.02 +	-	-	-	-	ReadOnly
`label`	1.5 +	-	6.0 +	-	-	-	1 +	-	-
`prototype`	1.0 +	1.0 +	2.0 +	3.02 +	-	2.0 +	-	-	Warning
`selected`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	2.0 +	1 +	-	-
`text`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	2.0 +	1 +	-	ReadOnly
`value`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	2.0 +	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	NES	DOM	HTML	Notes
`onClick`	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	-	4.0 +	Warning
`onDblClick`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	-	Warning
`onKeyDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning
`onKeyPress`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning
`onKeyUp`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning
`onMouseDown`	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	NES	DOM	HTML	Notes
onMouseMove	1.2 +	3.0 +	4.0 +	4.0 +	-	-	-	4.0 +	Warning
onMouseOut	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

Option() (Constructor)

An Option object constructor.

Availability:	JavaScript –1.1 Netscape –3.0	
JavaScript syntax:	N	`new Option`
	N	`new Option()`
	N	`new Option(`*`aValue`*`)`
Argument list:	*`aValue`*	An initial value for the new option object

You can dynamically create new `option` objects and add them to the `options` array belonging to a `Select` object in a form.

See also:	Constructor function, constructor property, Garbage collection, Memory leak, Reference counting, `Select.options[]`

Option.defaultSelected (Property)

The selected state of this item when the form was created.

Availability:	DOM level –1 JavaScript –1.1 JScript –1.0 Internet Explorer –3.02 Netscape –3.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`myOption`*`.defaultSelected`

This is a Boolean value that indicates whether the `<OPTION>` tag in the HTML document source has the `SELECTED` HTML tag attribute present or not. Only one of the `<OPTION>` tags in a `<SELECT>` block should have the `SELECTED` attribute, unless multiple sections are allowed.

You can refer to this value in the form checking script to see if the value of the select block has been changed since the page was loaded.

Option.index (Property)

The index position within the select object set.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myOption*.index

When you define `<OPTION>` tags within a `<SELECT>` block, they instantiate objects to represent each option. These are then made available as members of a collection belonging to the `Select` object and accessible via its `options[]` property.

This property indicates the position of this `Option` object within that collection. The first `Option` object in the collection is located at index position zero. Note that modifying the set of objects in this collection can cause the index numbers of an option to change.

See also:	`Select.options[]`

Property attributes:

`ReadOnly`.

Option.label (Property)

The text string that the user sees in the popup menu. This is another name for the `Option.text` property.

Availability:	DOM level –1 JavaScript –1.5 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myOption*.label

Refer to:

`Option.text`

Option.prototype (Property)

The prototype for the `Option` object that can be used to extend the interface for all `Option` objects.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0	
Property/method value type:	`Option` object	
JavaScript syntax:	-	`Option.prototype`
	-	*`myOption`*`.constructor.prototype`

Warnings:

- Of all the objects supported by MSIE, this is the only one to provide an enumerable property that points at the prototype for the object. This is likely to be a bug in the enumeration flag settings for the `Option` object type.

See also:	`prototype` property

Option.selected (Property)

The selected state of this option item.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`myOption`*`.selected`

This is the current selected state of the option item. If the user has not interacted with the parent `Select` object, this value will be the same as its initial `defaultSelected` value. If the user has chosen an alternative item from the collection, then this property will be set accordingly.

Option.text (Property)

The text string that the user sees in the popup menu.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOption*.text

Option items have a textual value enclosed between the opening and closing tags. This is a means of accessing that text without needing to resort to complex `innerText` or `innerHTML` tricks.

Property attributes:

`ReadOnly.`

Option.value (Property)

The text value that is returned to the server if this item is selected.

Availability:	DOM level –1 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server version –2.0 Opera browser –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myOption*.value

The text that the user sees is not necessarily the same as that sent back when the form is submitted. Some degree of normalization is available so that the user may see a text string but a lookup mechanism can replace that with a numeric value thereby saving some work in the server.

See also:	`Input.value`

OptionElement object (Object/DOM)

One of a set of objects belonging to a select object in a form.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
JavaScript syntax:	-	*myOptionElement* = new OptionElement()

Refer to:

`Option` object

OptionsArray object (Object/browser)

A collection object that belongs to a select popup.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
JavaScript syntax:	-	*myOptionsArray* = *mySelector*.options
Object properties:	length	
Object methods:	add(), item(), remove(), select()	

Warnings:

- Netscape 6.0 implements this in a DOM-compliant manner. That means the object type is an `HTMLCollection` object. This is a generic object type and there are no special methods or properties added to it. The things you might have done with an `OptionsArray` object are not going to work.
- MSIE appears to implement this as a `NodeList` although you cannot tell because it doesn't make a constructor or prototype available for you to inspect.

See also:	`Collection` object, `Option` object, `Select` object, `Select.options[]`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
length	1.0 +	1.0 +	2.0 +	3.02 +	-	-	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`add()`	-	3.0 +	-	4.0 +	-	-	-
`item()`	-	3.0 +	-	4.0 +	-	-	-
`remove()`	-	3.0 +	-	4.0 +	-	-	-
`select()`	-	3.0 +	-	4.0 +	-	-	-

OptionsArray.add() (Method)

Adds a new option item to a select popup object.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*myOptionsArray*.add(*anObject*)
	IE	*myOptionsArray*.add(*anObject*, *anIndex*)
Argument list:	*anObject*	An object to be added to the collection
	anIndex	The index position at which it should be added

You can use this method call to add a new item to a list of options belonging to a `Select` object. This would be manifested to the user as a new item being visible when the select menu is popped onto the display.

OptionsArray.item() (Method)

Access to a particular item in the options collection of a select popup object.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Option` object	
JavaScript syntax:	IE	*myOptionsArray*.item(*anIndex*)
	IE	*myOptionsArray*.item(*aSelector*)
	IE	*myOptionsArray*.item(*aSelector*, *anIndex*)
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Because the `OptionsArray` is a sub-class of the generic `Collection` object, all the normal things you can do with a collection are possible with an `OptionsArray` belonging to a `Select` object.

See also:	`Collection.Item()`

OptionsArray.length (Property)

The number of options in a select popup.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myOptionsArray`*`.length`

Property attributes:

`ReadOnly.`

Refer to:

`Collection.length`

OptionsArray.remove() (Method)

Removes an option from the collection belonging to a `select` popup object.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myOptionsArray`*`.remove(`*`anIndex`*`)`
Argument list:	*`anIndex`*	A zero-based index into the collection

This should affect the display causing the popup at least to be refreshed. Manipulating the popup contents in this way may be useful and is particularly appropriate if you have two popups, one of which is a secondary selector whose available choices depend on the settings of the first.

OptionsArray.select() (Method)

Select an item in an options array belonging to a select popup object.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	*`myOptionsArray`*`.select()`

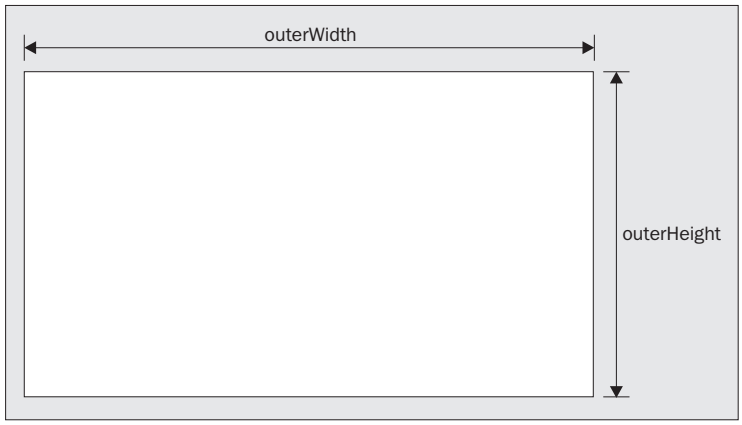
Behaves as if the user had selected an item. This should highlight the item in the popup's usual user interface feedback manner and should set the appropriate values in the properties of the previously selected and freshly selected `Option` objects.

See also:	`Input.select()`

outerHeight (Property)

An alias for the `window.outerHeight` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myWindow*`.outerHeight`
	-	`outerHeight`



Property attributes:

`ReadOnly.`

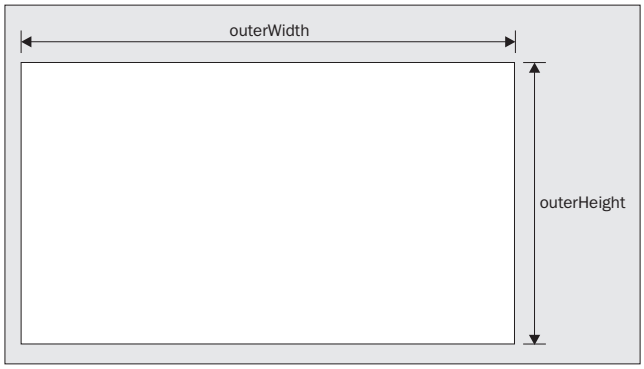
Refer to:

`Window.outerHeight`

outerWidth (Property)

An alias for the `window.outerWidth` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`myWindow.outerWidth`
	-	`outerWidth`



Property attributes:

`ReadOnly.`

Refer to:

`Window.outerWidth`

Overview (Background)

JavaScript language and functionality overview.

Availability:	ECMAScript edition –2

JavaScript originally started as a Netscape extension to provide some script-driven dynamic effects within the web page. At this time, Netscape had by far the greater penetration and was much more popular than the MSIE browser.

MSIE rapidly caught up with the scripting functionality and extended it in different directions. In the typically competitive style of the Microsoft company, JScript rapidly became the equal of the Netscape 4.0 browser. However, now it's the turn of Netscape to up the stakes again with the introduction of Netscape 6.0, although Microsoft has a new version of MSIE at the stage of beta testing.

In the two years Netscape has taken in releasing new browser, JavaScript has become standardized through the ECMA organization and has been deployed in a variety of non-browser contexts. It is now part of the fundamental scripting interface in Windows where its duty with the VBScript interpreter lies in automating desktop operations.

JavaScript is now available on Unix platforms as a shell scripting language and in web servers for server-side programming.

More recently, it has been adopted and modified to become WMLScript which is used in WAP-standard mobile phone. Even more recently it is becoming popular in Digital TV set-top box systems as part of the rapid merger of broadcast TV and web content. This is likely to be where JavaScript becomes a fairly dominant tool for developing interactive TV content.

The language continues to evolve and penetrate new markets and systems. The core language has been standardized and several bindings are also reasonably stable through the efforts of the W3C, but there is still much to be done to ensure the language operates consistently across browsers. Now that Netscape and MSIE are implementing the standards-based features in similar ways for the most part, the differences between the two browsers are being squeezed into more esoteric areas such as sidebars and visual transition filters. Events still have some way to go, and it will be a while before DOM-style control is completely supported. There are also several new DOM components in level 2 and extensions in level 3.

See the web reference for the article by Brendan Eich on "*The Birth of JavaScript*".

P object (Object/HTML)

An object that encapsulates a paragraph delimited by a <P> tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0		
Inherits from:	`Element` object		
JavaScript syntax:	IE	*myP* = *myDocument*.*all*.*anElementID*	
	IE	*myP* = *myDocument*.*all*.*tags*("*P*")[*anIndex*]	
	IE	*myP* = *myDocument*.*all*[*aName*]	
	-	*myP* = *myDocument*.*getElementByID*(*anElementID*)	
	-	*myP* = *myDocument*.*getElementsByName*(*aName*)[*anIndex*]	
	-	*myP* = *myDocument*.*getElementsByTagName*("P")[*anIndex*]	
HTML syntax:	<P>,<P> ... </P>		
Argument list:	*anIndex*	A reference to an element in a collection	
	aName	An associative array reference	
	anElementID	The `ID` value of an `Element` object	
Object properties:	`align`		
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`		

The <P> tag is a block-level tag. That means that it forces a line break before and after itself.

The DOM level 1 specification refers to this as a `Paragraph` object.

See also:	`Element` object

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
align	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	1 +	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDblClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onKeyUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseDown	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseMove	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

.align (Property)

The alignment of the paragraph object with respect to its parent object.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myP*.align

The alignment of the `P` object with respect to its containing parent object is defined in this property. The expected and widely available set of alignment specifiers are available:

- `absbottom`
- `absmiddle`

- `baseline`
- `bottom`
- `center`
- `left`
- `middle`
- `right`
- `texttop`
- `top`

.pac (File extension)

Proxy lookup conversion file.

This is a script container for a small and compact JavaScript function that returns a computed value indicating whether to proxy-serve a URL or not.

See also:	Proxies, `proxy.pac`

Packages (Property)

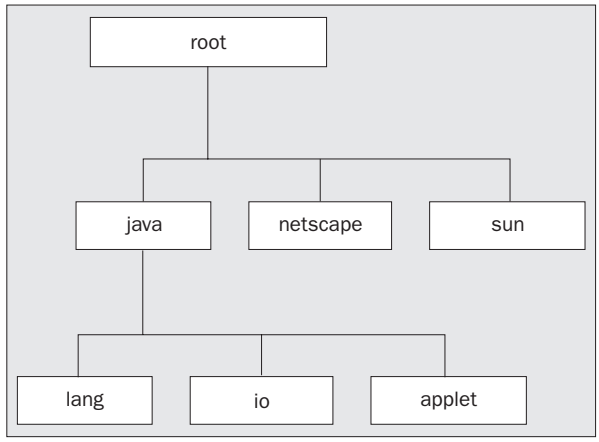
An alias for the `window.Packages` property.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0	
Property/method value type:	`JavaPackage` object	
JavaScript syntax:	N	*`myWindow`*`.Packages`
	N	`Packages`

This property contains a read-only reference to a JavaPackage that sits at the top of the Java package hierarchy, the root node of the tree. A JavaPackage is a container for other JavaPackage objects and JavaClass objects. By default, the Netscape Navigator browser will have three packages belonging to this top-level node (java, sun, and Netscape), and these will contain other packages. There may be additional externally, supplied packages over and above these three default items.

It is understandable that Microsoft does not go very far with support for Java other than being able to run a Java applet. There is no access to Java packages directly from script in the same way. You can run a Java Applet and interact with that, but its not quite the same thing.

Perhaps because it is so platform-specific, not very many people have explored the use of packages very deeply, even on Netscape Navigator. That seems a shame because within a captive intranet situation, you might be able to accomplish some useful things by creating fragments of very powerful Java code and then calling them from JavaScript. There doesn't seem to be the lengthy start up time that's required to initiate an Applet either.



See also:	`Window.Packages`

Property attributes:

`ReadOnly`.

Packages.java (Java package)

A package containing a collection of generic Java classes maintained as a package.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0

An example of a Package reference is the Java Date class stored in the `java.util` package.

To access this from JavaScript you would use this kind of construction:

```
myJavaClass = Packages.java.util.Date;
```

That mode of access would yield a reference to the Class and would produce a `JavaClass` object in the JavaScript environment. To create an instance and yield an object of that class, use the class as a constructor. Like this:

```
myJavaObject = new Packages.java.util.Date;
```

That would create a `JavaObject` object in the JavaScript environment.

If necessary, you may want to access a collection of Classes, which is called a Package. Here is how to create a JavaScript environment's `JavaPackage` object:

```
myJavaPackage = Packages.java.util;
```

See also:	`JavaClass` object, `JavaObject` object, `JavaPackage` object, `Window.java`

Packages.netscape (Java package)

A package containing a collection of Netscape-defined Java classes maintained as a package.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0

This is a code support for Java applets that use LiveConnect to access JavaScript from within the Java context.

See also:	`JavaClass` object, `JavaObject` object, `JavaPackage` object, `Window.netscape`

Packages.netscape.javascript (Java package)

A package containing support for Java code that needs to integrate with JavaScript via LiveConnect.

Availability:	JavaScript –1.1 Netscape –3.0

Refer to:

Java calling JavaScript

Packages.netscape.plugin (Java package)

A package containing support for applets and plugins that integrate with JavaScript via LiveConnect.

Availability:	JavaScript –1.1 Netscape –3.0
See also:	`Plugin.description` `Plugin` object

Packages.sun (Java package)

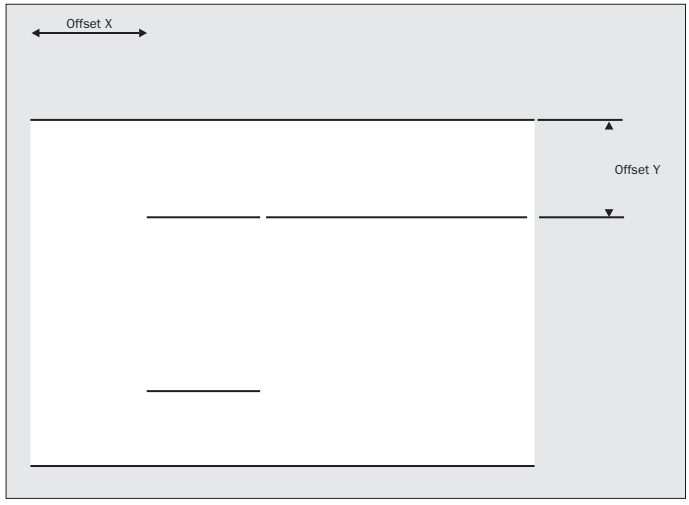
A package containing a collection of Sun Microsystem- defined Java classes maintained as a package. This includes some Sun Java security support as well.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0
See also:	`JavaClass` object, `JavaObject` object, `JavaPackage` object, `Window.sun` Java calling JavaScript

pageXOffset (Property)

An alias for the `window.pageXOffset` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myWindow*`.pageXOffset`
	N	`pageXOffset`



Property attributes:

`ReadOnly`.

Refer to:

`Window.pageXOffset`

pageYOffset (Property)

An alias for the window `pageYOffset` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myWindow*.pageYOffset
	N	pageYOffset

Property attributes:

`ReadOnly`.

Refer to:

`Window.pageYOffset`

ParamElement object (Object/HTML)

An object that encapsulates one of the parameters passed to an `OBJECT` object from its `<PARAM>` tags.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myParam* = *myDocument*.all.*anElementID*
	IE	*myParam* = *myDocument*.all.tags("PARAMETER")[*anIndex*]
	IE	*myParam* = *myDocument*.all.[*aName*]
	-	*myParam* = *myDocument*.getElementByID(*anElementID*)
	-	*myParam* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myParam* = *myDocument*.getElementsByTagName("PARAMETER")[*anIndex*]
HTML syntax:	`<PARAM>`	

Argument list:	*anElementID*	The ID value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Object properties:	name, type, value, valueType	
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp	

This is a new object introduced with the DOM specification. Its full name is HTMLParamElement. It can only exist as a child element within a block structured <OBJECT> tag.

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
name	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
type	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
value	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
valueType	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onDblClick	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onHelp	-	5.0 +	-	5.0 +	-	-	-	Warning
onKeyDown	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onKeyUp	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseDown	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseMove	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseOut	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseOver	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onMouseUp	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning

Inheritance chain:

Element object, Node object

ParamElement.name (Property)

The name of the parameter passed to the OBJECT object.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myParamElement*.name

ParamElement.type (Property)

The type of parameter being passed to an `OBJECT` object when the `valueType` property is set to "`ref`".

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myParamElement.type`*

ParamElement.value (Property)

The data value being passed to the `OBJECT` object in the parameter.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myParamElement`*`.value`

ParamElement.valueType (Property)

The type of the value data that is being passed.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myParamElement`*`.valueType`

Parameter (Definition)

The formal description of a function interface.

The arguments that a function expects to be passed when it is called are described as a set of formal parameters when it is declared.

The parameters are called arguments from within the function when it is executed.

Since JavaScript is weakly data-typed, you do not need to specify the data type of the parameters in the function declaration. Nor are the arguments tested for compliance with any data type when the function is invoked. Rather the values of any arguments are coerced or cast as they are used according to the context in which they are referred to. This makes it very important that you take care with the type and value of parameters you are passing to functions. In particular with numeric and string values.

See also:	Argument, Argument list, `Arguments` object, Definition, Function, `Function` object, `function( ... ) ...`, `Function.arguments[]`, Reserved word, Scope chain

parent (Property)

An alias for the `window.parent` property.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Window` object	
JavaScript syntax:	-	*myWindow*`.parent`
	-	`parent`

Property attributes:

`ReadOnly`.

Refer to:

`Window.parent`

Parentheses ( ) (Delimiter)

A precedence of execution control mechanism.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0

Expression evaluation order is controlled by enclosing expressions in parentheses.

See also:	Grouping operator ( )

Cross-references:

ECMA 262 edition 2 –section –11.1.4

ECMA 262 edition 3 –section –11.1.6

parseFloat() (Function/global)

Parse a string to extract a floating-point value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`parseFloat(`*`aNumericString`*`)`
Argument list:	*`aNumericString`*	A meaningful numeric value

The `parseFloat()` function returns a numeric value, unless the string cannot be resolved to a meaningful value in which case `NaN` is returned instead.

It produces a number value dictated by interpreting the contents of the string as if it were a decimal literal value. During conversion `parseFloat()` ignores leading white space characters so you don't have to remove them from the string before conversion takes place.

Note that `parseFloat()` will only process the leading portion of the string. As soon as it encounters an invalid floating-point numeric character it will assume the scanning is complete. It will then silently ignore any remaining characters in the input argument.

See also:	`Cast` operator, `Global` object, `parseInt()`, String concatenate (+)

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.1.2.3

ECMA 262 edition 3 –section –15.1.2.3

parseInt() (Function/global)

Parse a string to extract an integer value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`parseInt(`*`aNumericString`*`,` *`aRadixValue`*`)`
Argument list:	*`aNumericString`*	A string that comprises a meaningful numeric value
	`aRadixValue`	A numeric value indicating the radix for conversion

The `parseInt()` function produces an integer value dictated by interpreting the string argument according to the specified radix. It can happily cope with hexadecimal values specified with the leading 0x or 0X notation. During conversion `parseInt()` will remove any leading whitespace characters. You don't need to do that to the string before parsing it.

Note also that `parseInt()` may only interpret the leading portion of a string. As soon as it encounters an invalid integer numeric character it will assume the scanning is complete. It will then silently ignore any remaining characters in the input argument.

Typical radix values are:

- 2 –Binary
- 8 –Octal
- 10 –Decimal
- 16 –Hexadecimal

The result of this function call is an integer value, unless the string cannot be resolved to a meaningful value in which case `NaN` is returned instead.

See also:	`Cast` operator, `Function` property, `Global` object, `parseFloat()`, String concatenate (+)

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 2 –section –15.1.2.2

ECMA 262 edition 3 –section –15.1.2.2

Password object (Object/DOM)

A text field in a form that echoes bullets instead of the typed character. Behaves as if it were a text cell but you cannot see what was typed.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Inherits from:	`Input` object
JavaScript syntax:	- *myPassword* = *myDocument*.*aFormName*.*anElementName* - *myPassword* = *myDocument*.*aFormName*.elements[*anItemIndex*] IE *myPassword* = *myDocument*.all.*anElementID* IE *myPassword* = *myDocument*.all.tags("INPUT")[*anIndex*] IE *myPassword* = *myDocument*.all[*aName*] - *myPassword* = *myDocument*.forms[*aFormIndex*].*anElementName* - *myPassword* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*] - *myPassword* = *myDocument*.getElementByID(*anElementID*) - *myPassword* = *myDocument*.getElementsByName(*aName*)[*anIndex*] - *myPassword* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	`<INPUT TYPE="password">`
Argument list:	*anIndex* — A valid reference to an item in the collection *aName* — The `name` attribute of an element *anElementID* — The `ID` attribute of an element *anItemIndex* — A valid reference to an item in the collection *aFormIndex* — A reference to a particular form in the forms collection
Object properties:	`maxLength, readOnly, size, type, value`
Object methods:	`handleEvent(), select()`
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onChange, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onSelect, onSelectStart`

Many properties, methods, and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

Event-handling support via properties containing function objects was added to `Password` objects at version 1.1 of JavaScript.

Some implementations will not allow JavaScript to read the password string that the user has entered. This is good. You might imagine otherwise on the grounds that you'd expect then that JavaScript then won't be able to validate the password. If you think about this for a minute you'll realize that View Source in a web browser exposes your entire security checking regime. Its actually quite sensible to disallow JavaScript from inspecting the password field. But then, all the user has to do is run different browser –one that does access the contents of the password field.

Realistically the validation of the password can only be done back at the server anyway and other than some simple range checking in the client end access to password values from JavaScript is of doubtful use.

See also:	`Element` object, `Form.elements[]`, `FormElement` object, `Input` object, `Input.accessKey`, `onBlur`, `onChange`, `onFocus`, `Password.handleEvent()`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

O'Reilly *JavaScript Definitive Guide* –page –645

Password.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	undefined	
JavaScript syntax:	N	*myPassword*.handleEvent(*anEvent*)
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event-handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent()`, `Password` object

Password.maxLength (Property)

The maximum length allowed for a password entry field.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myPassword*.maxLength

This defines the maximum number of characters that can be entered into the password field. The browsers differ in how they handle this value. Some will warn the user with a beep or flash on the screen, others simply stop accepting keystrokes when this number of characters has been entered.

See also:	`Input.maxLength`, `TextCell.maxLength`

Password.readOnly (Property)

Set to `true` if the Password field cannot be changed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean value`	
JavaScript syntax:	IE	*`myPassword`*`.readOnly`

The password value is defined but cannot be changed by the user. The user should not be able to see the password on the screen; however, you might be able to view source to see the value in the HTML document source. Don't rely on this for hiding passwords in pages and assume that users will discretely ignore them. You might as well publish the password in the page heading.

See also:	`Input.readOnly`, `TEXTAREA.readOnly`, `TextCell.readOnly`

Property attributes:

`ReadOnly`.

Password.select() (Method)

All text in the password text entry cell is selected and can be cut and pasted by the user.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
JavaScript syntax:	-	*`myPassword`*`.select()`

If the browser supports a `Selection` object or `TextRange` objects, you may then be able to access the selected text using JavaScript. Of course in a form object, the text of the whole object can also be accessed but this may not be what was selected because the user may select all or part of a page and that selection may span several form elements or select only part of a form element.

See also:	`Input.select()`, `Selection` object

Password.size (Property)

The width of the password text box measured in characters.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myPassword*`.size`

This is an approximate measure at best. You cannot be sure how wide this box really needs to be when using a proportionally spaced font in it. The browser will size the box close to an optimal size to cope with the specified number of characters.

Warnings:

- It can be quite distracting if the box size is too small to accommodate the `maxLength` number of characters. This can leave the user having to do some cumbersome select actions with the mouse or use arrow keys to reveal the hidden parts of the textual content of the box.

See also:	`Input.size,TextCell.size`

Password.type (Property)

The type value for the `<INPUT>` object that describes the password text entry field in a form.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myPassword*`.type`

The type value for a password input text cell is always "`password`". This value is necessary to determine the type of form element because this object is really an instance of the `Input` class and not the `Password` class. There is actually no `Password` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

Password.value (Property)

The user-entered value for the password text cell.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myPassword*.value

This is the string value that is sent back to the web server when the form is submitted. It is difficult to store script-driven values in this property or to define default values in the HTML document source without revealing the password value to the user. More experienced users will be able to work out any default password values if you hide them.

See also:	`Input.value`

Pattern matching (Definition)

Part of the regular expression support in some implementations of JavaScript.

Refer to:

`RegExp` pattern

PDF (Standard)

A de facto standard for portable documents, which is owned by Adobe Inc.

JavaScript is used inside Acrobat 4.0 as a forms-handling language. This provides a scripting environment in which you can manipulate the form data whose layout is defined by PostScript but whose content can then be 'activated' by JavaScript. There are a few minor limitations imposed due to the fact that Acrobat is not a web browser. There are also several additional objects provided to support the PDF forms environment.

See also:	Host environment, Platform, Script execution

Web-references:

http://www.pdfzone.com/pdfs/PDFSPEC13.PDF

Perl Connect (Product)

A mechanism for communicating between JavaScript and Perl scripts.

This is a means of allowing JavaScript code to call a Perl interpreter from inside the JavaScript environment. It is functionally similar to using the `eval()` method but instead of evaluating JavaScript, some Perl source is passed instead.

Web-references:

http://lxr.mozilla.org/mozilla/source/js/src/perlconnect/README.html

personalbar (Property)

An alias for the `window.personalbar` property.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Bar` object	
JavaScript syntax:	-	*myWindow*`.personalbar`
	-	`personalbar`

See also:	`Bar` object

Property attributes:

`ReadOnly`.

Refer to:

`Window.personalbar`

Pitfalls (Advice)

There are many pitfalls for the unwary in JavaScript.

Although JavaScript is a very forgiving language, over the years it has become large and complex. There are certainly ways in which the unwary can be caught out. Even long experienced script developers are taken unawares from time to time.

We present warning sub-sections summarized under each topic. Several pitfalls are so large as to warrant a topic of their own. These are some examples:

- Accidentally closing `</SCRIPT>` tags within the script itself
- Interpreting punctuation as tags
- Quotes can be a problem
- Hiding scripts from old browsers
- Line breaks in `document.write()` methods
- Browser detection for handling layers

The topic names (and hence their lexical order in this reference) are summarized in the See Also list:

See also:	`</SCRIPT>`, Deprecated functionality, Escaped JavaScript quotes in HTML, Hiding scripts from old browsers, HTML entity escape, JavaScript entity, Newlines are not ` ` tags, Off by one errors

Pixelate() (Filter/transition)

A transition effect with the appearance of a coarse pixelated dissolve.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

filter – `pixelate()`

Pixelate() (Filter/visual)

An effect that simulates the pixelation achieved when lowering the display resolution of an image.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `Pixelate()`

Pkcs11 object (Object/Navigator)

A hitherto undocumented object type supported by Netscape.

Availability:	JavaScript –1.2 Netscape –4.04	
JavaScript syntax:	N	*myPkcs11* = *myWindow*.pkcs11
	N	*myPkcs11* = pkcs11

The `Pkcs11` object is part of the security model built into Netscape Navigator. It is otherwise known as Cryptoki and is provided by RSA Data Security, Inc.

They implement a C language API that has now been mapped to Java as well. According to the Netscape web site, it is not a fully-fledged object-oriented API, but can be readily understood by programmers already familiar with Cryptoki.

According to the release notes, Netscape 4.04 added support for the FORTEZZA PKCS#11 module for making use of the FORTEZZA Crypto Card and FORTEZZA cryptographic algorithms (KEA and Skipjack) when using SSL and S/MIME. Although a link was provided for more details, it appears that the support documents may have been moved or deleted.

See also:	Cryptoki, `Window.pkcs11`

Property attributes:

`ReadOnly`.

Web-references:

http://developer.netscape.com/support/faqs/pkcs_11.html

PLAINTEXT object (Object/HTML)

An object that encapsulates a deprecated `<PLAINTEXT>` tag.

Availability:	JScript –3.0 Internet Explorer –4.0 Deprecated	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myPLAINTEXT* = *myDocument*.all.*anElementID*
	IE	*myPLAINTEXT* = *myDocument*.all.tags("PLAINTEXT")[*anIndex*]
	IE	*myPLAINTEXT* = *myDocument*.all[*aName*]
	-	*myPLAINTEXT* = *myDocument*.getElementByID(*anElementID*)
	-	*myPLAINTEXT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myPLAINTEXT* = *myDocument*.getElementsByTagName ("PLAINTEXT")[*anIndex*]
HTML syntax:	`<PLAINTEXT>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

Platform (Definition)

An environment is built to run on a platform that describes an OS and a hardware configuration.

JavaScript is becoming available on a variety of platforms:

- Web browsers
- TV set-top boxes
- Mobile phones
- Portable documents

Each of these uses JavaScript in a different way, although the core interpreted functionality is the same. Generally the differences will be in the area of the object model they support as part of the host environment. This is added to the core object model defined in the ECMA standard.

Plugin compatibility issues (Definition)

Not all plugins behave the same.

The area where you may experience the most difficulty with plugins is to do with video and media. There are now three major competing technologies and many other minority plugins that can play audio and video.

If you just concentrate on the main players, you still have a lot of work to do. These are:

- Apple QuickTime
- Progressive Networks Real Media
- Windows Media Services

Functionally they are all very similar. Some of the protocols are shared between them and they all deliver multiple streams to a player plugin.

Other plugins that you'll encounter will be:

- Macromedia Shockwave
- Macromedia Flash
- LiveAudio
- Beatnik
- PDF viewer
- VRML viewer

Beyond that, some prefer an `<EMBED>` while others prefer `<OBJECT>` tags. This is platform- and browser-dependant so on one browser a plugin may `<EMBED>` and on another, the same plugin will work best in an `<OBJECT>` tag.

Be aware that using the same plugin in the same browser and implementing it as an `<OBJECT>` or an `<EMBED>` may mean that certain functionality is only available in one or the other.

Given that you have got the plugin working with the correct tag and the features you need are available, the call-back message they use are not the same, nor are the method calls you can make on the plugin. Indeed, for some plugins, you may only be able to talk to them from JavaScript with the very latest version. Older versions simply ignore the JavaScript messages.

Given that you now have your plugin running, in the right tags, and can talk to it, the functionality is different. Some plugins may allow the clip to be played backwards while others won't. Some may let you pause and play with different method calls, while at least one provides only a `play_pause` command. In that scenario, you can play or pause the clip but you won't actually know what state it is in.

Warnings:

- Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the `EMBED` class. In Netscape they are objects commonly referred to as belonging to the `Plugin` class.
- There is additional confusion in that there is a `plugins[]` array that belongs to the document and another than belongs to the navigator object. They both contain collections of objects but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.
- Due to this confusing situation, the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` array. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and, `Embed` objects, will be an instance of a plugin that is alive and running in a document.

See also:	Compatibility, Plugin events

Plugin events (Definition)

The events that are triggered by plugins are commonly referred to as callbacks.

There are basically three kinds of plugins available with web browsers. These are:

- Microsoft `<OBJECT>` tags enclosing ActiveX objects
- Netscape `<EMBED>` tags enclosing browser plugins
- Java `<APPLET>` tags enclosing Java applets

In Netscape Navigator, the LiveConnect mechanisms can run specific functions by name. This callback mechanism is available to `<EMBED>` and `<APPLET>` plugins, but it isn't clear to what extent this is supported by `<OBJECT>` plugins so you may need to experiment with your browser to see what works and what doesn't. Use the `<EMBED>` and `<APPLET>` functionality as a guideline because the plugin handlers are all likely to share some code. Even so, it requires the Java VM (Virtual Machine) to be started for it to work. LiveConnect also requires that the `<APPLET>` tag contains the `MAYSCRIPT` attribute to give the applet permission to communicate with JavaScript.

In MSIE, the callbacks are managed via ActiveX mechanisms. Again, an ActiveX object can call a named JavaScript function.

Warnings:

- The distinctions between these different plugin architectures become increasingly blurred and basically all of their functionality could probably have been provided with a single mechanism had the browser manufacturers worked together more co-operatively and been less concerned with carving out territory and gaining market share at each other's expense.
- Interacting with plugins using JavaScript is possibly one of the least portable and most frustrating things to develop solutions for. The competing plugin suppliers have also utterly failed to develop common API calls for media players such that you need to treat each one as a special case even if you only want to play, pause, and stop video clips under JavaScript control.

- Neither of the mainstream browsers supports the other's chosen technology fully or reliably. It is not uncommon to find MSIE crashes on Windows with <EMBED> style plugins. Netscape Navigator does not support <OBJECT> plugins at all well, and ActiveX code crashes a Macintosh horribly when either browser tries to run it. That's understandable since it's usually X86 machine code and right now Power PC processors don't like it. The latest MSIE version 5.0 for the Macintosh provides a switch to disable ActiveX plugins altogether. Even Microsoft Windows Media Player on Macintosh is supported by way of an <EMBED> tag. Real player is recommended to be used as an <OBJECT> plugin on MSIE for Windows although it mostly works the same as an <EMBED>. There are some JavaScript API calls that are not available in both modes though.
- This means for example to embed video into a page, even with the same kind of video, you basically have to implement four different containers to support MSIE and Netscape on Macintosh and Windows. Given that, there are now other browsers that can cope with plugins. That increases the number of varieties of HTML page content that needs to be created. Now that QuickTime, Windows Media Services and Real Media are all contending for market share, they all require different plugins and that multiplies your problem threefold. Now, it is likely that some of the platform/media combinations will be similar enough to share the same code. Even then, it still leaves you with something like six radically different ways that you will need to construct the plugin container if you want to do anything sophisticated and JavaScript driven.

Cross-references:

Wrox *Instant JavaScript* –page –55

Plugin object (Object/browser)

An object representing a plugin.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	-	*myPlugin* = document.plugins[*anIndex*]
	N	*myPlugin* = navigator.plugins[*anIndex*]
	-	*myPlugin* = *myPluginArray*[*anIndex*]
HTML syntax:	<APPLET><EMBED><OBJECT>	
Argument list:	*anIndex*	A reference to an element in a collection
Object properties:	description, filename, length, name	
Object methods:	isActive(), refresh()	

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the EMBED class. In Netscape Navigator they are objects commonly referred to as belonging to the Plugin class although they are really implemented as JavaObject objects. In MSIE, this is an ActiveX object.

There is additional confusion in that there is a `plugins[]` array that belongs to the document and another than belongs to the navigator object. They both contain collections of objects but of different types. This is further confused by the fact that the `document.plugins[]` array is another name for the `document.embeds[]` array.

Because of this confusing situation the best recommendation is that we refer to `document.embeds[]` and `navigator.plugins[]` and quietly ignore the `document.plugins[]` array. Furthermore we shall refer to `Plugin` objects as being something the browser can use to play embedded content and an `Embed` object will be an instance of a plugin that is alive and running in a document.

Warnings:

- Do not confuse `Plugin` and `Embed` objects with one another. Plugin objects are owned by the `navigator.plugins` array. `Embed` objects are owned by the `document.embeds` array.

See also:	`<EMBED>`, `Collection` object, `Embed` object, `EmbedArray` object, Glue code, Java, `Navigator.plugins[]`, Plugin events, `PluginArray` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`description`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	ReadOnly
`filename`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	ReadOnly
`length`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	Warning, ReadOnly
`name`	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`isActive()`	1.3 +	-	4.7 +	-	-	-	-
`refresh()`	1.1 +	-	3.0 +	-	3.0 +	-	-

Plugin.description (Property)

The descriptive text that a plugin yields when requested to do so.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myPlugin`*`.description`

The content of this string depends on what the plugin developer coded. It might be helpful for debugging and maybe you could present a list of installed plugins to the user. The standardization of the plugin descriptions is likely to be worse than that of the `Navigator.userAgent` string and therefore trying to formulate rules for parsing these descriptions is going to be difficult.

Property attributes:

`ReadOnly`.

Plugin.filename (Property)

The filename that a plugin is stored in.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myPlugin`*`.filename`

This property may help in diagnosing plugins that are not working. If you can find out where in the file system it has installed, you may be able to go and replace it with an up-to-date copy if it is failing to work.

Property attributes:

`ReadOnly`.

Plugin.isActive() (Method)

A means of detecting whether an applet or plugin is still active.

Availability:	JavaScript –1.3 Netscape –4.7	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*`myPlugin`*`.isActive()`

Refer to:

LiveConnect

Plugin.length (Property)

The number of MIME types supported by the plugin.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myPlugin`*`.length`

Warnings:

- Be careful not to confuse this property with the `document.plugins.length` and `navigator.plugins.length` properties.
- The `Plugin.length` property is the number of MIME types that a plugin can respond to.
- The `document.plugins.length` property gives a count of the number of plugins there are embedded into a document.
- The `navigator.plugins.length` property is the number of plugin support modules that are installed and available to the browser.

See also:	`Collection.length`, `PluginArray.length`

Property attributes:

`ReadOnly`.

Plugin.name (Property)

This corresponds to the `NAME` attribute of the tag that contains the plugin.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myPlugin*.name
HTML syntax:	`<EMBED NAME="`*aName*`">`	
Argument list:	*aName*	A name to identify the plugin object

Objects are identified either by the `NAME="..."` HTML tag attribute or by the `ID="..."` HTML tag attribute.

Netscape shows a marginal preference for the `name` property while MSIE seems slightly better disposed towards the `ID` property. However in many cases, both browsers support either technique and in some cases will locate items named with either tag as if they existed in a single namespace.

See also:	`NAME="..."`

Property attributes:

`ReadOnly`.

Plugin.refresh() (Method)

A method to reload the plugin.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0	
JavaScript syntax:	N	*myPlugin*.refresh()

You need to refresh a plugin if you have installed it since the browser was started. This method is sometimes placed in pages that use plugins so that a refresh is forced every time the page is loaded. This is not strictly necessary but has been found to prevent some strange run-time errors in older versions of Netscape Navigator.

PluginArray object (Object/browser)

A collection of plugin modules that the browser can use to playback embedded content.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
JavaScript syntax:	IE	*myPluginArray* = document.plugins
	N	*myPluginArray* = navigator.plugins
Object properties:	length	
Object methods:	item(), refresh()	

Netscape and MSIE encapsulate plugin/embedded objects in a different way. In MSIE they are objects of the EMBED class. In Netscape Navigator they are objects commonly referred to as belonging to the Plugin class although they are really implemented as JavaObject objects. In MSIE, this is an ActiveX object.

There is additional confusion in that there is a plugins[] array that belongs to the document and another than belongs to the navigator object. They both contain collections of objects but of different types. This is further confused by the fact that the document.plugins[] array is another name for the document.embeds[] array.

Due to this confusing situation, the best recommendation is that we refer to document.embeds[] and navigator.plugins[] and quietly ignore the document.plugins[] array. Furthermore we shall refer to Plugin objects as being something the browser can use to play embedded content and an Embed object will be an instance of a plugin that is alive and running in a document.

Warnings:

- Beware of confusion between `document.plugins` and `navigator.plugins`. One relates to the plugins currently used in the document while the other lists the plugins currently available and supported by the browser.
- In Netscape 4.7 for Macintosh, there is a strange enumeration problem. Immediately after starting the Netscape browser, when you enumerate the properties of the `netscape.plugins PluginArray` object, it appears to have no properties at all. If you explicitly ask for the `length` property, you will get a value. During investigation, it returned the value 8 but this will depend on the number of plugins you have installed.
- Now, this suggests that you should be able to access the plugins individually by index number. As soon as you access one of the plugins by its numeric index, Netscape Navigator also adds an entry using the plugin name so you can access it associatively. However, you can also enumerate the item you just created until the browser clears the array (probably when the application exits). So, although you cannot enumerate the plugins from cold, you can enumerate the ones that you have accessed by index value.
- Sending a refresh message to a plugin object also allows it to be enumerable. Based on this idea, a short fragment of code is given in the example that will force all the plugins to be added to the collection as associative items, which can then be enumerated.
- MSIE allows the plugins to be enumerated and the length property is also enumerable. However, the plugins can only be accessed by their numeric index.
- To make this properly portable, execute the bug fix code and access plugins by their numeric index and your scripts should then be reasonably portable.

Example code:

```
// Execute this in Netscape Navigator to fix the
// navigator.plugins enumeration bug
for(ii=0; ii<navigator.plugins.length; ii++)
{
   navigator.plugins[ii].refresh;
}
```

See also:	`Collection` object, `EmbedArray` object, `Navigator.plugins[]`, `Plugin` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	1.1 +	3.0 +	3.0 +	4.0 +	-	-	Warning, ReadOnly

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`item()`	-	3.0 +	-	4.0 +	-	-	-
`refresh()`	1.1 +	-	3.0 +	-	3.0 +	-	-

PluginArray.item() (Method)

An item selector for accessing a single plugin within the collection.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Plugin` object	
JavaScript syntax:	IE	*`myPluginArray`*`.item(`*`anIndex`*`)`
	IE	*`myPluginArray`*`.item(`*`aSelector`*`)`
	IE	*`myPluginArray`*`.item(`*`aSelector`*`, `*`anIndex`*`)`
Argument list:	*`anIndex`*	A zero based index into the collection
	`aSelector`	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

PluginArray.length (Property)

The number of plugin objects currently supported by the browser.

Availability:	JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`document.plugins.length`
	-	`navigator.plugins.length`

Warnings:

- Be careful not to confuse this property with the `Plugin.length` property.
- The `Plugin.length` property is the number of MIME types that a plugin can respond to.
- The `document.plugins.length` property gives a count of the number of plugins there are embedded into a document.
- The `navigator.plugins.length` property is the number of plugin support modules that are installed and available to the browser.

See also:	`Collection.length`, `Plugin.length`

Property attributes:

`ReadOnly`.

PluginArray.refresh() (Method)

Refresh all the plugins in the current page.

Availability:	JavaScript –1.1 Netscape –3.0 Opera –3.0	
JavaScript syntax:	N	`document.plugins.refresh()`
	N	`navigator.plugins.refresh()`

See also:	`Navigator.plugins.refresh(),Plugin.refresh()`

Pointers (Overview)

JavaScript does not have pointers. On the other hand it does have good garbage collection.

Refer to:

Garbage collection

Polymorphic (Definition)

Operations that are workable on a variety of data types.

Refer to:

Type conversion

Portability (Definition)

The ability of your script to run on multiple platforms.

In general, JavaScript is highly portable. However, it is dubious as to whether a server-side script would be useful on the client side, so some measure of discretion is required when talking about portability. Even so, it is likely that many useful functions would work in different contexts although the way they are used may be different.

Portability of code needs to be considered at the outset of any development project. A script is portable to the extent that it can be used on a variety of platforms.

Generally, code in a function is more portable than an entire script-driven application. You might reuse functional blocks of code from one project to another. JavaScript facilitates this reuse due to its semi-object-oriented nature.

If you adhere strictly to the ECMAScript standard, then your script may port between compliant implementations with the minimum of difficulty.

Note that portability does not imply that a script you design to work client side is guaranteed to work meaningfully on the server side. There is the small matter of fitness for purpose and suitability.

However, it is not unreasonable to expect a script be able to run identically in all versions and flavors of web browsers. Realistically though, this is very difficult to accomplish because of the browser developers having added proprietary extensions to their implementations. They also increase the difficulty due to the amount of incomplete and incorrect support for standardized behavior. Furthermore the standard is ambiguous in a few areas leading to functional interpretations, which can vary from browser to browser.

For example, both MSIE and Netscape can scroll the contents of a window or frame. MSIE will scroll under script control whether the window has a scroll bar or not. Netscape Navigator will only scroll if a scroll bar is flagged `true` and is actually present.

Furthermore when scrolling is possible (on Netscape it can be accomplished without scroll bars by using layers), each browser scrolls in the opposite direction, as the scroll value is incremented.

Do not assume that expressions will evaluate the operands in the order of presentation. There are various ways to tokenize and interpret expressions and they can evaluate individual items in different sequence order, or in some cases may omit to evaluate an operand, when an early prediction of the outcome is possible.

Be wary of using non uniform character values that appear to display a certain character, which is not the correct one, defined in the Unicode character set. Rather, escape the character either with a Unicode escape or if it is appropriate for the context as an HTML character entity.

Be careful with quotes and escaping of them. If you escape a single quote using the HTML character entity, then some web browsers will un-escape the source text before interpretation. This breaks:

```
myString = 'some text with a &#039; single quote';
```

the HTML character entity is decoded too soon, by the browser as the page is read into its memory cache. Then the script is interpreted, and the interpreter sees this:

```
myString = 'some text with a ' single quote';
```

The additional quote terminates the string too soon and the remainder is interpreted as code. This can have very unpredictable consequences. The apostrophe should be escaped like this:

```
myString = 'some text with a \' single quote';
```

Inevitably, there will be occasions where you need to factor your script to cope with machine-dependant behavior. You should collect the machine-dependant code into clearly identified functions. You can use the `eval()` function to great effect here by detecting the name of the browser and algorithmically generating the name of a function to call, which you can then invoke via an `eval()`.

Wrox *Instant JavaScript* –page –11

Positive value (+) (Operator/unary)

Indicate positive value or numeric cast a non-numeric value.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`+anOperand`
Argument list:	`anOperand`	A value that can reasonably be converted to a number

The operand is evaluated and converted to a numeric value.

A positive value is unchanged.

A negative value is unchanged.

A string value will be converted to a Numeric value and replaced in context.

Although this is classified as a unary operator, its functionality is really that of an additive operator.

The result will be the value of the operand, cast to a Numeric type.

See also:	Additive operator, Unary operator

Cross-references:

ECMA 262 edition 2 –section –11.4.6

ECMA 262 edition 3 –section –11.4.6

Postfix decrement (–) (Operator/postfix)

Decrement after access.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*anOperand*--
Argument list:	*anOperand*	A numeric value that can be decremented

The operand is decremented by one.

The operand is evaluated first and is then decremented when the evaluation is completed

The associativity is from right to left.

Refer to the Operator Precedence topic for details of execution order.

See also:	Associativity, Decrement value (--), Operator Precedence, Postfix expression, Postfix operator, Prefix decrement (--), Prefix expression

Cross-references:

ECMA 262 edition 2 –section –11.3.2

ECMA 262 edition 3 –section –11.3.2

Postfix expression (Operator/postfix)

Increment or decrement an operand after access.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Postfix expressions operate on Left-Hand-Side (sometimes called LValue) expressions.

There are two postfix operators:

- ++ performs a numeric increment on the operand
- -- performs a numeric decrement on the operand

These can also be classified as additive operators and because they modify a value in place, they also imply that an assignment takes place as well.

See also:	Additive operator, Assignment operator, Decrement value (--), Expression, Increment value (++), Postfix decrement (--), Postfix increment (++), Prefix expression

Cross-references:

ECMA 262 edition 2 –section –11.3

ECMA 262 edition 3 –section –11.3

Postfix increment (++) (Operator/postfix)

Increment after access.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*anOperand*++
Argument list:	*anOperand*	An incrementable numeric value

The operand is incremented by one.

The operand is evaluated first and is then incremented when the evaluation is completed.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

See also:	Associativity, Decrement value (--), Increment value (++), Operator Precedence, Postfix expression, Postfix operator, Prefix expression

Cross-references:

ECMA 262 edition 2 –section –11.3.1

ECMA 262 edition 3 –section –11.3.1

Postfix operator (Definition)

Operators that are placed after the operand.

Postfix operators are placed immediately after their operands. The following postfix operators are supported:

Operator	Description
`( )`	Function arguments delimiter
`++`	Increment the operand
`--`	Decrement the operand
`.`	Object property delimiter
`[ ]`	Array element delimiter

The meanings of some of these operators may vary in other contexts.

See also:	Arithmetic operator, Array index delimiter ([ ]), Associativity, Object property delimiter (.), Operator, Operator Precedence, Postfix decrement (--), Postfix increment (++), Prefix operator, Unary operator

Cross-references:

Wrox *Instant JavaScript* –page –19

Power function (Definition)

A function that deals with powers of numbers.

There are several mathematical functions that deal with powers of numbers and some pre-computed constants that are useful in the same context. The following table summarizes JavaScript capabilities in this area:

Item	Type
`Math.pow()`	Function
`Math.sqrt()`	Function
`Math.SQRT1_2`	Constant
`Math.SQRT2`	Constant

See also:	Exponent-log function, Integer-value-remainder, `Math.pow()`, Mathematics, Trigonometric function

PRE object (Object/HTML)

An object that encapsulates the content of a <PRE> tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	Element object	
JavaScript syntax:	IE	myPRE = *myDocument*.all.*anElementID*
	IE	myPRE = *myDocument*.all.tags("PRE")[*anIndex*]
	IE	myPRE = *myDocument*.all[*aName*]
	-	myPRE = *myDocument*.getElementByID(*anElementID*)
	-	myPRE = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	myPRE = *myDocument*.getElementsByTagName ("PRE")[*anIndex*]
HTML syntax:	<PRE> ... </PRE>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	width	
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

The <PRE> tag is a block-level tag. That means that it forces a line break before and after itself.

See also:	Element object, KBD object, LISTING object, style.overflow

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
width	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

PRE.width (Property)

The width of a block of pre-formatted text.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myPRE*.width

This width value has a an upper range limit of 100, which represents 100% of the available width of the screen. This is not the usual percentage width of its parent containing element.

Pre-processing (Definition)

An extra processing step performed on the script source text before interpretation commences.

Programmers who come from a C programming background will be familiar with the C language pre-processor.

This is a stage in the compilation process that performs some processing on the source code prior to it being compiled.

Typically, this allows for the substitution of constant values, the expansion of macros (small fragments of code that are used very often) and the conditional inclusion or exclusion of code usually based on the platform being used.

Standard JavaScript does not support this functionality but several embedded interpreter products do, as does the ScriptEase interpreter. Now, it is available in JScript although you should limit its use to those situations where you know the script will be executed on a compliant system.

To avoid problems with non-compliant systems, you should place the pre-processor directives inside comment blocks. This at least will hide them from the platforms that don't support this capability. However, you need to be aware of how your script will behave if the pre-processor directives are ignored. This can become quite complex and may outweigh any advantages of using the pre-processor. You must make provision for this if your scripts need to run on Netscape Navigator for example, because it will cause an interpretation error when it sees the `@` symbol at the beginning of each directive.

The leading comment should be placed immediately in front of the `@` symbol. The trailing comment delimiter should have an additional `@` sign to indicate it matches the prefixing comment symbol. So the activation directive:

```
@cc_on
```

Should be coded like this:

```
/*@cc_on@*/
```

In a predictable environment, there are no concerns about portability and you need not use the comment encapsulation technique to hide the directives.

Placing the pre-processor directives inside quotes makes them ineffective.

Undefined values return the `NaN` value. There are no error reports when a directive that does not exist is used. However, placing a trailing `@` symbol without it being part of the comment hiding mechanism will generate a parsing error.

Warnings:

- Note that each implementation of a pre-processor is implementation-specific. There are as yet no standards for this and there are several alternative and mutually non-compliant alternatives. Some copy the C language pre-processor directives and commence with a hash symbol (#) while others use a completely different syntax altogether (for example, JScript with its `@` symbol).
- Although this capability was introduced in JScript 3.0, which was available in version 4 of MSIE, attempting to use the pre-processor directives may well crash a Macintosh version 4.5 MSIE browser. Some directives may work in certain restricted situations.
- MSIE version 5 for Macintosh exhibits some shortcomings in its implementation of the platform detection mechanisms.

Pre-processing –/*@ ... @*/ (Delimiter)

A special form of the comment delimiters for enclosing pre-processor directives.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`/*@someDirectives@*/`
Argument list:	`someDirectives`	One or more pre-processor directives

This form of the comment delimiters is important when you need to use the JScript pre-processor directives. Enclosing them in a comment block hides them from non-compliant browsers and script interpreters.

The pre-processor directive has the following general format:

```
@<some_keyword>
```

To hide it within comments, you need to modify it so it resembles this general form:

```
/*@<some_keyword> @*/
```

There are special requirements for enclosing entire blocks of code when the conditional inclusion directives are used. Refer to the `@if` topic for more details.

It seems to be convention to place a space character in front of the closing `@*/` comment delimiter. This may not be strictly necessary for functional reasons but aids the readability of the directives when placed into portable code.

See also:	`@*/`, Pre-processing, Pre-processing - `@<variable_name>`, Pre-processing - `@_alpha`, Pre-processing - `@_jscript`, Pre-processing - `@_jscript_build`, Pre-processing - `@_jscript_version`, Pre-processing - `@_mac`, Pre-processing - `@_mc680x0`, Pre-processing - `@_PowerPC`, Pre-processing - `@_win16`, Pre-processing - `@_win32`, Pre-processing - `@_x86`, Pre-processing - `@cc_on`, Pre-processing - `@elif( ... ) ...`, Pre-processing - `@else ...`, Pre-processing - `@end`, Pre-processing - `@if( ... ) ...`, Pre-processing - `@set`

Pre-processing –@<variable_name> (Pre-processor)

A special pre-processor variable container.

Availability:	JScript –3.0 Internet Explorer –4.0
Property/method value type:	`User defined`

JavaScript syntax:	IE	`@aVariable`
	IE	`@aVariable=aValue`
Argument list:	`aValue`	A value to be assigned
	`aVariable`	A variable created with the `@set` directive

The pre-processor sub-system supports the definition and use of a special kind of variable. These are defined and modified with the `@set` pre-processor directive.

Once created, the variable can be used anywhere in the code, like this:

```
myString = "***" + @myvariable;
```

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@myvariable @*/
```

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_alpha (Pre-processor)

A pre-processor constant indicating whether the script is running in a DEC alpha workstation.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_alpha`

This pre-processor constant yields `true` when used on a DEC alpha processor and `NaN` otherwise.

Since MSIE only runs on Macintosh and Windows platforms, and a DEC alpha is not a Macintosh, there is an implication here that this will be `true` only when MSIE is running on Windows NT on a DEC alpha. It should also be the case that the `@_win32` directive returns `true` as well.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_alpha @*/
```

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_jscript (Pre-processor)

A pre-processor constant indicating whether the script is executing in a JScript interpreter.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_jscript`

This preprocessor constant yields `true` if the script is running in a genuine Microsoft JScript interpreter, and `NaN` if it is JavaScript but not JScript.

These directives may have been defined with a `@` symbol rather than a `#` symbol for reasons of consistency across a variety of Microsoft platforms. Therefore, this directive may be useful to be able to conditionally include script source that depends on the kind of interpreter being used.

For now this directive will always return the `true` value when used in the MSIE browser.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_jscript @*/
```

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_jscript_build (Pre-processor)

A pre-processor constant indicating the build version of the JScript environment.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`@_jscript_build`

This preprocessor constant returns the build number of the interpreter (but not the browser) in which the script is running.

For example, in version 5.0 of MSIE for Macintosh, the browser build number is 2022 but the JScript build number reported by this pre-processor directive is 3715.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_jscript_build @*/
```

Warnings:

- Oddly enough, in version 4.5 of MSIE, the value reported is also 3715 even though the build number of the browser is 0408 and is therefore much older.
- Because both versions of the browser were tested in the same machine, it is possible that by installing the MSIE 5 browser, some components of the browser are stored in the System folder. These may well have overwritten components that the version 4.5 browser was using and so you need to be aware of the possibility of MSIE browsers exhibiting odd behavior due to the way the application is factored into components. In fact this is confirmed by the fact that the `@_jscript_version` directive reports JScript 5 from within MSIE 4.5 which is not correct. Other aspects of the interpreter that interact with the browser core may exhibit JScript 3 functionality. So installing MSIE 5 on a Macintosh over the top of an MSIE 4.5 yields an interesting hybrid variant of the version 4.5 browser. Performing upgrades of your browser and JScript components on a Windows platform may yield similar hybrid variants.
- You should be careful that if you code for a version of something you should be testing that same thing. Don't test browser versions to conditionally execute JScript version-specific code.
- The Netscape Navigator browser code is contained more integrally within its own application space and you may be able to have several versions of that browser without any subtle interaction between low-level shared library modules.
- You may assume the version of the interpreter tells you something useful but don't assume any other implications regarding browser versions based on the interpreter version.

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_jscript_version (Pre-processor)

A pre-processor constant indicating the version number of the JScript interpreter.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`@_jscript_version`

This preprocessor constant provides the version number of the interpreter (but not the browser) in which the script is running.

For example, in version 5.0 of MSIE for Macintosh, the version of JScript expected is version 5.0 and you do get the value 5 reported by this directive.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_jscript_version @*/
```

Warnings:

- As is the case with the `@_jscript_build` directive, this one may be affected by the installation history of your workstation.
- Installing MSIE 5 on a Macintosh over the top of an MSIE 4.5 yields an interesting hybrid variant of the version 4.5 browser. Due to the component nature of Microsoft browsers and interpreters, the same is true on the Windows platform and you can very easily find the versions of browser and JScript integerpreter have diverged as a result of installing another application that may upgrade some shared components.
- You may assume the version of the interpreter tells you something useful but don't assume any other implications regarding browser versions based on the interpreter version or vice versa. Test the thing you need to know about and do not assume that the browser and interpreter are directly related to one another.
- The version history tables suggest they are related but this simply lists the versions of JScript that were shipped as part of the browser install kit for a fresh and complete installation.

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_mac (Pre-processor)

A pre-processor constant indicating whether the script is running in a Macintosh workstation.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_mac`

This directive should yield the value `true` when tested on any Macintosh system.

In MSIE version 5, it yields the value `NaN` which is what you would expect on a non-Macintosh system.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_mac @*/
```

Warnings:

- This does not appear to work in MSIE 5 for Macintosh.

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_mc680x0 (Pre-processor)

A pre-processor constant indicating whether the system contains a Motorola 68000 CPU.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_mc680x0`

This directive should yield the value `true` when tested on any older pre Power PC equipped Macintosh system and `NaN` when tested on a modern Power PC machine.

In MSIE version 5, it yields the value `NaN` regardless of the CPU, which is what you would expect on a non-68K equipped system.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_mc680x0 @*/
```

Warnings:

- This does not appear to work in MSIE 5 for Macintosh.

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_PowerPC (Pre-processor)

A pre-processor constant indicating whether the system contains a Motorola PowerPC CPU.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_PowerPC`

This directive should yield the value `true` when tested on any newer Power PC equipped Macintosh system and `NaN` when tested on an older 68K machine.

In MSIE version 5, it yields the value `NaN` regardless of the CPU, which is what you would expect on a non Power PC system.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_PowerPC @*/
```

Warnings:

- This does not appear to work in MSIE 5 for Macintosh.
- Be careful with capitalization on this directive; none of the others seem to require capital letters but this one does.

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_win16 (Pre-processor)

A pre-processor constant indicating whether the script is running in a 16 bit Windows environment.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_win16`

This directive should yield the value `true` when tested on any older 16 bit Windows system.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_win16 @*/
```

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_win32 (Pre-processor)

A pre-processor constant indicating whether the script is running in a 32 bit Windows environment.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_win32`

This directive should yield the value `true` when tested on any modern 32 bit Windows system.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_win32 @*/
```

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@_x86 (Pre-processor)

A pre-processor constant indicating whether the system contains an Intel X-86 series CPU.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`@_x86`

This directive should yield the value `true` when tested on any system equipped with an Intel X86 CPU. It should yield `NaN` on any non Intel system and always read `NaN` on a Macintosh.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@_x86 @*/
```

See also:	Pre-processing, Pre-processing - `/*@ ... @*/`

Pre-processing –@cc_on (Pre-processor)

A switch to activate the pre-processor phase of the script interpreter.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`@cc_on`

The pre-processor directives will not work unless they are first activated by placing this directive near the top of the script.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@cc_on @*/
```

See also:	Conditional code block, Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@elif(...) ... (Pre-processor)

An optional else-if pre-processor token.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`... @elif(`*`aCondition`*`) ...`
Argument list:	*`aCondition`*	A pre-processor supported condition test

This can be used in a conditional code block to indicate a supplementary conditional block.

Refer to the `@if()` topic for more details.

If you intend to hide this directive inside some comments, you must place the comment around the entire construct and not the individual pre-processor directives.

See also:	Conditional code block, Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@else ... (Pre-processor)

Part of the conditional code use directive.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`... @else ...`

This can be used in a conditional code block to indicate an alternative conditional block.

Refer to the `@if()` topic for more details.

If you intend to hide this directive inside some comments, you must place the comment around the entire construct and not the individual pre-processor directives.

See also:	Conditional code block, Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@end (Pre-processor)

Terminator for a conditional code block.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`... @end`

This should be used to terminate a conditional code block.

Refer to the `@if()` topic for more details.

If you intend to hide this directive inside some comments, you must place the comment around the entire construct and not the individual pre-processor directives.

See also:	Conditional code block, Pre-processing, Pre-processing – `/*@ ... @*/`

Pre-processing –@if(...) ... (Pre-processor)

Conditionally include a block of code.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`@if(`*`aCondition`*`)` *`someCode`* `@elif(`*`aCondition`*`)` *`someCode`* `@else` *`someCode`* `@end`
	IE	`@if(`*`aCondition`*`)` *`someCode`* `@elif(`*`aCondition`*`)` *`someCode`* `@end`
	IE	`@if(`*`aCondition`*`)` *`someCode`* `@else` *`someCode`* `@end`
	IE	`@if(`*`aCondition`*`)` *`someCode`* `@end`
Argument list:	*`aCondition`*	A condition that yeilds a Boolean value
	`someCode`	A block of code that is conditionally included

The `@if()` directive is very flexible, having two optional associated directives (`@elif()` and `@else`), which provide a variety of different configurations.

The simplest form is where a section of code is included or not. That would be organized like this:

```
@if(anExpression)

...

someCode

...

@end
```

If the expression yields a `true` value then the code will be included, otherwise it will be skipped, as if it had been completely commented out.

The next simplest form is to place an alternative section of code in the conditional section and have that used when the expression yields a `false` value. That would be laid out like this:

```
@if(anExpression)

...

someCode

...

@else

...

someOtherCode

...

@end
```

The result of the expression selects one block of code or the other.

A third and somewhat more complex configuration allows a series of conditions to be tested. This is somewhat like a switch tree although it is a little less elegant in its presentation. You can test for several conditions and include an appropriate block of code for the one that holds true. However, only one will be selected. This is accomplished with the `@elif()` directive. This is only tested when a prior `@if()` or `@elif()` test proves `false`.

Here is an configuration that tests for three possible conditions:

```
@if(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
...
@end
```

Note that in this form, there is no alternative block of code associated with an `@else` directive. One of these expressions must prove `true` for any code to be included. If none of them prove `true`, then the entire conditional block is ignored.

The final configuration provides a fall-back alternative code block and is constructed like this:

```
@if(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
```

```
...
@else
...
someOtherCode
...
@end
```

You may be able to nest these directives but it is recommended that you avoid complexity when building conditional code structures as it makes the code more difficult to maintain.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@if(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
...
@elif(anExpression)
...
someCode
...
@else
...
someOtherCode
...
@end @*/
```

See also:	Conditional code block, Pre-processing, Pre-processing - `/*@ ... @*/`

Pre-processing –@set (Pre-processor)

Set the contents of a pre-processor variable.

Availability:	JScript –3.0 Internet Explorer –4.0	
JavaScript syntax:	IE	`@set aVariable=aValue`
Argument list:	`aValue`	A value to assign
	`aVariable`	A pre-processor variable name

You can define variables that exist in the namespace of the pre-processor and which can then be used as if they were directives that you had created. For example, you might test some complex set of conditions and set a variable so that you can simply test for its existence later. Or you might use that variable in some fragment of code as a manifest constant, perhaps to specify the size of an array or a flag to activate some capability.

You should note that these pre-processor directives will likely not survive from one script block to another or for any duration in the time domain. They are not variables in the sense of a script variable.

To create a new pre-processor variable, use the `@set` directive, name the variable, and assign a value to it, like this:

```
@set @myvariable=1000
```

You can then use the variable in the source text like this:

```
document.write(@myvariable);
```

You may need to experiment to establish how long one of these variables actually persists. It is unlikely to still be defined when an event handler is called. However, that event handler may have been interpreted and stored when the script was loaded, in which case the variable would have been replaced by its value at that time.

If you intend to hide this directive inside some comments, it must be done like this:

```
/*@set @myvariable=1000 @*/
```

ECMA 262 edition 3 –section –11.1.6

Wrox *Instant JavaScript* –page –18

Preferences (Definition)

Browser preferences can sometimes be manipulated from JavaScript.

Netscape 4.0 introduced some new methods for storing preference settings in external JavaScript configuration files. Earlier version required an Admin Kit to be used to set defaults and the user could then only modify preferences from the options menu.

The JavaScript preferences information is contained in:

- `prefs.js`
- `netscape.cfg`
- `config.jsc`

The `prefs.js` file contains a collection of user preferences. It is read by the browser as it starts up and written by the browser as it shuts down. If you want to modify `prefs.js` by hand, you will need to do it while Netscape is not running. There are a few modifications that can be done to this file that will help when you are developing JavaScript source code.

Note that you can have a different `prefs.js` file for each user profile. On UNIX versions of Netscape Navigator, the `prefs.js` file becomes `preferences.js` instead.

Additional preference information may be stored in a file called `netscape.cfg`, which replaces the `netscape.lck` found on older versions of Netscape. This file overrides the settings in `prefs.js` but is not written to by the browser. It is an encrypted file that you cannot unwrap without a lot of work. It is possible to edit it carefully by hand but you really need the admin tools from Netscape to work on it. There is a tool called Mission Control that contains a configuration editor. There is also an install builder for delivering an encrypted file to the target system.

The third file is called `config.jsc` and overrides the other two. This file will likely only be present if you are running under the supervision of an administrator who uses the admin tools to configure hundreds of browsers. The `config.jsc` file can be loaded from a URL defined in `netscape.cfg`. Furthermore it can be read frequently and regularly by the browser so it is possible to turn features on and off during the day having configured `netscape.cfg` to re-read it from time to time.

Using these configuration scripts and the tools that Netscape provides, you can alter hundreds of parameter settings within the browser.

Prefix decrement (–) (Operator/prefix)

Decrement an operand before access.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`--anOperand`*
Argument list:	*`anOperand`*	A numeric value that can be decremented

The operand is evaluated, converted to a numeric value, and decremented by 1.

Although this is classified as a unary operator, its functionality is really that of an additive operator.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

See also:	Additive operator, Arithmetic operator, Associativity, Decrement value (--), Operator Precedence, Postfix decrement (--), Prefix expression, Prefix operator, Unary expression

Cross-references:

ECMA 262 edition 2 –section –11.4.5

ECMA 262 edition 2 –section –11.6.3

ECMA 262 edition 3 –section –11.4.5

Prefix expression (Operator/prefix)

Increment or decrement an operand before access.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Prefix expressions operate on Left-Hand-Side (sometimes called LValue) expressions.

There are two prefix operators:

- ++ performs a numeric increment on the operand
- -- performs a numeric decrement on the operand

These can also be classified as additive operators and because they modify a value in place; they also imply that an assignment takes place as well.

See also:	Additive operator, Assignment operator, Decrement value (--), Expression, Increment value (++), Postfix decrement (--), Postfix expression, Postfix increment (++), Prefix decrement (--), Prefix increment (++)

Cross-references:

ECMA 262 edition 2 –section –11.3

ECMA 262 edition 3 –section –11.3

Prefix increment (++) (Operator/prefix)

Increment an operand before access.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server version –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*++anOperand*
Argument list:	*anOperand*	An incrementable numeric value

The operand is evaluated, converted to a numeric value, and incremented by 1.

Although this is classified as a unary operator, its functionality is really that of an additive operator.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

See also:	Additive operator, Arithmetic operator, Associativity, Decrement value (--), Operator Precedence, Prefix expression, Prefix operator, Unary expression

Wrox *Instant JavaScript* –page –59

Primary expression (Definition)

Primary expressions are used with operators to form more complex expression types.

Availability:	ECMAScript edition –2

A primary expression is one that needs no further evaluation to resolve its value.

A Primary expression is a specific object, identifier or literal and may also be the result of evaluating another nested expression that is surrounded by the grouping operators (parentheses).

The `this` keyword is classed as a Primary expression. The value returned by the `this` keyword depends on the execution context currently being processed.

An identifier is a primary expression if it refers to an object or function.

Constants and string literals are by definition primary expressions.

Any expression within the grouping operators (parentheses) becomes a primary expression since the rules of precedence dictate that it must be resolved completely before being replaced into the expression to which it is an operand.

An identifier is evaluated according to the current scoping rules presently in force. This would return an internal reference value inside the interpreter but this would be transparent to the user.

Literal values of the following types are considered to be primary expressions:

- Null literal
- Boolean literals
- Numeric literals
- String literals

Expressions can be evaluated in the desired order by using the grouping operator or parentheses to nest the expressions. This allows the `delete` and `typeof` operations to be applied to expressions.

See also:	Constant, Execution context, Expression, Grouping operator ( ), Identifier resolution, Literal, Operator Precedence, `this`

Primitive value (Definition)

A built-in native value type.

Availability:	ECMAScript edition –2

A primitive value is one of the types Undefined, Null, Boolean, Number, or String.

The foundation set of primitive values is represented at the lowest level of the language implementation within the core functionality sub-set. The host environment may add other primitive values.

Type Name	Description
Aggregate	A collection of atomic types assembled collectively into an object.
Arithmetic	All types that yield a value that can be operated on numerically.
Array	Collections of objects and identifiers assembled into a sequence.
Basic	The fundamental simple, non-object types.
Boolean	This type can store and yield `true` or `false` values.
Completion	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
List	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Null	This has exactly one value, `null` and is distinct from `undefined`.
Number	Integer and floating-point values are all stored in a generic number type.
Object	An object is an unordered collection of properties. Each property consists of a name, a value, and a set of attributes.
Reference	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Scalar	The non-object types.
String	Strings are arrays of characters that are accessible individually by indexing their position in the sequence.
Undefined	This value is returned by variables that have not yet been assigned a value.

Note that arrays and objects are not primitive types.

Wrox *Instant JavaScript* –page –14

print() (Method)

An alias for the `window.print()` method.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.print()`
	-	`print()`

Refer to:

`Window.print()`

Printing character (Definition)

A character with a visible glyph.

A printing character is one that given the current locale, represents a printable glyph or character shape.

The `isprint()` function (that is described elsewhere in this manual) lists printable characters.

See also:	Character handling, Control character, `isPrint()`, Letter

ECMA 262 edition 3 –section –7.5.3

PrivilegeManager object (Java class)

A Java class that administers privileges.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myPrivilegeManager* = netscape.security.PrivilegeManager
Object methods:	disablePrivilege(), enablePrivilege()	

Because the Netscape security model is based on the Java security model, the Netscape Navigator browser requests its privileges through the Java mechanisms. These are encapsulated in a class that you can access from inside JavaScript.

The downside of this is that there is no meaningful value returned when the request is made. If the request for a privilege is denied, the error causes a Java exception that is difficult to trap from JavaScript. It is possible that more recent browser versions will support an exception-handling mechanism.

There are two principle methods that are useful here, one to request the privilege and the other to relinquish it.

- `enablePrivilege()` –Requests the privilege passed as a string argument
- `disablePrivilege()` –Relinquishes the privilege based on a string argument

It is good practice to disable the privilege as soon as you no longer need it. In any case the privilege is given up when the function that requested it exits.

Trying to examine an instance of this class leads to some interesting run-time errors. That is perhaps understandable since the object is involved with keeping things secret. Even after requesting privileges, you cannot examine the internals of an instance of this class.

See also:	`netscape.security.PrivilegeManager`, Requesting privileges, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `UniversalFileRead`, `UniversalPreferencesRead`, `UniversalPreferencesWrite`, `UniversalSendMail`

Method	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
`disable Privilege()`	1.2 +	-	4.0 +	-	-	-	-	-	-	-	-
`enable Privilege()`	1.2 +	-	4.0 +	-	-	-	-	-	-	-	-

PrivilegeManager.disablePrivilege() (Method)

A method for removing a privilege from a user.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myPrivilegeManager*.disablePrivilege (*aPrivName*)
Argument list:	*aPrivName*	The name of a privilege to be relinquished

The method should be called with a string argument containing the name of the privilege that is no longer required.

Example code:

```
// Relinquish the file reading priviledge
netscape.security.PrivilegeManager.disablePrivilege("UniversalFileRead");
```

See also:	Requesting privileges, UniversalBrowserAccess, UniversalBrowserRead, UniversalBrowserWrite, UniversalFileRead, UniversalPreferencesRead, UniversalPreferencesWrite, UniversalSendMail

PrivilegeManager.enablePrivilege() (Method)

A method for granting an additional privilege to a user.

Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myPrivilegeManager*.enablePrivilege(*aPrivName*)
Argument list:	*aPrivName*	The name of a privilege to be requested

The method should be called with a string argument containing the name of the privilege that is needed to gain access to the secure facilities of the browser.

Example code:

```
// Request the file reading priviledge
netscape.security.PrivilegeManager.enablePrivilege("UniversalFileRead")
```

See also:	Requesting privileges, UniversalBrowserAccess, UniversalBrowserRead, UniversalBrowserWrite, UniversalFileRead, UniversalPreferencesRead, UniversalPreferencesWrite, UniversalSendMail

Privileges (Definition)

Secure access can be controlled by privileges.

Refer to:

Restricted access

Procedural surfaces (Definition)

A means of space filling an area within an HTML `Element` object using a shading algorithm.

This can be a means of making web page downloads much smaller because you specify an algorithm to use to fill a space rather than a pixel image map.

These are the available procedural surface generators you can use with MSIE:

- `AlphaImageLoader()`
- `Gradient()`

These procedural shaders compute the alpha channel transparency and the pixel color of the area in RGB coordinates.

See also:	filter – `alphaimageloader()`, filter – `gradient()`, `style.filter`, Visual filters

Procedure (Definition)

A procedure is a function that does not return a meaningful result and which is meant to be called outside of a context where its value will be assigned or substituted in an expression.

Refer to:

`function( ... ) ...`

ProcessingInstruction object (Object/DOM)

Part of the DOM level support for XML that relates to the handling of a processing instruction embedded in the text of the document.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0
Inherits from:	`Node` object
JavaScript syntax:	- *myProcessingInstruction* = new ProcessingInstruction()
Object properties:	`data, target`

See also:	`Document.createProcessingInstruction()`

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	DOM	CSS	HTML	Notes
`data`	1.5 +	5.0 +	6.0 +	5.0 +	-	-	-	1 +	-	-	-
`target`	1.5 +	5.0 +	6.0 +	5.0 +	-	-	-	1 +	-	-	ReadOnly

Inheritance chain:

`Node` object

ProcessingInstruction.data (Property)

The data content of the processing instruction.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myProcessingInstruction`*`.data`

ProcessingInstruction.target (Property)

The target of the processing instruction is defined by XML as being the first token following the markup that begins the processing instruction.

Availability:	DOM level –1 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myProcessingInstruction`*`.target`

Property attributes:

`ReadOnly`.

Program (Definition)

Another name for a JavaScript script.

Refer to:

Script

project object (Object/NES)

A server-side host object provided inside NES. This object represents a running application inside the server.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
JavaScript syntax:	NES	`project`
Object methods:	`lock(), unlock()`	

The `client` object provides a means of maintaining state during a client session. This object is used for maintaining state across all sessions running in a single application. There may be several applications running in a server.

If you need to maintain state across the entire server then you need to access the `server` object which is discussed in a separate topic.

See also:	`client` object, Netscape Enterprise Server, `response.project`, `server` object, `unwatch()`, `watch()`

Method	JavaScript	JScript	NES	Notes
`lock()`	1.1 +	-	2.0 +	-
`unlock()`	1.1 +	-	2.0 +	-

project.lock() (Method)

A means of locking resources that might be shared by several sessions.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
JavaScript syntax:	NES	`project.lock()`

The project lock would be used at a higher hierarchical level than the `Lock` object that you might use for general purpose locking within a session.

It is even more important that you don't hog a lock on the `project` object as this can cause severe performance problems.

The lock will stall if another script currently has a lock extant on this project. The method will then return when that lock is relinquished.

If you are accessing files for writing in a server-side application (within NES), you should make sure the project locking is activated to avoid file corruption happening if there are multiple simultaneous accesses to the file.

Example code:

```
<SERVER>
// An example file access with project level locking to prevent
// file corruption.
project.lock();
myFileObject.open("a");
myFileObject.writeln("Append this line to the file.");
myFileObject.close();
project.unlock();
</SERVER>
```

See also:	`File.open(),server.lock()`

project.unlock() (Method)

Relinquish a lock on a project object.

Availability:	JavaScript –1.1 Netscape Enterprise Server version –2.0	
JavaScript syntax:	NES	`project.unlock()`

You should try and unlock any resources you have reserved with a lock as soon as you can.

See also:	`server.unlock()`

prompt() (Method)

An alias for the `window.prompt()` method.

Availability:	JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myResult* = *myWindow*.prompt(*aString*, *aDefaultValue*)
	-	*myResult* = prompt(*aString*, *aDefaultValue*)
Argument list:	*aDefaultValue*	An initial content for the text box
	aString	Some text to explain what to enter

See also:	Window.alert(),Window.confirm()

Refer to:

Window.prompt()

Property (Definition)

A property consists of a name, a value, and a set of attributes.

Availability:	ECMAScript edition –2

A property consists of a name, a value, and a set of attributes. It belongs to an object.

Since it belongs to an object, each instance of a particular object class can own its own private properties as well as inheriting shared properties from its prototype. Privately owned properties are sometimes called instance variables.

A property can have zero or more attributes. The attributes control how the property is accessed both internally from inside the interpreter and externally from your script.

A property is somewhat like a method, at least in the way it is described in a script. However, properties are containers whereas methods are actions. Properties can have values assigned to them or can have their values retrieved. A method will generally cause something within the receiving object to change. Properties are read-only, write-only, or read and write. Some properties are internal and private to the object and are not therefore exposed as scriptable items.

Methods are really references to function objects that can be called.

See also:	Function, Global object, java.util, Method, Object, Property accessor, Property attribute, Property name, Property value

Cross-references:

ECMA 262 edition 2 –section –15.1

ECMA 262 edition 3 –section –15.1

Property accessor (Definition)

Properties are accessed by name.

Availability:	ECMAScript edition –2

Properties are accessed by name either using the dot notation or the square bracket notation.

The dot and bracket notations are generally exchangeable with one another.

The object to which the property-access message is being directed can be derived from an expression.

The name of the identifier can be derived from an expression but it must yield a meaningful string value that corresponds to a genuine or potential property of the receiver.

See also:	Decimal point (.), Left-Hand-Side expression, Property

Cross-references:

ECMA 262 edition 2 –section –11.2.1

ECMA 262 edition 3 –section –11.2.1

Property attribute (Definition)

A property can have zero or more attributes.

Availability:	ECMAScript edition –2

A property can have zero or more attributes. The attributes control how the property is accessed both internally from inside the interpreter and externally from your script.

Here is a list of the property attributes defined by the ECMA Script standard:

Attribute	Description
`ReadOnly`	The property is a read-only value. Scripts will not be allowed to change the value although the value may change from time to time if it is dependant on some host related facility.
`DontEnum`	You cannot enumerate this property with a `for in` repetition.
`DontDelete`	You cannot delete this property.
`Internal`	This is an internal property, which you normally won't have any access to. It's likely it would be hidden inside the host-managed objects and inaccessible to your scripts.

Where properties are `ReadOnly`, this is flagged in the documentation. Read/Write access is assumed to be the default case otherwise.

There is conflicting information in the reference sources regarding the read/write ability of some properties. Some suggest a particular property is `ReadOnly` and others suggest you can assign a value to it. It may be that you can assign a value to it without the JavaScript interpreter complaining but that any value you assign is ignored.

See also:	delete, Object, Property

Cross-references:

ECMA 262 edition 2 –section –8.6.1

ECMA 262 edition 3 –section –8.6.1

Property name (Definition)

The name of an object property.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0

Accessing properties of an object by name simply requires the name to be added to the object reference with a dot separator between them.

However, the properties in an object are also kept in an array. You can access items in an array by index number. However, the objects are really accessed by name and so item 4 is really accessed as item "4". You can use the property names as symbolic names for an array index.

Now, assuming that we had deduced that the property we were interested in was stored in item 4 of the property array and had the name `property4` as well, all of these would access the same property:

- `myObject.4`
- `myObject.property4`
- `myObject[4]`
- `myObject["4"]`
- `myObject["property4"]`

See also:	Array index delimiter ([ ]), Property

Wrox *Instant JavaScript* –page –32

Property value (Definition)

The value of an object property that is returned when that property is requested.

Availability:	ECMAScript edition –2

Objects own a set of properties that are named containers for values. You can create new properties belonging to the object itself or to its prototype if you want to share them among all instances of an object class. Using the object and property reference as an LValue allows you to assign a new value to the property. To retrieve the property value, use it as you would any other RValue.

See also:	LValue, Property, RValue

Prototype–Based Inheritance (Definition)

JavaScript supports an inheritance chain based on prototypes.

Availability:	ECMAScript edition –2

JavaScript supports an inheritance chain based on prototypes. Every constructor has an associated prototype and every object created with that constructor has a link to the prototype as an integral part of its instantiation. This is called the Object's Prototype.

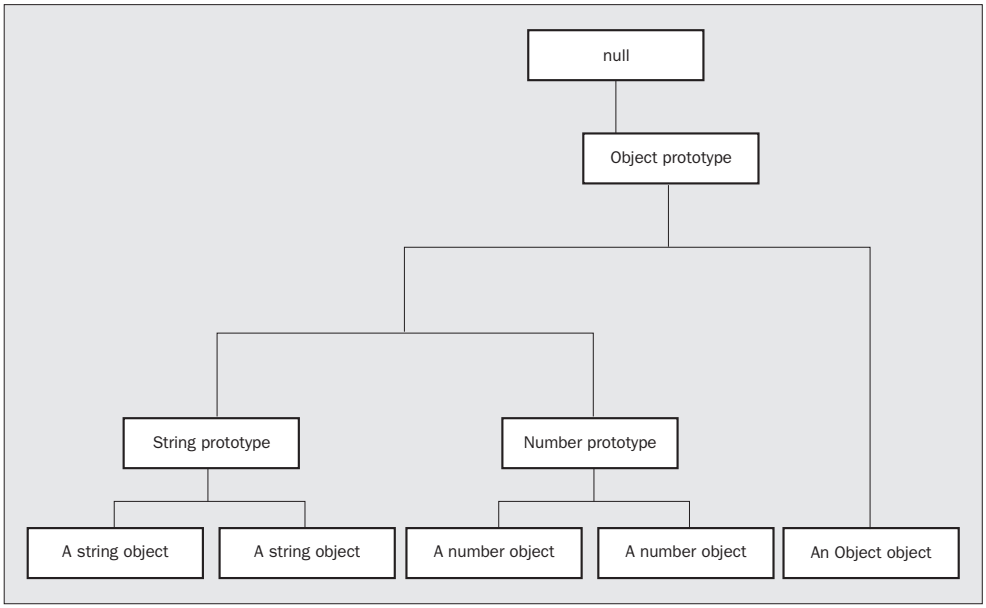
A prototype may have an implicit reference to it's parent prototype. This provides inheritance through a Prototype Chain that is analogous to the Super-Class and Sub-Class mechanisms in a class-based object-oriented language.

This allows for properties to be overridden or provided by parent prototypes if the properties are not implemented in the target object.

In a class-based object-oriented environment, as a general rule, state values are embodied in object instances of a class but methods are contained in the classes themselves so the inheritance only projects structure and behavior down through the sub-classing mechanism.

In the prototype-based inheritance the state AND methods are carried by the objects so structure, state, and behavior are all inherited down the prototype chain.

All objects that do not contain a particular property and that are descended via the inheritance tree from a single object that does contain that property will all share that one single property instance.



See also:	`function( ... ) ...`, Hierarchy of objects, Inheritance, Namespace, Prototype chain, `prototype` property, Shared Property

Cross-references:

ECMA 262 edition 2 –section –4.2.1

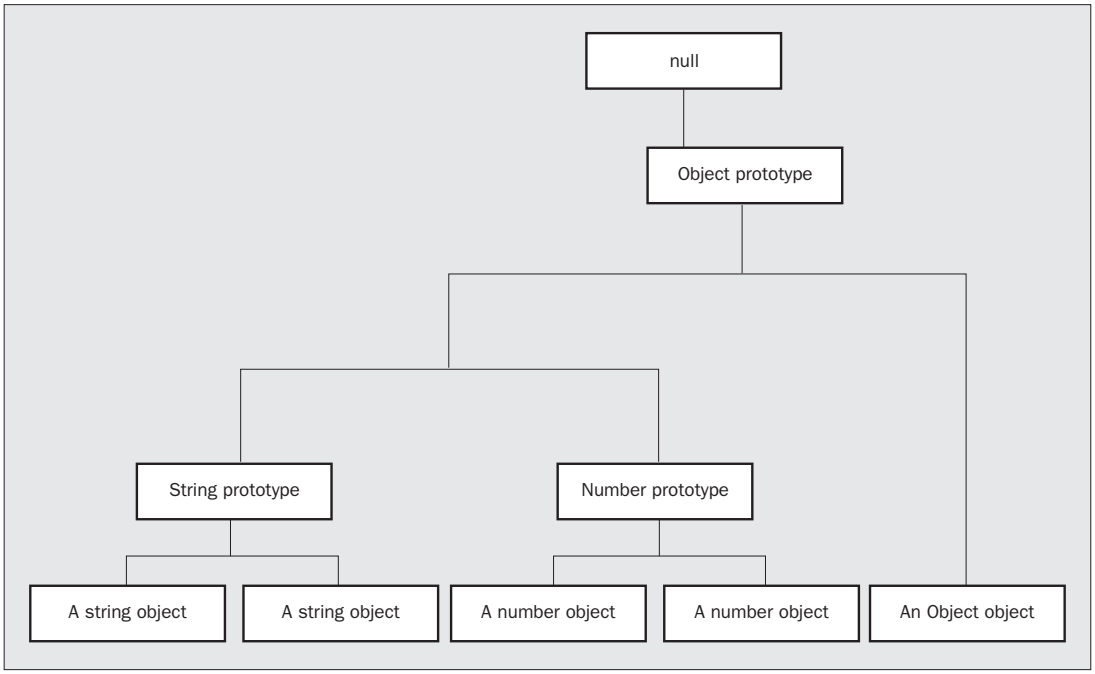
ECMA 262 edition 3 –section –4.2.1

Prototype chain (Definition)

JavaScript supports an inheritance chain based on prototypes.

Availability:	ECMAScript edition –2

A prototype chain is analogous to the super/sub-class inheritance mechanisms in an object-oriented environment. It is not quite the same, however, because the inheritance takes place at the object level and there are no true classes to instantiate. Instead you clone existing objects.



See also:	Prototype Based Inheritance, `prototype` property, Shared Property

Cross-references:

ECMA 262 edition 2 –section –4.2.1

ECMA 262 edition 2 –section –8.6.2

ECMA 262 edition 3 –section –4.2.1

ECMA 262 edition 3 –section –8.6.2

Prototype object (Definition)

Prototypes are analogous to default instances in a truly object-oriented system.

Availability:	ECMAScript edition –2

Prototypes are analogous to default instances in a truly object-oriented system. A constructor would copy this default instance to create a new instance of its object class.

A prototype is an object that implements structure, state, and behavior inheritance. When a constructor creates a new object, that new object implicitly refers to the constructor's associated prototype to resolve property references.

Prototypes can be referenced using the dot separated object hierarchy notation. With an object constructor called `myObject`, its prototype would be accessed like this:

```
myObject.prototype
```

If any properties are added to the prototype, they will be shared by and available to all objects created by the constructor associated with that prototype. Such objects may override the inheritance by having identically named properties added to them directly.

A Prototype would be expected to support the following property by default:

- `constructor`

It should also support the following method by default:

- `toString()`

Cross-references:

ECMA 262 edition 2 –section –4.3.5

ECMA 262 edition 3 –section –4.3.5

prototype.constructor (Definition)

The prototype object has a constructor that refers to the object that the prototype object is a property of.

See also:	Shared Property Constructor property

prototype.toString() (Definition)

A method that you should redefine in your own classes to yield a meaningful string value.

When you create a custom object type of your own, you add various methods to it to give it some capabilities that are unique to that type (otherwise why are you creating a new object type?).

Unless you override the default `toString()` method will be provided by the object that you cloned to make your class. By default that will be the global `Object` object.

The example show how to do this in a way that is consistent with normal JavaScript behavior.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>

// Make a constructor for a new class
function Car()
{
   this.myClass = "Car";
}

// Create a special toString() override
function myToString()
{
   return "[object " + this.myClass + "]";
}

// Register our overriding toString()
Car.prototype.toString = myToString;

// Instantiate an object from the new class
var myCar = new Car();

// Test the new object
document.write("To string : " + myCar.toString() + "<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	`toString()`

prototype property (Definition)

An internal method that returns a prototype.

Availability:	ECMAScript edition –2
Property/method value type:	Depends on the object

This property returns the prototype for the containing object.

The `prototype` property for an object returns a reference to the object that is the parent of the receiver in the prototype inheritance chain.

Any methods, properties, or functions present in the prototype will also be available in the child unless they are overridden.

This means that you can locate the parent prototype for a group of objects and store a value into a property there and it will be immediately available as a property of all the objects that share the same prototype.

The typical time you do this is when you are creating a prototype for a new class of object of your own. In that case you would also create a constructor function to initialize new instances of the object as well.

This property will either return `null` or an object that is the prototype for the object responding to the property request. This is used for maintaining the inheritance through the prototype chain.

Properties of the prototype object are exposed to the child object through the get accessor method. However since they are shared, they cannot be changed with the put accessor through the child. If they are changeable at all, the specific object that explicitly owns them is the only one with rights to modify the values as long as they are not read-only. This prevents a child object from modifying a property and that change propagating across all the objects that share the same property between them.

There is an internal property called `Prototype`, which yields the same value. Note the capitalization. Internal properties are not generally exposed to the scripting language. The `Prototype` property is one of the few that are.

Prototypes are also useful as a means of extending the interface for a particular type of object. By adding new properties and methods to the prototype, you make them available to all objects of that class.

Warnings:

- Do not create your own object properties with this name. You can assign new values to the prototype property in some implementations if you want to modify the inheritance chain but you should not use this property name for any other purpose.
- You cannot assign values to the prototype of the native objects in MSIE version 3.
- Be careful if you are adding to the prototype for some of the more obscure classes as this may reveal some shortcomings in the prototype-constructor mapping, which is implemented incorrectly for some objects.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Make a constructor for a new class
function Car(engineSize)
{
   this.enginesize   = engineSize;
   this.totalMileage = 0;
}

// Create a special toString() override
function myToString()
{
   return "This is a car object";
}

// Register our overriding toString()
Car.prototype.toString = myToString;
```

```
// Make a couple of other methods to add to it
function mileage()
{
   return this.totalMileage;
}
function addMiles(newMiles)
{
   this.totalMileage += newMiles;
}

// Add some shared properties
Car.prototype.wheels = "Alloy";
Car.prototype.body   = "Cabriolet";

// Register the mileage methods
Car.prototype.mileage  = mileage;
Car.prototype.addMiles = addMiles;

// Instantiate an object from the new class
var myCar = new Car(2000);

// Drive it around some to add miles to its clock
myCar.addMiles(100);
myCar.addMiles(150);
myCar.addMiles(200);

// Display its properties and call its methods
document.write("To string : " + myCar.toString() + "<BR>");
document.write("Engine size : " + myCar.enginesize + "<BR>");
document.write("Wheels : " + myCar.wheels     + "<BR>");
document.write("Body : " + myCar.body       + "<BR>");
document.write("Mileage : " + myCar.mileage()  + "<BR>");
</SCRIPT>
</BODY>
</HTML>
```

Wrox *Instant JavaScript* –page –31

Proxies (Definition)

A proxy server mediates on your behalf to span a firewall and gather items that your browser has requested.

This won't generally have any impact on the coding of your JavaScript but in the case of the Netscape Navigator browser, the proxy connection setup can be defined in a `proxy.pac` file that is coded using JavaScript to describe the proxy preference settings.

See also:	`.pac,FindProxyForURL(),isInNet(),proxy.pac`

proxy.pac (Special file)

This is a special file containing rules for accessing sites through proxy servers.

If you are using a browser inside a firewall, you will likely reach the internet by using a proxy server. This is a special kind of web server that spans or bridges the firewall and fetches things across the internet for you.

Generally these proxy servers will also limit access or log details of everything you fetch.

You can operate with no proxies, manually defined proxies, or automatic proxies in the case of Netscape Navigator.

When you select Automatic mode, you are connecting in to a piece of JavaScript code that can work out whether to use a proxy or not and if so, which one.

In this context, some language features may be unavailable but then others are provided to assist in the deconstruction of URL values, and are only available in this context.

The only purpose of a `proxy.pac` file is to define the content of the `FindProxyForURL()` function.

The `proxy.pac` file can be retrieved from any location that can be defined by a URL. This means it could be a local file on your desktop or served directly by a web server inside your firewall. In theory it could be served by a web server outside your firewall so long as your firewall had a 'hole' in it to allow you to gain direct access to the server. That could lead to problems where the file you pull back might thereafter prevent access to that location, and it obviates the whole purpose of having a firewall in the first place.

Providing this file on a local web server inside your firewall means that it can be shared by all your Netscape Navigator browser users and maintained from a central locations. This is not very much use if you only have one user but when you have 500 it is a great time saver. However, the downside is that if you publish a broken `proxy.pac` file, all of your users go offline as soon as their browsers download it.

You cannot browse a `proxy.pac` file with a Netscape Navigator browser; however, you might be able to download one with MSIE if you are curious to see what it looks like.

To set this mechanism working, you need to go to the proxy configuration panel in your browser preferences and choose automatic proxy configuration. Then you need to type in the URL where the `proxy.pac` file lives.

Punctuator (Definition)

Punctuators are composed of special non-alphabetic characters.

Availability:	ECMAScript edition –2

Punctuators are composed of special non alphabetic characters and are considered to be valid tokens by the interpreter.

Here is a summary of all the valid tokens:

Value	Meaning
!	Logical not
!=	Not equal to
!==	Not exactly equal to (ECMA edition 3)
%	Remainder
%=	Remainder and assign
&	Bitwise AND
&&	Logical AND
&=	Bitwise AND and assign
(	Function argument delimiter and precedence control
)	Function argument delimiter and precedence control
*	Multiply
*=	Multiply and assign
+	Unary plus, add, concatenate string
++	Postfix and prefix increment
+=	Add and assign
,	Argument delimiter
-	Unary minus, subtract
--	Postfix and prefix decrement
-=	Subtract and assign
.	Property accessor
/	Divide
/=	Divide and assign
:	Part of conditional operator
;	Statement terminator
<	Less than
<<	Bitwise shift left
<<=	Bitwise shift left and assign
<=	Less than or equal to
=	Assign value
==	Equal to
===	Exactly equal to (ECMA edition 3)
>	Greater than
>=	Greater than or equal to
>>	Bitwise shift right
>>=	Bitwise shift right and assign

Table continued on following page

Value	Meaning
>>>	Bitwise shift right (unsigned)
>>>=	Bitwise shift right (unsigned) and assign
?	Conditional operator
[	Array index delimiter
]	Array index delimiter
^	Bitwise XOR
^=	Bitwise XOR and assign
{	Start code block
|	Bitwise OR
|=	Bitwise OR and assign
||	Logical OR
}	End code block
~	Bitwise NOT

Refer to the items in the see-also list for more details of their functionality.

The [ ], { }, and ( ) punctuators must be used in pairs and must also be nested correctly.

Some punctuator symbols are also used as operators.

See also:	Code block delimiter {}, Lexical element, Operator, Operator Precedence, Statement, Token

Put() (Function/internal)

Internal private function.

Availability:	ECMAScript edition –2

This internal function is used to store a new value into an internal property.

The property is set or not according to the result of the `CanPut` function for the property. If the property does not exist, then a new property is created with its attributes set to an empty condition.

The `Put` internal function may indeed allow a property value to be changed when received by a host object, even if that host object would respond to the `HasProperty` function with a `false` result indicating that the property does not exist.

See also:	Internal Method, `PutValue()`

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 –section –8.6.2.2

ECMA 262 edition 3 –section –8.6.2.2

put() (Method/internal)

Write publicly accessible properties.

Availability:	ECMAScript edition –2

Used to store new values into publicly exposed properties.

See also:	Accessor method

Cross-references:

ECMA 262 edition 2 –section –8.6.2.2

ECMA 262 edition 3 –section –8.6.2.2

PutValue() (Function/internal)

Internal private function.

Availability:	ECMAScript edition –2

This internal function stores a value in the property belonging to the reference item passed as its argument.

A run-time error is generated if the argument passed in is not a reference item.

If the target object does exist, the usual `Put()` function logic is invoked to store the value in the object property.

If the target object does not exist, then the property is added to the global object and takes the value that is passed as a new value.

See also:	`Global` object, `Put()`, Reference

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 –section –8.7.4

ECMA 262 edition 3 –section –8.7.2

Q object (Object/HTML)

An object instantiated by the HTML `<Q>` tag which indicates that a part of the document content is a quotation.

Availability:	JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myQ* = *myDocument*.all.*anElementID*
	IE	*myQ* = *myDocument*.all.tags("Q")[*anIndex*]
	IE	*myQ* = *myDocument*.all[*aName*]
	-	*myQ* = *myDocument*.getElementById(*anElementID*)
	-	*myQ* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myQ* = *myDocument*.getElementsByTagName("Q")[*anIndex*]
HTML syntax:	`<Q> ... </Q>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	An `ID` attribute value
Object properties:	`cite`	
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`cite`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	3.0 +	3.0 +	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

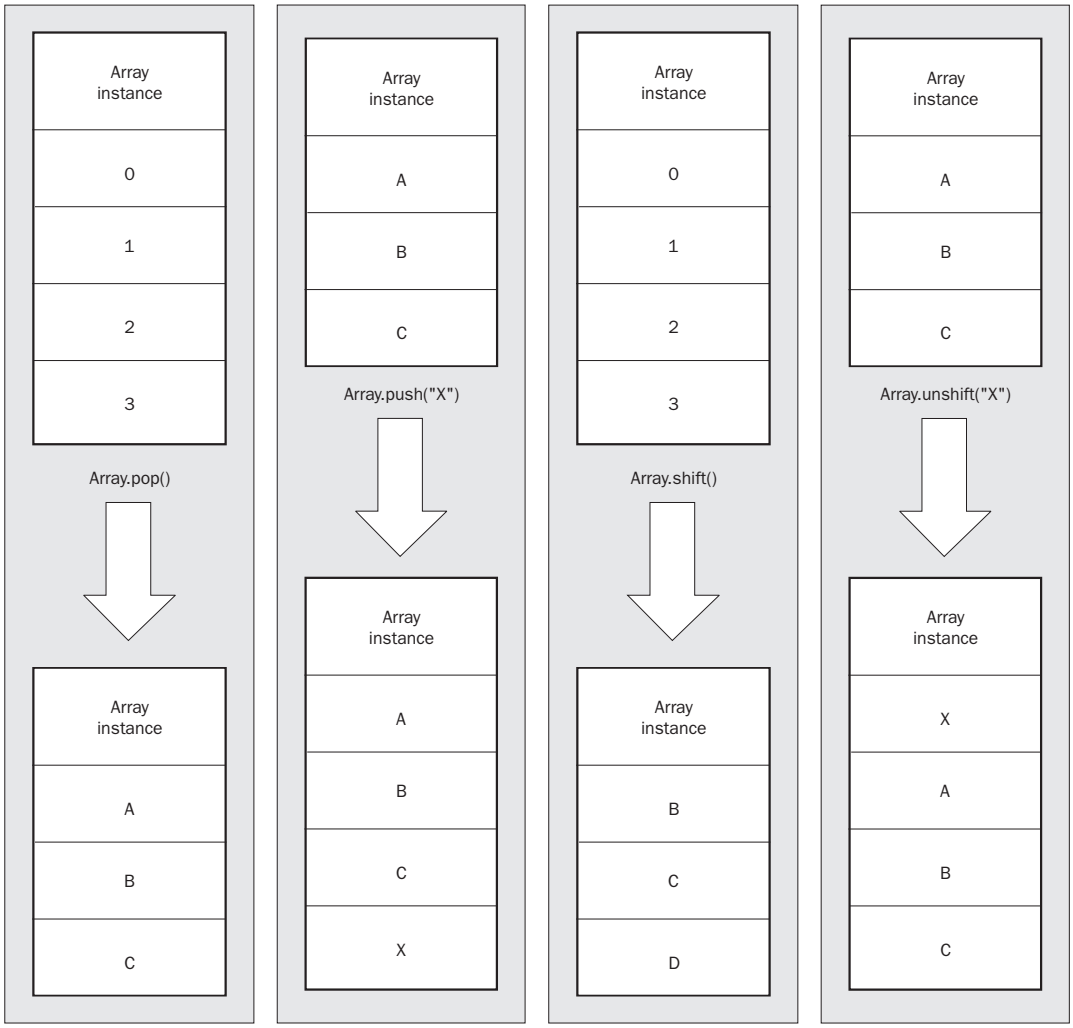
Queue manipulation (Useful tip)

With the enhanced array manipulation tools of JavaScript, you can build queue managers.

With the `Array` object methods `push()`, `pop()`, `unshift()` and `shift()`, you can build various stacks and queues.

'First In First Out' queues can be built with either `unshift()` and `pop()` or `push()` and `shift()` depending on which direction you want the objects to be queued in.

These capabilities have been available in Netscape since version 4, but are only available in MSIE at version 5.5, having been added to gain ECMA edition 3 compliance.



See also:	`Array.pop()`,`Array.push()`,`Array.shift()`,`Array.unshift()`, Stack manipulation

Quotation mark (" and ') (Delimiter)

String literal delimiter.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.0 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`'ABCDEF'`
	-	`"ABCDEF"`

See also:	ASCII, Escape sequence (\), Escaped JavaScript quotes in HTML, Line terminator, Literal, Punctuator, String, Unicode, `var`, String literal

Cross-references:

ECMA 262 edition 2 –section –7.7.3

ECMA 262 edition 2 –section –7.7.4

ECMA 262 edition 3 –section –7.8.4

R.E. (Definition)

Another name for a regular expression.

Refer to:

Regular expression

RadialWipe() (Filter/transition)

A transition effect similar to that seen on radar displays.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `RadialWipe()`

RadioButton object (Object/DOM)

A toggle button that acts together with a group of radio buttons in a family. Clicking one deselects any others in the group. These are used in forms to choose one item from a set.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Inherits from:	`Input` object

JavaScript syntax:	-	*myRadioButton* = *myDocument*.*aFormName*.*anElementName*
	-	*myRadioButton* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*myRadioButton* = *myDocument*.all.*anElementID*
	IE	*myRadioButton* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myRadioButton* = *myDocument*.all[*aName*]
	-	*myRadioButton* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myRadioButton* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*myRadioButton* = *myDocument*.getElementById(*anElementID*)
	-	*myRadioButton* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myRadioButton* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	<INPUT TYPE="radio">	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The ID attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the forms collection
Object properties:	checked, defaultChecked, status, type, value	
Object methods:	handleEvent()	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDblClick, onErrorUpdate, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit	

Many properties, methods, and event handlers are inherited from the Input object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the Input object super-class.

There isn't really a RadioButton object class but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a radio button. In actual fact, the object is represented as an item of the Input object class.

The RadioButton sub-class of the Input object does not support the select() method or the defaultValue property except on MSIE.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT">?</DIV>
<FORM onClick="handleClick()">
<INPUT TYPE="radio" VALUE="A" NAME="SET">Selection A<BR>
<INPUT TYPE="radio" VALUE="B" NAME="SET">Selection B<BR>
<INPUT TYPE="radio" VALUE="C" NAME="SET">Selection C<BR>
<INPUT TYPE="radio" VALUE="D" NAME="SET">Selection D<BR>
</FORM>
<SCRIPT>
//Code for IE only
function handleClick()
{
   myString  = "[";
   myString += document.forms[0].elements[0].checked;
   myString += "] [";
   myString += document.forms[0].elements[1].checked;
   myString += "] [";
   myString += document.forms[0].elements[2].checked;
   myString += "] [";
   myString += document.forms[0].elements[3].checked;
   myString += "]";
   document.all.RESULT.innerText = myString;
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	Element object, `Form.elements[]`, `FormElement` object, `Input` object, `Input.accessKey`, `onClick`, `RadioButton.handleEvent()`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onRowExit	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Input` object, `Node` object

RadioButton.checked (Property)

The state of the button is returned by this property.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`myRadioButton`*`.checked`
HTML syntax:	`<INPUT CHECKED>`	

If the radio button has a mark in it (it is the only one of the family it belongs to that is selected), then this value will return `true`. Otherwise it will return `false`.

RadioButton.defaultChecked (Property)

The default checked state for a radio button in a form.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *`myRadioButton`*`.defaultChecked`
HTML syntax:	`<INPUT CHECKED>`

The `defaultChecked` state of an `Input` item is the value that was defined in the HTML document source when the page was loaded. You can use this value if you need to reset the status of a page or determine whether the user changed the settings on an input item since the page was loaded.

RadioButton.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N *`myRadioButton`*`.handleEvent(`*`anEvent`*`)`	
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape Navigator prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent()`, `RadioButton` object

RadioButton.status (Property)

The current status of a particular radio button.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myRadioButton`*`.status`

This is the current status of the radio button item. It is either checked or not. If the radio button has not been changed since the page was loaded from the server, then this value will be the same as the `defaultChecked` state of the radio button.

RadioButton.type (Property)

The type value for the `<INPUT>` object that describes the radio button.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myRadioButton`*`.type`

The type value for a `RadioButton` is always "radio". This value is necessary to determine the type of form element because this object is really an instance of the `Input` class and not a `RadioButton` class, because there is no `RadioButton` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

RadioButton.value (Property)

The text string value of this particular radio button.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myRadioButton`*`.value`

This value is returned to the server during a submit only if the checked state for this radio button is on.

Warnings:

- The state of the checkbox is in the checked property not the value property.

See also:	`Input.value`

RandomBars() (Filter/transition)

A transition effect with the appearance of random bars sliding down.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `RandomBars()`

RandomDissolve() (Filter/transition)

A transition effect with the appearance of a fine pixelated dissolve.

Availability:	JScript –5.5 Internet Explorer –5.5

Refer to:

Filter – `RandomDissolve()`

Range error (Definition)

Some functions (especially math functions) have a limited range of valid arguments.

Range errors occur when the value passed to a function falls outside the range of possible valid values for that function. This problem is most prevalent with functions belonging to the `Math` object.

An out-of-range error is caused because the function cannot resolve the input value to a meaningful output value.

Because JavaScript is more forgiving than a compiled language, these exceptions are managed by returning one of the following values:

- `NaN`
- `+Infinity`
- `-Infinity`
- `undefined`
- `null`

The host implementation may provide other values and, if it so chooses, can deliver a specific range error value for its own function calls.

Refer to descriptions of the `Math` object and its functions for details of the range of suitable values for each function call.

See also:	`Infinity`, `Math` object, Mathematics, Minima-maxima, `NaN`, Null literal, undefined, Undefined behavior

RangeError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition –3 JavaScript –1.5 Netscape –6.0	
Inherits from:	&`Error object`	
JavaScript syntax:	N	*`myError`* `= new RangeError()`
	N	*`myError`* `= new RangeError(`*`aNumber`*`)`
	N	*`myError`* `= new RangeError(`*`aNumber, aText`*`)`
Argument list:	*`aNumber`*	An error number
	`aText`	A text describing the error

This sub-class of the `Error` object is used when an exception is caused by a numeric value exceeding its allowable range.

See also:	`catch( ... )`, `Error` object, `EvalError` object, `ReferenceError` object, `SyntaxError` object, `throw`, `try ... catch ... finally`, `TypeError` object, `URIError` object

Inheritance chain:

`Error` object

Cross-references:

ECMA 262 edition 3 –section –15.1.4.11

ECMA 262 edition 3 –section –15.11.6.2

Raw event (Definition)

An event that describes a physical action.

See also:	`onBlur`, `onFocus`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseDrag`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, Event propagation

ReadOnly (Property attribute)

An internal property attribute that controls whether a property value can be changed.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

This is intended to prevent the script from modifying a property value.

You should note however that this does not mean that the property must always be `ReadOnly`. There may be times when the hosting environment changes the `ReadOnly` settings for a property.

Generally, the `ReadOnly` state would not change very often but the standard mandates that it does not mean constant and unchanging, only that while the `ReadOnly` state is `true`, the property should be locked out against any attempts to change its value.

Note that this is not the `readOnly` property that belongs to a Form Input element. That is intended to stop the user from altering the current state of an input item.

See also:	`DontDelete`, `DontEnumerate`, `Input.readOnly`

Cross-references:

ECMA 262 edition 2 –section –8.6.1

ECMA 262 edition 3 –section –8.6.1

Rect object (Object/browser)

A rectangle object used for Layer clip rectangles.

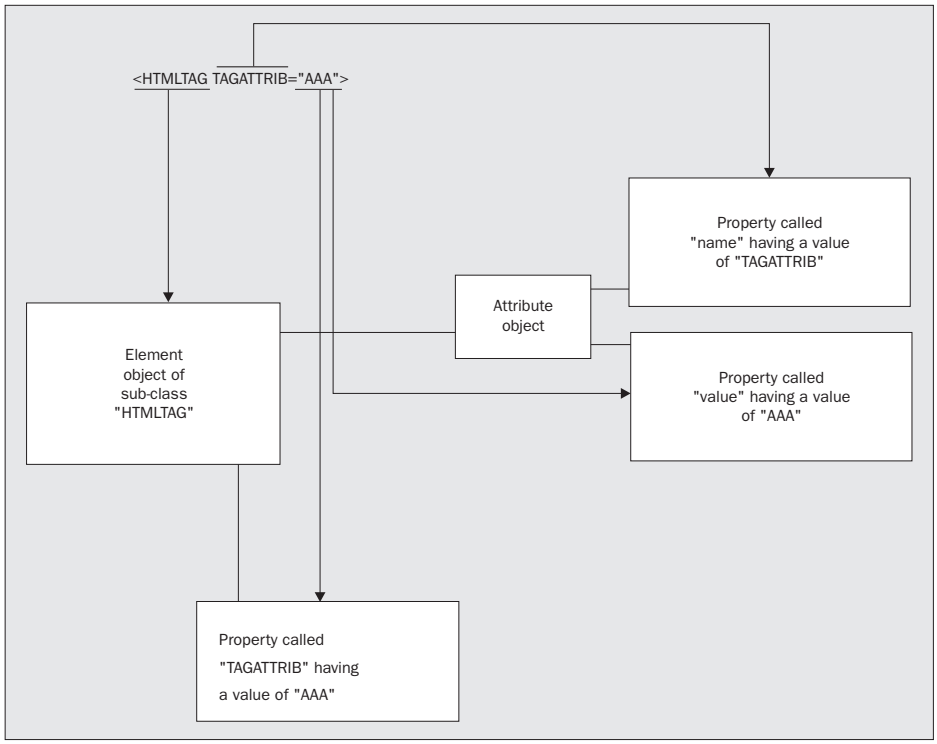
Availability:	JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	*myRect* = myLayer.clip
	N	*myRect* = myStyle.clip
Object properties:	bottom, height, left, right, top, width	

This object represents a clipping rectangle that the visible part of a display object is viewed through. This is most likely used with a `layer` object. The layer contents would be drawn off-screen and then that part which falls within the clipping rectangle would be displayed in the window.

This can be useful for performing wipes and making parts of a layer progressively visible within some kind of transition loop.

In the MSIE browser, these rectangular objects are manufactured as needed with the `rect()` constructor function.

These rectangles are not the same as you can create with the `getBoundingClientRect()` method, which applies to a `TextRange` object. That method creates `TextRectangle` which responds differently to the pixel rectangle we have here.



See also:	`Clip` object, `Layer.clip`, `style.clip`, `TextRange.getBoundingClientRect()`, `textRectangle` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`bottom`	1.2 +	-	4.0 +	-	-	-	-
`height`	1.2 +	-	4.0 +	-	-	-	-
`left`	1.2 +	-	4.0 +	-	-	-	-
`right`	1.2 +	-	4.0 +	-	-	-	-
`top`	1.2 +	-	4.0 +	-	-	-	-
`width`	1.2 +	-	4.0 +	-	-	-	-

Rect.bottom (Property)

The bottom edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myRect*`.bottom`

This defines the bottom edge of the rectangle described by the object. You could modify this in a loop to create a vertical upwards wipe transition effect.

See also:	`Clip.bottom`, `Layer.clip.bottom`

Rect.height (Property)

The height of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myRect*`.height`

The clip region is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

See also:	`Clip.height`, `Layer.clip.height`

Rect.left (Property)

The left edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myRect*`.left`

This defines the left edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

See also:	`Clip.left,Layer.clip.left`

Rect.right (Property)

The right edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myRect*`.right`

This defines the right edge of the clip region. You could modify this in a loop to create a horizontal wipe transition effect.

See also:	`Clip.right,Layer.clip.right`

Rect.top (Property)

The top edge of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myRect*`.top`

This defines the top edge of the clip region. You could modify this in a loop to create a vertical downwards wipe transition effect.

See also:	`Clip.top,Layer.clip.top`

Rect.width (Property)

The width of a layer's clip region.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	`myRect.width`

The clip region is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

See also:	`Clip.width`, `Layer.clip.width`

Reference (Definition)

An internal type used by the interpreter.

Availability:	ECMAScript edition –2

This is an internal type used by the interpreter for processing expression evaluation results. It cannot be stored as an object property.

JavaScript supports references to objects via variables that contain them. This is a useful facility to be able to make use of as it can increase performance and also allow code to be reused.

Conceptually at least, the storage of objects in variables works as if the variable assumed a `Reference` type.

A `Reference` item points at the property of an object. Therefore it consists of two parts: the base object and the property name.

It is ephemeral and is not necessarily implemented in the interpreter, but it is used in the ECMA standard to help explain how some of the internal algorithms operate.

It facilitates a simplified syntax grammar and therefore adds value in the understanding of how the internals of the grammar should behave.

It helps describe the operation of the `delete` and `typeof` operators, the assignment of values and function calls. It also assists in the grammar of the '`this`' value for function calls that are associated with objects and used as methods.

See also:	Assign value (=), Function arguments, `GetBase()`, `GetPropertyName()`, `GetValue()`, `PutValue()`, `this`, Type, `typeof`

ECMA 262 edition 3 –section –8.7

Reference counting (Definition)

The manner in which we keep track of object usage.

Using the `new` operator creates a new object with a reference count of zero. Assigning that object creation to a variable increments the reference count as does storing it in an array or saving it as an object property. Deleting a variable containing a reference to an object decrements the reference count for that object.

When you assign the result of a new operation to a variable, first the object gets instantiated and stored and a reference to it is stored in the variable. If you assign the variable to another, you copy the reference. Now two variables are referring to the same object. Modifying the object that one points at modifies the other.

Using the `delete` operator on one variable removes a reference to the object. The other variable continues to refer to it and the object must remain persistent while it does. When no variables are referring to the object and there are no other references such as items in arrays or properties in other objects, the reference count is zero.

When the reference count is zero, the object can be garbage collected. Also, because there are no references to it, you have no handle by which you can reach it, so if it isn't garbage collected, it will waste the space it occupies. When that happens, you have a memory leak.

You would not normally have any access to the reference count for a variable and indeed, some implementations may use a different technique to manage garbage collection. However, it is a useful concept and allows the idea of objects, references and garbage collection be more easily understood.

See also:	`delete`, Function arguments, Garbage collection, Memory leak, `Object()`, `Option()`, Variable

ReferenceError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition –3 JavaScript –1.5 Netscape –6.0	
Inherits from:	`Error` object	
JavaScript syntax:	N	*myError* `= new ReferenceError()`
	N	*myError* `= new ReferenceError(`*aNumber*`)`
	N	*myError* `= new ReferenceError(`*aNumber*`, `*aText*`)`
Argument list:	*aNumber*	An error number
	aText	Text describing the error

This sub-class of the `Error` object is used when an exception is caused by an incorrect reference being made to an object.

Regex (Definition)

Another name for regular expression handling.

See also:	`RegExp` pattern –character literal, Regular expression

RegExp literal (Definition)

A way of creating and initializing regular expression objects.

Availability:	ECMAScript edition –3

A `RegExp` literal is defined as some matching expression enclosed in slash characters.

The grammar for building regular expressions is somewhat complex. The rules are basically straightforward with there being a sequence of individual matching rules assembled together and enclosed in slashes. There can be some modifier flags placed after the second (terminating) slash delimiter.

Here are some example Regular Expression literals:

```
/^JavaScript/

/19[0-9][0-9]*/

/\binterpreter/i

/squeek/g
```

You can assign these expressions to variables, which will then contain a `RegExp` object.

Warnings:

- You cannot define a `RegExp` literal that is empty simply with a pair of slash characters. This would define a single line comment delimiter instead.
- You must specify an empty `RegExp` literal like this:
  - `/(?:)/`

Example code:

```
// Declare a variable and assign a RegExp literal to it
var myPattern = /x$/;
// Now do the same thing with a RegExp constructor
var myPattern = new RegExp("x$");
```

See also:	`RegExp` pattern –character literal, `RegExp()`

O'Reilly *JavaScript Definitive Guide* –page –49

RegExp object (Object/core)

An object that encapsulates regular expressions.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
JavaScript syntax:	-	*myRegExp* = RegExp
	-	*myRegExp* = new RegExp()
	-	*myRegExp* = RegExp(*aPattern*)
	-	*myRegExp* = RegExp(*aPattern*, *someAttribs*)
Argument list:	*aPattern*	A regular expression pattern
	someAttribs	One or more regular expression attributes
Class properties:	$n, index, input, lastMatch, lastParen, leftContext, multiline, rightContext	
Object properties:	$&, $', $*, $+, $_, $`, constructor, global, ignoreCase, index, lastIndex, prototype, source	
Object methods:	compile(), exec(), test(), toSource(), toString()	

The `RegExp` object implements some class (or static) methods which is fairly untypical of classes that support a constructor. There are also instance methods and properties.

Warnings:

- The static properties of a regular expression object do not conform to the same static scoping rules as the rest of JavaScript. Their static or class based properties are dynamically scoped and available in the scope chain from which they are executed. This is not the same as the scope rules for functions, which dictates that they run in the scope in which they are declared and not the scope from which they are called. This means that if a regular expression object is accessed in a function declared in one frame, when that function is called, the static properties are modified for the global built-in regular expression object that belongs to the calling frame. This avoids all manner of multithreaded simultaneous execution problems that would be difficult to deal with if the scoping rules for regular expression objects were the same as the rest of JavaScript.
- In Netscape Navigator, many properties of the `RegExp` built-in object are enumerable but they are not available in this way in MSIE.
- IE 5 does not properly support the `RegExp` object on the Macintosh platform. Many properties such as `lastMatch`, `leftContext`, etc. return an undefined value regardless of the `RegExp` result.

Example code:

```
// Create a RegExp object using a constructor
var myRegExp = new RegExp("sque[ea]ky", "g");
// Create the same RegExp object with a RegExp literal
var myRegExp = /sque[ea]ky/g;
```

See also:	Function scope, `RegExp` pattern –character literal, `RegExp()`, `RegExp.multiline`, `unwatch()`, `watch()`

RegExp() (Constructor)

A constructor function for creating new regular expression objects.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera 5.0	
JavaScript syntax:	-	`new RegExp(aPattern)`
	-	`new RegExp(aPattern, someAttribs)`
Argument list:	*aPattern*	A regular expression-matching pattern contained in a string
	someAttribs	A string containing the regular expression attributes

A `RegExp` constructor is used to create a new regular expression object containing a search pattern.

The first argument is a string containing a properly escaped pattern. Because the backslash character (\) is an escape when used in a string, for the back slashes to remain in the regular expression pattern, they will need to be double escaped. For example, this pattern:

```
/\d+/
```

Must be escaped like this when used in a string:

```
"\\d+"
```

The second argument is the attributes for the pattern. You should not put the attributes on the end of the pattern but specify them separately. These are available:

Operator	Description	JavaScript
`i`	Ignore case	JavaScript 1.2
`g`	Match globally	JavaScript 1.2
`ig`	Ignore case and match globally	JavaScript 1.2
`m`	Multiple line parsing	JavaScript 1.5

The regular expression constructor is useful for those occasions when you cannot easily predict what string you will need to match. If you could, it is likely you would use a regular expression literal. If the user is going to enter some value that determines what the search characteristics are to be then a `RegExp()` constructor may be useful.

Example code:

```
// Declare a variable and assign a RegExp literal to it
var myPattern = /x$/;
// Now do the same thing with a RegExp constructor
var myPattern = new RegExp("x$");
```

See also:	new, RegExp literal, `RegExp` object, RegExp pattern –attributes, RegExp pattern –character literal, `RegExp.constructor`, Regular expression

ECMA 262 edition 3 –section –15.10.4

RegExp() (Function)

Another way to call the `exec()` method for the regular expression object.

Availability:	ECMAScript edition –3 JavaScript –1.2 Netscape –4.0	
JavaScript syntax:	N	`RegExp()`

See also:	`RegExp.$n`, `RegExp.input`, `RegExp.lastMatch`, `RegExp.lastParen`, `RegExp.leftContext`, `RegExp.multiline`, `RegExp.rightContext`, `RegExp.exec()`

Cross-references:

ECMA 262 edition 3 –section –15.10.3.1

RegExp.$_ (Property)

An alias for the input buffer of the regular expression.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myRegExp.$_`

Refer to:

`RegExp.input`

RegExp.$n (Property/static)

A property of the global `RegExp` object.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
JavaScript syntax:	-	`RegExp.$1`
	-	`RegExp.$2`
	-	`RegExp.$3`
	-	`RegExp.$4`
	-	`RegExp.$5`
	-	`RegExp.$6`
	-	`RegExp.$7`
	-	`RegExp.$8`
	-	`RegExp.$9`

There are nine similarly named properties whose name is a dollar symbol followed by a single digit, each of these holding text matched by a sub-expression (in parentheses) for the most recent match.

The ECMAScript edition 3 specification suggests that the range of values for this is $01 to $99 and for an implementation to be ECMA compliant, it should support that range of possibilities, as well as the $1 to $9 values.

Warnings:

- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately your regular expression has evaluated and before you call another.
- Note that there are only 9 of these. If you create a complex pattern that has more than 9 sub-expressions, you won't be able to access the sub-expressions above the ninth one unless the implementation is fully compliant with ECMAScript edition 3.
- Early versions of MSIE did not fully support this numbered property mechanism.

See also:	`RegExp` pattern –grouping, `RegExp` pattern –references, `RegExp.exec()`, `RegExp.test()`

Property attributes:

`ReadOnly.`

Cross-references:

ECMA 262 edition 3 –section –15.5.4.11

RegExp.compile() (Method)

Recompile a regular expression object's search mechanics.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
JavaScript syntax:	-	*myRegExp*.compile(*aPattern*)
	-	*myRegExp*.compile(*aPattern*, *someAttribs*)
Argument list:	*aPattern*	A regular expression-matching pattern contained in a string
	someAttribs	A string containing the regular expression attributes

This takes the same argument as the constructor and can be used to recycle an existing `RegExp` object with a freshly initialized search pattern and attributes.

The first argument is a string containing a properly escaped pattern. Because the backslash character (\) is an escape when used in a string, for the backslashes to remain in the regular expression pattern, they will need to be double escaped. For example, this pattern:

```
/\d+/
```

Must be escaped like this when used in a string:

```
"\\d+"
```

The second argument is the attributes for the pattern. You should not put the attributes on the end of the pattern but specify them separately. These are available:

Operator	Description	JavaScript
i	Ignore case	JavaScript 1.2
g	Match globally	JavaScript 1.2
ig	Ignore case and match globally	JavaScript 1.2
m	Multiple line parsing	JavaScript 1.5

The regular expression `compile()` method is useful for those occasions when you cannot easily predict what string you will need to match. As is the case with the constructor you can define the pattern based on a user-specified value. With the `compile()` method, you can replace the pattern as needed without destroying and recreating the object again.

Calling the `compile()` method on a `RegExp` object is a good way to gain some performance improvements if the regular expression is used frequently during a session. It will need compiling again each time it is instantiated.

RegExp.constructor (Property)

A reference to the constructor object for regular expressions.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera 5.0	
Property/method value type:	`RegExp` object	
JavaScript syntax:	-	*myRegExp*`.constructor`

The constructor is that of the built-in `RegExp` prototype object.

You can use this as one way of creating regular expressions although it is more popular to use the new `RegExp()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape Navigator provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`RegExp()`

Cross-references:

ECMA 262 edition 3 –section –15.10.6.1

RegExp.exec() (Method)

This performs a non-destructive match on a target string.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
Property/method value type:	`Array` object	
JavaScript syntax:	-	*myRegExp*`.exec()`
	-	*myRegExp*`.exec(`*aString*`)`
Argument list:	*aString*	A string object to run a regular expression match against

This is functionally similar to the `String.match()` method. It returns an enhanced array object in the same way. You would use this if you need to know the location of the matched string and whether it occurs more than once.

The `g` attribute is ignored for `RegExp.exec()` methods unlike the `String.match()` method.

When the `exec()` method is received by a global `RegExp` object, the `lastIndex` property of that `RegExp` object is set to point at a character location immediately following the previous match. This means you can use sub-stringing techniques to walk through the string calling `exec()` in an iterator until a `null` value is returned. This lets you build an iterator based on the pattern and the number of times it recurs in the searched string. The `RegExp.exec()` method does most of the work for you since it continues where it left off during the previous search. This also means you can reset the search point or commence searching wherever you like in the target string.

A shortcut mechanism to calling the `exec()` method is to call the `RegExp` itself as a function. Thus we can create a regular expression object and a target string object:

```
myRegExp = new RegExp("/\\d+/");

myString = "aaa 111 bbb 222 ccc";
```

We can execute the regular expression either like this:

```
myRegExp.exec(myString);
```

Or like this:

```
myRegExp(myString);
```

The result of calling this method is the `null` value if no match occurs. Otherwise, an array as per the `String.match()` method is returned.

The array object has an additional property named `index`, which contains the character location where the match occurred. It also has an additional property called `input`, which contains the original string that was searched for a match.

Warnings:

- Support for this method is bugged in IE 4.
- If you do not pass a string to the `RegExp.exec()` method, it will match against the current value of the `RegExp.input` property that belongs as a static class property of the built-in `RegExp` object.
- The input property gets set automatically by client-side event handlers for `FormElement` objects in a web page form.

See also:	`Array.index`, `Array.input`, `RegExp` pattern, `RegExp.$n`, `RegExp.input`, `RegExp.lastIndex`, `RegExp.lastMatch`, `RegExp.lastParen`, `RegExp.leftContext`, `RegExp.multiline`, `RegExp.rightContext`, `RegExp.test()`, Regular expression, `String.match()`, `String.replace()`, `String.search()`, `String.split()`

Cross-references:

ECMA 262 edition 3 –section –15.10.6.2

RegExp.global (Property)

An instance property of a regular expression object.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myRegExp*`.global`

A Boolean value that indicates the state of the `g` attribute on the regular expression pattern.

Property attributes:

`ReadOnly`.

Cross-references:

ECMA 262 edition 3 –section –15.10.7.2

RegExp.ignoreCase (Property)

An instance property of a regular expression object.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3 Internet Explorer –4 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myRegExp*.ignoreCase

A Boolean value that indicates the state of the `i` attribute on the regular expression pattern.

Property attributes:

`ReadOnly`.

Cross-references:

ECMA 262 edition 3 –section –15.10.7.3

RegExp.index (Property)

The position of the first match in the string.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myRegExp*.index

A character index position into the source string where the first match is located.

RegExp.input (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera 5.0	
JavaScript syntax:	-	*RegExp*.input

A default string to search when the `exec()` and `test()` methods are called with no arguments.

You can set this and then call the `RegExp.exec()` or `RegExp.test()` methods without passing a string argument value. They will then use this property of the built-in global `RegExp` object as their target search string.

Warnings:

- This behaves slightly differently in JavaScript version 1.2 in Netscape Navigator.
- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately your regular expression has evaluated and before you call another.
- In Netscape 4, event handlers for `FormElement` objects in a web page form automatically load the input property of the built-in `RegExp` object as the event handlers are fired. Hence, you should not rely on the input property remaining consistent once your function call exits. Set it immediately before you need to parse the string and do not bank on it being there later.
- This property was not supported fully in IE 4 as it was read-only. The work-around was to always pass in a value to the `exec()` method when it is invoked.

See also:	`RegExp.exec(),RegExp.test()`

RegExp.lastIndex (Property)

A character index within the searched string immediately following the previous match.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`myRegExp.lastIndex`

The `lastIndex` property is set to point at the character following the previous match. This allows you to build an iterator that cycles according to the matches for the search pattern within the source string.

When a `null` result is returned from the `RegExp.exec()` method, this value is set to 0.

The `RegExp.exec()` method uses the `lastIndex` property as its starting point for the next search. This means that if you prematurely exit the pattern searching iterator, you should also manually set this value to 0 as well. This will allow the same `RegExp` object to be used with another pattern (or the same one) to search a different string.

Warnings:

- The `lastIndex` property will be reset to 0 when the regular expression is called by `String.search()`,`String.replace()` and `String.match()`.
- The `lastIndex` behaviour is only appropriate when the `g` attribute is applied to the pattern that searches the target string. It is of no consequence in a non-global pattern match.

See also:	`RegExp.exec()`,`String.match()`,`String.replace()`, `String.search()`

Cross-references:

ECMA 262 edition 3 –section –15.10.7.5

RegExp.lastMatch (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
JavaScript syntax:	-	`RegExp.lastMatch`

This property returns the most recently matched text.

Warnings:

- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately after your regular expression has been evaluated and before you call another.

See also:	`RegExp.exec()`,`RegExp.test()`,`RegExp["$&"]`

Property attributes:

`ReadOnly`.

RegExp.lastParen (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
JavaScript syntax:	-	`RegExp.lastParen`

This property returns the text matched by the last sub-expression which was part of the most recent match. It will contain a `null` or undefined value if there was no previous match.

Warnings:

- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately after your regular expression has been evaluated and before you call another.

See also:	`RegExp` pattern –grouping, `RegExp` pattern –references, `RegExp.exec()`,`RegExp.test()`,`RegExp["$+"]`

Property attributes:

`ReadOnly`.

RegExp.leftContext (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
JavaScript syntax:	-	`RegExp.leftContext`

This property returns the text to the left of the most recent match.

Warnings:

- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately after your regular expression has been evaluated and before you call another.

See also:	`RegExp.exec()`,`RegExp.test()`,`RegExp["$`"]`

Property attributes:

`ReadOnly`.

RegExp.multiline (Property/static)

A regular expression attribute to control the scope of the pattern.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`RegExp`*`.multiline = `*`aBoolean`*
Argument list:	*`aBoolean`*	A switch to set the property `true` or `false`

When you want the regular expression to apply to multiple lines separated by newline characters, this property should be set to `true`. When it is `false` the pattern is applied only to a single line.

Warnings:

- In JavaScript version 1.2 in Netscape Navigator, this is the only way to set the pattern to operate on multiple lines.
- The 'm' attribute is provided in JavaScript version 1.3 in some implementations.
- Note that client-side JavaScript used in Netscape 4 will set the multi-line property to `true` when it is used in an event handler for a `TextArea` object. The value is restored to whatever it was before exiting the handler. This suggests that you should explicitly set the multi-line property to the value you require when to parse a regular expression. You cannot rely on the stability of any value you may have stored in that attribute previously.
- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately before your regular expression has been evaluated and before you call another.

Example code:

```
RegExp.multiline = true;
RegExp.multiline = false;
```

Cross-references:

ECMA 262 edition 3 –section –15.10.7.4

RegExp.prototype (Property)

The prototype for the `RegExp` object that can be used to extend the interface for all `RegExp` objects.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera –5.0	
Property/method value type:	`RegExp object`	
JavaScript syntax:	-	`RegExp.prototype`
	-	*`myRegExp`*`.constructor.prototype`

You can use this to extend the interface to the object class and provide additional capabilities to your regular expressions.

See also:	`prototype` property, `RegExp.toString()`

Cross-references:

ECMA 262 edition 3 –section –15.10.5.1

ECMA 262 edition 3 –section –15.10.6.1

RegExp.rightContext (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5	
JavaScript syntax:	-	`RegExp.rightContext`

This property returns the text to the right of the most recent match.

Warnings:

- Since this is a class property (a static property), it belongs to the global built-in `RegExp` object. This means it is shared by all `RegExp` object instances and therefore is very transient and will be overwritten as soon as the next regular expression is evaluated. If you want to preserve the value, you will need to copy it immediately after your regular expression has been evaluated and before you call another.

See also:	`RegExp.exec(),RegExp.test(),RegExp["$'"]`

Property attributes:

`ReadOnly`.

RegExp.source (Property)

An instance property of a regular expression object.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myRegExp*`.source`

This is a read-only property that returns the regular expression pattern text.

Property attributes:

`ReadOnly`.

Cross-references:

ECMA 262 edition 3 –section –15.10.7.1

RegExp.test() (Method)

Another name for the `RegExp.exec()` method when used with global `RegExp` objects.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myRegExp*`.test(`*aString*`)`
Argument list:	*aString*	The string to be examined by the regular expression

This is not quite like the `exec()` method. In this case, you cannot establish whether the match occurs more than once or where in the string the match occurs.

This method simply returns `true` or `false` to indicate whether the pattern matches anything in the search string.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
document.write("1 "     + testForYearNumber("1")     + "<BR>");
document.write("12 "    + testForYearNumber("12")    + "<BR>");
document.write("123 "   + testForYearNumber("123")   + "<BR>");
document.write("1234 "  + testForYearNumber("1234")  + "<BR>");
document.write("12345 " + testForYearNumber("12345") + "<BR>");
function testForYearNumber(aString)
{
   var myRegExp = /^\d{4}$/;
   return myRegExp.test(aString);
}
</SCRIPT>
</BODY>
</HTML>
```

RegExp.toSource() (Method)

Outputs a regular expression object formatted as a `RegExp` literal contained in a string.

Availability:	JavaScript –1.3 Netscape –4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*`myRegExp`*`.toSource()`

This is an alternative way to deliver a string version of a regular expression object. In this case, it is formatted as a `RegExp` literal and can then be used in an `eval()` function to assign another regular expression.

RegExp.toString() (Method)

Returns a string primitive version of a `RegExp` object.

Availability:	ECMAScript edition –3 JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0 Opera –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myRegExp`*`.toString()`

This method returns a String primitive representation of the value of the present `RegExp` value.

See also:	Cast operator, `RegExp.prototype.toString()`

Cross-references:

ECMA 262 edition 3 –section –15.10.6.4

RegExp["$&"] (Property)

An alternative way to refer to the text of the most recent successful pattern match.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myRegExp*`["$&"]`

This property uses the array index notation because the property name contains punctuation characters that would cause syntactic errors if the property name were not in quotes.

Warnings:

- This is provided as a convenience to Perl programmers who may be familiar with its syntax in this form. However, it is recommended that you use the named property form when assigning values to regular expression objects.

See also:	`RegExp.lastMatch`

Property attributes:

`ReadOnly`.

RegExp["$'"] (Property/static)

An alternative means of referring to the text to the right of the most recent match.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5.0	
JavaScript syntax:	-	`RegExp["$'"]`

This property uses the array index notation because the property name contains punctuation characters that would cause syntactic errors if the property name were not in quotes.

Warnings:

- This is provided as a convenience to Perl programmers who may be familiar with its syntax in this form. However, it is recommended that you use the named property form when assigning values to regular expression objects.

See also:	`RegExp.rightContext`

Property attributes:

`ReadOnly`.

RegExp["$*"] (Property/static)

A switch property to determine whether multi-line matching is performed or not.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5	
JavaScript syntax:	-	`RegExp["$*"]`

This property uses the array index notation because the property name contains punctuation characters that would cause syntactic errors if the property name were not in quotes.

Warnings:

- This is provided as a convenience to Perl programmers who may be familiar with its syntax in this form. However, it is recommended that you use the named property form when assigning values to regular expression objects.

See also:	`RegExp.multiline`

RegExp["$+"] (Property/static)

An alias for the text that matches the most recent sub-expressions.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5	
JavaScript syntax:	-	`RegExp["$+"]`

This property uses the array index notation because the property name contains punctuation characters that would cause syntactic errors if the property name were not in quotes.

Warnings:

- This is provided as a convenience to Perl programmers who may be familiar with its syntax in this form. However, it is recommended that you use the named property form when assigning values to regular expression objects.

See also:	`RegExp.lastParen`

Property attributes:

`ReadOnly`.

RegExp["$`"] (Property/static)

An alias for the text to the left of the most recent match.

Availability:	JavaScript –1.2 JScript –5.5 Internet Explorer –5.5 Netscape –4.0 Netscape Enterprise Server –3.0 Opera –5	
JavaScript syntax:	-	`RegExp["$`"]`

This property uses the array index notation because the property name contains punctuation characters that would cause syntactic errors if the property name were not in quotes.

Warnings:

- This is provided as a convenience to Perl programmers who may be familiar with its syntax in this form. However, it is recommended that you use the named property form when assigning values to regular expression objects.

See also:	`RegExp.leftContext`

Property attributes:

`ReadOnly`.

RegExp pattern (Definition)

The sequence of characters that comprise a regular expression.

Availability:	ECMAScript edition –3

The rules for creating patterns are complex and involved, hence this topic has been broken into several related sub-topics.

The syntax is similar and almost as complete as that used for Perl.

A pattern is constructed using a sequence of characters. Most of the typeable characters can be used as matches for that particular character, but some special characters are used in the regular expression to mean something more abstract. Some characters need to be escaped, however they are not escaped in the same way as the normal escape sequences that are used in string literals. The literal characters are described in their own sub-topic.

There are other special character sequences, called meta-characters, that describe groups or classes of characters; these are also described in their own topic. They are called meta-characters.

You can build repetitions of literal characters and special character classes, which is also covered in a sub-topic.

See also:	`RegExp` pattern –alternation, `RegExp` pattern –attributes, `RegExp` pattern –character class, `RegExp` pattern –character literal, `RegExp` pattern –grouping, `RegExp` pattern –position, `RegExp` pattern –references, `RegExp` pattern –repetition, `RegExp` pattern –sub-patterns, `RegExp.exec()`, Regular expression, `String.match()`,`String.replace()`,`String.search()`,`String.split()`

Cross-references:

ECMA 262 edition 3 –section –15.10.1

RegExp pattern –alternation (Definition)

Sometimes you will want to match either one pattern or another using alternatives.

Availability:	ECMAScript edition –3

You can group sub-expressions and offer them as alternatives. For example, you might want to match "AB" or "CD". The alternation operator can be placed between each sub-expression to indicate choices like this:

```
/AB|CD/
```

This technique can be used in combinations with character literals, classes and repetition operators. Like this:

```
/[a-z]{3}|[0-9]{40}/
```

This matches with three lower case letters or 40 numeric digits and nothing else will match.

See also:	`RegExp` pattern, `RegExp` pattern –character class, `RegExp` pattern –character literal, `RegExp` pattern –repetition

Cross-references:

ECMA 262 edition 3 –section –15.10.1

ECMA 262 edition 3 –section –15.10.2.3

ECMA 262 edition 3 –section –15.10.2.4

RegExp pattern –attributes (Definition)

The attributes of a regular expression.

Availability:	ECMAScript edition –3

When you specify a regular expression, it will by default only match the first occurrence that it encounters. It is possible to specify a pattern to match that can occur several times in a line. To match all of these, you can use the '`g`' attribute. The '`g`' stands for global matching.

There is one other attribute that allows the matching to be carried out in a case-insensitive manner. That is the '`i`' attribute.

Both of these attributes are placed after the closing slash at the end of the pattern.

The case-insensitive match works like this:

```
/javascript/i
```

would match the following strings

```
JavaScript
```

```
javascript
```

```
JAVASCRIPT
```

```
JaVaScRiPt
```

The `g` attribute applied like this, would cause the pattern:

```
/0/g
```

to match every zero in the string:

```
'0100, 00123, "00067", 666000'
```

There is another attribute to control whether the pattern is applied to single lines or multiple lines. Because the regular expression is realized as an object, this is controlled by means of an object property accessed via the multi-line identifier, the letter 'm' in JavaScript 1.5 (shipped with Netscape 6.0)

Here is a list of the available attributes:

seq	Pattern	Description	JS
00	g	Global match for every occurrence of the pattern throughout the line.	1.2
01	i	Case-insensitive matching.	1.2
02	ig	Case-insensitive global match.	1.2
13	m	Multiple lines to be processed. Available only in JavaScript 1.5 and mutually exclusive with the 's' attribute.	1.5
15	gm	Global match on multiple lines.	1.5
15	im	Case-insensitive matching on multiple lines.	1.5
16	igm	Case-insensitive global match on multiple lines.	1.5

RegExp pattern –character class (Definition)

RegExp pattern components for describing character classes.

Availability:	ECMAScript edition –3

Character classes are a group of RegExp character literals enclosed in square brackets. This set of characters can then be placed into a RegExp pattern to provide a match for any character that is considered to be a member of the class.

You can use character classes to include or exclude groups of characters. An exclusion is called a negated class and is signified by placing a circumflex (^) character as the first one inside the square brackets. Thus, [abcd] will match true if the character being tested at that position in the pattern is the letter "a", "b", "c" or "d".

The character class [^abcd] will match any character as long as it is not one of those four.

You can indicate a range of characters by using a hyphen. Therefore [abcd] is the same as saying [a-d]. Other examples are summarized in the following table.

There are special character classes already built in so that you don't have to create your own. These are done using escaped characters very similar to those in the literal character set. These can also be used inside the square brackets to construct other class groups of characters.

Pattern	Description
`[ ... ]`	Any single character that is one of the set enclosed in the square brackets.
`[^ ... ]`	Any single character that is not one of the set enclosed in the square brackets.
`[^abcd]`	Any character that is not one of the letters "a", "b", "c" or "d".
`[abcd]`	Any one of the letters "a", "b", "c" or "d".
`[a-z]`	Any single lower case character.
`[A-Z]`	Any single upper case character.
`[a-zA-Z]`	Any single alphabetic character.
`[0-7]`	Any octal numeric digit.
`.`	Any character apart from newline.
`\d`	Any decimal digit character.
`\s`	Any whitespace character.
`\w`	Any word character (which is any letter, number or underscore). This does not mean a whitespace character.
`\D`	Any non-digit character.
`\S`	Any non-whitespace character. This is not necessarily a valid word character.
`\W`	Any non-word character.
`[\b]`	A literal backspace not to be confused with a word boundary match (using the \b outside of the square brackets)
`[0-1]`	Any binary numeric digit.
`[0-9A-F]`	Any hexadecimal numeric digit.
`[\dA-F]`	Any hexadecimal numeric digit (alternative form).
`[a-zA-Z0-9]`	Any single alphanumeric character.
`[a-zA-Z\d]`	Any single alphanumeric character (alternative form).
`[^a-zA-Z0-9_\$]`	Any character that is not valid within an identifier name.
`[a-zA-Z0-9_\$]`	Any character that is valid within an identifier name.
`[0-9]`	Any decimal numeric digit, (alternative version).
`[^0-9]`	Any any character that is not a digit, (alternative version).
`[\t\n\r\f\v]`	Any whitespace character, (alternative version).
`[^\t\n\r\f\v]`	Any non-whitespace character, (alternative version).
`[^\n]`	Any character apart from newline, (alternative version).
`[^a-zA-Z0-9_]`	Any non-word character, (alternative version).
`[a-zA-Z0-9_]`	Any word character, (alternative version).

Warnings:

- Beware of the backspace escape `\b`. To match against a backspace it must be enclosed in square brackets to create a character class. If it is used outside of the brackets, it is interpreted to mean a word boundary.

RegExp pattern –character literal (Definition)

These are the characters that can be used in the pattern to match against themselves.

Availability:	ECMAScript edition –3

The literal characters in a regular expression denote a particular character and have no special meaning other than to match that character at the position in the string they are defined within the overall pattern.

Simple, fixed and constant patterns can be defined purely with literal characters.

The string "JavaScript" can be matched exactly and exclusively with the pattern `/JavaScript/`. Unless some additional information is added to the pattern description, neither `/javascript/` nor `/JAVASCRIPT/` will match. However, the pattern `/Java/` will match strings containing both "JavaScript" and "Java".

Here is a list of the literal characters as they would be used in the pattern:

Pattern	Description
`0` to `9`	Itself
`a` to `z`	Itself
`A` to `Z`	Itself
`\$`	A single dollar sign ($)
`\*`	A single asterisk (*)
`\+`	A single plus sign (+)
`\,`	A single comma (,)
`\.`	A single period (.)

Table continued on following page

Pattern	Description
`\/`	A single slash (/)
`\?`	A single question mark (?)
`\\`	A single backslash (\)
`\^`	A single circumflex (^)
`\d`	Any digit character as per [0-9]
`\D`	Any non-digit character as per [^0-9]
`\f`	A form feed
`\n`	A newline
`\r`	A carriage return
`\S`	A non-space character
`\s`	A space character
`\t`	A tab character
`\v`	A vertical tab
`\w`	An alphanumeric character and underscore as per [0-9a-zA-Z_]
`\W`	An non-alphanumeric character and underscore as per [^0-9a-zA-Z_]
`\\|`	A single vertical bar (|)
`\(`	A single opening parenthesis (()
`\)`	A single closing parenthesis ())
`\[`	A single opening square bracket ([)
`\]`	A single closing square bracket (])
`\{`	A single opening curly brace ({)
`\}`	A single closing curly brace (})
`\nnn`	The ASCII character encoded by the octal value nnn
`\onnn`	The ASCII character encoded by the octal value nnn
`\uhhhh`	The Unicode character encoded by the hexadecimal value hhhh
`\xhh`	The ASCII character encoded by the hexadecimal value hh
`\c*`	The control character equivalent to ^*
`\c@`	(NUL) –Null character
`\c[`	(ESC) –Escape
`\c\`	(FS) –File separator (Form separator)
`\c]`	(GS) –Group separator
`\c^`	(RS) –Record separator
`\c_`	(US) –Unit separator
`\cA`	(SOH) –Start of header
`\cB`	(STX) –Start of text
`\cC`	(ETX) –End of text
`\cD`	(EOT) –End of transmission
`\cE`	(ENQ) –Enquiry

Table continued on following page

Pattern	Description
\cF	(ACK) –Positive acknowledge
\cG	(BEL) –Alert (bell)
\cH	(BS) –Backspace
\cI	(HT) –Horizontal tab
\cJ	(LF) –Line feed
\cK	(VT) –Vertical tab
\cL	(FF) –Form feed
\cM	(CR) –Carriage return
\cN	(SO) –Shift out
\cO	(SI) –Shift in
\cP	(DLE) –Data link escape
\cQ	(DC1) –Device control 1 (XON)
\cR	(DC2) –Device control 2 (tape on)
\cS	(DC3) –Device control 3 (XOFF)
\cT	(DC4) –Device control 4 (tape off)
\cU	(NAK) –Negative acknowledgement
\cV	(SYN) –Synchronous idle
\cW	(ETB) –End of transmission block
\cX	(CAN) –Cancel
\cY	(EM) –End of medium
\cZ	(SUB) –Substitute
\0 to \9	The last remembered substring as per the $n property
[\b]	A literal backspace not to be confused with a word boundary match (using the \b outside of square brackets)

It is necessary to escape the punctuation characters as they assume special meanings when used in a pattern on their own. Refer to the other RegExp topics for further details.

RegExp pattern –extension syntax (Definition)

A Perl 5 capability for specifying anchors with look-ahead patterns.

Availability:	ECMAScript edition –3

Positional anchors can be constructed using patterns. These are enclosed in grouping operators and commence with a question mark.

A logical negation is also possible. However the syntax for this uses the JavaScript convention of an exclamation mark (`!`) rather than the regular expression convention of a circumflex (`^`).

A positional anchor, marking the location immediately before a capital letter would look like this:

```
(?=[A-Z])
```

A positional anchor marking a location immediately before any non-capital letter would look like this:

```
(?![A-Z])
```

The second example uses the logical negation operator.

Note that these are positional anchors that behave like the `^` and `$` which denote the start and end of a line. They do not select any characters.

See also:	`RegExp` pattern –grouping, `RegExp` pattern –position, `RegExp` pattern –references

RegExp pattern –grouping (Definition)

Sometimes you may want to group several items to treat them conditionally or repetitively. The grouping operator provides the means to do that.

Availability:	ECMAScript edition –3

The parentheses grouping operator works inside regular expressions much as you would expect it to. Everything inside the parentheses can be operated on by a repetition. This example matches the word java or javascript:

```
/java(script)?/
```

The grouping operator is also used to delimit sub-strings.

See also:	`RegExp` pattern, `RegExp` pattern –extension syntax, `RegExp` pattern –references, `RegExp` pattern –sub-patterns, `RegExp.$n`, `RegExp.lastParen`

Cross-references:

ECMA 262 edition 3 –section –15.10.1

ECMA 262 edition 3 –section –15.10.2.8

RegExp pattern –position (Definition)

Aligning the pattern to one or other end of the string sometimes helps to remove ambiguity from the match.

Availability:	ECMAScript edition –3

Occasionally, you may want to match a string that is explicitly at the front or back end of a line. You can do this by adding the special characters to the expression to mark the location of the start of the line or the end of the line. You can also align the pattern with word boundaries as well. Here is a summary of some special patterns that are position aligned:

Pattern	Description
`^`	Indicate the start of the line
`$`	Indicate the end of the line
`\b`	Indicate a word boundary. Note that this cannot be used in a bracketed character class [\b] means backspace not word boundary
`\B`	Indicate any non-word boundary location
`.$`	The last character at the end of the line (the dot matches one character)
`\b\d*\b`	A complete word composed only of numeric digits
`\b\w*\b`	A complete word
`\s*$`	All of the trailing whitespace
`^$`	A line with nothing between the start and end, an empty line
`^.`	The first character at the beginning of the line (the dot matches one character)
`^.*$`	The entire line regardless of its contents
`^\s`	A leading whitespace character

Warnings:

- In multi-line mode, the markers for the start and end of the line apply to each line in turn.

See also:	`RegExp` pattern, `RegExp` pattern –attributes, `RegExp` pattern –extension syntax, `RegExp.multiline`

Cross-references:

ECMA 262 edition 3 –section –15.10.1

RegExp pattern –references (Definition)

Groups of characters in a pattern can be referred to symbolically later in the expression.

Availability:	ECMAScript edition –3

We can use parentheses to repeat a match so that the same text is matched in more than one place in the expression. It is not the pattern that is repeated but the matched value. We do this by referring to the sub-expression according to its indexed location within the pattern. The index is incremented for every left parenthesis encountered. The first is referred to as `\1`, the second as `\2` and so on. This is useful for balancing matching quote symbols around a text string that might have either single or double quote marks around it. Unless we can relate the matches at each end, we might find that we do in fact have either one of the two quote symbols but we don't necessarily have a balanced pair.

This matches a single or double quote character:

```
/['"]/
```

This matches a single or double quote character at either end of any other character sequence:

```
/['"].*['"]/
```

However, the text between the quotes could contain a quote so we'll replace the match between them with any non-quote character. Like this:

```
/['"][^'"]*['"]/
```

To use a reference to a previous sub-expression, we need to mark the sub-expression with parentheses:

```
/(['"])[^'"]*['"]/
```

Now we can refer to the first sub-expression at a later stage and require that the same characters be repeated:

```
/(['"])[^'"]*\1/
```

This ensures that the sequence of characters `'AAA'` would match but `'AAA"` would not even though `"AAA"` would.

A grouped sub-expression can be prevented from being indexed by placing a question mark and colon immediately inside the parentheses and then the item cannot be indexed as a reference. This works in JavaScript version 1.3 onwards.

Warnings:

- Beware that you do not use an index greater than the number of sub-patterns available. The backslash and digit will be interpreted as a character escape otherwise.
- Because the backslash can also be interpreted as a character escape you must be unambiguous as to your intentions. To ensure that it is interpreted as a character escape, use a value that is more than one digit long.

See also:	`RegExp` pattern, `RegExp` pattern –extension syntax, `RegExp` pattern –grouping, `RegExp` pattern –sub-patterns, `RegExp.$n`, `RegExp.lastParen`

Cross-references:

ECMA 262 edition 3 –section –15.10.1

RegExp pattern –repetition (Definition)

Parts of a matching pattern can be repeated for multiple characters.

Availability:	ECMAScript edition –3

We can create matching patterns that will match a fixed number of characters. For example, a pattern for a zero padded decimal number that is 4 digits long would be:

```
/\d\d\d\d/
```

Or it could be expressed like this:

```
/[0-9][0-9][0-9][0-9]/
```

Or even like this:

```
/[0123456789][0123456789][0123456789][0123456789]/
```

These are fine for fixed length formatted numbers but very often the formatting of some text can be variable and unless numbers are zero padded, we don't know how long they are. We can extend a matching pattern to signify that it should match a certain number of times or an unspecified and variable number of times.

The curly braces are used to indicate a repetition count. A single value indicates a repeat count that is a fixed length. So our first example could be expressed like this:

```
/\d{4}/
```

If the curly braces include a pair of comma separated values, the first is a minimum number and the second is a maximum. So if we wanted to match a value that was between 10 and 1000 and it was not zero padded, we could do this:

```
/\d{2,4}/
```

UK style postcodes are formatted in general with a standard layout. Mostly they conform to the pattern:

```
AANN NNAA
```

That is two letters, up to two numbers, a space and then up to two numbers and two letters.

You could match a UK style postcode with something like this:

```
/\w{2}\d{1,2}\s\d{1,2}\w{2}/
```

A United States Zip code is simpler, being made up of two letters, a space and 5 digits. So it could be matched with:

```
/\w\w\s\d{5}/
```

There is a way to indicate that characters are optional with the question mark character (`?`).

The UK postcode example could then be simplified to allow the second character group to be optional as could the inner space character. Like this:

```
/\w\w\d\d?\s?\d?\d?\w?\w?/
```

The plus sign is used to match one or more instances of the character to its left and the asterisk to match zero or more occurrences. Here are some examples:

Seq	Pattern	Description
01	`{a,b}`	Match the item to the left between `a` and `b` times.
02	`{a,}`	Match the item to the left at least `a` times or more.
03	`{a}`	Match the item to the left exactly `a` times, no more, no less.
04	`?`	Match the item to the left zero or one times.
05	`+`	Match the item to the left 1 or more times.
05	`+?`	Match the item to the left 1 or more times using a minimal matching technique. (JavaScript 1.3)
06	`*`	Match the item to the left zero or more times.
06	`*?`	Match the item to the left zero or more times using a minimal matching technique. (JavaScript 1.3)
99	`{0,1}`	Match the item to the left zero or one times (alternative form).
99	`{0,}`	Match the item to the left zero or more times (alternative form).
99	`{1,}`	Match the item to the left 1 or more times (alternative form).

The minimal matching technique is implemented in JavaScript version 1.3 and is based on the facilities of Perl version 5 interpreters. Minimal matching is where a match occurs with the minimum number of characters necessary to make a match. This is as opposed to the normal technique, which matches as many characters as possible.

Cross-references:

ECMA 262 edition 3 –section –15.10.2.5

ECMA 262 edition 3 –section –15.10.10

RegExp pattern –sub-patterns (Definition)

When a pattern matches, it is possible to extract a portion of that for re-use.

Availability:	ECMAScript edition –3

By using parentheses creatively in a regular expression a sub-pattern can be marked out such that when a match occurs, that sub-pattern can be extracted.

Here is a pattern that matches a date format:

```
/[0-9]{2}-[a-zA-Z]{3}-[0-9]{4}/
```

We might want to extract just the month name. We can place parentheses around that so it can be extracted later. Like this:

```
/[0-9]{2}-([a-zA-Z]{3})-[0-9]{4}/
```

The example shows how this works:

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Make the RegExp from a literal
myRegExp = /[0-9]{2}-([a-zA-Z]{3})-[0-9]{4}/;
// Create the input search string
myString = "01-Jan-1954";
// Run the search
myArray = myRegExp.exec(myString);
// How many items are there in the array
document.write(myArray.length);
document.write("<BR>");
// Display the source string
document.write(myArray[0]);
document.write("<BR>");
// Display the month name sub-match
document.write(myArray[1]);
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 –section –15.10.1

Regular expression (Definition)

A means of matching patterns of text in string values.

Regular expressions are a way of describing a pattern match that can be used to select a group of characters from an input string. This usually then leads on to replacing them with some other set of characters. It is analogous to the find and replace capability in a word processor.

JavaScript version 1.2 introduced regular expression support by way of a specialized object, a utility that UNIX developers have long known about and used. It has migrated into many desktop applications now and has become a somewhat portable way of matching text strings with one another and performing edits on them. The regular expression syntax adopted by JavaScript version 1.2 emulates that which is commonly used in Perl interpreters, specifically the syntax that is supported is generally called Perl version 4. In JavaScript version 1.3, the regular expression syntax was expanded to support Perl version 5 syntax.

Regular expressions are managed by creating a `RegExp` object with the `RegExp()` constructor. `RegExp` objects support a literal syntax and can be created on the fly without needing a constructor call which makes them extremely convenient to deploy.

The ECMAScript standard ratifies regular expressions in the third edition. They were not present in the second edition.

Warnings:

- Regular expressions are still an area of concern when developing portable content. For example, they are completely unsupported on the WebTV platform as of the Summer 2000 release of the JellyScript interpreter.

O'Reilly *JavaScript Definitive Guide* –page –49

Relational expression (Definition)

Relational expressions yield a Boolean result.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

Relational expressions yield a Boolean result according to the relational test of the values either side of the operator.

Numerical values are compared according to sign and magnitude while string values are compared according to the Unicode collating sort sequence.

Relational operators will attempt to convert both arguments to a Number, and if at least one argument can be converted to a Number then the other will be forced to be a Number for comparison purposes. If both arguments are Strings or string-like objects, the relational test will be String-based.

If a prefixing plus sign is present, then a numeric coercion of a string takes place before the comparison.

Example code:

```
// Force a string comparison
myResult = (a+'' <= b+'');
// Force a numeric comparison
myResult = (a-0 <= b-0);
// Force a boolean comparison
myResult = (!a <= !b);
```

Wrox *Instant JavaScript* –page –39

Relational operator (Definition)

Relational operators are used to create relational expressions.

Availability:	ECMAScript edition –2
Property/method value type:	`Boolean primitive`

Relational operators are used in relational expressions and always yield a Boolean result.

Although generally considered to be members of the relational operator set, equality and non-equality tests are classified as equality operators in the ECMA standard.

The following table lists all operators that could be loosely classified or specifically classified as relational operators:

Operator	Description
`==`	Equal to
`===`	Identically equal to
`!=`	NOT equal to
`!==`	NOT identically equal to
`<`	Less than
`<=`	Less than or equal to
`>`	Greater than
`>=`	Greater than or equal to

It follows that all equality operators are generally classifiable as relational operators and all relational operators are members of the set of logical operators, since they all yield a Boolean value as a result.

See also:	Equal to (==), Equality operator, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), NOT Equal to (!=), NOT Identically equal to (!==), Relational expression

Wrox *Instant JavaScript* –page –19

releaseEvents() (Function)

Netscape Navigator 4 event management function.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.releaseEvents(`*anEventMask*`)`
	N	`releaseEvents(`*anEventMask*`)`
Argument list:	*anEventMask*	A mask defined with the manifest event constants

See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event handler, Event management, Event propagation, Event type constants, `Event.modifiers`, `Frame` object, `handleEvent()`, `Layer.captureEvents()`, `Layer.releaseEvents()`, `onLoseCapture`, `onMouseMove`, `Window` object, `Window.routeEvent()`, `Window.releaseEvents()`

Remainder (%) (Operator/multiplicative)

Divides one operand by another and yields the remainder.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*anOperand1* `%` *anOperand2*
Argument list:	*anOperand1*	The dividend value
	anOperand2	The divisor value

The `%` operator yields the remainder after dividing the left operand by the right. This is otherwise known as the modulo or modulus operator.

In an ECMAScript compliant interpreter, the remainder is a floating-point value and, unlike the C and C++ languages, the input operands can also be floating point values.

The result of performing a remainder on floating point values is not the same as the IEEE 754 remainder operation. IEEE 754 mandates a remainder computed via a rounding division whereas ECMA mandates a truncating remainder. In ECMAScript the remainder behaves similarly to the Java integer remainder operator and is analogous to the `fmod()` library function in C language compilers.

The behavior in an ECMA complaint JavaScript implementation should obey these rules:

- If either operand is `NaN` then the result is `NaN`.
- The sign of the result is the same as the sign of the dividend (the operand on the left).
- If the dividend is an infinity, the result is `NaN`.
- If the divisor is zero, the result is `NaN`.
- If the dividend is a finite value and the divisor is infinity, the result equals the dividend.
- If the dividend is zero and the divisor is finite, the result is zero.

Otherwise, as long as neither an infinity, zero or `NaN` is involved, the floating remainder is calculated like this. The dividend `n` is divided by the divisor `d` to produce a quotient, `q`. The quotient is forced to be an integer and multiplied again by `d` and the result subtracted from `n` to yield the remainder. Thus:

```
q = n/d
r = n - (d * q)
```

The value `q` will be forced to be an integer although the resulting value `r` may not be.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

Warnings:

- JScript version 1.0 truncates floating-point values to integers before applying the remainder operator. This means that the expression `5.5 % 2.2` yields the value `1`.

See also:	Arithmetic operator, Associativity, Divide (`/`), Divide then assign (`/=`), Integer arithmetic, Integer-value-remainder, `Math.ceil()`, `Math.floor()`, Multiplicative expression, Multiplicative operator, Operator Precedence, Remainder then assign (`%=`)

Cross-references:

ECMA 262 edition 2 –section –11.5.3

ECMA 262 edition 2 –section –11.13

ECMA 262 edition 3 –section –11.5.3

Wrox *Instant JavaScript* –page –19

Remainder then assign (%=) (Operator/assignment)

Divide one operand by another, leaving the remainder in the first.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 %= anOperand2`*
Argument list:	*`anOperand1`*	The dividend value where the result is also assigned
	`anOperand2`	The divisor value

Divide the left operand by the right operand and assign the remainder to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 % anOperand2;
```

Although this is classified as an assignment operator it is really a compound of an assignment and a multiplicative operator.

The associativity is right to left.

Refer to the operator precedence topic for details of execution order.

The new value of `anOperand1` is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an *`LValue`*. That is, it should be able to take an assignment and store the value.

See also:	Arithmetic operator, Assign value (=), Assignment expression, Assignment operator, Associativity, Integer arithmetic, Integer-value-remainder, `LValue`, `Math.ceil()`, `Math.floor()`, Multiplicative operator, Operator Precedence, Remainder (`%`)

ECMA 262 edition 2 –section –11.13

ECMA 262 edition 3 –section –11.13

request object (Object/NES)

A server-side object maintained by NES for each `HTTP:` request.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`request`
Object properties:	`<input_name>, <urlExtension>, agent, imageX, imageY, ip, method, protocol`	

Whenever a user requests a page from a Netscape Enterprise Server, a `request` object is created to manage storage, methods and properties for that request. When the request is returned, the object can be destroyed as it will have no further use.

The request object contains details of the URL, form data and search criteria. This is the way that you access the data in a form submit for example.

There are other properties belonging to this object that can tell you a lot about the client and what is happening there.

The ASP server also supports a `Request` object, whose name is capitalized. It's there for the same purpose and manages the incoming requests from the the clients' browsers.

Warnings:

- The Request object supported by ASP is quite different to that supported by NES. Since the tag introducer is quite different for each server-side system, it is unlikely you'll deploy common scripts across NES and ASP running on IIS.

See also:	Netscape Enterprise Server, `response.client`, `response.request`, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
<input_name>	1.1 +	-	2.0 +	-
<urlExtension>	1.1 +	-	2.0 +	-
agent	1.1 +	-	2.0 +	-
imageX	1.1 +	-	2.0 +	-
imageY	1.1 +	-	2.0 +	-
ip	1.1 +	-	2.0 +	Warning
method	1.1 +	-	2.0 +	-
protocol	1.1 +	-	2.0 +	-

request.<input_name> (Property)

Input elements can be accessed associatively by name.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	String primitive	
JavaScript syntax:	NES	request.*anInputElement*
Argument list:	*anInputElement*	The value of the NAME="..." tag attribute

The NAME="..." attribute of an <INPUT> element in a <FORM> can be used as a key to access the item as a property of the request object.

For example, a text filed can be created like this:

```
<INPUT NAME="MyNamedTextObject" TYPE="TEXT">
```

You can then access it as a property belonging to the response with this object and property reference:

```
response.MyNamedTextObject
```

request.<urlExtension> (Property)

Additional properties can be passed from URL extensions.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	String primitive	
JavaScript syntax:	NES	request.<urlExtension>

When you submit a request, you can pass parameter values in the request with a special coding technique that allows them to convey information in the URL that is reflected into special properties in the request object.

The question mark (?) is the control sequence introducer for this. Sometimes these values are referred to as the query or search portion of the URL when they are accessed as properties of an Anchor, Url, or Area object in the client.

The properties are then added as a name=value pair with multiple name=value pairs separated by an ampersand (&) character.

See also:	Anchor.search, Url.search

request.agent (Property)

A string containing the user agent details.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	String primitive	
JavaScript syntax:	NES	request.agent

This property contains the name and version of the client software making the request. This is a means of building client user agent dependent responses that deliver pages that are tailored to the particular browser being used.

You might use this to respond with a Netscape Navigator version of a page that behaves differently to the page you return to a user who requested the page from an MSIE browser.

request.imageX (Property)

The X coordinate of the mouse when an image map is clicked on.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	Number primitive	
JavaScript syntax:	NES	request.imageX

If a client-side input object whose type is "image" was used, this is the horizontal coordinate value of the mouse relative to the origin of the image when the user clicked the button on the image.

This would have been placed into the page with a tag like this:

```
<INPUT TYPE="image" NAME="imageName" SRC="...">
```

request.imageY (Property)

The Y coordinate of the mouse when an image map is clicked on.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`request.imageY`

If a client-side input object whose type is "`image`" was used, this is the vertical coordinate value of the mouse relative to the origin of the image when the user clicked the button on the image.

This would have been placed into the page with a tag like this:

```
<INPUT TYPE="image" NAME="imageName" SRC="...">
```

request.ip (Property)

The IP address of the client.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`request.ip`

IP addresses are interesting and useful if you know their provenance but should not be relied upon to uniquely identify a user.

Warnings:

- Be careful when using this value. Proxy servers and firewalls can modify the value you actually see and can completely mask the IP address of the client. This can make all users behind the firewall or proxy appear to be using the same machine.
- Multiple users running Netscape Navigator via an X-Windows environment may indeed all be running the browser core on the same machine and only viewing the windows on their desktop systems.
- Finally, clients connected via an ISP may have floating IP address values and may be served through proxy and firewall systems. Indeed, some ISP-based users may even submit each request during a session through a different firewall. The session state can then only be identified by means of hidden values in the URL or with a cookie.

request.method (Property)

The request method determines to some extent how a server should respond to the request.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`request.method`

The request method could be one of the following:

- `get`
- `post`
- `head`
- `put`
- `delete`
- `options`
- `trace`

These values may be in upper or lower case so you should use a case-insensitive test if you need to check them.

request.protocol (Property)

The client may not support all the available protocols. This is the level of HTTP protocol that the client is prepared to accept.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`request.protocol`

HTTP/1.1 protocol is much more efficient than HTTP/1.0 because it reduces the number of TCP connections required. However, not all browsers support it and you may need to check this value if you are sending back multiple items in a single response.

Request-response loop (Definition)

The mechanism by which a web server handles a request and serves a page back to a browser.

The web browser sends a request to a web server. This is passed to the middleware application server which may create a special object to represent the request. Values passed to the web server by the browser will be reflected as properties of that request object.

This mechanism will invoke an appropriate handler. That handler may be compiled code or perhaps a script, possibly written in JavaScript in some middleware implementations.

As the handler is invoked, it is passed the request object and also an empty response object. The handler then populates the response object with headers and body contents. This may be done by means of property accessors or method calls.

Eventually the response is despatched back to the requesting browser. At this point some clean-up takes place, the request logging takes place and the request response loop is completed.

See also:	Storage duration

Requesting privileges (Security related)

Your script needs to request privileges when it requires them.

So long as you can sign scripts for Netscape Navigator, you can then make requests for privileges when those scripts run. This is done by means of the privilege manager.

Because the Netscape Navigator security model is based on the Java security model, the Netscape Navigator browser requests its privileges through the Java mechanisms. These are encapsulated in a class that you can access from inside JavaScript.

The downside of this is that there is no meaningful value returned when the request is made. If the request for a privilege is denied, the error causes a Java exception which is difficult to trap from JavaScript. It is possible that new browser versions will support an exception handling mechanism.

There are two principle methods that are useful here, one to request the privilege and the other to relinquish it.

`enablePrivilege()` –Requests the privilege passed as a string argument

`disablePrivilege()` –Relinquishes the privilege based on a string argument

Example code:

```
// Request the file reading
privilegenetscape.security.PrivilegeManager.enablePrivilege("UniversalFileRead")
```

See also:	`netscape.security.PrivilegeManager`, `PrivilegeManager` object, `PrivilegeManager.disablePrivilege()`, `PrivilegeManager.enablePrivilege()`, Signed scripts, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `UniversalFileRead`, `UniversalPreferencesRead`, `UniversalPreferencesWrite`, `UniversalSendMail`

Reserved Word (Definition)

JavaScript reserves certain words and maps computational functionality to them.

Availability:	ECMAScript edition –2

Reserved words are keywords that the interpreter uses to determine the instructions your script is going to execute.

Generally, reserved words will be one of the following:

- A keyword
- A reserved word
- A `null` literal
- A Boolean literal

Here is a complete list of reserved words as defined by the ECMA 262 standard. It also includes words that are dangerous because they are properties or method names.

Name	Notes
abstract	Java keyword reserved
alert	Identifier name
arguments	Identifier name
Array	Object type
blur	Identifier name
boolean	Java keyword reserved
Boolean	Object type
break	Keyword
byte	Java keyword reserved
callee	Identifier name
caller	Identifier name

valueOf	Identifier name

Table continued on following page

Name	Notes
var	Keyword
void	Keyword
volatile	Reserved word
watch	Identifier name
while	Keyword
window	Identifier name
with	Keyword

Looking at the some of the particular keywords being reserved, it suggests that future revisions of ECMAScript will become more object oriented. Or at least even if the underlying implementation is not truly object oriented, then the visible interface to the interpreter from a script will behave very much as if it is.

The third edition of the ECMA standard does not add any new keywords but removes those that have been defined as part of the upgrade to the standard. There are still several that are classed as reserved words that have already been implemented in some browser versions. Simply avoiding parse errors does not qualify them as features to be documented as being available in the browser.

On the Netscape developer web site, there is talk of developing a version 2.0 of the JavaScript language, to change JavaScript into a truly class-based object oriented language. At that time, many of the currently reserved words will likely become functional parts of the language.

Warnings:

- You must not use reserved words as identifier names.
- The table lists words you should avoid in a client-side context. You could argue that because `alert` is not a reserved word on the server-side that it would be safe to use it there. I would recommend against that because it is possible you might develop a library of JavaScript functions for general purpose use. It wouldn't be hard to imagine how an identifier that was server-side safe could eventually end up being executed client-side.
- The list in the table is not exhaustive and you should always think carefully about the identifier names you choose for properties, methods, functions, and variables.

ECMA 262 edition 3 –section –7.5.1

O'Reilly *JavaScript Definitive Guide* –page –31

ResetButton object (Object/DOM)

A button in a form that will reset the form fields to their default values.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0
Inherits from:	`Input` object
JavaScript syntax:	- *myResetButton* = *myDocument*.*aFormName*.*anElementName* - *myResetButton* = *myDocument*.*aFormName*.elements[*anItemIndex*] IE *myResetButton* = *myDocument*.all.*anElementID* IE *myResetButton* = *myDocument*.all.tags("INPUT")[*anIndex*] IE *myResetButton* = *myDocument*.all[*aName*] - *myResetButton* = *myDocument*.forms[*aFormIndex*].*anElementName* - *myResetButton* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*] - *myResetButton* = *myDocument*.getElementById(*anElementID*) - *myResetButton* = *myDocument*.getElementsByName(*aName*)[*anIndex*] - *myResetButton* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	`<INPUT TYPE="reset">`
Argument list:	*anIndex* – A valid reference to an item in the collection *aName* – The `name` attribute of an element *anElementID* – The `ID` attribute of an element *anItemIndex* – A valid reference to an item in the collection *aFormIndex* – A reference to a particular form in the forms collection
Object properties:	`type, value`
Object methods:	`handleEvent()`
Event handlers:	`onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDblClick, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit`

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

There isn't really a `ResetButton` object class, but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a reset button. In actual fact, the object is represented as an item of the `Input` object class.

Event handling support via properties containing function objects was added to `ResetButton` objects at version 1.1 of JavaScript.

Unlike MSIE, Netscape Navigator does not support the `defaultValue` property or the `select()` method in this sub-class of the `Input` object.

See also:	`Element` object, `Form.elements[]`, `FormElement` object, `Input` object, `Input.accessKey`, `onClick`, `ResetButton.handleEvent()`

Inheritance chain:

`Element` object, `Input` object, `Node` object

ResetButton.handleEvent() (Method)

Passes an event to the appropriate handler for this object.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myResetButton`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape Navigator prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`handleEvent(),ResetButton` object

ResetButton.type (Property)

The type value for the `<INPUT>` object that describes the reset button.

Availability:	DOM level –1 JavaScript –1.1 JScript –3.0 Internet Explorer –4.0 Netscape –3.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myResetButton.type`

The type value for a `ResetButton` is always "`reset`". This value is necessary to determine the type of form element because this object is really an instance of the `Input` class and not the `ResetButton` class. There is actually no `ResetButton` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

ResetButton.value (Property)

The text string in the button.

Availability:	DOM level –1 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Opera –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myResetButton*.value

Although this value may be sent back to the web server when the form is submitted, the main purpose of a `ResetButton` is to reset the form element contents to the values defined in the HTML document source. This property provides a convenient means of labelling the button.

Warnings:

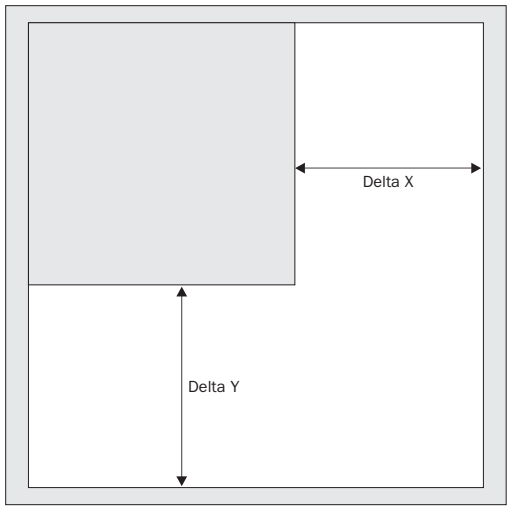
- This may be changed on some platforms but not others.

See also:	`Input.value`, `SubmitButton.value`

resizeBy() (Method)

An alias for the `window.resizeBy()` method.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*.resizeBy(*aChangeX*, *aChangeY*)
	-	resizeBy(*aChangeX*, *aChangeY*)
Argument list:	*aChangeX*	The difference in pixels
	aChangeY	The difference in pixels

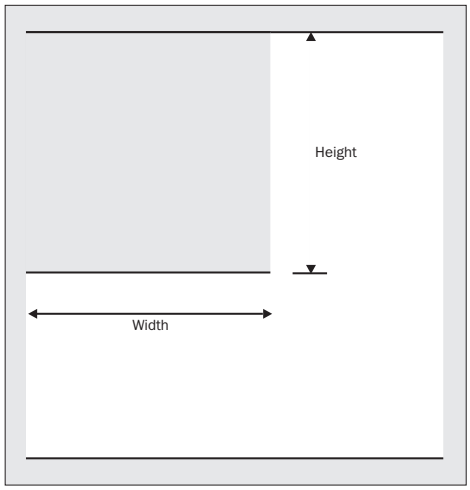


See also:	`Window.onresize`,`Window.resizeBy()`

resizeTo() (Method)

An alias for the `window.resizeTo()` method.

Availability:	JavaScript –1.2 JScript –3.0 Internet Explorer –4.0 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*`myWindow`*`.resizeTo(`*`aSizeX`*`, `*`aSizeY`*`)`
	-	`resizeTo(`*`aSizeX`*`, `*`aSizeY`*`)`
Argument list:	*`aSizeX`*	A distance in pixels
	`aSizeY`	A distance in pixels



See also:	`Window.onresize`,`Window.resizeTo()`

response object (Object/NES)

Part of the server-side support for JavaScript. This is the `Global` object in NES.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`response`
Object properties:	`client, database, project, request, server`	
Object methods:	`addClient(), addResponseHeader(), blob(), callC(), debug(), deleteResponseHeader(), flush(), getOptionValue(), getOptionValueCount(), redirect(), registerCFunction(), ssjs_generateClientID(), ssjs_getCGIVariable(), ssjs_getClientID(), trace(), write()`	

The response object in NES is the global object as well. This means the methods and properties that belong to the global object also belong to the response.

Because it is the global object there is no explicit way of referring to it.

We have collated all the response object methods and properties together in a group to aid the rapid location of related topics. Additional index entries are provided for the properties and methods as they would be addressed as members of the global object.

Warnings:

- The `Response` object is the `Global` object in a NES request-response context.

See also:	Netscape Enterprise Server, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
`client`	1.1 +	-	2.0 +	-
`database`	1.1 +	-	2.0 +	-
`project`	1.1 +	-	2.0 +	-
`request`	1.1 +	-	2.0 +	-
`server`	1.1 +	-	2.0 +	-

Method	JavaScript	JScript	NES	Notes
`addClient()`	1.1 +	-	2.0 +	-
`addResponseHeader()`	1.2 +	-	3.0 +	-
`blob()`	1.1 +	-	2.0 +	-
`callC()`	1.1 +	-	2.0 +	-
`debug()`	1.1 +	-	2.0 +	-
`deleteResponseHeader()`	1.2 +	-	3.0 +	-
`flush()`	1.1 +	-	2.0 +	-
`getOptionValue()`	1.1 +	-	2.0 +	-
`getOptionValueCount()`	1.1 +	-	2.0 +	-
`redirect()`	1.1 +	-	2.0 +	-
`registerCFunction()`	1.1 +	-	2.0 +	-
`ssjs_generateClientID()`	1.2 +	-	3.0 +	-
`ssjs_getCGIVariable()`	1.2 +	-	3.0 +	-
`ssjs_getClientID()`	1.2 +	-	3.0 +	-
`trace()`	1.1 +	-	2.0 +	-
`write()`	1.2 +	-	3.0 +	-

response.addClient() (Method)

Information about the client is added to a URL.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`addClient()`

Use this method to maintain state across requests by hiding information about the client in the URL. This allows you to send a page to the client and when they submit a form you can associate that request with the previous one.

See also:	Netscape Enterprise Server

response.addResponseHeader() (Method)

Adds a header record to the response object.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	NES	`addResponseHeader()`

The header to be added is presented as a name-value pair.

See also:	Netscape Enterprise Server

response.blob() (Method)

Extracts a binary large object from a data file in the server's file system.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`blob object`	
JavaScript syntax:	NES	`blob()`

BLOBs can be pulled out of the database and presented as images or as links (that is, documents).

See also:	Netscape Enterprise Server

response.callC() (Method)

Calls a native function within the server.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`callC(`*`aFunctionName`*`, `*`arguments`*`, ...)`
Argument list:	*`aFunctionName`*	The name of a function that has been registered
	`arguments`	A set of arguments to be passed to it when called

External library functions can be registered with the Netscape Enterprise Server and can then be called from scripts running in the request-response loop.

Such registered functions are invoked with the `callC()` method.

The function name is the one that was used when it was registered. Registering a function creates a wrapper that will always return a string primitive value.

See also:	Netscape Enterprise Server

response.client (Property)

A reference to a client object when scripts are used in NES.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`client object`	
JavaScript syntax:	NES	`client`

This global property points at a client object that is created automatically. The transactions between the Netscape Enterprise Server and the client browser maintain sufficient session state information that this object can be made available between one page request and the next.

See also:	`client` object, Netscape Enterprise Server, `request` object

response.database (Property)

A property that points at a globally available database access object.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`database object`	
JavaScript syntax:	NES	`database`

The object referred to by this property can be used to create connections to whatever database you have available in the server back-end environment.

See also:	`database` object

response.debug() (Method)

Prints a debugging message or value in the trace window.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`debug()`

This is a server-side method to assist in debugging script execution when developing scripts for NES.

This provides a means of watching the progress of a request-response handler which is running in a context that has no terminal I/O capabilities.

See also:	Netscape Enterprise Server

response.deleteResponseHeader() (Method)

Removes a specified header record from the response.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	NES	`deleteResponseHeader(`*`aHeader`*`)`
Argument list:	*`aHeader`*	The name of the header to be removed

This is part of the management of the request-response loop in the server. Many response headers will be added automatically by the NES server, and you may want to add others. Occasionally, the server may place a header into the response that you don't want to send back to the user. This method can be used to remove such a header.

See also:	Netscape Enterprise Server

response.flush() (Method)

Sends the current contents of the output buffer to the client.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`flush()`

Response writing tends to involve a certain amount of buffering by the response manager in the server back-end. This is necessary to improve performance and throughput. The data is only physically transferred to the client when a buffer full of data is ready or when the response is completed. This can mean that a JavaScript error can leave the response incomplete if it fails in a way that prevents the response from being completed properly. A run-time error would normally not write any pending response data out to a client or it might result in part of the data being sent but probably not all.

The `flush()` method allows you to force the response output to the client to be updated so that the response is complete up to this point and there are no pending contents yet to be transmitted. You might force a `flush()` at the end of a database record being read and processed for example.

See also:	`File.flush()`, Netscape Enterprise Server

response.getOptionValue() (Method)

Returns the value of the selected option items in a `<SELECT>` block.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`getOptionValue()`

Server-side access to the `<OPTION>` tag contents in a `<SELECT>` block is accomplished slightly differently in an NES server than in a Netscape Navigator browser. This is because the viewpoint is different as you look at the DOM. The DOM standard relates predominantly to how the document is modelled in the client.

See also:	Netscape Enterprise Server, `Option` object, `Select` object

response.getOptionValueCount() (Method)

Returns the number of items in a `<SELECT>` block.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`getOptionValueCount()`

This would normally be the `length` property of a collection or array.

See also:	Netscape Enterprise Server, `Option` object, `Select` object

response.project (Property)

A reference to a `project` object when scripts are executed in NES.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`project object`	
JavaScript syntax:	NES	`project`

This global property points at a `project` object that is created when the server application is starts running. The `project` object is created automatically and a reference to it is stored here for use when needed.

See also:	Netscape Enterprise Server, `project` object

response.redirect() (Method)

Send the appropriate headers and meta information to cause the client to do a redirect to a different URL.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`redirect(`*`URL`*`)`

This is a convenience method for populating headers in the response.

See also:	Netscape Enterprise Server

response.registerCFunction() (Method)

Register a native C language function for use with `callC()`.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	NES	`registerCFunction(`*`aFunctionName`*`, `*`aLibrary`*`, `*`aCFunction`*`)`
Argument list:	*`aCFunction`*	The name of the C function in the library
	`aFunctionName`	The name of the function in the JavaScript environment
	`aLibrary`	A path to the library containing the C function

External library functions can be registered with the Netscape Enterprise Server and can then be called from scripts running in the request-response loop.

Such registered functions are invoked with the `callC()` method.

The registration process creates a mapping between the JavaScript environment and the C language environment. This suggests that the two need not be named the same although it is good practice to preserve the names recognizably across such wrapping mechanisms.

The C function is encapsulated in a JavaScript object wrapper.

A Boolean `true` value is returned if the registration succeeds and a Boolean `false` if it fails.

See also:	Netscape Enterprise Server

response.request (Property)

A reference to a `request` object that encapsulates a client request arriving in an NES server.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`request object`	
JavaScript syntax:	NES	`request`

This global property points at a `request` object that is created when the client submits a request to the server. The `request` object is created automatically and a reference to it is stored here for use when needed.

See also:	Netscape Enterprise Server, `request` object

response.server (Property)

A reference to the `server` object is created automatically when the server is started.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
Property/method value type:	`server object`	
JavaScript syntax:	NES	`server`

This property refers to the globally available server-wide shared `server` object. There is only one of these and it is available to all sessions, application projects and client requests.

This is an object that allows you to share property values across all sessions running in all applications across the entire server. The locking facilities permit you to lock resources while you are using them.

Because this applies server-wide, there is even more reason to ensure you lock objects for the minimum of time and relinquish the locks as soon as possible. It is quite feasible to completely stall the whole server by locking a vital resource during the processing of a single client request. The effect of this is to make your server a single-threaded non-concurrent session server. That is, it will only actually serve one client request at a time.

See also:	Netscape Enterprise Server, server object

response.ssjs_generateClientID() (Method)

Generate a unique identifier for a new `client` object.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`ssjs_generateClientID()`

There may be times during session-state management that you need a unique `ID` value for the clients. This method provides a means of generating a guaranteed unique `ID` value.

See also:	Netscape Enterprise Server

response.ssjs_getCGIVariable() (Method)

Return the value of the requested environment variable.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`ssjs_getCGIVariable()`

The server-side execution occurs within an environment that may have been inherited from the hosting operating system. Other environment values will have been provided by the web server.

See also:	Netscape Enterprise Server

response.ssjs_getClientID() (Method)

Obtains the unique identifier value from a `client` object.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`ssjs_getClientID()`

This is a somewhat inconsistent way of obtaining property values and there may be other undocumented ways of obtaining client `ID` values.

See also:	Netscape Enterprise Server

response.trace() (Method)

A server-side method to assist in tracing script execution when developing scripts for NES.

Availability:	JavaScript –1.1 Netscape Enterprise Server –2.0	
JavaScript syntax:	NES	`trace()`

Debugging server-side execution is difficult because you cannot normally see the execution happening. Placing a debugging console onto the server is notoriously difficult, so this method may provide some much needed assistance when trying to debug a non-working request handler.

See also:	Netscape Enterprise Server

response.write() (Method)

Writes the string value passed as an argument to the outgoing HTML response stream.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	NES	`write()`

This is a server-side method that is not to be confused with the method that belongs to the `document` object.

The `write()` method can be used to output values generated by any legal JavaScript. It is the only way that server-side JavaScript can generate any output and it should be used to generate HTML for insertion into the document.

You can get some quite interesting output if you are prepared to study and exploit the server-side environment.

See also:	`Document.write()`,`Document.writeln()`, Netscape Enterprise Server

Restricted access (Definition)

There are ways in which security is restricted and controlled by means of privileges.

The private information in the `history` object can only be accessed if a script has `UniversalBrowserRead` privileges.

See also:	Data-tainting, Security policy, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `UniversalFileRead`, `UniversalPreferencesRead`, `UniversalPreferencesWrite`, `UniversalSendMail`

ResultSet object (Object/NES)

This is part of the database access suite in Netscape Enterprise Server. It is returned by a stored procedure call.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	nes	*myResultSet* = *myStProc*.resultSet();
Object properties:	`prototype`	
Object methods:	`close(), columnName(), columns(), next()`	

When you call a stored procedure in a RDMS, you don't always get back a sequence of records in the same layout and structure as when you just do a simple SQL select style query.

An SQL query would return a series of records separated by newline characters. A stored procedure might return a mixed collection of records of different types.

A `ResultSet` object is created by asking the `Stproc` object for it when the stored procedure has been called and returned from the database.

The traversing mechanisms provided with a result set allow you to move forwards through the data but you cannot move backwards. Also, you can only read values from a result set as opposed to a `cursor` which allows you to update it and write new values back.

Example code:

```
<SERVER>
// An example derived from Wrox Professional JavaScript
database.connect("ODBC", "myDatabase", "me", "myPassword", "");
myStoredProc = database.storedProc("myProcedure", 40);
myResultSet = myStoredProc.resultSet();
</SERVER>
```

See also:	`database.storedProc()`, Netscape Enterprise Server, `Stproc.resultSet()`, `unwatch()`, `watch()`

Property	JavaScript	JScript	NES	Notes
`prototype`	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
`close()`	1.2 +	-	3.0 +	-
`columnName()`	1.2 +	-	3.0 +	-
`columns()`	1.2 +	-	3.0 +	-
`next()`	1.2 +	-	3.0 +	-

ResultSet.close() (Method)

Closes the `ResultSet` object when you have finished accessing its contents.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	NES	*`myResultSet`*`.close()`

Although closures generally get dealt with automatically for you when a request handler exits, it's good style to call the closure methods yourself when you no longer need the database connection.

See also:	`Stproc.close()`

ResultSet.columnName() (Method)

Returns the name of the column with the specified index number.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`myResultSet`*`.columnName(`*`anIndex`*`)`
Argument list:	*`anIndex`*	A valid column number

If you are enumerating through the columns in the result set, this yields up the name of the indexed column. You may need to use this technique if you have a table structure that could change.

ResultSet.columns() (Method)

Returns the number of columns in the result set.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*`myResultSet`*`.columns()`

If your tables are being modified in the database or you are changing the way the result set is requested, the number of columns may be indeterminate until you actually make the request. This method provides a column count so you can enumerate through the columns to extract the values from them.

See also:	`Stproc.outParamCount()`

ResultSet.next() (Method)

Moves the access pointer to the next row in the result set.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
JavaScript syntax:	NES	*`myResultSet`*`.next()`

When building tables of extracted database content, this provides a way to enumerate through the rows one at a time.

ResultSet.prototype (Property)

The prototype for the `ResultSet` object that can be used to extend the interface for all `ResultSet` objects.

Availability:	JavaScript –1.2 Netscape Enterprise Server –3.0	
Property/method value type:	`ResultSet` object	
JavaScript syntax:	NES	`ResultSet.prototype`
	NES	`myResultSet.constructor.prototype`

Refer to:

`prototype` property

return (Statement)

Returns control back to the caller of a function.

Availability:	ECMAScript edition –2 JavaScript –1.0 JScript –1.0 Internet Explorer –3.02 Netscape –2.0 Netscape Enterprise Server –2.0 Opera –3.0	
JavaScript syntax:	-	`return(`*anExpression*`);`
	-	`return` *anExpression*`;`
	-	`return;`
Argument list:	*anExpression*	A value to return to the function caller

A `return` keyword is a jump statement. It is used to unconditionally exit from a function, pass back a result, and make execution flow to the caller of the function.

When the `return` statement is executed, the execution context is disposed of and removed from the stack. Execution continues at the point in the caller where the function was invoked. The function is replaced by the value being returned.

If the function is not being assigned to an LValue or Left Hand Side expression or has been cast to a `void` type, the result will be discarded.

If the expression is omitted in the `return` statement, the `undefined` value is returned in its place. While compiled languages are far more particular about the presence or absence of this expression, JavaScript is far more forgiving.

Functions that return undefined values are likely to be used as procedures rather than functions. A procedure is invoked as a statement that stands alone. The intent of a function is to return a result that will be substituted in its place.

It is considered illegal for the `return` statement to be present in any statement block other than that belonging to a function. However it can exist inside the statement block associated with a conditional statement or iterator statement as long as they themselves are within a function block. They may be nested more than one level deep but must ultimately belong to a function.

Warnings:

- It is considered to be a syntax error to use the `return` statement anywhere other than in a function body.
- You will not get the `return` value back properly if there is a line terminator between the `return` keyword and the value it was supposed to return. There is a temptation to break long strings over several lines like this:

```
return

"A very long string goes here ...";
```

- This will return the value `undefined` and not the string you intended to return. It is probably better style to assign the string to a variable and return that but there are implications there of string construction-destruction, garbage collection, and potential memory leaks and to trade those problems off it's best to try and eliminate string creation and memory usage if possible.

Example code:

```
// Declare a procedure with an implied return
function aProcedure()
{
document.write("Hello");
}
// Declare a procedure that returns an undefined value
function anotherProcedure()
{
   alert("Click OK to continue");
   return;
}
// Declare a function that returns a result
function aRealFunction()
{
   return 1000;
}
// Use the functions and procedures
aProcedure();
anotherProcedure();
x = aRealFunction();
```

See also:	`break`, Completion type, `continue`, `function( ... ) ...`, Iteration statement, Jump statement, Statement

ECMA 262 edition 3 –section –12.9

Wrox *Instant JavaScript* –page –27

returnValue (Property)

An alias for the `window.returnValue` property.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	*myWindow*`.returnValue`
	IE	*myWindow*`.returnValue = `*aNewValue*
	IE	`returnValue`
	IE	`returnValue = `*aNewValue*
Argument list:	*aNewValue*	The value to be returned when the modal dialog closes

Refer to:

`Window.returnValue`

RevealTrans() (Filter/reveal)

A reveal filter for controlling transitions.

Availability:	JScript –3.0 Internet Explorer –4.0

Refer to:

filter – `RevealTrans()`

rgb() (Function)

A special color definition function used in style sheet color specifications.

Availability:	JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
JavaScript syntax:	-	`rgb(`*`rValue gValue bValue`*`)`
Argument list:	*`bValue`*	Blue intensity
	`gValue`	Green intensity
	`rValue`	Red intensity

The values are separated by spaces and you must specify all three. This value can then be used in the property assignment for a style property that controls color. You can use it in any position where a color value would be used.

See also:	Color value, `style.backgroundColor`, `style.borderColor`, `style.color`, `style.outlineColor`

Right shift (Operator/bitwise)

A rightwards shift of a bit pattern.

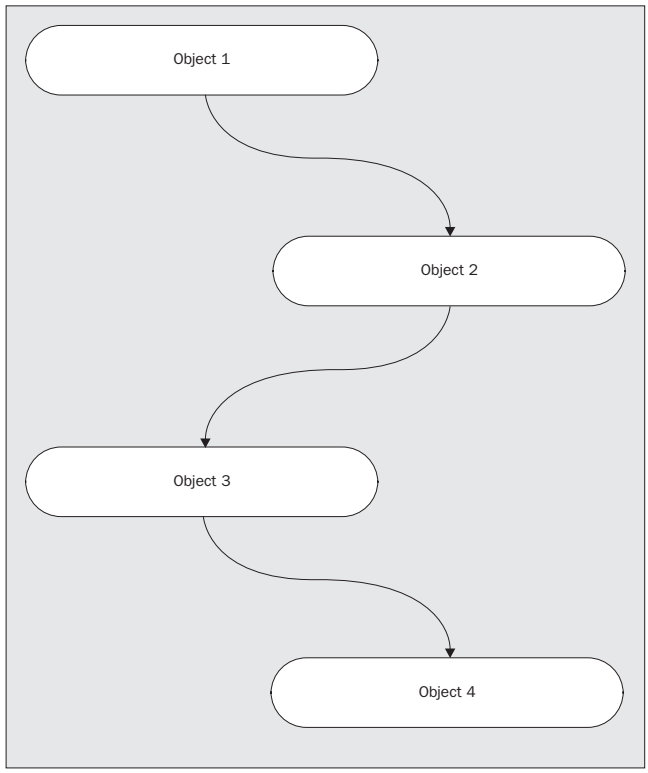
Refer to:

Bitwise shift right (>>)

routeEvent() (Function)

Part of the Netscape Navigator 4 event propagation complex.

Availability:	JavaScript –1.2 Netscape –4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.routeEvent(`*anEvent*`)`
	N	`routeEvent(`*anEvent*`)`
Argument list:	*anEvent*	An `event` object



See also:	`captureEvents()`, Event handler, Event management, `handleEvent()`, `Window.routeEvent()`

Cross-references:

Wrox *Instant JavaScript* –page –55

rows object (Definition)

Some documentation sources describes a `rows` object class that contains an object representing each row in a table. There is no such class, it's simply a collection.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0
Object properties:	`length`
Object methods:	`item(), tags()`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`length`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Method	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`item()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`tags()`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Refer to:

`Collection` object

RT object (Object/HTML)

This is the ruby text associated with a `RUBY` object.

Availability:	JScript –5.0 Internet Explorer –5.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myRT* = *myDocument*.all.*anElementID*
	IE	*myRT* = *myDocument*.all.tags("RT")[*anIndex*]
	IE	*myRT* = *myDocument*.all[*aName*]
	-	*myRT* = *myDocument*.getElementById(*anElementID*)
	-	*myRT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	myRT = *myDocument*.getElementsByTagName("RT")[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Collections:	`all[], attributes[], childNodes[], children[], filters[]`	

See also:	RUBY object, style.rubyAlign, style.rubyOverhang, style.rubyPosition, Element object

Inheritance chain:

Element object, Node object

RUBY object (Object/HTML)

A ruby is an annotation or pronunciation guide for a string of text. The string of text annotated with a ruby is referred to as the base.

Availability:	JScript –5.0 Internet Explorer –5.0	
Inherits from:	Element object	
JavaScript syntax:	IE	*myRuby* = *myDocument*.all.*anElementID*
	IE	*myRuby* = *myDocument*.all.tags("RUBY")[*anIndex*]
	IE	*myRuby* = *myDocument*.all[*aName*]
	-	*myRuby* = *myDocument*.getElementById(*anElementID*)
	-	*myRuby* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myRuby* = *myDocument*.getElementsByTagName("RUBY")[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Collections:	all[], attributes[], childNodes[], children[], filters[]	

To create a RUBY object, you use the <RUBY> HTML tag like this:

```
<RUBY>

Some base text

<RT>Some ruby text

</RUBY>

The <RT> tag creates an RT object.
```

See also:	Element object, style.rubyAlign, style.rubyOverhang, style.rubyPosition

Inheritance chain:

`Element` object, `Node` object

rule object (Object/DOM)

An object that contains a single CSS styling rule.

Availability:	DOM level –2 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0		
JavaScript syntax:	IE	*myRule* = *myDocument*.all.aStyleSheetID.rules[*anIndex*]	
	IE	*myRule* = *myStyleSheet*.rules[*anIndex*]	
	IE	*myRule* = *mySelectorArray*[*anIndex*]	
	-	*myRule* = *myDocument*.styleSheets[*anIndex*].cssRules[*anIndex*]	
Argument list:	*anIndex*		A reference to an element in a collection
Object properties:	`cssText, parentStyleSheet, readOnly, runtimeStyle, selectorText, style`		

This is referred to as a selector and one or more declarations within a cascading style sheet (CSS). It is supported by MSIE.

DOM level 2 calls this a `CSSRule` object. It also describes a `CSSStyleRule` object as a sub-class of that object. The MSIE browser implements both as a single class. The `CSSRule` class maintains the following named constants:

Value	Name	DOM
0	UNKNOWN_RULE	2
1	STYLE_RULE	2
2	CHARSET_RULE	2
3	IMPORT_RULE	2
4	MEDIA_RULE	2
5	FONT_FACE_RULE	2
6	PAGE_RULE	2

DOM level 2 specifies these additional properties:

- `type`
- `parentRule`

See also:	`Document.styleSheets[]`, `SelectorArray` object, `StyleSheet` object, `StyleSheet.rules[]`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
cssText	1.5 +	5.0 +	6.0 +	5.0 +	-	2 +	-
parentStyleSheet	1.5 +	5.0 +	6.0 +	5.0 +	-	2 +	-
readOnly	-	3.0 +	-	3.0 +	-	-	ReadOnly
runtimeStyle	-	5.0 +	-	5.0 +	-	-	-
selectorText	1.5 +	3.0+	6.0 +	4.0+	-	2 +	ReadOnly
style	1.5 +	5.0 +	6.0 +	5.0 +	-	2 +	-

rule.cssText (Property)

The CSS text belonging to a style sheet rule.

Availability:	DOM level –2 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myRule*`.cssText`

This is the text that would be entered into a style sheet to describe a particular CSS rule. Since it is returned as text, there is no implied structure to it so you will need to parse it out if necessary.

rule.parentStyleSheet (Property)

The style sheet that owns this `rule` object.

Availability:	DOM level –2 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0	
Property/method value type:	`StyleSheet object`	
JavaScript syntax:	-	*myRule*`.parentStyleSheet`

There is a hierarchy of objects contained in the CSS style sheet support. Rules describe a style and are collected together into owning parent style sheets.

See also:	Hierarchy of objects

rule.readOnly (Property)

Some rules can be set read-only to prevent their styles from being changed.

Availability:	JScript –3.0 Internet Explorer –4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*`myRule`*`.readOnly`

You may want to define a style in a style sheet and lock it down to prevent the JavaScript code from altering its appearance. Setting this property to `true` will lock the rule and prevent it from being changed.

See also:	StyleSheet.readOnly

Property attributes:

`ReadOnly`.

rule.runtimeStyle (Property)

The style values at run-time taking into account all cascades and dynamic style changes.

Availability:	JScript –5.0 Internet Explorer –5.0	
Property/method value type:	`Style` object	
JavaScript syntax:	IE	*`myRule`*`.runtimeStyle`

Various objects are used to describe the cascading style effect. Rules are associated with style sheets and yet more are instantiated and associated with objects. The current style takes into account the cascaded effect and run-time style further extends this to include style changes that are driven by scripts. This gives you a level of access that may help to un-cascade a style and apply new styling effects dynamically as needed.

rule.selectorText (Property)

The selector text for a rule.

Availability:	DOM level –2 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myRule`*`.selectorText`

This is the part of the CSS style definition text that associates the rule with a document element. For example, a rule that applies to the `BODY` of a document has the value "`BODY`" stored in its `selectorText` property.

See also:	`SelectorArray` object

Property attributes:

`ReadOnly`.

rule.style (Property)

The style settings for a rule.

Availability:	DOM level –2 JavaScript –1.5 JScript –5.0 Internet Explorer –5.0 Netscape –6.0
Property/method value type:	`Style` object
JavaScript syntax:	- *myRule*.style

The rule is the owner of a `style` object which contains properties governing the various style attributes. The order and priority of the rules dictate how the `style` objects cascade to create the `currentStyle` and the `runtimeStyle` objects.

See also:	`style` object (2)

runtimeStyle object (Object/JScript)

A style that applies to an object at run-time and overrides other style settings.

Availability:	JScript –5.0 Internet Explorer –5.0
Inherits from:	`style` object
JavaScript syntax:	IE *myRuntimeStyle* = *myElement*.runtimeStyle
Object methods:	`getAttribute(), getExpression(), removeExpression(), setAttribute(), setExpression()`

This represents the cascaded format and style of its parent object. The value in this object overrides global style-sheets, inline styles and HTML tag attribute values. It overwrites the values provided by `currentStyle` objects but not those supplied by the `style` object.

The properties belonging to this object correspond closely to those of the `style` object and so there is little point in discussing them again here. Refer to the `style` object property descriptions for details of the various properties.

Because the style values are cascaded from style sheet to style sheet and may include some inline styles as well as some explicit styles, objects need to maintain a current style value that is the result of all the inheritances applied on top of one another.

In addition they maintain a run-time style which reflects dynamic changes as well. The `runtimeStyle` is based on the `currentStyle` originally.

See also:	`currentStyle` object, `Element.currentStyle`, `Element.runtimeStyle`, `style` object (2)

Method	JavaScript	JScript	N	IE	Opera	Notes
`getAttribute()`	-	5.0 +	-	5.0 +	-	-
`getExpression()`	-	5.0 +	-	5.0 +	-	-
`removeExpression()`	-	5.0 +	-	5.0 +	-	-
`setAttribute()`	-	5.0 +	-	5.0 +	-	-
`setExpression()`	-	5.0 +	-	5.0 +	-	-

RValue (Definition)

The result of evaluating an expression.

An `RValue` is the value of an expression. This is based on the assignment expression in its general form being like this:

```
LValue = RValue;
```

This is otherwise known as the "value of an expression".

An `RValue` can be a variable or a constant whereas an LValue must be a variable or some other identifier that indicates a modifiable storage location.

See also:	Assignment expression, Definition, LValue, Property value

S object (Object/HTML)

An object that represents the font style controlled by the <S> HTML tag.

Availability:	JScript –3.0 Internet Explorer –4.0	
Deprecated:	Yes	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myS* = *myDocument*.all.anElementID
	IE	*myS* = *myDocument*.all.tags("S")[*anIndex*]
	IE	*myS* = *myDocument*.all[*aName*]
	-	*myS* = *myDocument*.getElementById(*anElementID*)
	-	*myS* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myS* = *myDocument*.getElementsByTagName("S")[*anIndex*]
HTML syntax:	<S> ... </S>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

Event name	JavaScript	JScript	Nav	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-

Table continued on following page

Event name	JavaScript	JScript	Nav	IE	Opera	DOM	HTML	Notes
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Refer to:

`Element` object

Same origin (Security related)

A policy for granting access across window boundaries.

The same origin policy is a foundational concept as far as browser security is concerned. Put simply, it states that a script can access the contents of another window or frame if the `HREF` for that target was loaded from the same host at the same IP port number and with the same protocol.

This ensures that `http:` pages cannot read `https:` content and that pages served by a web server on port 80 cannot read values from a potentially different web server on port 8080 for example. Both of those also require that the host be the same.

This can be circumvented with `UniversalBrowserRead` privilege which allows properties to be read from windows containing objects that were from a different origin. The `UniversalBrowserWrite` property allows those objects with a different origin to be modified. Granting both would allow a script to read and write properties in a window with a different origin.

The same origin policy applies to most but not all properties of a window. It does apply to almost every property belonging to a document object.

You can allow documents from different origins to access properties belonging to your window and document but you need to provide a public API to let them do this. You can alias the private properties by publishing them as user-defined values.

You can also relax the same origin policy as far as hostnames are concerned by setting the domain property. You could set the domain value inside a document as long as it is a genuine fragment of the host name. If you do this in two documents, both served from different hosts belonging to a higher level domain that is the same, the same origin policy is relaxed when the domain value is identical for both documents.

Warnings:

- The common domain access relaxation technique only works for JavaScript version 1.1 and higher.

See also:	`export`, `import`, Security policy, Signed scripts, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`

SAMP object (Object/HTML)

An object representing the HTML content delimited by the `<SAMP>` tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySAMP* = *myDocument*.all.anElementID
	IE	*mySAMP* = myDocument.all.tags("SAMP")[*anIndex*]
	IE	*mySAMP* = *myDocument*.all[*aName*]
	-	*mySAMP* = *myDocument*.getElementById(*anElementID*)
	-	*mySAMP* = myDocument.getElementsByName(*aName*)[*anIndex*]
	-	*mySAMP* = *myDocument*.getElementsByTagName("SAMP")[*anIndex*]
HTML syntax:	`<SAMP> ... </SAMP>`	
Argument list:	*anElementID*	The `ID` value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	1.0 +	-	3.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	1.0 +	-	3.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

Scalar type (Definition)

Data types composed of a single arithmetic atomic component.

Scalar type values are those which are not aggregate and which are numeric or arithmetic in capability.

See also:	Aggregate type, Type

Scope (Definition)

The part of the script within which an identifier is reachable.

An identifier is scoped to be globally available everywhere or locally available only within a function block.

However, JavaScript allows identifier names in local contexts to override those in the global context.

This means that an identifier name can be reused within a function and the local value will be used in place of the global value. Other global variables not overridden will be accessed from the global pool.

Example code:

```
// Declare a global value
var myVariable = "Global Value";
// Declare a local value inside a function
 bodyfunction local_scope(){var myVariable = "Local Value";
document.write(myVariable);}
// Demonstrate the scope override local replacing global
document.write(myVariable);
local_scope();
```

Wrox *Instant JavaScript* – page – 27

Scope chain (Definition)

A scope chain is a logical list of objects associated with an execution context.

Availability:	ECMAScript edition – 2

Identifiers are accessible within the scope of the function body they are created in, or within the global scope.

A scope chain is a logical list of objects associated with an execution context and which indicates the order in which target objects are bound to identifiers.

When the flow of control enters an execution context, the scope chain is created and populated with an initial set of objects. What objects these are depends on the type of code being executed. The scope chain is destroyed on exit from the execution context. This means that factors that affect the construction and ordering of a scope chain may cause it to be created differently each time a particular execution context is entered.

Calling one function from within another builds an increasingly deep scope chain containing each function's identifiers as it builds.

During execution, the scope chain of an execution context is only affected by the presence of a `with` code block. If a `with` block is entered, the scope chain has the `with` block added to the front of it. This is because variables may be local to the `with` block and may override earlier defined variables during the name binding process. When the `with` block is left, the scope chain is bumped to remove the item at the front. This happens when the code exits normally, with a `break` or because of a `continue` statement.

This scope chain behaviour is different to that you may be used to with a procedural language where the scope is block structured.

The scoping rules allow for identifiers in the global pool to be overridden by identifiers in the local context that have the same name.

Scope chains are only affected by `with` blocks and function calls. An `if` block or an iterator loop block does not have a context in which to create a new scope item. In a compiled language, such as ANSI C, you can create variables that are local to conditional and iterator blocks. The code in a conditional and iterator block in a JavaScript session uses the scope chain as it was when the block was entered.

Wrox *Instant JavaScript* – page – 27

Scope of event handler (Definition)

The scope of an event handler is somewhat different to the normal scope.

Refer to:

Event handler scope

screen (Property)

An alias for the `window.screen` property.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Screen object`	
JavaScript syntax:	-	*myWindow*`.screen`
	-	`screen`

Property attributes:

`ReadOnly`.

Refer to:

`Window.screen`

Screen object (Object/browser)

An object that represents the screen display and its rendering capabilities.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
JavaScript syntax:	-	*myScreen* `=` *myWindow*`.screen`
	-	*myScreen* `= screen`
Object properties:	`availHeight, availLeft, availTop, availWidth, bufferDepth, colorDepth, fontSmoothingEnabled, height, pixelDepth, updateInterval, width`	

The properties of this object describe the physical attributes of the display screen the browser is currently operating in. The values reflected by users of desktop computers will describe a much higher resolution than a WebTV set-top box, for example. Other set-top boxes for use with TV should conform to the same resolution but it is likely that they will all vary slightly from one another.

Warnings:

- Some documentation resources have referred to this object as a `screen` object rather than a `Screen` object. Note the capitalization. When examined, we found that several browsers spell the object with a capital S.

See also:	JellyScript, `Window`.screen

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
availHeight	1.2 +	3.0 +	4.0 +	4.0 +	5.0+	-	-	ReadOnly
availLeft	1.2 +	-	4.0 +	-	-	-	-	ReadOnly
availTop	1.2 +	-	4.0 +	-	-	-	-	ReadOnly
availWidth	1.2 +	3.0 +	4.0 +	4.0 +	5.0+	-	-	ReadOnly
bufferDepth	-	3.0 +	-	4.0 +	-	-	-	-
colorDepth	1.2 +	3.0 +	4.0 +	4.0 +	5.0+	-	-	ReadOnly
fontSmoothing Enabled	-	3.0 +	-	4.0 +	-	-	-	-
height	1.2 +	3.0 +	4.0 +	4.0 +	5.0+	-	-	ReadOnly
pixelDepth	1.2 +	-	4.0 +	-	5.0+	-	-	ReadOnly
updateInterval	-	3.0 +	-	4.0 +	-	-	-	-
width	1.2 +	3.0 +	4.0 +	4.0 +	5.0+	-	-	ReadOnly

Screen.availHeight (Property)

The available height taking task bars and menu bars into consideration.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myScreen*.availHeight

This property is extremely important when developing content for platforms with different screen sizes. Although historically, screen sizes have been more or less the same, with the advent of web on TV set-top boxes, this property can have a much wider range of possble values.

Property attributes:

`ReadOnly`.

Screen.availLeft (Property)

The left-most pixel that is accessible in this screen.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myScreen*.availLeft

Property attributes:

`ReadOnly`.

Refer to:

`Screen.availHeight`

Screen.availTop (Property)

The top-most pixel that is accessible in this screen.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*`myScreen`*`.availTop`

Property attributes:

`ReadOnly`.

Refer to:

`Screen.availHeight`

Screen.availWidth (Property)

The available width taking task bars and menu bars into account.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myScreen`*`.availWidth`

Property attributes:

`ReadOnly`.

Refer to:

`Screen.availHeight`

Screen.bufferDepth (Property)

The pixel Z-depth for the off-screen buffer.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	`myScreen.bufferDepth`

This property is important if you are trying to match colors properly. Knowing that you have a limited display palette available means you can optimize your content accordingly.

Screen.colorDepth (Property)

The number of bits available to resolve color values.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myScreen`*`.colorDepth`

To establish the number of available colours, raise the value 2 to the power of this value.

The technical description of this value is that it is the base-2 logarithm of the number of colours available.

You will likely get one of the following values:

- 1 bit – black and white
- 8 bits – 256 colours
- 16 bits – thousands of colours
- 24 bits – millions of colours
- 32 bits – millions of colours (possibly with transparency thrown in)

Other values are possible but unlikely.

Property attributes:

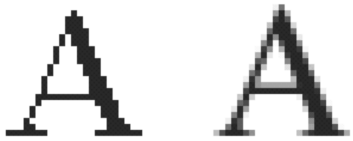
`ReadOnly`.

Screen.fontSmoothingEnabled (Property)

A switch to control the kind of font rendering on the screen.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myScreen*`.fontSmoothingEnabled`

This may not be supported on all available platforms. The effects of font smoothing are subtle but can significantly improve readability of the content on the screen.



Screen.height (Property)

The physical height of the screen display in pixels.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myScreen*`.height`

Property attributes:

`ReadOnly`.

Refer to:

`Screen.availHeight`

Screen.pixelDepth (Property)

The pixel Z-depth for the screen display.

Availability:	JavaScript – 1.2 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myScreen*.pixelDepth

Property attributes:

`ReadOnly`.

Refer to:

`Screen.colorDepth`

Screen.updateInterval (Property)

The screen refresh rate.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myScreen*.updateInterval

This may be important for creating animated effects. You can avoid strobing and flickering artefacts if you are aware of the refresh rate of the screen and don't try to update the display too often for the available refresh rate.

Screen.width (Property)

The physical width of the screen display in pixels.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myScreen*.wiidth

Property attributes:

`ReadOnly`.

Refer to:

`Screen.availHeight`

screenLeft (Property)

The left edge of the display screen.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myWindow`*`.screenLeft`
	IE	`screenLeft`

Refer to:

Window.screenLeft

screenTop (Property)

The top edge of the display screen.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myWindow`*`.screenTop`
	IE	`screenTop`

Refer to:

`Window.screenTop`

screenX (Property)

The X coordinate of the window within the screen display.

Availability:	JavaScript – 1.2 Netscape – 4.0
Property/method value type:	`Number primitive`

JavaScript syntax:	N	*myWindow*.screenX
	N	*myWindow*.screenX = *aCoordinate*
	N	screenX
	N	screenX = *aCoordinate*
Argument list:	*aCoordinate*	A pixel position on the screen

Refer to:

Window.screenX

screenY (Property)

The Y coordinate of the window within the screen display.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myWindow*.screenY
	N	*myWindow*.screenY = *aCoordinate*
	N	screenY
	N	screenY = *aCoordinate*
Argument list:	*aCoordinate*	A pixel position on the screen

Refer to:

Window.screenY

Script (Definition)

A collection of source elements and optional function declarations.

Availability:	ECMAScript edition – 2

The ECMAScript standard describes a script as a collection of source elements and optional function declarations.

Any statements that are not part of a function body are considered to be part of the global code. The statements encountered as part of the global code are executed as they are parsed. Any statements that are inside a function body are simply stored and deferred for execution until the function is actually called.

See also:	Function code, function(...) ..., Global code, Script execution, Script source text, Script termination

ECMA 262 edition 2 – section – 14

ECMA 262 edition 3 – section – 14

Script execution (Definition)

The process of running script.

Scripts are executed in several different ways according to the context and environment in which they are run.

Script code enclosed inside `<SCRIPT>` tags in a web page is executed as the page is rendered or when the browser generates events. Some of the code (the global code) is executed as the page is loaded. Code contained in functions is called as it is needed, however it's probably a good idea not to call function code that is defined in `<SCRIPT>` tags within the `<BODY>` from global code that is in the `<HEAD>` of a web page. Some implementations may not mind but others may fail.

Some web browsers will allow you to access objects within the document while it is being built, others will only allow access to objects once the closing `</BODY>` tag has been processed. This suggests that there is some fixing up of the internal object referencing structures that is required before the DOM tree can be traversed. An example of this is the way that MSIE handles `<DIV>` and `<OBJECT>` tags. You may not reference an `<OBJECT>` tag from a script until the `body.onLoad` event. You can sometimes access `<DIV>` blocks after they have been created but before the `</BODY>` has been reached. This behaviour may be version-1specific and also OS-specific and it may be that Macintosh and Windows versions of a browser behave differently. In the case of MSIE and Netscape Navigator, the rendering engines of both were rewritten at versions 5 and 6 respectively, and therefore many previous problems will be gone, only to be replaced by many new ones.

Scripts may be activated by a CGI interface when they are used in the middle-ware part of a server-side solution. These implementations will generally lack any kind of document model but instead will have a file system model and possible a means of reaching a database.

Scripts in embedded implementations may be triggered by a variety of situations. TV set-top boxes may trigger a JavaScript in receipt of a URL encoded into the vertical interval of the TV signal. This is a way of hiding URL data in the same way as closed caption and teletext information. Analogue TV is being phased out over the next few years but similar mechanisms will be provided with the new digital TV platforms.

Scripts used in WAP phones provided a card and stack metaphor very like HyperCard. This is embodied in WML and WScript. The scripts are the mechanism by which the pages are presented to the user. They are transmitted in a compact byte-code form, which needs to be compiled before delivery.

Warnings:

- In Navigator 2, when a window is resized, all the scripts in a page are executed again. You may not want this to happen.

Script fragment (Definition)

A small portion of a script source text.

A script fragment is so small that it hardly qualifies as a script in its own right.

You might find a fragment of script in a `<SCRIPT>` block that is placed into am `<HTML>` document and executed inline as the page is loaded. It might contain only a single `document.write()` statement.

Another likely candidate for being called a script fragment is an event handler in an anchor tag. This might call a function or just set a variable value. It might be one or even several lines of JavaScript code separated by semi-colons.

See also:	Script Source Text, Statement

Cross-references:

Wrox *Instant JavaScript* – page – 16

SCRIPT object (Object/HTML)

An object that represents a `<SCRIPT>` block within the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySCRIPT* = *myDocument*.all.*anElementID*
	IE	*mySCRIPT* = *myDocument*.all.tags("SCRIPT")[*anIndex*]
	IE	*mySCRIPT* = *myDocument*.all[*aName*]
	-	*mySCRIPT* = *myDocument*.getElementById(*anElementID*)
	-	*mySCRIPT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySCRIPT* = *myDocument*.getElementsByTagName("SCRIPT")[*anIndex*]
HTML syntax:	`<SCRIPT> ... </SCRIPT>`	

Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`charset, defer, event, htmlFor, readyState, recordNumber, src, text, type`	
Event handlers:	`onClick, onDblClick, onError, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReadyStateChange`	

Given that you can access a `SCRIPT` object, you may be tempted to write some self-modifying code. This is not recommended. You should be able to accomplish everything you need to do in that respect with an `eval()` method and that would be more widely supported across browsers.

Accessing the script block may be useful to ascertain whether a particular function is available, although you should know that since you wrote the page yourself. On the other hand, if you imported a script block with a reference to a `.js` file, you may not know the provenance of its contents.

In the example, the source text is extracted from a script block and executed with an `eval()` function. The variable value is set according to the evaluated script which replaces the default value.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT ID="ONE">
block = "ONE";
</SCRIPT>
<SCRIPT ID="TWO">
block = "TWO";
</SCRIPT>
<SCRIPT ID="THREE">
block = "THREE";
</SCRIPT>
<SCRIPT ID="FOUR">
block = "FOUR";
mySourceText = eval(document.scripts.THREE.text);

document.write(block);
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Node` object

SCRIPT.charset (Property)

The character set that a script conforms to.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	N	mySCRIPT.charset

This would contain the character set being used by the script file referred to by the SRC="..." HTML tag attribute. For example the value "iso-8859-1" is likely to be returned but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry (see web reference below).

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

Web-references:

ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets

SCRIPT.defer (Property)

Whether the execution of a script object is to be deferred during page loading to speed the construction of a page.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	-	*mySCRIPT*.defer

Deferring script execution can sometimes get round some tricky problems with accessing a page before it is ready. There are certain stages that the page object model undergoes which are not apparent from the outside.

For example, when loading a page a complex object hierarchy needs to be built. That is not going to be complete until the closing </BODY> tag is encountered. Before that time, certain objects may be accessed but others may not. For instance, prior to the body closure, you cannot use a document.write() to insert an ActiveX <OBJECT> tag using inline coding techniques. You can do a <DIV> block replacement when the body has closed but an error results if you try to do this too soon.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

See also:	XML.defer

SCRIPT.event (Property)

Scripts can be associated with events in the event model.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySCRIPT*.event

Although this is not portable, it might be very useful as a debugging aid when developing scripts.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

Property attributes:

`ReadOnly`.

SCRIPT.htmlFor (Property)

The element `ID` associated with the `FOR="..."` HTML tag attribute in the `<SCRIPT>` tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySCRIPT*.htmlFor

Scripts can be bound to a named document element object. This returns the `ID` value for the HTML element to which the script object is bound.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

Property attributes:

`ReadOnly`.

SCRIPT.readyState (Property)

The current status disposition of a <SCRIPT> block as it is being loaded.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*mySCRIPT*.readyState

This property reflects the loading state of a <SCRIPT> block that is loaded from a source file.

Sometimes, you can design scripts to execute while the document is downloading, inline scripts for example. At that time, you may even be able to trigger interval timed deferred executions as well.

If it is important that the document has completed loading before execution, you can check this property for one of the following values:

State	Value
uninitialized	The object is first instantiated but has not begun loading.
loading	The object has commenced loading.
loaded	The object has completed loading.
interactive	The object is loaded but not yet closed but is ready to handle interaction.
complete	The object body has been closed and the loading is finished.

An object may not need to reflect the complete status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an OBJECT object that represents an <OBJECT> tag until the <BODY> has completed loading. This is because the ActiveX object construction requires a complete document body structure to attach itself to.

Every time this readyState value changes, it triggers an onReadyStateChange event call-back.

See also:	onReadyStateChange

Property attributes:

ReadOnly.

SCRIPT.recordNumber (Property)

The record number within the data set that created the script's content.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Property/method value type:	Number primitive	
JavaScript syntax:	IE	*mySCRIPT*.recordNumber

This is a property that is part of the MSIE data binding support. It contains an integer value that is the record number within the data set that created this object.

This is useful when you are building pages with ASP and Active Data Objects (ADO).

Warnings:

- This is not supported by Netscape Navigator.

See also:	Active Server Pages, ADO

Property attributes:

ReadOnly.

SCRIPT.src (Property)

The URL where the source text for a script block is kept.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*mySCRIPT*.src

This property is read-only. There would be little point in reloading the script code from a new URL and it could be quite dangerous to allow this to happen under script control.

MSIE may yet still provide some access to the contents of a script object in a way that lets you change the script source contained in a <SCRIPT> block. It certainly lets you read the source text.

Warnings:

- This is not supported by Netscape Navigator.

See also:	<SCRIPT SRC="...">

Property attributes:

ReadOnly.

SCRIPT.text (Property)

The textual content of a script block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySCRIPT*.text

You can use this to check for the existence of a function before attempting to call it.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

Property attributes:

`ReadOnly`.

SCRIPT.type (Property)

The MIME type of the `<SCRIPT>` block's content.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySCRIPT*.type
HTML syntax:	`<SCRIPT TYPE="...">`	

The MIME type of the script object is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

Warnings:

- This is not supported by Netscape Navigator prior to version 6.0.

See also:	`<SCRIPT TYPE="...">`, `<STYLE TYPE="...">`, `StyleSheet.type`

Property attributes:

`ReadOnly`.

Script Source Text (Definition)

The original source text that is interpreted and executed.

Availability:	ECMAScript edition – 2

JavaScript implementations that conform to ECMAScript are embodied as a source text that a human can read and edit in a programming environment or text editor. The text of the script source must be expressed using the lower 128 character entities in the Unicode version 2.0 character set.

You can use other Unicode characters but only within comments and string literals.

Any Unicode character can be represented with an escape sequence composed only of characters in the lower 128 range. The escape sequence follows the normal tradition of specifying the character value (in hex) using its numeric position within the character set, like this:

```
\u47AD
```

Within a comment, such an escaped Unicode character is effectively ignored while within a string literal, it contributes a single character to the string.

Although all the characters in a conforming script are Unicode, they are treated with any context dependent interpretation as specified in the Unicode standard. The value of a 16 bit character is sometimes called a code point.

In JavaScript, escape sequences inside comments are never interpreted. That's actually a good thing, because the `\u000A` escape sequence is a line terminator and if you had one and commented out the line suddenly your script would break.

ECMA 262 edition 2 – section – 6

ECMA 262 edition 3 – section – 6

<SCRIPT SRC="..."> (HTML Tag Attribute)

The URL to access an insertable fragment of JavaScript contained in an include file.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
HTML syntax:	`<SCRIPT SRC="..."></SCRIPT>`	
Argument list:	`...`	A URL to reach an includable `.js` file.

This provides a way to include JavaScript from an external file and share some common functionality among several pages. No data is transported from page to page apart from that which is in the included file as assignment statements, so this is not a means of maintaining state between pages.

Although this behaves in the same way as script that is in the HTML page itself, some people prefer not to call this inline code because it's held in a separate file. It depends whether you are referring to the location of the code when you use the term inline or whether you are talking about how it is executed; included script code is executed inline.

You can refer to javascript `.js` files on your local client-side hard disk as long as the page is not being requested from a web server. To access a local client file in a page coming from a web server would be to break the security regimes established to prevent client systems being hacked by intruders.

This is a really useful technique for debugging because you can build an entire library of object disassembly and diagnostic tools and include them in a script block which you can then eliminate when the code goes into production use.

A lot of the undocumented features of the browsers were uncovered in this way.

Warnings:

- Included files sometimes do not work as expected. Browsers do not always support the capability, or may not be configured to accept the `application/x-JavaScript` MIME type as an executable file with a `.js` file extension.
- Note also that although you can examine the properties of `SCRIPT` objects within the MSIE browser, the `SCRIPT` objects that are created as a result of a `SRC="..."` include will not enumerate their properties without causing a run-time error in your script.

Example code:

```
<SCRIPT SRC="include.js">
</SCRIPT>
-----------------------------------------------------
// This content goes into include.js
function getBrowserType()
{
   var myUserAgent;
   var myMajor;
   myUserAgent   = navigator.userAgent.toLowerCase();
   myMajor       = parseInt(navigator.appVersion);
```

```
    if( (myUserAgent.indexOf('mozilla')    != -1) &&
        (myUserAgent.indexOf('spoofer')    == -1) &&
        (myUserAgent.indexOf('compatible') == -1) &&
        (myUserAgent.indexOf('opera')      == -1) &&
        (myUserAgent.indexOf('webtv')      == -1)
       )
    {
       return "N";
    }
    if (myUserAgent.indexOf("msie") != -1)
    {
       return "msie";
    }
    return "other";
}

document.write(getBrowserType());
```

Cross-references:

Wrox *Instant JavaScript* – page 42

Script termination (Definition)

The act of halting the execution of a script.

Scripts may terminate in an expected and normal way or abnormally due to some problem. The predominant reason for premature aborts of scripts is some kind of programmer error, most likely a syntax error or a reference to a non-existent object.

Web browsers behave in different ways and you may be able to add development tools around the browser to catch the exception as it happens and carry out some debugging.

Generally speaking the debugging tools for JavaScript are weak by comparison with those that you use with a compiled language. Some environments provide better tools than others do.

See also:	Environment, Error handling, Execution environment, Script, Script execution, Storage duration

<SCRIPT TYPE="..."> (HTML Tag Attribute)

The MIME type for a block of script code.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
HTML syntax:	`<SCRIPT TYPE="...">` *`someCode`* `</SCRIPT>`	
Argument list:	`...`	A MIME type that signifies JavaScript source text.
	`someCode`	Some script source text

This is an alternative method of selecting the interpreter to be used for the <SCRIPT> block. It has limited support prior to the version 4.0 browsers and so it may be less portable for a while.

Warnings:

- If a browser does not understand this attribute and if there is not a corresponding LANGUAGE attribute that it does understand, it is possible that the script block will be ignored and the script code may not be executed.

Example code:

```
<SCRIPT TYPE="text/JavaScript">document.write("Basic functionality")</SCRIPT>
```

See also:	<SCRIPT LANGUAGE="...">, <SCRIPT>, <STYLE TYPE="...">, MIME types, SCRIPT.type, StyleSheet.type, text/JavaScript

Cross-references:

Wrox *Instant JavaScript* – page 42

</SCRIPT> (Pitfall)

Problems with closing <SCRIPT> tags.

You cannot use the string '</SCRIPT>' within an inline JavaScript fragment. Even if it is enclosed inside quotation marks, it will still be seen by the parser and interpreted as a closure to the <SCRIPT> tag. You will need to hide it by constructing the string from component parts and using concatenation techniques to manufacture the string you need.

If you need to say this:

```
var myScriptTag = '</SCRIPT>';
```

Then you should do this:

```
var myScriptTag = '<' + '/SCRIPT' + '>';
```
which should hide the tag from the parser.

Another alternative is to escape the slash character with a backslash like this:

```
var myScriptTag = '<\/SCRIPT>';
```

Look at that previous line carefully, and see how the forward slash is preceeded by a backslash. After a long day cranking code out that might look like an upper case V, so it might be best to use the concatenation technique.

See also:	<SCRIPT>, Pitfalls

Cross-references:

Wrox *Instant JavaScript* – page 45

<SCRIPT ARCHIVE="..."> (HTML Tag Attribute)

The URL to access an archive containing insertable fragments of JavaScript contained in a single file.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0	
HTML syntax:	`<SCRIPT ARCHIVE="..." SRC="..."></SCRIPT>`	
Argument list:	`...`	A URL to reach an includable `.js` or `.jar` file

This tag attribute allows an archive file to be specified. This allows a whole collection of `.js` files to be shipped as a single unit. The required `.js` file can then be included by extracting it from the archive. If the archive is requested from the web server, it will likely persist in the cache and therefore some time is saved by collecting these archives and referring to items contained within them.

The `ARCHIVE` tag attribute has no use on its own in this context and you must use it with the `SRC` attribute.

Archives are called `.jar` files and are basically a zip-compressed collection of `.js` files. You will probably find one of the Java development environments contains all the tools you need to create these archives in a straightforward way. Actually you don't need anything more complex than a text editor and a zip compression tool.

You can do this manually if you follow these steps:

- Create your collection of `.js` files
- Collect them into a zipped archive file whose file extension is `.jar`
- Construct some HTML to include them
- Call the functions as needed

Refer to the example for script and HTML code. Create the two files `test1.js` and `test2.js` and store them in an archive called `test.jar`. Then create `test.html` with its `<SCRIPT>` tags to call in the files from the archive. When you run it, you can see both functions are called during the `document.write()` methods.

Example code:

```
// Save this into file test1.js
function test1()
{
   return "Test 1";
}
------------------------------------------------------------
// Save this into file test2.js
function test2()
{
   return "Test 2";
}
```

```
------------------------------------------------------------
<!-- Save this as file test.html -->
<HTML>
<HEAD>
<SCRIPT ARCHIVE="./test.jar" SRC="test1.js"></SCRIPT>
<SCRIPT ARCHIVE="./test.jar" SRC="test2.js"></SCRIPT>
</HEAD>
<BODY>
<SCRIPT>
document.write(test1());
document.write("<BR>");
document.write(test2());
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

See also:	.jar, .js, <SCRIPT SRC="...">, <SCRIPT>, Adding JavaScript to HTML, File extensions, Inline script, MIME types, Security policy

<SCRIPT EVENT="..."> (HTML Tag Attribute)

A tag attribute to associate a script block with an event to be handled.

Availability:	JScript – 3.0 Internet Explorer – 4.0

This HTML tag attribute is quite useful when using ActiveX controls in web pages. You can use this to attach a fragment of script to an event so that the screen gets updated.

Here is a skeleton of some HTML that attaches a script to an object that has been embedded:

```
<SCRIPT FOR="Xbutton" EVENT="Click()">
// Do some kind of stuff in here as a
// result of the ActiveX calling this
<SCRIPT>
<OBJECT ID="Xbutton" CLASSID="..." CODEBASE="..." STYLE="...">
<PARAM NAME="..." VALUE="...">
</OBJECT>
```

The CLASSID, CODEBASE, and other parameters depend on the ActiveX control you are embedding. The point to make here is that as the page is loaded, the control will be displayed and when the user clicks on it, the browser makes the association by mapping the FOR="..." HTML tag attribute in the <SCRIPT> tag to the ID="..." attribute of the <OBJECT> tag. Then the event that the control triggers is mapped to the EVENT="..." HTML tag attribute of the <SCRIPT> tag.

You can create a whole set of <SCRIPT> blocks, one for each event and control you expect to use. This means the browser does the mapping and dispatching of events for you.

See also:	<SCRIPT>, Event handler in <SCRIPT>, Script execution

<SCRIPT FOR="..."> (HTML Tag Attribute)

A tag attribute to associate a script block with an input element or for mapping script blocks to objects embedded in web pages.

Availability:	JScript – 3.0 Internet Explorer – 4.0
See also:	`<SCRIPT EVENT="...">`, `<SCRIPT>`, Script execution

Refer to:

Event handler in `<SCRIPT>`

<SCRIPT ID="..."> (HTML Tag Attribute)

Script blocks can be given `ID` values so they can be identified within the document scripts array.

If you can identify a script block by its `ID` value, you should be able to locate the object and at least read the contents of the script block. Some browsers may let you change the script block but it has always been recommended practice to avoid self-modifying code.

See also:	`Document.scripts[]`

<SCRIPT LANGUAGE="..."> (HTML Tag Attribute)

The required version of JavaScript to interpret the enclosed code.

HTML syntax:	`<SCRIPT LANGUAGE="...">` *`someCode`* `</SCRIPT>`	
Argument list:	`...`	The script language to use for this block of script source
	`someCode`	Some script source text

As you embed the script code into an HTML page with the `<SCRIPT>` tag, you can indicate by means of the `LANGUAGE` attribute which version of JavaScript (or indeed other scripting languages) the interpreter should use to process the script. This is subtle and allows various aspects of the language to be switched so that they behave differently according to the version selection.

It also provides a way to hide JavaScript written according to newer syntax conventions from older browsers that cannot cope with it. In general, you should always try to specify the lowest version of JavaScript to achieve maximum portability.

JavaScript version 1.2 implemented some different capabilities regarding equality tests where the operands were different types. Selecting `LANGUAGE="JavaScript"` as opposed to `LANGUAGE="JavaScript1.2"` affects how these tests are carried out when the script is executed.

The following values are legal for the <SCRIPT> tag's LANGUAGE attribute:

Attribute Value	Description
Nothing, attribute omitted	Basic JavaScript functionality.
JavaScript	Basic JavaScript functionality.
JavaScript1.1	Version 1.1 language capabilities.
JavaScript1.2	Version 1.2 language capabilities.
JavaScript1.3	Version 1.3 language capabilities.
JavaScript1.4	Version 1.4 language capabilities.
JavaScript1.5	Version 1.5 language capabilities.
VBScript	Visual BASIC scripting in MSIE browsers.
Tcl	In the HTML 4.0 specification, Tcl is used as an example.

The example below will display the text 1.3 in a Netscape 4.7 browser and the value 1.4 in version 5 of MSIE for Macintosh.

Note with this technique that you should ensure you test for a high enough version. The browsers will execute the versions indicated. If you only test up to version 1.2, then the variable assignment is never going to reflect a 1.4 version capability.

Warnings:

- If a browser does not support the specified language, it may not execute the script block, even with a degraded version of the interpreter.
- Be aware that Netscape 4 supports some special capabilities in JavaScript version 1.2 mode that are not strictly correct according to the ECMA standard nor are they compatible with earlier versions of Netscape Navigator and other browsers. If you find that you need to turn on JavaScript version 1.2 with the LANGUAGE attribute, check your scripts for portability very carefully.

Example code:

```
<!-- JavaScript version detector --->
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">    myVersion = "Generic";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.0"> myVersion = "1.0";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.1"> myVersion = "1.1";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.2"> myVersion = "1.2";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.3"> myVersion = "1.3";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.4"> myVersion = "1.4";</SCRIPT>
<SCRIPT LANGUAGE="JavaScript1.5"> myVersion = "1.5";</SCRIPT>
</HEAD>
<BODY>
<SCRIPT>
document.write(myVersion);
</SCRIPT>
</BODY>
</HTML>
```

Wrox *Instant JavaScript* – page 42

<SCRIPT> (HTML Tag)

A container for JavaScript in an HTML page.

HTML syntax:	`<SCRIPT> someCode </SCRIPT>`	
Argument list:	*someCode*	Some script source text

The <SCRIPT> tag is how the JavaScript code is embedded into a web page. There are several ways to do this. Note that the <SCRIPT> tag must have an associated closing </SCRIPT> tag at the end of the script source text. The following attributes may be useful:

- LANGUAGE
- SRC
- ARCHIVE
- TYPE

You can place the <SCRIPT> tag in the <HEAD> or <BODY> section of the page.

In the <HEAD> context, it is expected to provide some support to the rest of the page so you might place useful functions and event handlers here. You can also put some global code here and it will get executed inline, probably initializing some global variables. The intent is for the <HEAD> block to contain only meta-information about the document. This implies you should not place a `document.write()` method into the <HEAD> area such that it will be executed during page loading. However, both the Netscape and MSIE browsers will allow the `document.write()` if it is called during page loading even if it is located in the <HEAD> block.

It makes some sense to be sure that if you do a `document.write()` in the <HEAD> block, that you make sure it writes something sensible. For example, you can write the document title from a script that is executed inline. If you just write some textual output, the browsers are at least smart enough to place it into the page body.

Because JavaScript is interpreted, it needs to have any functions declared before they are called. However, this means they must be declared chronologically before they are called. This is not the same as positionally defining them before they are called because the page content may be traversed several times. For example, an event handler can probably be placed anywhere because very few events happen before the </BODY> closure happens. Nevertheless, it is still probably good practice to locate any functions that you can in <SCRIPT> blocks placed in the <HEAD> area.

You can place <SCRIPT> tags throughout the <BODY> of the document. These might also contain functions but are more likely to contain inline code to be executed as the page is loading. Although they are in different <SCRIPT> tag blocks, they are all conceptually part of the same script.

If your inline script code is going to do any `document.write()` calls to modify the HTML as the page is loaded, then this is the optimum place to put the code. It's quite sensible to break the code into smaller <SCRIPT> blocks and place them appropriately throughout the document. If the code starts to become complicated, then factor some of it into functions placed in the <HEAD> area and then call it as needed from the <BODY> area.

If you are using a frame-set, you can put the <SCRIPT> block after the <HEAD> tag but before the <FRAMESET> tag. You could write the entire <FRAMESET> description at this point using document.write() methods. You could do that with the entire <BODY> content too.

You can break your script code into smaller blocks, each one associated with a different <SCRIPT></SCRIPT> area and, if necessary, each can be executed in a different version of JavaScript. They will each have a different execution context and the scope chain may be affected, although global variables should be reachable from anywhere.

When the browser encounters a <SCRIPT> tag, it pauses the processing of the HTML page description and executes the <SCRIPT> tag's source code. That may affect subsequent HTML output anyway, and may generate some HTML to be placed into the page at the point where the <SCRIPT> block appears. Any lengthy script evaluation is going to slow down the display of your page. You should defer any lengthy processing until you can use some sleight of hand to hide it. For example, perhaps you can wait until the <BODY> tag is closed and then activate some processing with a <BODY ONLOAD="...">handler. This may be an issue if you are using included .js files since they will need to be requested and fetched from a web server.

You can build event handlers and associate them with the event by means of the <SCRIPT> tag attributes, but this only works in MSIE.

Warnings:

- Be aware that if you place <SCRIPT> blocks inside the <HEAD> of a document, you may be able to initialize some data structures but you certainly won't be able to access any objects that belong to the <BODY> since they won't yet exist.
- Note that during page loading, until you have reached the closing </BODY> tag, the page may be in some intermediate state where objects and memory locations are not locked down. This may cause some difficulties in writing to the document or changing the content of <DIV> blocks. In particular, you cannot inline document.write() into the content of an <OBJECT> block. Until the page is completed, the <OBJECT> is not properly linked into a structure in which you can access it from JavaScript, this is the case with MSIE version 4 browsers, at least.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myResult = 100;
myExpr = myResult %= 1000;
document.write(myResult);
document.write("<BR>");
document.write(myExpr);
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>
```

Cross-references:

Wrox *Instant JavaScript* – page 42

ScriptArray object (Object/browser)

A collection of script blocks belonging to a document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myScriptArray* = *myDocument*.scripts
Object properties:	length	
Object methods:	item()	

In the example, the document contains several script blocks. The script source is extracted and formatted with an escape() function and line breaks are reinserted by means of the String.split() and Array.join() methods.

Warnings:

- This is not supported by Netscape Navigator.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<TABLE BORDER=1>
<TH>Index</TH>
<TH>ID</TH>
<TH>Text</TH>
<SCRIPT ID="ONE">
block1 = "ONE";
</SCRIPT>
<SCRIPT ID="TWO">
block2 = "TWO";
</SCRIPT>
<SCRIPT ID="THREE">block3 = "THREE";</SCRIPT>
<SCRIPT ID="FOUR">
block4 = "FOUR";
```

```
myLength = document.scripts.length;
for (myEnumerator=0; myEnumerator<myLength; myEnumerator++ )
{
   mySourceText = escape(document.scripts[myEnumerator].text);
myArray = mySourceText.split("%0D");

   document.write("<TR><TD>");
   document.write(myEnumerator);
   document.write("</TD><TD>");
   document.write(document.scripts[myEnumerator].id);
   document.write("</TD><TD>");
   document.write(myArray.join("%0D<BR>"));
   document.write("</TD></TR>");
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

See also:	Collection object, `Document.scripts[]`, `ScriptArray.length`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
length	-	3.0 +	-	4.0 +	-	-	Warning, ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
item()	-	3.0 +	-	4.0 +	-	-	-

ScriptArray.item() (Method)

An item selector for accessing a single script within the collection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Script object`	
JavaScript syntax:	IE	*myScriptArray*`.item(anIndex)`
	IE	*myScriptArray*`.item(`*aSelector*`)`
	IE	*myScriptArray*`.item(`*aSelector*`, `*anIndex*`)`
Argument list:	*anIndex*	A zero based index into the collection
	aSelector	A textual value that selects all matching objects

Refer to:

`Collection.Item()`

ScriptArray.length (Property)

The number of script blocks in the current document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myDocument*`.scripts.length`

Warnings:

- This is not supported by Netscape Navigator.

See also:	`Collection.length`, `ScriptArray` object

Property attributes:

`ReadOnly`.

ScriptEase (Product)

A standalone JavaScript interpreter sold by Nombas Inc.

See also:	Server-side JavaScript

Refer to:

Standalone JavaScript

ScriptEngine() (Function)

A special MSIE globally available function that describes the scripting engine currently installed for use with the browser.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`ScriptEngine()`

The following values will be returned by this function depending on the context in which it is called:

- `JScript`
- `VBA`
- `VBScript`

See also:	`Navigator.appMinorVersion`

ScriptEngineBuildVersion() (Function/global)

A special MSIE globally available function that describes the build version of scripting engine currently installed for use with the browser.

Availability:	JScript – 2.0 Internet Explorer – 4.0
Property/method value type:	`String primitive`

This is only available in the MSIE browser. It is useful if you are developing scripts and it is possible that you could build a reference to this into a form that is submitted as part of an error handler. That way you might determine what the error is, what caused it and note the build number of the script interpreter. This may then yield a pattern. An essential part of the fault diagnosis process involves the search for a pattern in the failures of a system. It is very possible that a certain build of the interpreter could manifest a bug which is not present in other builds.

See also:	`Navigator.appMinorVersion`

ScriptEngineMajorVersion() (Function/global)

A special MSIE globally available function that describes the major version number of the scripting engine currently installed for use with the browser.

Availability:	JScript – 2.0 Internet Explorer – 4.0
Property/method value type:	`String primitive`

See also:	`Navigator.appMinorVersion`

Refer to:

`ScriptEngineBuildVersion()`

ScriptEngineMinorVersion() (Function/global)

A special MSIE globally available function that describes the minor version number of the scripting engine currently installed for use with the browser.

Availability:	JScript – 2.0 Internet Explorer – 4.0
Property/method value type:	`String primitive`

See also:	`Navigator.appMinorVersion`

Refer to:

`ScriptEngineBuildVersion()`

Scriptlet (Definition)

A scripting component within the Windows Script Host environment.

Scriptlets are built in the WSH environment or in the web browser. They have evolved over time and become useful for a variety of purposes.

Those items that used to be called scriptlets in the MSIE browser have evolved into what is now called HTML components or HTCs for short.

The original kind of scriptlet (nowadays called a version 1 scriptlet) should now be referred to as a DHTML scriptlet. It is used to construct an HTML object with XML and JavaScript.

A version 2 scriptlet is compiled from its XML and JavaScript source into an ActiveX object which can be used in contexts other than web pages.

Standalone JavaScript scripts that run in WSH are not scriptlets but are simply scripts.

Scriptlets can be built in a variety of ways. Although we are mainly concerned with JavaScript, you can use Perl or VBScript, too. They all use a similar XML framework.

See also:	`.htc`, HTML Component

scroll() (Method)

An alias for the `window.scroll()` method.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0
Deprecated:	Yes
Property/method value type:	`undefined`

JavaScript syntax:	-	*myWindow*.scroll(*aPositionX*, *aPositionY*)
	-	scroll(*aPositionX*, *aPositionY*)
Argument list:	*aPositionX*	A position in pixels
	aPositionY	A position in pixels

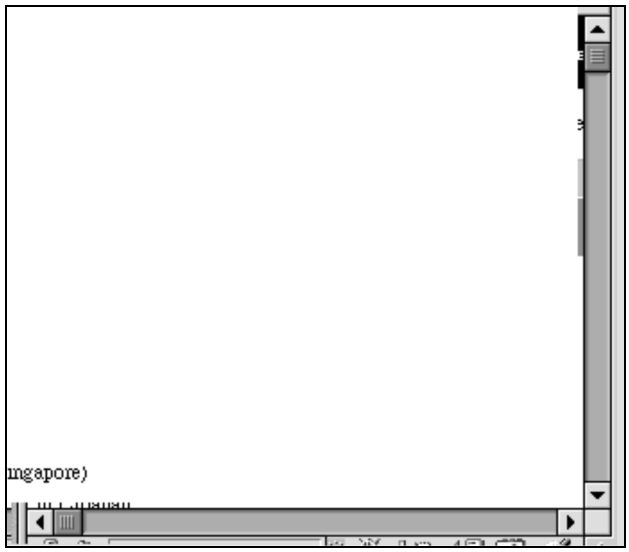
Refer to:

Window.scroll()

scrollbars (Property)

An alias for the window.scrollbars property.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	Bar object	
JavaScript syntax:	-	*myWindow*.scrollbars
	-	scrollbars



See also:	Bar object

Property attributes:

ReadOnly.

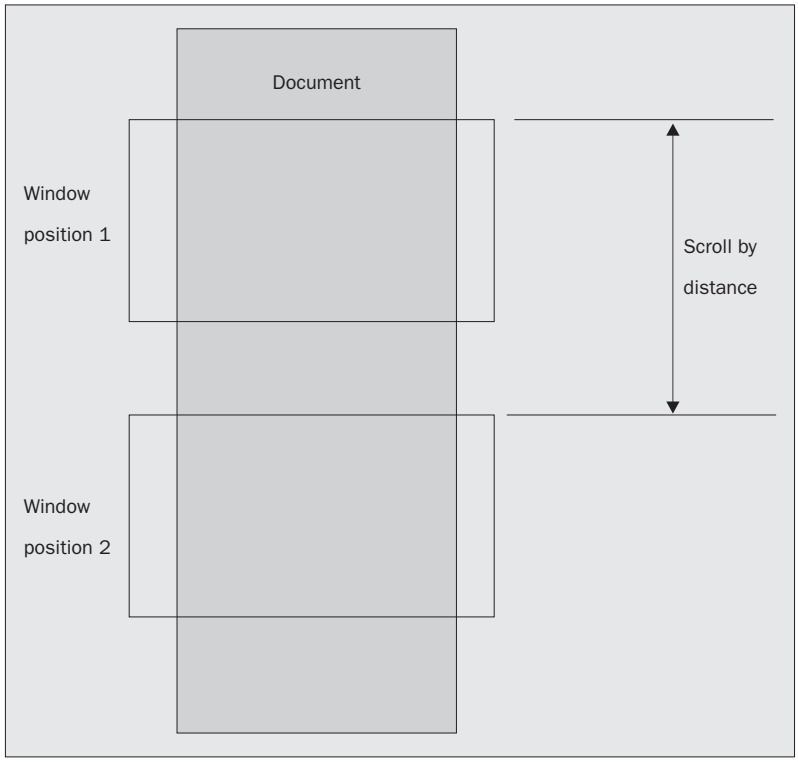
Refer to:

Window.scrollbars

scrollBy() (Method)

An alias for the `window.scrollBy()` method.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.scrollBy(`*anOffsetX*`,` *anOffsetY*`)`
	-	`scrollBy(`*anOffsetX*`,` *anOffsetY*`)`
Argument list:	*anOffsetX*	A distance in pixels
	anOffsetY	A distance in pixels



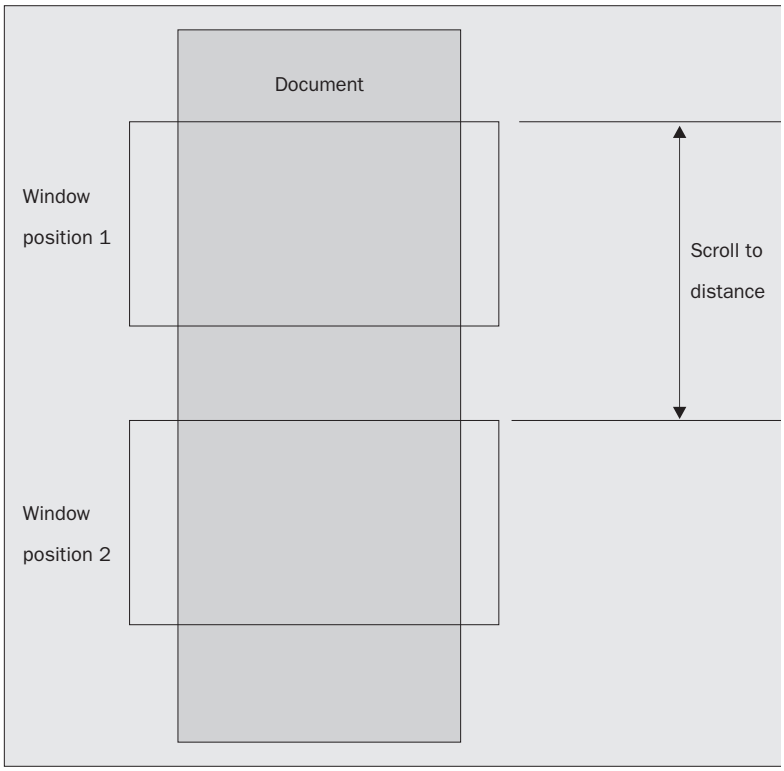
Refer to:

`Window.scrollBy()`

scrollTo() (Method)

An alias for the `window.scrollTo()` method.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.scrollTo(`*aPositionX*`,` *aPositionY*`)`
	-	`scrollTo(`*aPositionX*`,` *aPositionY*`)`
Argument list:	*aPositionX*	A location in pixels
	aPositionY	A location in pixels



Refer to:

`Window.scrollTo()`

secure (Property)

A flag indicating that a window was loaded from a secure source.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myWindow*`.secure`
	N	`secure`
Argument list:	*false*	Window is not currently securely served
	true	Window was loaded from a secure location

Property attributes:

`ReadOnly`.

Refer to:

`Window.secure`

Security policy (Definition)

The rules about what can access local client-side resources.

The basic approach to security in JavaScript is to disallow anything that might be risky, which is quite straightforward in the context of a web browser. However, there are ways to work around this with signed scripts and calls to Java applets and ActiveX controls which may or may not be secure and in any case are platform dependent.

JavaScript is now beginning to be used outside the browser and so scripts may be executed in all kinds of contexts:

- Server side
- Unix command line shell
- Desktop standalone
- TV set-top box
- PDF forms
- WAP phones

Each of these has its own needs and limitations regarding security so there is not one overall approach that works everywhere but rather a variety of techniques that apply on a platform by platform basis. This means that particular fragments of script may work in one context but not in another.

In the browser, all networking capabilities are disabled. This is not so with some of the stand-alone or some of the command-line shell environments where JavaScript may run.

In Netscape 2, the security was very lax allowing JavaScript to send mail purporting to be from another user.

Netscape 3 improved security while version 4 is built around a complete new security model.

MSIE supports different security models, in particular the Authenticode model that allows for signed ActiveX objects to be used.

See also:	`.jar`, `<SCRIPT ARCHIVE="...">`, `<SCRIPT SRC="...">`, AuthentiCode, Code signing, Data-tainting, `Document.domain`, `Document.links[]`, `Global` object, https: URL, Netscape Enterprise Server, Restricted access, Same origin, snews: URL, telnet: URL, `UniversalBrowserAccess`, `UniversalBrowserRead`, `UniversalBrowserWrite`, `UniversalFileRead`, `UniversalPreferencesRead`, `UniversalPreferencesWrite`, `UniversalSendMail`

Select object (Object/HTML)

A drop-down menu containing a list of `<OPTION>` items. These are used in forms to build menus and pop-ups. They may select single items or multiple items.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`mySelect = myDocument.all.anElementID`
	IE	`mySelect = myDocument.all.anElementID.elements[anIndex]`
	IE	`mySelect = myDocument.all.tags("SELECT")[anIndex]`
	IE	`mySelect = myDocument.all[aName]`
	-	`mySelect = myDocument.getElementById(anElementID)`
	-	`mySelect = myDocument.getElementsByName(aName)[anIndex]`
	-	`mySelect = myDocument.getElementsByTagName("SELECT")[anIndex]`
	-	`mySelect = myForm.aSelectName`
	-	`mySelect = myForm.elements[anIndex]`
	-	`mySelect = myForm[anIndex]`
HTML syntax:	`<SELECT> ... </SELECT>`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The `ID` attribute of an element
	aFormIndex	A reference to a particular form in the forms collection

Object properties:	accessKey, dataFld, dataSrc, form, length, multiple, selectedIndex, size, tabIndex, type, value
Object methods:	add(), remove(), tags()
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onChange, onDragStart, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onSelectStart
Collections:	options[]

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "`Input`" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

Unusually, there actually is a `Select` object class where most other kinds of input are instances of an `Input` object.

Event handling support via properties containing function objects was added to `Select` popup objects at version 1.1 of JavaScript.

Unlike MSIE, the Netscape Navigator implementation of this object type does not support the `click()` method.

The MSIE instance of this object is actually a `SELECT` object and not a `Select` object. This is another example of class naming differences between browsers that may cause problems later.

Warnings:

- Note that this `FormElement` object type does not have a `value` property. You may need to make allowances for that in generic form object handlers. Its value is reflected by the option item that is currently selected. This `FormElement` object is not a sub-class of the `Input` object as many other `FormElements` are.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT">???</DIV>
<FORM>
<HR>
<SELECT ID="IN1">
<OPTION VALUE="0">Sunday
<OPTION VALUE="1">Monday
<OPTION VALUE="2">Tuesday
<OPTION VALUE="3">Wednesday
<OPTION VALUE="4">Thursday
<OPTION VALUE="5">Friday
<OPTION VALUE="6">Saturday
</SELECT>
<INPUT TYPE="button" VALUE="CLICK ME" onClick="clickMe()">
```

```
</FORM>
<SCRIPT>
//MSIE Only
function clickMe()
{
   selectedValue  = document.all.IN1.value;
   document.all.RESULT.innerText = selectedValue;
}
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Node` object

Select.add() (Method)

Adds a new option object to a select list collection.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*mySelect*.add(*anElement*, *anIndex*)
Argument list:	*anElement*	The option element to add
	anIndex	The index to insert it at

Select.length (Property)

The length of a select block for a popup menu.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*mySelect*.length

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

Select.multiple (Property)

A flag indicating whether a select block can have multiple or single items only selected.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*mySelect*`.multiple`
HTML syntax:	`<SELECT MULTIPLE>`	

If this flag is set to the Boolean `true` value, then several items in the list of options can be selected simultaneously. They will be passed back in the form data as a comma separated list when the form is sumitted.

See also:	`Select.options[]`, `Select.selectedIndex`, `Select.size`

Select.options[] (Collection)

An array of options objects one each per menu item.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	-	*mySelect*`.options`

You can create new option items dynamically with the `Option()` constructor. They can then be assigned into the array of options. If you want to remove one, then simply assign `null` to its array entry and the option will be removed from the popup menu.

See also:	`Option()`, `Option.index`, `OptionsArray` object, `Select.multiple`, `Select.selectedIndex`

Property attributes:

`ReadOnly`.

Select.remove() (Method)

Remove an item from a select list collection.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*mySelect*.remove(*anIndex*)
Argument list:	*anIndex*	The option item to remove

Select.selectedIndex (Property)

The index of the selected item in a <SELECT> block.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*mySelect*.selectedIndex

This is the index number of the Option object in the options[] collection belonging to the receiving Select object. Note that this index number is only good while the options collection is not modified. Adding new options or deleting options will change the ordering of the collection.

Feedback from several people suggests that in the case of a multiple selection taking place this property returns the index of the first selected item.

See also:	Select.multiple, Select.options[]

Select.size (Property)

The number of items currently chosen in the select popup.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*mySelect*.size

This is an integer value which is likely to be `1` most of the time. It is only meaningful if the `Select.multiple` property is `true` and more than one item has been selected.

Here is a workaround for other browsers that don't have this property, kindly donated by Jon Stephens:

```
<SCRIPT>var mySize=0;for(var i=0; i<mySelect.options.length; i++){   mySize +=
mySelect.options[i].selected ? 1 : 0;}mySelect.size = mySize;</SCRIPT>
```

See also:	`Select.multiple`

Select.tags() (Method)

A method for retrieving collections of objects belonging to a particular class and which are a subset of the `all[]` collection for this object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	IE	*`mySelect`*`.tags(`*`aTagName`*`)`
Argument list:	*`aTagName`*	The name of a tag to be filtered

This is a technique that only works in MSIE. The `tags()` method is used on all manner of collections.

The collection is traversed and all objects are examined to see if they were created by an HTML tag that is the same as that specified in the argument.

The argument must always be specified in upper case and the resulting collection will contain all objects of that type selected from the receiving collection object.

You can then manipulate the sub-set collection in the normal way, accessing items within it by index or by other means.

See also:	`Collection.tags()`

Select.type (Property)

The type of select object.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`mySelect`*`.type`

Because the `Select` object is not simulated by an `Input` object but by a specific class of its own, it can support a non-standard behavior for the `type` property.

In this case, the type indicates the number of simultaneous selections within the popup.

The values for this property may be one of the following:

- `SELECT-ONE`
- `SELECT-MULTI`

Property attributes:

`ReadOnly`.

Select.value (Property)

The presently selected option value.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySelect*.value

This is the string value that is sent back to the web server when the form is submitted.

This is equivalent to:

mySelect.options[*mySelect.selectedIndex*].value

It is the value of the first or only item selected in the popup. It will be the value of the first item when multiple items have been selected.

See also:	`Input.value`

Selection object (Object/browser)

An object representing a user selection in the current window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*mySelection* = *myDocument*.selection
Object properties:	type	
Object methods:	`clear(), createRange(), empty()`	

This object represents a portion of the document in the current window that is currently highlighted, having been selected by the user or by a script. The selection is operated on by means of a `TextRange` object. This object is created by calling a `createRange()` method on the `Selection` object. This step is necessary because a selection cannot by its very nature persist very long, so a `TextRange` object encapsulates its value into a persistent store so it can be operated on, even though the original selection may have been deselected.

In Netscape Navigator, an entirely different technique is used that involves the `document.getSelection()` method.

Because it is easy to deselect the highlighted text by clicking on some other active object in the page, you will need to access the selection inside an event handler that is triggered by the selection action itself. This might be done quite effectively in an `onSelectStart` handler.

Warnings:

- `Selection` objects do not appear to be functional on any version of MSIE for the Macintosh. This may be because the `TextRange` objects have not been mapped to the Macintosh cut and paste architecture.

See also:	`Document.getSelection()`, `Document.selection`, `Password.select()`, `TextRange` object

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`type`	-	3.0 +	-	4.0 +	-	-	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`clear()`	-	3.0 +	-	4.0 +	-	-	-
`createRange()`	-	3.0 +	-	4.0 +	-	-	-
`empty()`	-	3.0 +	-	4.0 +	-	-	-

selection.clear() (Method)

A method to clear the area selected by the user.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*mySelection*`.clear()`

The contects of the current selection are cleared. This is very tricky to do neatly and even harder to accomplish in a portable manner. It is probably better to use the more structured `innerHTML` and related properties of the DOM hierarchy to accomplish the effects you want.

selection.createRange() (Method)

A factory method for creating a text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`TextRange` object	
JavaScript syntax:	*myTextRange* = IE	*mySelection*`.createRange()`

You will need to create a `TextRange` to operate on a `Selection` object in the MSIE browser. Once you have the `TextRange` you can then use script code to manipulate the content.

See also:	`TextRange` object

selection.empty() (Method)

A means of emptying a selection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*mySelection*`.empty()`

This deselects the text and sets the `Selection` object's type to "`None`". The document content is unchanged and the only visible artifact is that the highlighted area returns to its normal unhighlighted state.

selection.type (Property)

A property containing a type for the selection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*mySelection*`.type`

The selection type is reflected here. There are only two reasonable settings for this in the context of a web browser (although there are potentially many other kinds of selection that are possible). The property should contain either `None` or `Text`.

You can build a conditional check into your handler which only does something if the type of the `Selection` object is set to "`Text`".

See also:	`Input.type`

Property attributes:

`ReadOnly`.

Selection statement (Definition)

A means of selecting one or other code block to be executed.

Selection statements provide a means of executing one of several possible blocks of code. The simplest is the `if( ... )` selector. The next most complex is the `if( ... ) ... else ...` selector.

A similar and related concept is the condition execution operator `?:` which is functionally very similar to an `if (...) ... else ...` selection.

The ECMAScript standard reserves the `switch`, `case` and `default` keywords at edition 2 and mandates that they be supported functionally at edition 3.

See also:	Conditionally execute (`?:`), `else ...`, `if( ... ) ...`, `if( ... ) ... else ...`, `switch( ... ) ... case: ... default: ...`

SelectorArray object (Object/browser)

A collection of style sheet rules.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*mySelectorArray* = *myStyleSheet*.rules
Object properties:	length	
Object methods:	`item()`	

This is sometimes referred to as a `rules` object which is not strictly true. It is often so named because it is referenced by the `rules` property of a stylesheet.

DOM level 2 describes this object as a `CSSRuleList` object. It implies it is a sub-class of the `Collection` object and therefore it supports the `item()` method.

See also:	`Collection` object, `rule` object, `rule.selectorText`, `StyleSheet.rules[]`

Property	JavaScript	JScript	N	IE	Opera	HTML	Notes
`length`	-	3.0 +	-	4.0 +	-	-	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	HTML	Notes
`item()`	-	3.0 +	-	4.0 +	-	-	-

SelectorArray.length (Property)

A count of the number of rules in a style sheet.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myStyleSheet*`.rules.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

self (Property)

An alias for the `window.self` property.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Window` object	
JavaScript syntax:	-	*myWindow*`.self`
	-	`self`
	-	`top`
	-	`window`

This property yields a reference to the current window in which a script is running. This means that the statement `self.close()` is effectively `window.close()`.

This is another name for the `window.window` property in this context. However, `self` is useful because you can build reusable scripts with it that can be used with a variety of object types and instances. Don't forget that this can also refer to a `Frame` as well as a `Window` since they are both represented by the `Window` object.

The `self` property can be used without the `window` prefix because it belongs to the global object in a web browser window. Using the `self` keyword makes no difference to the functionality of a script but it makes it easier to understand. For the same reason, you may want to use the `window` property in the same way.

See also:	`Frame` object, `UniversalBrowserAccess`, `UniversalBrowserWrite`, `Window` object, `Window.frame`, `Window.self`

Property attributes:

`ReadOnly`.

Semantic event (Definition)

An event that has been mapped to the DOM.

See also:	Error handler, Event propagation

Semi-colon (;) (Delimiter)

Semi-colon characters are used to mark the end of a statement.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
JavaScript syntax:	-	*aStatement*;
Argument list:	*aStatement*	A JavaScript statement

Semi-colon characters are used to mark the end of a statement, separating one from another.

JavaScript is somewhat forgiving and will place semi-colons into the script automatically as needed except in some rare cases. Refer to the discussion on Automatic Semi-colon Insertion for more details.

Placing two semi-colons one after the other indicates a `null` statement. A line terminator can separate them and an optional comment is also permitted.

See also:	Automatic semi-colon insertion, Empty statement (;), Expression statement, Line terminator, Statement, `var`

Wrox *Instant JavaScript* – page 18

SendMail object (Object/NES)

An object that encapsulates an outgoing e-mail message.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	*mySendMail* = SendMail
	NES	*mySendMail* = new SendMail()
Object properties:	Bcc, Body, Cc, constructor, ErrorsTo, From, Organization, prototype, ReplyTo, Smtpserver, Subject, To	
Object methods:	errorCode(), errorMessage(), send()	

This provides a way for the Netscape Enterprise Server to send e-mail messages as a result of a client request.

You create a new message handling object with the `SendMail()` constructor. Then you define where it is going to be sent, its subject matter and content by storing string values in its various properties.

Finally, you transmit the message via an SMTP server with the `send()` method.

Example code:

```
<SERVER>
mySendMail = new SendMail();
mySendMail.Smtpserver = "mailhost";
mySendMail.To = "someone@somewhere.com";
mySendMail.From = "me@here.com";
mySendMail.Subject = "A test message";
mySendMail.Body = "Some body text";
mySendMail.send();
</SERVER>
```

See also:	Netscape Enterprise Server, `SendMail(),unwatch(),watch()`

Property	JavaScript	JScript	NES	Notes
Bcc	1.2 +	-	3.0 +	-
Body	1.2 +	-	3.0 +	-
Cc	1.2 +	-	3.0 +	-
constructor	1.2 +	-	3.0 +	-
ErrorsTo	1.2 +	-	3.0 +	-
From	1.2 +	-	3.0 +	-
Organization	1.2 +	-	3.0 +	-
prototype	1.2 +	-	3.0 +	-
ReplyTo	1.2 +	-	3.0 +	-
Smtpserver	1.2 +	-	3.0 +	-
Subject	1.2 +	-	3.0 +	-
To	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
`errorCode()`	1.2 +	-	3.0 +	-
`errorMessage()`	1.2 +	-	3.0 +	-
`send()`	1.2 +	-	3.0 +	-

SendMail() (Constructor)

A constructor for creating objects that encapsulate an outgoing e-mail message.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`SendMail` object	
JavaScript syntax:	NES	`new SendMail()`

Use this as an alternative method of constructing instances by cloning objects rather than instantiating fresh ones from the owning class.

See also:	Netscape Enterprise Server, `SendMail` object

SendMail.Bcc (Property)

Defines the list of blind copy recipients.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`mySendMail.Bcc`

This property contains the value that is transmitted in the BCC: header of the outgoing e-mail.

The value assigned to this property should be a comma separated list of BCC: recipient e-mail addresses.

SendMail.Body (Property)

The body text for the e-mail message.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.Body`

This property contains the value that is transmitted in the body of the outgoing e-mail.

You can store any valid 7 bit ASCII text here. If you want to get really sneaky, you can construct a MIME type separator and embed some attachments or send a multi-part message.

SendMail.Cc (Property)

Defines a list of CC recipients.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.Cc`

This property contains the value that is transmitted in the CC: header of the outgoing e-mail.

The value assigned to this property should be a comma separated list of CC: recipient e-mail addresses.

SendMail.constructor (Property)

A constructor function for object instances.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`Function` object	
JavaScript syntax:	NES	*`mySendMail`*`.constructor`

The constructor is that of the built-in `SendMail` prototype object.

You can use this as one way of creating mail dispatchers although it is more popular to use the new `SendMail()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

SendMail.errorCode() (Method)

Retrieves an error code value after attempting to transmit.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.errorCode()`

If the message sending failed, then you should be able to retrieve an error code value with this method.

SendMail.errorMessage() (Method)

If there is an error, then you can obtain the message text with this method.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.errorMessage()`

Use this method after calling the `send()` method to retrieve any pending error message text.

SendMail.ErrorsTo (Property)

Defines the recipient of error e-mails if the message fails to arrive.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.ErrorsTo`

This property contains the value that is transmitted in the ErrorsTo: header of the outgoing e-mail.

The value assigned to this property should be a valid email address (or comma separated addresses).

If the receiving mail system experiences any problems during the onwards delivery to the recipient's mailbox (for example, if it doesn't exist or is full), then a message is reflected back to the e-mail address in the ErrorsTo: header.

SendMail.From (Property)

Defines the From address of the e-mail.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`mySendMail.From`

This property contains the value that is transmitted in the From: header of the outgoing e-mail.

The value assigned to this property should be a valid e-mail address. It is considered to be bad practice to forge From addresses in mail headers, and some mail systems will not allow you to do this and will override the settings you define for this value.

Whatever value ends up in the From: header, the recipient can reply to this address if they mean to. It makes sense for this to be a mail address that a human being will ultimately check although you may want to put in some automation to read incoming e-mails if you expect a lot of responses.

SendMail.Organization (Property)

A standard header to describe the organisation you belong to.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.Organization`

This property contains the value that is transmitted in the Organization: header of the outgoing e-mail.

The value assigned to this property can be any 7 bit ASCII string.

SendMail.prototype (Property)

The prototype for the `SendMail` object that can be used to extend the interface for all `SendMail` objects.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`SendMail` object	
JavaScript syntax:	NES	`SendMail.prototype`
	NES	*`mySendMail`*`.constructor.prototype`

Refer to:

`prototype` property

SendMail.ReplyTo (Property)

The address to which replies should be sent.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.ReplyTo`

This property contains the value that is transmitted in the ReplyTo: header of the outgoing e-mail.

The value assigned to this property should be a comma separated list of ReplyTo: recipient e-mail addresses.

Beware that many mail clients do not honor this field, they will attempt to send messages back to the ErrorsTo: or From: addresses or may even make one up. These header values are merely conventions and although they are described in various RFC documents, mail clients are written by people whose skills and attention to detail range from the plain careless to the highly professional.

SendMail.send() (Method)

Sends the message encapsulated by this object.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	`mySendMail.send()`

This connects to the `sendmail` process in the server and dispatches the message. There is an implication here that because it uses `sendmail`, then the server can only run on platforms that support `sendmail`. That further implies the platform is a Unix system, although `sendmail` is open source and may be deployed on non-Unix platforms.

If `sendmail` is not available the results of calling this method are uncertain.

SendMail.Smtpserver (Property)

Defines the name of the SMTP server to which we shall connect and request that our message be sent.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.Smptpserver`

You will need to consult your system administrator about this value. It is impossible to state with any certainty what value you should assign to this property there are so many possible ways to configure a mail server and deploy it. It may or may not be on the same machine as your web server.

SendMail.Subject (Property)

Defines the subject heading for the message.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.Subject`

This property contains the value that is transmitted in the Subject: header of the outgoing e-mail.

The value assigned to this property should be a 7 bit ASCII string.

SendMail.To (Property)

Defines the To: address for the e-mail.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	*`mySendMail`*`.To`

This property contains the value that is transmitted in the To: header of the outgoing e-mail.

The value assigned to this property should be a comma separated list of To: recipient e-mail addresses.

These are the recipients of the e-mail and if you specify several, it may be more efficient as your SMTP server can bulk deliver several messages at once.

server object (Object/NES)

An object that represents the server in server-side JavaScript implementations.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
JavaScript syntax:	NES	`server`
Object properties:	`agent, host, hostname, port, protocol`	
Object methods:	`lock(), unlock()`	

This is a server-side host object representing the server. There is only one and you cannot instantiate it although you can make references to it. All users on the web server share this object.

This is an object that allows you to share values across all sessions running in all applications across the entire server. The locking facilities permit you to lock resources while you are using them.

Because this applies server-wide, there is even more reason to ensure you lock objects for the minimum of time and relinquish the locks as soon as possible. It is quite feasible to completely stall the whole server by locking a vital resource during the processing of a single client request. The effect of this is to make your server a single-threaded non-concurrent session server. That is, it will only actually serve one client request at a time.

See also:	Netscape Enterprise Server, `project` object, `response.server`, `unwatch(),watch()`

Property	JavaScript	JScript	NES	Notes
`agent`	1.1 +	-	2.0 +	-
`host`	1.1 +	-	2.0 +	-
`hostname`	1.1 +	-	2.0 +	-
`port`	1.1 +	-	2.0 +	-
`protocol`	1.1 +	-	2.0 +	-

Method	JavaScript	JScript	NES	Notes
`lock()`	1.1 +	-	2.0 +	Warning
`unlock()`	1.1 +	-	2.0 +	-

Cross-references:

Wrox *Instant JavaScript* – page 65

Wrox *Instant JavaScript* – page 67

server.agent (Property)

Describes the server being used.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`server.agent`

The `userAgent` property of the navigator object in a web browser describes the kind of browser being used. This value is presented as a text string.

This is the corresponding property in a web server and provides a way to deploy scripts that are shared amongst several variants of a server that are compatible but different.

See also:	`Navigator.userAgent`

server.host (Property)

The machine and domain name values for the server host.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`server.host`

This value will be the DNS name that you can use to reach the server.

You might use this value to manufacture URL values for use in `HREF="..."` HTML tag attributes for example.

See also:	Netscape Enterprise Server, `unwatch(),watch()`

server.hostname (Property)

The hostname and port property of the receiving server object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`server.hostname`

This value will be the same as the `host` property if the port number the server listens on is 80. Otherwise, the port number will be appended to the `host` value and that will be the `hostname` value. A colon separator is introduced between the host and port values.

See also:	Netscape Enterprise Server

server.lock() (Method)

A means of locking the server object to prevent contention between scripts.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
JavaScript syntax:	NES	`server.lock()`

The server lock would be used at a higher hierarchical level than the project lock mechanism.

It is vitally important that you don't hog a lock on the server object as this can deny server access to all other users

The lock will stall if another script currently has a lock extant on this project. The method will then return when that lock is relinquished.

Warnings:

- Locking the server object can lead to severe performance degradation. While it is locked, any lock requests made by other scripts will stall pending the lock being relinquished with an `unlock()` method call.
- You can render your server virtually useless by over-locking the `server` object. You should aim to relinquish any locks as soon as you possibly can. Ideally you should seek to avoid locking the server object if at all possible.

See also:	`project.lock()`

server.port (Property)

The port number that the server listens on for incoming requests.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	NES	`server.port`

This value is normally port number 80, but ports 81, 8080 or 8081 are also commonly used. It can be any port number you like although there are many reserved ports for other services on the host. On a Unix system, there is an `/etc/services` file that will enumerate the ports that are likely to be reserved for other non web-server purposes.

You may also have difficulty in using ports below number 1024 unless you have access to the system administrator account.

server.protocol (Property)

The protocol supported by the server is available from this property.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	NES	`server.protocol`

Typical values for this property will be "`http:`" or "`https:`". The latter will be used if the server is a secure server providing e-commerce support for example.

server.unlock() (Method)

Relinquisesh a lock on the server object.

Availability:	JavaScript – 1.1 Netscape Enterprise Server version – 2.0	
JavaScript syntax:	NES	`server.unlock()`

If you ever lock the server object from a script, you should call this as soon as you possibly can after you have completed your lock critical code. Retaining a lock on your `server` object is not only bad manners but is seriously bad for the health and well-being of your server. Locking `server` objects persistently will hog resources and your server performance will slow to a crawl.

See also:	`project.unlock()`

Server side browser detection (Useful tip)

You can do a great deal of browser portability handling if you are prepared to serve browser specific pages from your web server.

A wholly dynamic site may be able to serve browser, platform and version specific HTML according to the value of the `userAgent` string that the browser sends when it makes a request. This technique is fine for a few pages and when they don't experience high traffic. To serve static pages this way needs a smarter server-side trick to be deployed.

You could render very browser specific copies of your pages and store them under document path names that contain a component that could be derived by disassembling the `userAgent` string. Then in your web server, you can trap every request that needs this capability, route it through a special module and generate a browser-specific path modification. If you do this creatively, you could provide a mechanism that allows the web pages to request an unmodified URL but the web server serves a page that is as close to ideal as it can get.

For example, the browser might be Netscape 3 on a Macintosh. That might yield a string containing a `3` for the version, an `N` for the browser and an `M` for the platform. The `3` might become a `4` or even a `6` for other versions of Netscape Navigator. The `N` might become an `E` for MSIE, an `I` for iCab or an `O` for Opera. The `M` might become a `W` for windows. So we have a string that represents the browser, platform and version in three letters. We might get a string such as `NM3`, for example. When the browser requests a page called `index.html`, the web server would inspect the `userAgent` string and work out that its normalized signature is `NM3`. The web server can then attempt to serve the page `NM3index.html`. If this does not exist, the web server can fall back to `NMindex.html` and then `Nindex.html` before eventually serving just plain old `index.html`. These tests in the web server will take fractions of a second with something like a `stat()` function call to test for the existence of a file.

With this technique, your publishing logic can generate some very platform, browser and version specific static files and the web server can locate them quickly and efficiently even when there are high traffic loads on the server farm. It's also workable for style sheets and can be deployed in a load-balanced multi-machine server farm as well.

See also:	Compatibility

Server-side JavaScript (Definition)

That JavaScript which is executed in the web server, probably in response to a browser request and accessed via CGI.

Server-side JavaScript is when the JavaScript source is executed in response to a request from a user's client application. That request arrives as a server, which then determines that a JavaScript needs to be executed to build the response. The server then runs the script and returns the output of it to the user, most likely in the form of a web page but possibly in the form of some image data or other textual or binary content.

Some server-side implementations are designed to yield performance improvements by semi-compiling the JavaScript and retaining that byte-code form in a cache.

Each server may offer alternative ways to invoke the server-side scripting. It is hoped that all the servers that use JavaScript and which conform to ECMAScript may well use the same tags for enclosing the server-side script. However, since the tags are not defined in the standard, this may be a vain hope.

setHotkeys() (Method)

Activate or deactivate keyboard shortcuts for this window.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.setHotKeys(`*aSwitch*`)`
	N	`setHotKeys(`*aSwitch*`)`
Argument list:	*aSwitch*	A Boolean switch value

Refer to:

`Window.setHotkeys()`

setInterval() (Method)

A method for setting timer intervals.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	- `myWindow.setInterval(aFunction, anInterval, someArguments)`	
	- `myWindow.setInterval(aSourceText, anInterval)`	
	- `setInterval(aFunction, anInterval, someArguments)`	
	- `setInterval(aSourceText, anInterval)`	
Argument list:	*aFunction*	A function object (not supported in MSIE)
	anInterval	A time interval in milliseconds
	aSourceText	Some valid JavaScript source text
	someArguments	The arguments to the function object (not supported in MSIE)

See also:	Timer events, `Window.clearInterval()`, `Window.setTimeout()`, `Window.setInterval()`

setResizable() (Method)

Enable or inhibit the window resize capability.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`myWindow.setResizable(aSwitch)`
	N	`setResizable(aSwitch)`
Argument list:	*aSwitch*	A Boolean value to control the functionality

Refer to:

`Window.setResizable()`

setTimeout() (Method)

A method for setting a one shot timer.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`myWindow.setTimeout(`*`aSourceText, aWaitTime`*`)`
	-	`setTimeout(`*`aSourceText, aWaitTime`*`)`
Argument list:	*`aSourceText`*	Some valid JavaScript source text
	`aWaitTime`	A delay in milliseconds

See also:	Timer events, `Window.setInterval()`, `Window.setTimeout()`

setZOptions() (Method)

Defines the window stacking behaviour.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myWindow`*`.setZOptions(`*`anOptionValue`*`)`
	N	`setZOptions(`*`anOptionValue`*`)`
Argument list:	*`anOptionValue`*	One of a range of possible settings for the feature

Refer to:

`Window.setZOptions()`

Shadow() (Filter/visual)

A visual filter for creating a shadow.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Filter – `Shadow()`

Shallow copying (Definition)

Copying object references and not the objects.

See also:	`Array.toSource()`

Refer to:

Copying objects

Shared Property (Definition)

A property contained in a prototype and shared between several instances.

Availability:	ECMAScript edition – 2

You can create several objects and make them share a common ancestor. In a class-based object oriented world, this would be called sub-classing. Instantiating each one means it would inherit properties from its super-class, but objects of the same class in a real object oriented system do not share property values unless the static (class) factory method that instantiates them presets the same values as they are initialized.

In JavaScript, because the prototype chain is used to inherit properties from parent objects and not parent classes, then objects will inherit property values unless they override them locally.

If you are used to the class-based object oriented way of doing things, this can be quite distracting.

Shell Scripting with JavaScript (Definition)

Unix command line tools written in JavaScript.

Once you have a JavaScript interpreter installed on your system, possibly to provide a server-side or CGI handling mechanism, you can easily use it then to do the things you might previously have done in Perl, Tcl, Bourne, Korn or C-Shell.

Not that you would necessarily choose JavaScript over the other alternatives but for some projects it might be better suited due to the kind of data you are manipulating or what you need to do to it.

The main strength of the Unix environment is the way multiple scripting languages can be used at will and a project may be built from code that runs in many different environments and contexts.

Shift expression (Definition)

Shifts the left value by an amount specified by the right value.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Bitwise shift operators convert their left operands to a 32-bit integer value and shift them according to their right operation. The operator determines the kind of shifting that is applied.

See also:	Bitwise shift operator, Expression

Cross-references:

ECMA 262 edition 2 – section – 11.7

short (Reserved word)

Reserved for future language enhancements.

The inclusion of this reserved keyword in the ECMAScript standard suggests that future versions of ECMAScript may be more strongly typed.

This keyword also represents a Java data type and the `short` keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

showHelp() (Method)

Displays the help window.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myWindow*.showHelp()
	IE	showHelp()

Refer to:

Window.showHelp()

showModalDialog() (Method)

An alias for the `window.showModalDialog()` method.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	User defined	
JavaScript syntax:	IE	*myWindow*.showModalDialog(*aURL*, *someArguments*)
	IE	showModalDialog(*aURL*, *someArguments*)
Argument list:	*aURL*	A URL to load into the modal dialog
	someArguments	Arguments to pass to the modal dialog

Refer to:

`Window.showModalDialog()`

showModelessDialog() (Method)

An alias for the `window.showModelessDialog()` method.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	User defined	
JavaScript syntax:	IE	*myWindow*.showModelessDialog(*aURL*, *someArguments*)
	IE	showModelessDialog(*aURL*, *someArguments*)
Argument list:	*aURL*	A URL to load into the modal dialog
	someArguments	Arguments to pass to the modal dialog

Refer to:

`Window.showModelessDialog()`

.shtm (File extension)

Server-side processed HTML file.

Refer to:

File extensions

.shtml (File extension)

Server-side processed HTML file.

Refer to:

File extensions

Side effect (Definition)

The changes to the execution environment due to some code being executed.

When functions are executed, they may alter some item in memory or cause some change to occur aside from simply returning a value. For example, a function may create an object and add it to a persistent array and return some value such as the number of elements in that array. The calling expression was not aware that the array was extended and simply received a numeric value as a result of evaluating the function. The side effect was that the array became longer by one element.

See also:	Expression, Script execution

Sidebar object (Object/Navigator)

A new object introduced with Netscape 6.0 to manage the left side navigation bar.

Availability:	JavaScript – 1.5 Netscape – 6.0	
JavaScript syntax:	N	*myWindow*.sidebar
	N	sidebar

This is a new object which needs to be explored as we get to know the netscape Navigator 6.0 browser. It encapsulates the behavior and appearance of the sidebar frame on the left of the browser window.

See also:	`Window.sidebar`

Signed scripts (Security related)

A means of giving scripts a privilege to access secure content.

Netscape Navigator allows scripts to have digital signatures attached to them. These signatures can control the level of privilege that a script is allowed to have in a web browser. This is ultimately under user control but if the user allows, the scripts can be secured at source.

The signature combines the identity of the signatory and a checksum of the content. The content cannot be modified without invalidating the checksum and hence voiding the signature.

It would be difficult to establish the exact security criteria beforehand, so Netscape Navigator forces scripts to request the privileges they need. Then, you can allow or deny the access which can be stored and mapped against the identity of the person signing the script. This means a security policy can gradually be established by training the browser to recognize and make decisions on access. Initially, no access is available but after some time, your browser preferences will contain a very sophisticated set of rules that govern the access to the secure values.

To sign your scripts, you will need additional tools and utilities. These are available from Netscape and should form part of your publishing pipeline.

An alternative is to serve your scripts separately from a secure server. Scripts served in this way will assumed to have been signed by the secure server itself.

As a way round the inconvenience of signing scripts after every minor correction, you can sign the codebase of a script. This means you can establish a security setting for scripts from a specific web server. It is slightly less secure than signing a checksum but more convenient during development. It is recommended that proper signing be used; once the script changes are less frequent and the development process is complete, the scripts will be more stable and signing will be carried out less frequently. With some automation in the publishing work flow, you may be able to sign scripts as part of the releasing procedure that your developers employ.

Your web page may contain more than one script. For signed script access control to work, all of the scripts on a page must be signed. If an unsigned script is present, it defeats the entire signing status of the whole page. Scripts can be signed by more than one person. Netscape Navigator will try and find the highest most complete coverage of the scripts in a page. Ideally it will find a particular signer who has signed all of the scripts. Other signers may have conferred a higher level of security but not on all of the scripts. The more complete coverage will prevail.

Although these fairly strict same-signer policies apply to the scripts within a window, scripts in multiple windows may operate under a slightly relaxed policy. The "same signer" policy is a variation of the "same origin" policy. Different signers cause the browser to behave as if the pages were from different origins. Both scripts may have rights to request `UniversalBrowserRead` access which might work around the problem.

Unsigned scripts have quite restricted access to window properties for windows that contain signed scripts. This means that untrusted and insecure scripts cannot access secure data by subverting an already trusted script.

Warnings:

- MSIE version 4 does not support the Netscape Navigator privilege model. Therefore scripts are always unprivileged. The MSIE security model is based on zones. This is a fairly coarse grained approach and simply allows scripts to be executed or not as a whole. The Netscape Navigator model allows access to be controlled object by object.
- Being so closely related to the MSIE browser, the WebTV box also does not support signed scripts.

Single line comment (Definition)

A pair of slash characters (`//`) indicates single line comments.

Single line comments are indicated by a pair of slash characters (`//`) and are completed by a line terminator.

The pair of slash characters and everything following them to the end of the line is considered to be a comment. Comments are discarded during the interpretation phase of a line of script. A pair of slash characters would not behave as a comment delimiter if one of them were escaped with a backslash character or if they appeared inside a single or double quoted string literal.

See also:	Comment, Comment (`//` and `/* ... */`), Line

Slide() (Filter/transition)

A transition effect with the appearance of one image sliding over another.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `Slide()`

SMALL object (Object/HTML)

An object that represents the font style controlled by the `<SMALL>` HTML tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Deprecated:	Yes	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`mySMALL = myDocument.all.anElementID`
	IE	*`mySMALL`* `=` *`myDocument`*`.all.tags("SMALL")[`*`anIndex`*`]`
	IE	*`mySMALL`* `=` *`myDocument`*`.all[`*`aName`*`]`
	-	*`mySMALL`* `=` *`myDocument`*`.getElementById(`*`anElementID`*`)`
	-	*`mySMALL`* `=` *`myDocument`*`.getElementsByName(`*`aName`*`)[`*`anIndex`*`]`
	-	*`mySMALL`* `=` *`myDocument`*`.getElementsByTagName("SMALL")[`*`anIndex`*`]`
HTML syntax:	`<SMALL> ... </SMALL>`	
Argument list:	*`anIndex`*	A reference to an element in a collection
	`aName`	An associative array reference
	`anElementID`	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
onDblClick	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Wrox *Instant JavaScript* – page – 65

Wrox *Professional JavaScript* – page – 103

Source text (Definition)

Human readable script source text to be parsed and executed.

Availability:	ECMAScript edition – 2
See also:	Comment, Escape sequence (\), Lexical convention, Script

Refer to:

Script source text

Cross-references:

ECMA 262 edition 2 – section 6

ECMA 262 edition 3 – section 6

SPAN object (Object/HTML)

An object that encapsulates the contents of an inline `<SPAN>` tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySPAN* = *myDocument*.all.*anElementID*
	IE	*mySPAN* = *myDocument*.all.tags("SPAN")[*anIndex*]
	IE	*mySPAN* = *myDocument*.all[*aName*]
	-	*mySPAN* = *myDocument*.getElementById(*anElementID*)
	-	*mySPAN* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySPAN* = *myDocument*.getElementsByTagName("SPAN")[*anIndex*]
HTML syntax:	`<SPAN> ... </SPAN>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`dataFld, dataFormatAs, dataSrc`	
Event handlers:	`onBlur, onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

<SPAN> tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

Note that a positioned <SPAN> elements will appear as a member of the document.layers[] collection in Netscape 4.

The example shows how properties of <SPAN> blocks can be moved from one to another. In this example, the background color of each block is moved along to the next in a cyclic manner as the mouse is clicked:

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SPAN ID="AAA" STYLE="background-color:RED">ONE</SPAN>
<SPAN ID="BBB" STYLE="background-color:BLUE">TWO</SPAN>
<SPAN ID="CCC" STYLE="background-color:GREEN">THREE</SPAN>
<SPAN ID="DDD" STYLE="background-color:CYAN">FOUR</SPAN>
<SPAN ID="EEE" STYLE="background-color:YELLOW">FIVE</SPAN>
<SPAN ID="FFF" STYLE="background-color:GRAY">SIX</SPAN>
<FORM>
<INPUT TYPE="button" VALUE="CLICK ME" onClick="clickMe()">
</FORM>
<SCRIPT>
//IE only
function clickMe()
{
   mySpans = document.all.tags("SPAN");
   myStyle1 = mySpans[mySpans.length-1].style.cssText;

   for(myEnum=0; myEnum<mySpans.length; myEnum++)
   {
      myStyle2 = mySpans[myEnum].style.cssText;
      mySpans[myEnum].style.cssText = myStyle1;
      myStyle1 = myStyle2;
   }
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	Element object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

Inheritance chain:

`Element` object, `Node` object

Special number values (Definition)

Special properties of the `Global` and `Number` objects.

Special number values are provided so that scripts can test for exceptional values yielded as a result of arithmetic expressions.

You can check for infinity or non-number errors as a result of a divide by zero for example. Maximum and minimum values are also available to range check input data to make sure it can be used in arithmetic computations.

You cannot assign constant values of `Infinity` or `NaN` because you cannot type in a constant value to denote them. However because they exist as properties of the `Global` object, you can refer to them by name.

Warnings:

- Be careful that you don't accidentally assign new values to the `Infinity` and `NaN` properties of the global object. Some implementations do not properly protect them against being written to and your script may assign new values to them. This can lead to very unpredictable behavior.

See also:	`Infinity`, `NaN`, `Number.MAX_VALUE`, `Number.MIN_VALUE`, `Number.NaN`, `Number.NEGATIVE_INFINITY`, `Number.POSITIVE_INFINITY`

Cross-references:

Wrox *Instant JavaScript* – page 14

Special type (Definition)

Special data types are available to test variable content.

There are two special data types available to test references to objects or the contents of variables. If a variable is currently of the type `undefined`, then it has not had any value stored in it. If it is a property, perhaps it has been deleted from the object.

A variable reference would also yield the undefined value if it has not been declared. However, a reference to an undeclared variable causes a run-time error.

Properties will yield the value `null` if they are supposed to contain an object and have been purposely nulled out. They will be `undefined` unless they have been set to `null` by an assignment.

You can examine variables and object properties with the enquiry function to determine the type of the value stored there. The enquiry functions are:

- `isNaN()`
- `isFinite()`

This operator behaves like an enquiry function:

- `typeof`

Testing for `null` and `undefined` or comparing them one with another can be problematical and is certainly non-trivial. In older versions of the browsers, you can simulate missing values.

The `null` value can be simulated with this expression:

```
(void 0)
```

The `undefined` value can be simulated with this:

```
(void null)
```

Of course the simulations depend on the existence of some keywords that may or may not exist.

See also:	`isFinite(),isNaN(),null,typeof,undefined type`

Spiral() (Filter/transition)

Reveals the new image with a spiral effect.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `Spiral()`

SSJS (Definition)

An abbreviation for Server-Side JavaScript.

Refer to:

Server-side JavaScript

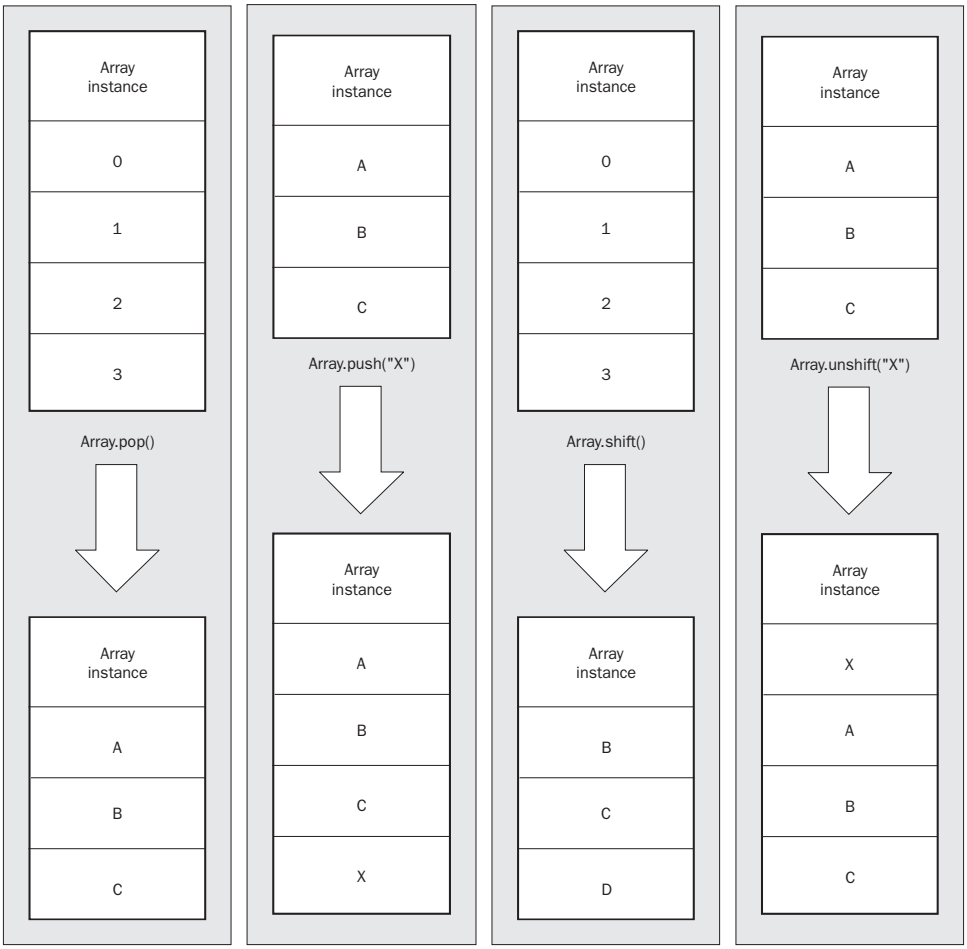
Stack manipulation (Useful tip)

In Netscape 4, you can build stack managers.

With the `Array` methods `push()`, `pop()`, `unshift()` and `shift()`, you can build various stacks and queues.

A First In Last Out stack can be constructed with `push()` and `pop()`. This works from the end of the array.

An alternative FILO stack can be constructed with `unshift()` and `shift()` but that will operate at the start of the array.



See also:	`Array.pop()`,`Array.push()`,`Array.shift()`, `Array.unshift()`,Queue manipulation

Standalone JavaScript (Definition)

JavaScript that is executed in an application not associated with web pages at all.

A stand-alone JavaScript implementation is when the interpreter is embedded into an application other than a web browser or web server. The application may utilize JavaScript as a mechanism for connecting its user interface to its internal functionality. This gives some benefits in being able to custom-tailor the way an application behaves and what is really delivered is a kit of components that are joined up with JavaScript glue.

Stand-alone interpreters may have the scripts embedded inside the application or they may read them in from external sources.

An example of a well known stand-alone interpreter is the Nombas ScriptEase range of JavaScript interpreters. The ScriptEase implementations have many additional objects to provide a very rich JavaScript programming environment indeed.

See also:	Nombas ScriptEase

Cross-references:

Wrox *Instant JavaScript* – page 68

Statement (Definition)

A functional section of a program.

Availability:	ECMAScript edition – 2

A statement is a discrete instruction in a script that causes something to happen.

The statements in JavaScript can be classified into several categories. Here are the basic set of classifications:

- Block – Some code enclosed in braces.
- Variable statement – A declaration of a local or global variable.
- Empty statement – A semi-colon on its own.
- Expression statement – An operator and its require operand(s).
- If statement – Conditional execution of a block of code with an optional alternative block of code.
- Iterative statement – A means of executing a block of code repetitively until a test condition is satisfied.
- Switch selector – A means of executing one of a variety of possible code blocks selecting the best according to an input value.
- Continue statement – A way of cancelling an iteration and commencing the next.

- Break statement – Means of breaking out of an iteration or a switch selector.
- Return statement – A way to unconditionally leave a function and return to its caller, optionally handing back a value.
- With statement – A means of adding an object to a scope chain.

Statements are executed in the order in which they appear in the script source text except when the flow of control is redirected by a conditional switching expression, function call, iterator or jump statement.

See also:	`break`, Compound statement, continue, Empty statement (`;`), Expression statement, `if( ... ) ...`, `if( ... ) ... else ...`, Iteration statement, JavaScript language, Jump statement, Method, Punctuator, `return`, Script fragment, Semi-colon (`;`), `var`, Variable statement, `with ...`

static (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

Static filters (Definition)

These filters are used to define the appearance of an HTML `Element` object.

They are all members of the visual filter family and are invoked through the stylesheet mechanisms or by the style object's filter property. Here is a list of the static filters:

- `Alpha()`
- `BasicImage()`
- `Blur()`
- `Chroma()`
- `Compositor()`
- `DropShadow()`
- `Emboss()`
- `Engrave()`

- `FlipH()`
- `FlipV()`
- `Glow()`
- `Grayscale()`
- `Invert()`
- `Light()`
- `Mask()`
- `MaskFilter()`
- `Matrix()`
- `MotionBlur()`
- `Pixelate()`
- `Shadow()`
- `Wave()`
- `XRay()`

Some of these may not be available with all versions of the MSIE browser. Refer to the individual topics for availability.

See also:	`style.filter`, Visual filters

Static method (Definition)

Defines static methods using function properties you add to a function object.

Static methods are also known as class methods. These are associated with a class rather than an instance of a class. The constructor function is analogous to the factory class for objects in truly object oriented systems.

Static methods have no real use for the `this` keyword, as it is meant to refer to the receiving instance.

These are called static methods because they are not associated with a local instance.

See also:	Function object properties

Static variable (Useful tip)

Defines static variables using properties you add to a function object.

Static variables are also known as class variables.

If we want to create some class variables, we need to add properties to the constructor function object.

If we have made our own constructor function, we can add our own class variables to it.

We can also add class variables to the built-in objects in some implementations.

These are called static variables because they are not associated with a local instance.

See also:	Function object properties

status (Property)

An alias for the `window.status` property.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myWindow*`.status`
	-	*myWindow*`.status = `*aString*
	-	`status`
	-	`status = `*aString*
Argument list:	*aString*	A string to display in the status bar

See also:	`Window.defaultStatus, Window.status`

Status code (Result value/NES)

Many of the NES supported methods return a status code that is consistently defined across all objects and methods.

The following methods will return a status code:

- `database.execute()`
- `database.beginTransaction()`
- `database.commitTransaction()`
- `database.rollbackTransaction()`
- `cursor.insertRow()`
- `cursor.updateRow()`
- `cursor.deleteRow()`

The status codes are summarized in the table:

Code	Meaning
00	No error
01	Out of memory
02	Object was never initialized
03	Type conversion error
04	Database not registered
05	Error reported by database engine
06	Message from database engine
07	Error from database vendor's library
08	Lost connection
09	End of fetch
10	Invalid use of object
11	Column does not exist
12	Bounds error – invalid positioning within object
13	Unsupported feature
14	Null reference parameter
15	Database object not found
16	Required information missing
17	Object cannot support multiple readers
18	Object cannot support deletes
19	Object cannot support inserts
20	Object cannot support updates (1)
21	Object cannot support updates (2)
22	Object cannot support indices
23	Object cannot be dropped
24	Incorrect connection supplied
25	Object cannot support privileges
26	Object cannot support cursors
27	Unable to open

Status codes 5 and 7 are significant. It depends on the database being used as to which is important.

Status code 5 is important for Oracle and ODBC.

Status code 7 is important for Informix and Sybase.

If these values are detected, then the major and minor error codes and messages can be inspected for further help in diagnosing the problems.

See also:	Connection.majorErrorCode(),Connection.majorErrorMessage(), Connection.minorErrorCode(),Connection.minorErrorMessage(), Cursor.deleteRow(),Cursor.insertRow(),Cursor.updateRow(), database.beginTransaction(),database.commitTransaction(), database.execute(),database.majorErrorCode(), database.majorErrorMessage(),database.minorErrorCode(), database.minorErrorMessage(),database.rollbackTransaction(), Error handling

Status line (Definition)

An area in the browser frame that status messages can be presented in.

When browsers open a new window, they will have a status line at the bottom (unless you choose to deactivate the status line).

This can have text messages presented to tell the user what is happening. One particularly popular usage is to present rollover text messages associated with links.

There are two property values on each window that control the content of this status line.

The `defaultStatus` property contains the text that is displayed when the mouse is not rolled over an active item.

The `status` property is set to a specific value by an `onMouseOver` event handler and resets when the mouse leaves.

Warnings:

- The correct behavior is for the `onMouseOver` event handler to override the default behavior and replace the text in the status bar. Then, when the mouse rolls off of the active item, the defaultStatus value should be restored automatically.
- This is not the case with all browsers. Macintosh and X-Windows versions of Netscape 3 (and possibly other browser versions) do not automatically restore the previous status line value. You will need to add a `onMouseOut` handler to explicitly reset the status line.

See also:	onMouseOut, onMouseOver, Window.defaultStatus, Window.status

statusbar (Property)

An alias for the `window.statusbar` property.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Bar` object	
JavaScript syntax:	-	*myWindow*.statusbar
	-	statusbar

See also:	`Bar` object, `Window.statusbar`

Property attributes:

`ReadOnly`.

.stm (File extension)

Server-side processed HTML file.

Refer to:

File extensions

stop() (Method)

An alias for the `window.stop()` method.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`myWindow.stop()`
	N	`stop()`

Refer to:

`Window.stop()`

Storage duration (Definition)

The time during which an entity is available for use.

Objects and other entities may be created and destroyed at will while a script is being executed.

Some are created automatically and some also get destroyed automatically. Some will be discarded when the script terminates either intentionally or accidentally due to an error of some kind.

Objects may only persist while a function is being executed. They may vanish when the function returns to its caller.

In a web browser, generally speaking, objects persist for the life of a page. They will be destroyed when the page is discarded or refreshed. Session storage can be accomplished effectively by maintaining a frame set where the outermost frame remains available throughout the session even though the pages it contains are replaced several times.

In a server-side environment, objects and entities will likely only persist during the request-response loop. Items may persist longer if the server-side implementation is able to archive them or if it is able to maintain session state information between one request and another.

In a TV set-top box environment, objects may persist for some time, perhaps for the duration of a broadcast program or for as long as the TV set-top box is tuned to a particular channel. Changing channels may purge out the object store. This particular kind of implementation is under constant and rapid development. One of the major areas of research is that of persistent and browsable cache systems where objects may repose and be recalled at will. In a system like that, objects may persist forever, or until the user chooses to dispose of them explicitly.

See also:	Identifier, Request-response loop, Scope chain, Script execution, Script termination

Stproc object (Object/NES)

An object that encapsulates a call to a stored procedure on a database from a Netscape Enterprise Server.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	`myStproc = database.storedProc(aProcName, aProcParm);`
	NES	`myStproc = myConnection.storedProc(aProcName, aProcParm)`
Argument list:	`aProcName`	The name of a stored procedure to call
	`aProcParm`	A parameter value to pass to the stored procedure
Object properties:	prototype	
Object methods:	`close(), outParamCount(), outParameters(), resultSet(), returnValue()`	

This object provides a container to manage the call to the stored procedure and somewhere that the results can be made available for further processing by your scripts.

You create `Stproc` objects by requesting them from the database or connection objects that are accessing the target database you are interested in.

Example code:

```
<SERVER>
// An example derived from Wrox Professional JavaScript
database.connect("ODBC", "myDatabase", "me", "myPassword", "");
myStproc = database.storedProc("myProcedure", 40);
</SERVER>
```

See also:	Connection.storedProc(), Netscape Enterprise Server

Property	JavaScript	JScript	NES	Notes
prototype	1.2 +	-	3.0 +	-

Method	JavaScript	JScript	NES	Notes
close()	1.2 +	-	3.0 +	-
outParamCount()	1.2 +	-	3.0 +	-
outParameters()	1.2 +	-	3.0 +	-
resultSet()	1.2 +	-	3.0 +	-
returnValue()	1.2 +	-	3.0 +	-

Stproc.close() (Method)

Closes a stored procedure object when it is no longer required.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
JavaScript syntax:	NES	*myStproc*.close()

Although closures generally get dealt with automatically for you when a request handler exits, it is good style to call the closure methods yourself when you no longer need the database connection.

See also:	ResultSet.close()

Stproc.outParamCount() (Method)

Retrieves a count of the number of parameter values the stored procedure has returned.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	Number primitive	
JavaScript syntax:	NES	*myStproc*.outParamCount()

Calling stored procedures is not like a normal database select. Because the results of a stored procedure are not strictly the results of a simple select but have been cached and processed by the procedure, the database will not generally return them as a record but as a collection of parameters. This method tells you how many there are so you can enumerate them in your script.

See also:	ResultSet.columns()

Stproc.outParameters() (Method)

Retrieves an output parameter from the stored procedure.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`User defined`	
JavaScript syntax:	NES	*myStproc*`.outParameters(`*anIndex*`)`
Argument list:	*anIndex*	A parameter number

Given that we can obtain a count of the number of parameters returned by a stored procedure by calling the `outParamCount()` method, we can then enumerate them all and access the values that have been returned.

Stproc.prototype (Property)

The prototype for the `Stproc` object that can be used to extend the interface for all `Stproc` objects.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`Stproc` object	
JavaScript syntax:	NES	`Stproc.prototype`
	NES	*myStproc*`.constructor.prototype`

Refer to:

prototype property

Stproc.resultSet() (Method)

Retrieves a result set object from the stored procedure.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`ResultSet` object	
JavaScript syntax:	NES	*myStproc*`.resultSet()`

When you call a stored procedure in a RDMS, you don't always get back a sequence of records in the same layout and structure as when you just do a simple SQL select style query.

An SQL query would return a series of records separated by newline characters. A stored procedure might return a mixed collection of records of different types.

A `ResultSet` object is created by asking the `Stproc` object for it when the stored procedure has been called and returned from the database.

The traversing mechanisms provided with a result set allow you to move forwards through the data but you cannot move backwards. You also can only read values from a result set as opposed to a cursor which allows you to update and write new values back.

See also:	`ResultSet` object

Stproc.returnValue() (Method)

Retrieves the return value of the stored procedure.

Availability:	JavaScript – 1.2 Netscape Enterprise Server version – 3.0	
Property/method value type:	`User defined`	
JavaScript syntax:	NES	*myStproc*`.returnValue()`

This is an indication of whether the stored procedure executed successfully or not. The values returned by this may depend on the kind of database adapter your middleware employed when connecting to the database.

Stretch() (Filter/transition)

A variation on a wipe effect except that the new image appears to stretch over the old one. The old one is squashed until it disappears.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `Stretch()`

Strictly equal to (===) (Operator/identity)

The two values must be exactly equal to one another in value and type.

Availability:	JavaScript – 1.3 JScript – 1.0 Internet Explorer – 3.02 Netscape – 4.06
Property/method value type:	`Boolean primitive`

Refer to:

Identically equal to (===)

STRIKE object (Object/HTML)

An object that represents the font style controlled by the `<STRIKE>` HTML tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySTRIKE* = *myDocument*.all.anElementID
	IE	*mySTRIKE* = *myDocument*.all.tags("STRIKE")[*anIndex*]
	IE	*mySTRIKE* = *myDocument*.all[*aName*]
	-	*mySTRIKE* = *myDocument*.getElementById(*anElementID*)
	-	*mySTRIKE* = *myDocument*.getElementsByName(aName)[anIndex]
	-	*mySTRIKE* = *myDocument*.getElementsByTagName("STRIKE")[*anIndex*]
HTML syntax:	`<STRIKE> ... </STRIKE>`	
Deprecated:	Yes	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

String (Type)

A native built-in type.

Availability:	ECMAScript edition – 2
Property/method value type:	`String primitive`

Entities of type `String` are collections of zero or more Unicode characters.

A string is arranged so that the characters in it can be accessed by their position. The leftmost character is considered to be at position 0 and the rightmost character is therefore at a position whose value is one less than the length of the string.

This is convenient when processing strings in a `for()` loop since you can check the enumerator against the length and as long as it is less than the length and is a positive value, it is indexing within the string.

Zero length strings are a special case.

Strings can only be accessed read-only. You cannot change the contents of a string, you can only replace it with another.

Warnings:

- You cannot reference strings with negative position values.

O'Reilly *JavaScript Definitive Guide* – page 38

O'Reilly *JavaScript Definitive Guide* – page 50

String (Primitive value)

A built-in primitive value.

Availability:	ECMAScript edition – 2
Property/method value type:	`String primitive`

A string value is a member of the type String and is a finite ordered sequence of zero or more Unicode characters. There is no way to represent a single character other than by means of a very short string.

A string is not an array of characters as it would be in the C language. It is also not mutable as the other object data types that are passed by reference are. Strings are immutable and therefore to change one, you must manufacture a new string and discard the old one. This can lead to memory leaks.

Strings can contain any Unicode character code point, however, many are not available on even the most international keyboard and must be escaped. You will need to check that the host environment can render the international symbols correctly if you use them.

Strings can be delimited by either single or double quotes. This can be very useful for the occasions when a fragment of JavaScript is contained within some HTML.

Refer to the String literal topic for a list of escape characters and more information on defining string values.

Warnings:

- Beware that the HTML escaping rules come into play when JavaScript is contained within HTML quote delimited name-value pairs in tags and you must be careful to escape any characters within scripts using the JavaScript escape mechanisms and not the HTML escape mechanisms. JavaScript inside `<SCRIPT>` tags may also be affected by the host environment's escaping mechanisms.

Wrox *Instant JavaScript* – page 14

String concatenate (+) (Operator/string)

Joins two string values together.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`aString1 + aString2`*
Argument list:	*`aString1`*	A string value
	`aString2`	Another string value

When the operands are a pair of strings, the plus sign will concatenate them together. This yields a single string combining both values joined end to end.

The string concatenation is not commutative. That is, the position of the two operands will affect the outcome if they are exchanged.

The addition/concatenation operator looks at the arguments and if either is a `String` already or preferentially converts to one, then a concatenation occurs. If neither argument prefers to be a `String` then a `Number` conversion happens and the values are added.

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

Warnings:

- Some conversion of type will occur if a mixture of data types is used in certain contexts.
- In string concatenations, when either of the operands is a string, the result will be a string concatenation. The same does not apply when relational expressions are involved when the subtraction operator can be used to coerce a string value into a numeric type.

Wrox *Instant JavaScript* – page 37

String literal (Primitive value)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition – 2
Property/method value type:	`String primitive`

A string literal is zero or more characters enclosed in matching single or double quotes. Each character may be represented by an escape sequence.

You can escape special characters with special escape sequences. You can also escape any character and specify it by its octal, hexadecimal or Unicode equivalent code point. Note that the octal values will be in the range 0 to 377 and the hexadecimal values will be in the range 0 to FF. The octal and hexadecimal escapes can only cover the first 256 character codes, some of which are control codes and should not be used anyway. The Unicode escape gives access to the full 65536 character codes in the Unicode set. Although you can specify octal or hexadecimal values, there is presently no standardized decimal-based escape mechanism. You'll just have to learn octal or hexadecimal, unfortunately.

Here are the valid common escape sequences:

Escape Sequence	Name	Symbol
`\"`	Double Quote	"
`\'`	Single Quote (Apostrophe)	'
`\\`	Backslash	\

Table continued on following page

Escape Sequence	Name	Symbol
\a	Audible alert (MSIE displays the letter a)	<BEL>
\b	Backspace (ignored silently in MSIE)	<BS>
\f	Form Feed (ignored silently in MSIE)	<FF>
\n	Line Feed (Newline – MSIE inserts a space)	<LF>
\r	Carriage Return (MSIE inserts a space)	<CR>
\t	Horizontal Tab (MSIE inserts a space)	<HT>
\v	Vertical tab (MSIE displays the letter v)	<VT>
\0nn	Octal escape	-
\042	Double Quote	"
\047	Single Quote (Apostrophe)	'
\134	Backslash	\
\xnn	Hexadecimal escape	-
\x22	Double Quote	"
\x27	Single Quote (Apostrophe)	'
\x5C	Backslash	\
\unnnn	Unicode escape	-
\u0022	Double Quote	"
\u0027	Single Quote (Apostrophe)	'
\u005C	Backslash	\
\uFFFE	A special Unicode sentinel character for flagging byte reversed text	-
\uFFFF	A special Unicode sentinel character	-

Here are some example string literals:

```
myString = "James Bond";

myString = 'Another String';

myString = 'A string with double " quotes';

myString = "He's got a single quote";
```

The characters in the quotes are converted to a String primitive value and will replace the expression in the context in which it has been used. This would normally be an assignment of a variable or perhaps part of a relational expression.

There are circumstances in HTML documents where JavaScript string delimiters may need to be single quotes, because the fragment of JavaScript is already enclosed in double quotes that are part of the HTML source code space.

For example:

```
<A HREF="javascript:passStringValue('ABCDEF');">ABCDEF</A>;
```

You can use double quotes without breaking the syntax rules of the HTML page containing the JavaScript.

You can exchange the pairs of quotes around between the contexts but it is good to stick one or the other. It tends to work out that double quotes are used in HTML which forces single quotes to be used in the JavaScript fragments that are placed into HTML tag attributes.

This is discussed with examples in the "Escaped JavaScript quotes in HTML" topic .

Warnings:

- If you use quotes in JavaScript that you plan to use inside HTML, then be sensible about the use of single and double quotes. Often you will find that double quotes will break, even though they are enclosed in single quotes when you include them in an HREF for an anchor. For example, this can break because the double quotes are seen by the HTML parser:

```
<A HREF="javascript:handleClick('bad " quotes');">
```

- Put an escape round the quotes. Sometimes a backslash is appropriate and sometimes an HTML character entity depending on who you are trying to hide the quotes from.
- Be careful if you use HTML escape sequences such as `&#39;` in JavaScript string literals. Some implementations will unescape that string in the JavaScript context and not the HTML context hoped for. That will restore the single quote inside the JavaScript string literal causing a run-time error. You should escape single quotes with a backslash.
- You cannot include a line terminator within a string literal. Instead use a newline (`\n`) escape sequence.
- Currency symbols are notoriously non-portable. Check that your target audience can display international currency symbols before using GB pounds or Euro symbols. Although these are defined in the standards, they are often missing from the installed character sets.

O'Reilly *JavaScript Definitive Guide* – page 38

String object (Object/core)

An object of the class "`String`".

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myString* = new String()
	-	*myString* = String
Object properties:	constructor, length, prototype	
Class methods:	fromCharCode()	
Object methods:	anchor(), big(), blink(), bold(), charAt(), charCodeAt(), concat(), fixed(), fontcolor(), fontsize(), fromCharCode(), indexOf(), italics(), lastIndexOf(), link(), localeCompare(), match(), replace(), search(), slice(), small(), split(), strike(), sub(), substr(), substring(), sup(), toLocaleLowerCase(), toLocaleUpperCase(), toLowerCase(), toSource(), toString(), toUpperCase(), valueOf()	

An instance of the class "`String`" is created by using the new operator on the `String()` constructor. The new object adopts the behavior of the built-in prototype object through the prototype-inheritance mechanisms.

All properties and methods of the prototype are available as if they were part of the instance.

A `String` object is a member of the type `Object`.

Cloning the built-in `String` object creates new `String` objects. This is done by calling the `String` constructor with the new operator being applied to an existing `String` object, thus:

```
myString = new String("a string of text");
```

A `String` object can be coerced to a string value and can be used anywhere where a string value would be expected.

Programmers familiar with object oriented techniques may prefer to use the `String` object while procedural language programmers may implement the same functionality with a string value instead.

This is an example of the flexibility of JavaScript in its ability to accommodate a variety of users from different backgrounds.

The prototype for the `String` prototype object is the `Object` prototype object.

In Netscape Navigator, you can traverse a string as if it were an array and access characters individually by their index position in the array. This doesn't work in MSIE.

Wrox *Instant JavaScript* – page – 33

String() constructor (Constructor)

A `String` object constructor.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
Property/method value type:	`String` object	
JavaScript syntax:	-	`new String()`
	-	`new String(`*`aValue`*`)`
Argument list:	*`aValue`*	Some value to be converted to a `String` object

When the `String()` constructor is used in a new expression it creates a new object based on the `String` prototype.

The value property of the new object is the same as the string that would have been returned when the constructor was invoked as a function call.

The result of this function is a String object version of the value passed in. If there is no passed-in argument an empty string `""` is returned.

Refer to the `String()` conversion function topic for a list of rules for converting other data types to strings.

Warnings:

- Note that unlike the `Object()` constructor which can be called without its parentheses, calling the `String()` constructor without them yields an uninitialized object.

See also:	Constructor function, `constructor` property, `Global` object, `new`, `Object()`

String() (Function)

A `String` object constructor called as a function.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 1.0 Internet Explorer – 3.02 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`String()`
	-	`String(aValue)`
Argument list:	*aValue*	Some value to be converted to a string

When `String()` is called as a function rather than a constructor, it performs a type conversion.

The internal `ToString` conversion facilities are used for type conversion with the additional handling of a missing argument provided by the constructor itself.

Value	Result
No argument	" An empty string ".
undefined	"`undefined`".
null	"`null`".
Boolean	If the argument is true, then the result is "`true`" otherwise the result is "`false`".
Number	Special cases are provided for `NaN` and Infinity where "`NaN`" and "`Infinity`" will be returned. Otherwise the string is a textual representation of the value.
String	No conversion, the input value is returned unchanged.
Object	An internal conversion to a primitive takes place followed by a conversion from that primitive to a string. Some objects will return a string value that is immediately useful.

The result of calling this function is a string version of the value passed in. If there is no value passed in argument an empty string is returned.

Warnings:

- Converting numbers to strings can yield some strange effects due to rounding errors. Taking a numeric value and simply converting it is fairly reliable. However, the result of a numeric expression, being cast to a string directly rather than to a number variable and thence to a string, seems to expose some weaknesses in the arithmetic in some implementations.

See also:	Cast operator, Constructor function, constructor property, Implicit `conversion`, `Number()`

Wrox *Instant JavaScript* – page 36

String.anchor() (Method)

Encapsulates the string within an `<A NAME="...">` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myString*.anchor()
	-	*myString*.anchor(*aName*)
Argument list:	*aName*	The value of the NAME attribute in the result string

Passing in the string "An Anchor" with the parameter "Anchor1" will result in the following string:

```
<A NAME="Anchor1">An Anchor</A>
```

This is useful for creating named anchors within the document.

See also:	Anchor object, Anchor.name, String.link(), Url object

String.big() (Method)

Encapsulates the string within an <BIG> tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	String primitive

JavaScript syntax:	-	*myString*.big()

Passing in the string "Big Text" will result in the following string:

```
<BIG>Big Text</BIG>
```

This is now officially deprecated in favor of the more sophisticated controls available with style sheets.

See also:	style.fontSize

String.blink() (Method)

Encapsulates the string within an `<BLINK>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Deprecated:	Yes	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myString.blink()`

Passing in the string "`Blinking text`" will result in the following string:

```
<BLINK>Blinking text</BLINK>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.textDecoration`, `style.textDecorationBlink`

String.bold() (Method)

Encapsulates the string within an `<B>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Deprecated	Yes	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myString.bold()`

Passing in the string "`Bold text`" will result in the following string:

```
<B>Bold text</B>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.fontWeight`

String.charAt() (Method)

A character within the string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*.charAt(*aPosition*)
Argument list:	*aPosition*	A valid character position within the string

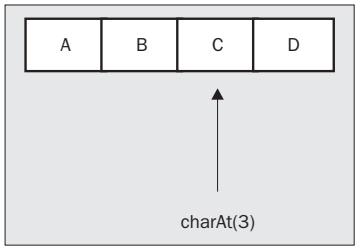
The character at the position in the string indicated by the argument value is returned by this method.

This may involve converting the receiving object to a string first. This means it can be used generically on many kinds of object.

If there is no character at that position, an empty string will be returned.

The result will be a string value and not a `String` object.

Note that there is no complementary `setCharAt()` method because strings are immutable and cannot be changed.



Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<TABLE BORDER=1>
<TR>
<TH>Index</TH>
<TH>Char</TH>
</TR>
<SCRIPT>
myString = "ABCDEFGHIJKLMNOPQRSTUVWXYZ";
for(myEnum=0; myEnum<myString.length; myEnum++)
{
document.write("<TR>");
document.write("<TD>");
document.write(myEnum);
```

```
    document.write("</TD>");
    document.write(myString.charAt(myEnum));
    document.write("</TD>");
    document.write("</TR>");
}
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

See also:	Character handling, Character testing, `File.stringToByte()`, `String.prototype`, `Window.atob()`

Cross-references:

ECMA 262 edition 2 – section – 15.5.4.4

ECMA 262 edition 3 – section – 15.5.4.4

String.charCodeAt() (Method)

The Unicode code point value of a character within the string.

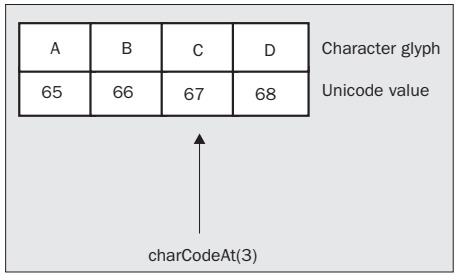
Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 5.5 Internet Explorer – 5.5 Netscape – 4.0 Netscape Enterprise Server version – 3.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myString*`.charCodeAt(`*aPosition*`)`
Argument list:	*aPosition*	A valid character position within the string

This method returns the Unicode code point of the character at the indicated position.

Note that the string index positions start at `0` and not `1`.

If there is no character at the indicated position the `NaN` value will be returned.

This method may involve the receiver being converted to a string and so it can be applied generically to many kinds of objects.



Warnings:

- If the result of calling this method creates a `null` string, then you may need to put in a special case handler. At the point where the `null` character appears, any string value will be truncated.
- For example this:

```
"AAA" + String.fromCharCode(0) + "BBB";
```

will only display the "AAA" portion of the string.

- You can create other undesirable character values as well such as the delete character at the code point 127.
- Characters at the code points 128 to 159 may display as question marks because they cannot be resolved to meaningful characters.
- Character codes 208, 222, 240 and 254 render as a caret delimited character entity description word rather than as a single character glyph. This suggests that you should not rely on the output string having the same number of characters as the input numeric array. It also suggests there may be some problems converting number arrays to binary BLOb objects using this technique.
- Note that the character code mapping does not necessarily correspond to the underlying code map of the platform the browser is running in.

Example code:

```
<HTML><HEAD></HEAD><BODY><TABLE
BORDER=1><TR><TH>Index</TH><TH>Char</TH><TH>Code</TH></TR><SCRIPT>myString =
"ABCDEFGHIJKLMNOPQRSTUVWXYZ";for(myEnum=0; myEnum<myString.length;
myEnum++){document.write("<TR>");document.write("<TD>");document.write(myEnum);doc
ument.write("</TD>");document.write("<TD>");document.write(myString.charAt(myEnum)
);document.write("</TD>");document.write("<TD>");document.write(myString.charCodeA
t(myEnum));document.write("</TD>");document.write("</TR>");}</SCRIPT></TABLE></BOD
Y></HTML>
```

ECMA 262 edition 3 – section – 15.5.4.5

String.Class (Property/internal)

Internal property that returns an object class.

Availability:	ECMAScript edition – 2

This is an internal property that describes the class that a `String` object instance is a member of. The reserved words suggest that in the future this property may be externalized.

See also:	Class, `String` object

Property attributes:

`DontEnum`, `Internal`.

Cross-references:

ECMA 262 edition 2 – section – 8.6.2

ECMA 262 edition 2 – section – 15.5.2.1

ECMA 262 edition 3 – section – 8.6.2

String.concat() (Method)

A method for concatenating as opposed to the concatenate operator.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*`.concat(`*aString*`)`
Argument list:	*aString*	A string to be concatenated to the receiving string

The concatenation operator (+) is the more common method of concatenating strings together.

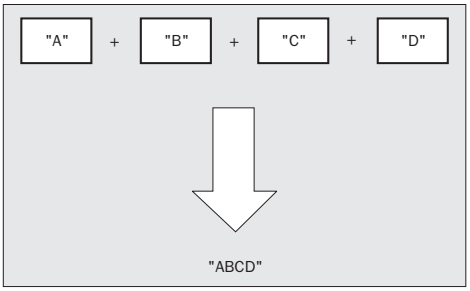
This method call:

```
myString1.concat(myString2)
```

is functionally equivalent to:

```
myString1 + myString2
```

The second form is more intuitive in its meaning, and hence is recommended in favor of the `concat()` method.



Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString1 = "ABCDEFGHIJKLM";
myString2 = "NOPQRSTUVWXYZ";
document.write(myString1);
document.write("<BR>");
document.write(myString2);
document.write("<BR>");
document.write(myString1.concat(myString2));
document.write("<BR>");
</SCRIPT>
</BODY>
</HTML>;
```

See also:	Array.`concat()`

Cross-references:

ECMA 262 edition 3 – section – 15.5.4.6

String.constructor (Property)

A reference to a constructor object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
Property/method value type:	`String` object	
JavaScript syntax:	-	*myString*`.constructor`

The initial value of the `String.prototype.constructor` is the built-in `String` constructor.

You can use this as one way of creating strings although it is more popular to use the new `String()` technique.

This property is useful if you have an object that you want to clone but you don't know what sort of object it is. Simply access the constructor belonging to the object you have a reference to.

Netscape Navigator provides constructors for many objects, virtually all of them in fact, even when it is highly inappropriate to do so. MSIE is far more selective and there are some occasions when you might wish for a constructor that MSIE does not make available.

See also:	`String.fromCharCode(),String.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.5.4.1

ECMA 262 edition 3 – section – 15.5.2

String.fixed() (Method)

Encapsulates the string within an `<TT>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`
JavaScript syntax:	- *myString*`.fixed()`

Passing in the string "`ABCD`" will result in the following string:

```
<TT>ABCD</TT>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.fontFamily`

String.fontcolor() (Method)

Encapsulate the string within an `<FONT COLOR="...">` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myString*.fontcolor()
	-	*myString*.fontcolor(*aColor*)
Argument list:	*aColor*	A color value to embed as an HTML tag attribute

Passing in the string "Colored text" with the parameter "RED" will result in the following string:

```
<FONT COLOR="RED">ABCD</FONT>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	FONT.color,style.color

String.fontsize() (Method)

Encapsulates the string within an <FONT SIZE="...">> tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Deprecated:	Yes	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myString*.fontsize()
	-	*myString*.fontsize(*aSize*)
Argument list:	*aSize*	A value to embed as an HTML tag attribute

Passing in the string "Small text" with the parameter "SMALL" will result in the following string:

```
<FONT SIZE="SMALL">ABCD</FONT>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	FONT.size,style.fontSize

String.fromCharCode() (Method/static)

A class-based factory method for converting numeric character codes to String objects.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server version – 3.0 Opera – 3.0

Property/method value type:	`String primitive`	
JavaScript syntax:	-	`String.fromCharCode(`*`aChar0`*`, `*`aChar1`*`, `*`aChar2`*`, ...)`
Argument list:	*`aCharN`*	a character code value

Constructs a new string from a sequence of Unicode character code point values each passed as a separate argument.

This is a static method. So called because it belongs to the `String()` constructor and not any of the string objects. This means it is analogous to a class method in other object oriented environments.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
document.write(String.fromCharCode(72, 69, 76, 76, 79));
</SCRIPT>
</BODY>
</HTML>
```

See also:	Arithmetic type, Cast operator, Character handling, Character testing, Character-case mapping, `File.byteToString()`, Java to JavaScript values, Keyboard events, `onKeyDown`, `String.charCodeAt()`, `String.constructor`, `ToUint16`, `Window.atob()`, `Window.btoa()`

Cross-references:

ECMA 262 edition 2 – section 15.5.3.2

ECMA 262 edition 3 – section 15.5.3.2

String.indexOf() (Method)

The location of a sub-string within a string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myString`*`.indexOf(`*`aSearchString`*`)`
	-	*`myString`*`.indexOf(`*`aSearchString`*`, `*`aPosition`*`)`

Argument list:	*aPosition*	An optional valid character position within the string to indicate the search start
	aSearchString	A string to search for within the `String` object

Returns a value indicating the location of the search string within the receiving `String` object.

If the search string is not found, the value `-1` is returned.

You can indicate a starting position within the target string and if that argument is missing, the whole string will be searched. The same happens if you put the value `0` into the second parameter.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString = "ABCDEFGHIJKLMNOPQRSTUVWXYZ";
myIndex = myString.indexOf("MN");
document.write(myString.substr(myIndex));
</SCRIPT>
</BODY>
</HTML>
```

See also:	`String.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.5.4.6

ECMA 262 edition 3 – section – 15.5.4.7

String.italics() (Method)

Encapsulates the string within an `<I>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Deprecated:	Yes	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*`.italics()`

Passing in the string "`Italicized text`" will result in the following string:

```
<I>ABCD</I>
```

This is now deprecated in favor of the more sophisticated controls available with stylesheets.

See also:	`style.fontStyle`

String.lastIndexOf() (Method)

The location of the rightmost sub-string within a string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	- *myString*`.lastIndexOf(`*aSearchString*`)`	
	- *myString*`.lastIndexOf(`*aSearchString*`,` *aPosition*`)`	
Argument list:	*aPosition*	An optional valid character position within the string to indicate the search start. Missing value or 0 indicates the entire string is to be searched
	aSearchString	A string to search for within the string object

Locates the rightmost occurrence of the search string within the receiving `String` object.

If the search string cannot be found, then the value `-1` is returned.

If the starting position is not indicated, the entire string will be searched.

The result of this method is the index of the rightmost occurrence of the sub-string or `-1` if it is not found.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString = "AAABBBCCCAAABBBCCC";
myIndex = myString.lastIndexOf("AAA");
document.write(myString.substr(myIndex));
</SCRIPT>
</BODY>
</HTML>
```

See also:	`String.prototype`

Cross-references:

ECMA 262 edition 2 – section – 15.5.4.7

ECMA 262 edition 3 – section – 15.5.4.8

String.length (Property)

The length of a `String` object's value.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myString*`.length`

The length of the `String` object's value measured in characters.

All `String` objects inherit properties and methods from the `String` prototype object. They will all return a value as a result of requesting the `length` property.

The length value of a `String` object is immutable.

This suggests that changing the value of a `String` object actually creates a new `String` object. This explains why continual string concatenations and modifications can sometimes cause a JavaScript execution to leak large amounts of memory as it runs.

See also:	`String` object, `String`.prototype

Property attributes:

`ReadOnly`, `DontDelete`, `DontEnum`.

Cross-references:

ECMA 262 edition 2 – section 15.5.5

ECMA 262 edition 3 – section 15.5.5.1

String.link() (Method)

Encapsulates the string within an `<A HREF="...">` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0

Property/method value type:	String primitive	
JavaScript syntax:	-	myString.link()
	-	*myString*.link(*aURL*)
Argument list:	*aURL*	The URL to be embedded into an HREF HTML tag attribute

Passing in the string "A link" with the parameter "Some site" will result in the following string:

```
<A HREF="AAA">ABCD</A>
```

This is useful for creating hyperlinks within the document.

See also:	LINK object, String.anchor(),Url object

String.localeCompare() (Method)

A locale sensitive string comparison.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	-	*myString*.localeCompare(*aString*)
Argument list:	*aString*	A string to compare the value of this object against

The string passed as an argument is compared with the primitive value of the receiving String object. Using simple character comparison techniques they may not match and would fail an A == B test. The locale sensitive comparison takes special international characters and locale specific text issues into account and properly matches the strings.

Cross-references:

ECMA 262 edition 3 – section – 15.5.4.9

String.match() (Method)

Searches a string using a regular expression and returns the matches in an array.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0

Property/method value type:	`Array` object	
JavaScript syntax:	-	*myObject*.match(*aPattern*)
Argument list:	*aPattern*	A regular expression pattern

This is one of the additions to the `String` object to support regular expressions.

The matches are returned in an array with each match in a separate element. You can use this to strip numeric values out of a string containing words and numbers by looking for a pattern such as:

```
/\d+/g
```

This would yield all the numeric values from a string.

The `g` attribute affects whether a single item matches or whether all of them match.

When the `g` attribute is not used, the array object has an additional property named `index`, which contains the character location where the match occurred. It also has an additional property called `input`, which contains the original string that was searched for a match.

Warnings:

- This resets the `lastIndex` property of a `RegExp` object to 0.

Example code:

```
myString = "JavaScript is good";
myLocation = myString.search(/GOOD/i);
document.write(myLocation);
```

See also:	`Array.index`, `Array.input`, `RegExp pattern`, `RegExp.exec()`, `RegExp.lastIndex`, `Regular expression`, `String.replace()`, `String.search()`, `String.split()`

Cross-references:

ECMA 262 edition 3 – section 15.5.4.10

String.prototype (Property)

The prototype for the `String` object that can be used to extend the interface for all `String` objects.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server version – 3.0 Opera – 3.0
Property/method value type:	`String` object

JavaScript syntax:	-	`String.prototype`
	-	*myString*`.constructor.prototype`

The `prototype` property refers to the built-in `String` prototype object.

The example demonstrates how to provide extensions to all instances of this class by adding a function to the prototype object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define a function that extends the capabilities of String objects
function reverse()
{
   myArray = new Array(this.length);

   for(myEnum=0; myEnum<this.length; myEnum++)
   {
      myArray[myEnum] = this.substr(myEnum,1)
   }

   myArray.reverse();

   return myArray.join("");
}
// Register the new function
String.prototype.reverse = reverse;
// Create a string object and test the String.reverse() method
myString = new String("ABCDEFGH");
document.write(myString.reverse())
document.write("<BR>")
</SCRIPT>
</BODY>
</HTML>
```

See also:	`prototype` property, `String` object, `String.charAt()`, `String.charCodeAt()`, `String.constructor`, `String.indexOf()`, `String.lastIndexOf()`, `String.length`, `String.split()`, `String.substring()`, `String.toLocaleLowerCase()`, `String.toLocaleUpperCase()`, `String.toLowerCase()`, `String.toString()`, `String.toUpperCase()`, `String.valueOf()`

Cross-references:

ECMA 262 edition 2 – section 15.2.3.1

ECMA 262 edition 2 – section 15.5.3.1

ECMA 262 edition 2 – section 15.5.4

ECMA 262 edition 3 – section 15.5.3.1

String.replace() (Method)

Searches a string using a regular expression and replace the matches.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myObject*.replace(*aPattern*, *aString*)
Argument list:	*aPattern*	A regular expression pattern
	aString	A replacement string

This is one of the additions to the `String` object to support regular expressions.

The search pattern locates matches, which are then replaced by the string value in the second argument.

The value is modified in place.

The replacement text can make use of the numbered sub-expression references and can use them in the replaced string.

Warnings:

- This resets the `lastIndex` property of a `RegExp` object to `0`.

Example code:

```
// Simple replacement
myString = "javascript, 'JAVASCRIPT', JavaScript";
myString.replace(/javascript/ig, "JavaScript");
document.write(myString);
myString.replace(/^.*\'([^\']*)\'.*$/, "---''$1''---")
```

See also:	`RegExp` pattern, `RegExp.exec()`, `RegExp.lastIndex`, Regular expression, `String.match()`, `String.search()`, `String.split()`

Cross-references:

ECMA 262 edition 3 – section – 15.5.4.11

String.search() (Method)

Searches a string using a regular expression.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myObject*.search(* *aPattern*)
Argument list:	*aPattern*	A regular expression pattern

This is one of the additions to the `String` object to support regular expressions.

The character location where the match occurred is returned. If there is no match then the value `-1` is returned instead.

If you use the global attribute ('`g`'), then it will be ignored.

Warnings:

- This resets the `lastIndex` property of a `RegExp` object to `0`.
- Don't mix this `search()` method up with the search property that belongs to the `Location` object as they are totally different things. The temptation might be to refer to the position that the string search yielded as a location. This could be very confusing for someone working on your scripts later on.

Example code:

```
myString = "JavaScript is good";
myResult = myString.search(/GOOD/i);
document.write(myResult);
```

See also:	`RegExp` pattern, `RegExp.exec()`, `RegExp.lastIndex`, Regular expression, `String.match()`, `String.replace()`, `String.split()`

Cross-references:

ECMA 262 edition 3 – section 15.5.4.12

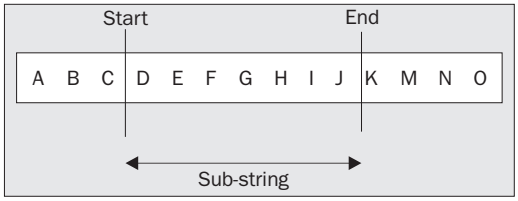
String.slice() (Method)

Returns a sub-string sliced out of the original.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*`.slice(`*startPos*`)`
	-	*myString*`.slice(`*startPos*`,` *endPos*`)`
Argument list:	*endPos*	The ending character position
	startPos	The starting character position

The sub-string is identified using the parameters passed as arguments in the method call.

The second argument is optional. If it is missing then it is assumed to mean the end of the string.



Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString = "AAABBBCCCAAABBBCCC";
myIndex = myString.lastIndexOf("AAA");
document.write(myString.slice(myIndex, myIndex+4));
</SCRIPT>
</BODY>
</HTML>
```

ECMA 262 edition 3 – section – 15.5.4.13

String.small() (Method)

Encapsulates the string within an `<SMALL>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`
JavaScript syntax:	- *myString*.small()

Passing in the string "Small text" will result in the following string:

```
<SMALL>Small text</SMALL>
```

This is now somewhat deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.fontSize`

String.split() (Method)

Splits a string and stores the components in an array.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`Array` object	
JavaScript syntax:	- *myString*.split(*aPattern*)	
	- *myString*.split(*aSeparator*)	
	- *myString*.split(*aSeparator*, *aCount*)	
Argument list:	*aPattern*	A regular expression to define the splitting sequence
	aSeparator	A separator string to use for slicing the string
	aCount	An iterator count to limit the number of splits

This method returns an array that contains the separated elements.

The string is split using the separator string and each separate item is stored in an array element. The items in the array are ordered in the same sequence they were presented in the original string.

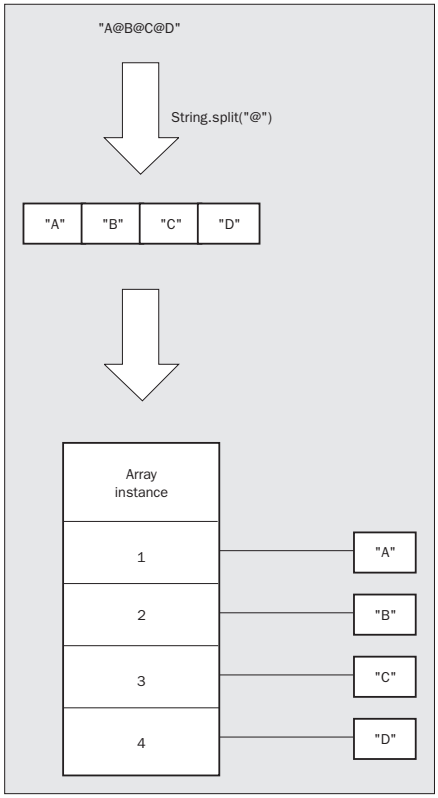
This method is the complement of the `join()` method that is applied to arrays.

The separator string is used to sub-divide the target string and is removed from the string component entities that result. The original string can be reconstructed by using the same separator in an `Array.join()` operation.

If the separator string is omitted, then the string is simply stored in the first element of a new array without being split. This is not the same as specifying an empty string. That will cause the split to happen but because you have specified an empty string, and there is an empty string between each character, the string will turned into an array of individual characters. This is amazingly useful sometimes.

In JavaScript version 1.2, this method is extended to allow the use of a regular expression as its argument. The match looks for the splitting delimiter. Using a constant character string inside the regular expression is functionally identical to using a string as the splitting value. Where this becomes powerful is where a character class or matching expression is used.

The example shows how a string of letters separated by a variety of numeric digits can be split apart using a regular expression. This would be very difficult to do any other way and would require many more lines of code.



Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myRegExp = new RegExp("[0-9]", "g");
myString = "A0B1C2D3E4F5G";
myArray = myString.split(myRegExp);
for(myEnum=0; myEnum < myArray.length; myEnum++)
{
document.write(myArray[myEnum]);
document.write("<BR>");
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Array` object, `Array.join()`, `RegExp` pattern, `RegExp.exec()`, Regular expression, String concatenate (+), `String.match()`, `String.prototype`, `String.replace()`, `String.search()`, `String.slice()`, `String.substr()`, `String.substring()`

ECMA 262 edition 3 – section – 15.5.4.14

String.strike() (Method)

Encapsulates the string within an `<STRIKE>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`
JavaScript syntax:	- *myString*`.strike()`

Passing in the string "Struck out" will result in the following string:

```
<STRIKE>Struck out</STRIKE>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.textDecoration`, `style.textDecorationLineThrough`

String.sub() (Method)

Encapsulates the string within an `<SUB>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`
JavaScript syntax:	- `myString.sub()`

Passing in the string "Subscript text" will result in the following string:

```
<SUB>Subscript text</SUB>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.fontSize`, `style.fontStyle`

String.substr() (Method)

Returns a sub-string extracted from the original.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server version – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	- `myString.substr(aStartPosition)`	
	- `myString.substr(aStartPosition, aLength)`	
Argument list:	*aStartPosition*	The index of the first character in the substring
	aLength	The length of the substring

This is a variation of the `String.substring()` method. The difference is that the substring length is passed as the second argument rather than the substring ending character index.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myString = "ABCDEFGHIJKLMNOPQRSTUVWXYZ";
myIndex = myString.indexOf("MN");
document.write(myString.substr(myIndex, 5));
</SCRIPT>
</BODY>
</HTML>
```

See also:	`String.slice(),String.split(),String.substring()`

Cross-references:

ECMA 262 edition 3 – section – B.2.3

String.substring() (Method)

Extracts a portion of a string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*`.substring(`*aStartPosition*`,` *anEndPosition*`)`
Argument list:	*anEndPosition*	A location within the string to end the sub-string extraction. If this is omitted then the end of the string is assumed to be the end position.
	aStartPosition	A location within the string to begin the sub-string extraction.

If only one argument is provided, this method returns a sub-string starting at the indicated character position and proceeding to the and of the string. Where two arguments are provided the start and end points of the string are used to slice out a portion and return just that part.

When just one argument is provided, the second is supplied internally and is taken to be end of the string.

Where an argument is actually `NaN` rather than a meaningful value, then `Zero` is used instead.

If any argument is greater than the length of the string, then the length of the string is used instead.

Where the start point is larger than the end point, the two values are swapped over.

This method is intentionally generic and can be applied to non-string objects. Where necessary, the receiving object may be converted to a string so that a sub-string can be extracted.

The result returned by this method is the sequence of characters between the start and end positions of the source string. The value returned is a string primitive.

See also:	`String.prototype`, `String.slice()`, `String.split()`, `String.substr()`

Cross-references:

ECMA 262 edition 2 – section – 15.5.4.9

ECMA 262 edition 2 – section – 15.5.4.10

ECMA 262 edition 3 – section – 15.5.4.15

String.sup() (Method)

Encapsulates the string within an `<SUP>` tag context.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Deprecated:	Yes
Property/method value type:	`String primitive`
JavaScript syntax:	- *`myString`*`.sup()`

Passing in the string "`ABCD`" will result in the following string:

```
<SUP>ABCD</SUP>
```

This is now deprecated in favor of the more sophisticated controls available with style sheets.

See also:	`style.fontSize`, `style.fontStyle`

String.toLocaleLowerCase() (Method)

Converts a string to all lower case using a locale sensitive character mapping.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myString`*`.toLocaleLowerCase()`

The result of this method will be a string primitive containing the value of the object with all characters converted to lower case.

The original string is converted from arbitrary case to lower case on a character by character basis, taking account of the locale when testing characters.

The characters in the output string will be the lower case equivalents of the characters in the input string according to the rules defined by the Unicode 2.0 standard, and the locale specific rules regarding special (accented) characters.

See also:	Bit, Character handling, Character-case mapping, `String.prototype`, `String.toLocaleUpperCase()`, `String.toLowerCase()`, `String.toUpperCase()`

Cross-references:

ECMA 262 edition 3 – section 15.5.4.17

String.toLocaleUpperCase() (Method)

Converts a string to all upper case.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myString`*`.toLocaleUpperCase()`

The result of this method is a string primitive containing the value of the object with all characters converted to upper case.

The original string is converted from arbitrary case to upper case on a character by character basis, taking account of the locale when testing characters.

The characters in the output string will be the upper case equivalents of the characters in the input string according to the rules defined by the Unicode 2.0 standard, and the locale specific rules regarding special (accented) characters.

See also:	Bit, Character handling, Character-case mapping, `String.prototype`, `String.toLocaleLowerCase()`, `String.toLowerCase()`, `String.toUpperCase()`

Cross-references:

ECMA 262 edition 3 – section 15.5.4.19

String.toLowerCase() (Method)

Converts a string to all lower case.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myString`*`.toLowerCase()`

This method returns a string primitive containing the value of the object with all characters converted to lower case.

The original string is converted from arbitrary case to lower case on a character by character basis.

The characters in the output string will be the lower case equivalents of the characters in the input string according to the rules defined by the Unicode 2.0 standard.

The Canonical Unicode 2.0 mapping will be used and therefore no special international character handling semantics take place. However non-ECMA compliant implementations may provide localization support not specified by ECMA 262.

This method is intentionally generic and may be applied to a variety of object types other than strings.

The effect of this method may depend on the locale settings in a fully localizable implementation.

See also:	Bit, Character handling, Character-case mapping, `String.prototype`, `String.toLocaleLowerCase()`, `String.toLocaleUpperCase()`, `String.toUpperCase()`

Cross-references:

ECMA 262 edition 2 – section 15.5.4.11

ECMA 262 edition 3 – section 15.5.4.16

String.toSource() (Method)

Outputs a string formatted as a string literal contained in a string.

Availability:	ECMAScript edition – 3 JavaScript – 1.3 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myBoolean`*`.toString()`

This is an alternative way to deliver a string primitive version of a `String` object's value. In this case, it is formatted as a string literal and can then be used in an `eval()` function to assign another string.

If you run the example below, it should yield this as a result:

```
(new String("ABCDEF"))
```

The result of calling this method is a string version of the `String` object formatted as a string literal.

Example code:

```
// Create a number and then examine its source
myString = new String("ABCDEF");
document.write(myString.toSource());
```

String.toString() (Method)

Returns a string primitive version of an object.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 2.0 Internet Explorer – 4 Netscape – 4.06	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myString`*`.toString()`

Returns the string value as a primitive rather than an object.

For a string object, the `toString()` method returns the same thing as the `valueOf()` method.

See also:	`String.prototype`, `String.valueOf()`, `toString()`

Cross-references:

ECMA 262 edition 2 – section 15.5.4.2

ECMA 262 edition 3 – section 15.5.4.2

String.toUpperCase() (Method)

Converts a string to all upper case.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myString*`.toUpperCase()`

The result of this method is a string primitive containing the value of the object with all characters converted to upper case.

The original string is converted from arbitrary case to upper case on a character by character basis.

The characters in the output string will be the upper case equivalents of the characters in the input string according to the rules defined by the Unicode 2.0 standard.

The Canonical Unicode 2.0 mapping will be used and therefore no special international character handling semantics take place. However non-ECMA compliant implementations may provided localization support not specified by ECMA 262.

This method is intentionally generic and may be applied to a variety of object types other than strings.

The effect of this method may depend on the locale settings in a fully localizable implementation.

Cross-references:

ECMA 262 edition 2 – section 15.5.4.12

ECMA 262 edition 3 – section 15.5.4.18

String.valueOf() (Method)

Returns the primitive value of the object.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myString*`.valueOf()`

The numeric equivalent of the string value is returned.

In the case of a `String` object, the `valueOf()` method returns the same thing as the `toString()` method.

This is proven by taking a string object and then using the == or === operators to compare the two values *myString*`.toString()` and *myString*`.valueOf()`.

See also:	Cast operator, `String.prototype`, `String.toString()`, `valueOf()`

Cross-references:

ECMA 262 edition 2 – section 15.5.4.3

ECMA 262 edition 3 – section 15.5.4.3

String operator (Definition)

Operators that act on string values.

There is only one string operator in the sense of a token that you can build a string expression out of. That is the concatenation operator. This may also be used to cast numeric values to string values by concatenating them to an empty string.

See also:	Additive operator, String concatenate (+)

Strips() (Filter/transition)

Reveals new image by sliding diagonal strips across the image.

Availability:	JScript – 5.5 Internet Explorer – 5.5

Refer to:

Filter – `Strips()`

STRONG object (Object/HTML)

An object representing the HTML content delimited by the `<STRONG>` tags.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySTRONG* = *myDocument*.all.*anElementID*
	IE	*mySTRONG* = *myDocument*.all.tags("STRONG")[*anIndex*]
	IE	*mySTRONG* = *myDocument*.all[*aName*]
	-	*mySTRONG* = *myDocument*.getElementById(*anElementID*)
	-	*mySTRONG* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySTRONG* = *myDocument*.getElementsByTagName("STRONG")[*anIndex*]
HTML syntax:	`<STRONG> ... </STRONG>`	
Argument list:	*anElementID*	The `ID` value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

`<STRONG>` tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

See also:	`Element` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

Inheritance chain:

`Element` object, `Node` object

STYLE object (1) (Object/HTML)

An object that encapsulates the `<STYLE>` tag in the document source as opposed to the internally created `style` objects manufactured from CSS style sheet contents.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySTYLE* = *myDocument*.all.*anElementID*
	IE	*mySTYLE* = *myDocument*.all.tags("STYLE")[*anIndex*]
	IE	*mySTYLE* = *myDocument*.all[*aName*]
	-	*mySTYLE* = *myDocument*.getElementById(*anElementID*)
	-	*mySTYLE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySTYLE* = *myDocument*.getElementsByTagName("STYLE")[*anIndex*]
HTML syntax:	`<STYLE> ... </STYLE>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`disabled, media, readyState, type`	
Event handlers:	`onClick, onDblClick, onError, onHelp, onKeyDown, onKeyPress, onKeyUp, onLoad, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onReadyStateChange`	

The `<STYLE>` tag conveys no apparent visible effect on the document. It is considered to be an invisible tag.

Warnings:

- Be careful not to confuse this DOM object with the internal CSS style object that MSIE supports. The `STYLE` object is instantiated by the `<STYLE>` tag and is defined in the DOM standard. The style object is based on the CSS attributes.

Inheritance chain:

`Element` object, `Node` object

STYLE.disabled (Property)

A switch to enable or disable a style object defined by the <STYLE> tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Boolean primitive	
JavaScript syntax:	-	*mySTYLE*.disabled

If this value is set to Boolean true, the STYLE object will be inactive and will not be included in the cascaded style.

Warnings:

- This is not supported on some versions of MSIE on the Macintosh platform.

STYLE.media (Property)

A description of the target presentation media that this <STYLE> tag is applicable to. This is not widely or fully supported as yet.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*mySTYLE*.media

At some time in the future style sheet support will allow a different styling model to be applied to the document according to the context in which it is being used. At the very least one would expect screen and print support to be available. The following values are allowed for in this property (according the HTML 4.0 specification) although there is no active support for this yet in any browser:

- all
- aural
- braille
- handheld
- print
- projection
- screen
- tty
- tv

For now at least, the MSIE browser supports `all`, `print` and `screen`.

Other values can be added and you can define multiple values by constructing a comma separated list in this property. Obviously the `all` keyword should be used on its own.

One would expect the TV set-top boxes to support the `tv` media style. However, they currently don't have very good support for stylesheets at all as they are predominantly based around the HTML 3.2 standard. This can only improve as time goes by.

See also:	`style.size`

STYLE.readyState (Property)

The current status disposition of a `<STYLE>` object as it is being loaded.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`mySTYLE`*`.readyState`

This property reflects the downloading of a style sheet from a server.

Sometimes, you can design scripts to execute while the document is downloading, for example, inline scripts and at that time, you may even be able to trigger interval timed deferred executions as well.

If it is important that the document has completed loading, you can check this property for one of the following values:

State	Value
`uninitialized`	The object is first instantiated but has not begun loading.
`loading`	The object has commenced loading.
`loaded`	The object has completed loading.
`interactive`	The object is loaded but not yet closed but is ready to handle interaction.
`complete`	The object body has been closed and the loading is finished.

An object may not need to reflect the `complete` status before you can commence operating on it. Other objects may require that they are completely loaded. For example, you cannot create an `OBJECT` object that represents an `<OBJECT>` tag until the `<BODY>` has completed loading. This is because the ActiveX object construction requires a complete document body structure to attach itself to.

Every time this `readyState` value changes, it triggers an `onReadyStateChange` event call-back.

See also:	`onReadyStateChange`

Property attributes:

`ReadOnly`.

STYLE.type (Property)

The MIME type that describes the kind of style information contained in the `<STYLE>` tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySTYLE*`.type`

The MIME type of the style is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

style object (2) (Object/CSS)

An object that represents an individual style element within a style sheet.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myStyle* `=` *myDocument*`.all.`*anElementID*`.style`
	-	*myStyle* `=` *myElement*`.style`
Argument list:	*aClassName*	The value in a `CLASS="..."` tag attribute.
	anElementName	The value in a `NAME="..."` or `ID="..."` tag attribute
	aTagName	An HTML tag name

Object properties:	azimuth, background, backgroundAttachment, backgroundColor, backgroundImage, backgroundPosition, backgroundPositionX, backgroundPositionY, backgroundRepeat, behavior, border, borderBottom, borderBottomColor, BorderBottomStyle, borderBottomWidth, borderCollapse, borderColor, borderLeft, borderLeftColor, borderLeftStyle, borderLeftWidth, borderRight, borderRightColor, borderRightStyle, borderRightWidth, borderSpacing, borderStyle, borderTop, borderTopColor, borderTopStyle, borderTopWidth, borderWidth, bottom, boxSizing, captionSide, cellSpacing, clear, clip, color, colorProfile, columnSpan, content, counterIncrement, counterReset, cssFloat, cssText, cue, cueAfter, cueBefore, cursor, direction, display, elevation, emptyCells, filter, float, floatStyle, font, fontFamily, fontSize, fontSizeAdjust, fontStretch, fontStyle, fontVariant, fontWeight, height, imeMode, important, layoutGrid, layoutGridChar, layoutGridCharSpacing, layoutGridLine, layoutGridMode, layoutGridType, left, length, letterSpacing, lineBreak, lineHeight, listStyle, listStyleImage, listStylePosition, listStyleType, margin, marginBottom, marginLeft, marginRight, marginTop, markerOffset, marks, maxHeight, maxWidth, minHeight, minWidth, orphans, outline, outlineColor, outlineStyle, outlineWidth, overflow, overflowX, overflowY, padding, paddingBottom, paddingLeft, paddingRight, paddingTop, page, pageBreakAfter, pageBreakBefore, pageBreakInside, pause, pauseAfter, pauseBefore, pitch, pitchRange, pixelBottom, pixelHeight, pixelLeft, pixelRight, pixelTop, pixelWidth, playDuring, posBottom, posHeight, position, posLeft, posRight, posTop, posWidth, quotes, renderingIntent, richness, right, rowSpan, rubyAlign, rubyOverhang, rubyPosition, scrollbar3dLightColor, scrollbarArrowColor, scrollbarBaseColor, scrollbarDarkShadowColor, scrollbarFaceColor, scrollbarHighlightColor, scrollbarShadowColor, size, speak, speakDate, speakHeader, speakNumeral, speakPunctuation, speakTime, speechRate, stress, styleFloat, tableLayout, textAlign, textAutospace, textDecoration, textDecorationBlink, textDecorationLineThrough, textDecorationNone, textDecorationOverline, textDecorationUnderline, textIndent, textJustify, textKashidaSpace, textShadow, textTransform, textUnderlinePosition, top, unicodeBidi, verticalAlign, visibility, voiceFamily, volume, whiteSpace, widows, width, wordBreak, wordSpacing, wordWrap, writingMode, zIndex, zoom
Object methods:	getAttribute(), getExpression(), item(), removeExpression(), setAttribute(), setExpression()
Event handlers:	onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp

DOM level 2 mandates that this object should really be called a `CSS2Properties` object and not a `style` object. It has become known as a `style` object due to the `Element` property name that points at it.

The `style` objects supported by MSIE and Netscape Navigator 4.x are quite different. For a start, the `style` objects are associated with each element in MSIE and are accessible quite easily via the `style` property. For Netscape Navigator 4, the style properties are documented under the `JSSTag` object. JSS style control permits the definition of element styles before an element has been instantiated into the document. You cannot use JSS to make dynamic style alterations.

With the release of Netscape 6.0, the style manipulation is virtually the same across both browsers. This works in both MSIE and Netscape 6 now:

```
document.getElementById("anID").style.backgroundColor="#003366";
```

Nearly all the attributes described in CSS level 1 and 2 are now supported by the `style` object. Because the codebase in Netscape 6.0 is totally new and it has only just been released, you may experience some minor instability in its support for styles.

When you look at the properties of the `style` object, you will observe that there are many alternative ways to define properties. This is quite commonplace where Microsoft define an interface to an object themselves or enhance one that has been defined by someone else (W3C or Netscape perhaps). For example, you can specify border attributes for all four borders but there are also separately defined attributes for each border. Although it's not that confusing, it does mean that there are a lot of additional keywords to learn and, from a parsing point of view, the more keywords there are, the slower the parser is going to be. It also means that programmers will employ a variety of different techniques which then forces the competing browser manufacturers to support the Microsoft extensions too.

Minimalist design is obviously not a priority here. Arguably there are benefits from this approach, too, and some people prefer having a variety of alternative ways to script around a problem. The `style` object could have been just as flexible with fewer properties at the expense of having scripts with a few more lines.

In the case of the border attributes, we might easily have coped with having a single border attribute that applied to all four sides because there are relatively few circumstances where we would want a different border on each side of a cell. On the other hand, we would then have lost some functionality so perhaps having individually addressable sides is beneficial, but then we could have omitted the collective reference leading to a need to explicitly define all four. At least this way, everyone's needs are catered for.

The properties for this object may apply styles to a variety of object types. Some are very specifically applicable to only a particular sub-set of objects. You should generally assume that the style attribute can apply to objects of any kind unless the property description topic enumerates a set of objects. In that case, the style attribute should only be applied to those object types and will likely be ignored by others. There is a possibility that applying a completely inappropriate styling to an object may cause problems or unpredictable behavior.

Warnings:

- Note that the object type for MSIE is a `style` object spelled without capitalization. The corresponding object type for Netscape 4 is a `JSSTag` object.
- MSIE also supports a `STYLE` object, which is instantiated by the `<STYLE>` tag. This is an object that represents an inline style element within the HTML of the document.

See also:	`CLASS="..."`, `Collection` object, `currentStyle` object, `Element` object, `Element.currentStyle`, `Element.style`, `JSSTag` object, `Layer` object, `rule.style`, `runtimeStyle` object

onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	5.0 +	-	-	4.0 +	Warning

Inheritance chain:

Element object, Node object

style.azimuth (Property)

Part of the aural style control suite that defines the horizontal angle of the sound source relative to the listener.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.azimuth
CSS syntax:	azimuth: *anAngle aDirection*	
Argument list:	*anAngle*	An angle specified with a value or keyword
	aDirection	A direction specifier

The value of this property describes the angle or direction from which the sound is coming from. This assumes you have a sound system that is capable of revolving a full 360 degree panorama. A stereo system should be able to place the sound source in approximately the correct position left to right and by careful use of phasing may be able to move the sound source in and out of the sound field.

The directional value can be specified either as a value in degrees or by using one or two keywords.

An azimuthal value specified in degrees must have the `deg` suffix. Thus 90 degrees would encoded as `90deg`.

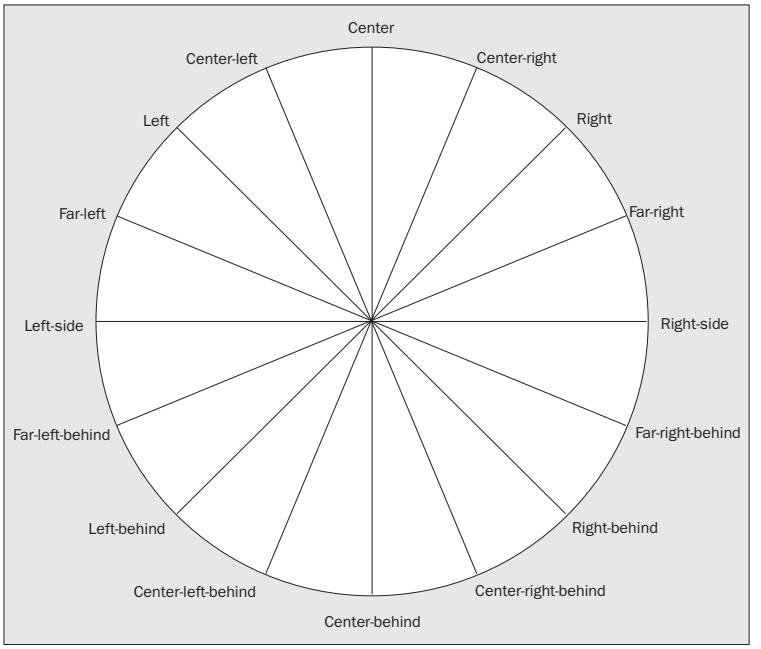
The keyword combinations and their azimuthal location are listed in the table:

Angle	Keywords
0	`center`
20	`center-right`
40	`right`
60	`far-right`
90	`right-side`
120	`far-right behind`
140	`right behind`
160	`center-right behind`
180	`center behind`
200	`center-left behind`
220	`left-behind`
240	`far-left behind`
270	`left-side`
300	`far-left`
320	`left`
340	`center-left`

In addition you can also specify these keywords:

- `leftwards`
- `rightwards`

These shift the sound source in the appropriate direction by 20 degrees.



Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `BGSOUND.balance`, `style.elevation`

style.background (Property)

A shortcut to specify several background properties.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.background`

CSS syntax:	`background: anAttachment aColor anImage aPosition aRepeat`	
Argument list:	*anAttachment*	Scrollability of the background
	aColor	Base color value
	anImage	Background image URL
	aPosition	Image location reference
	aRepeat	Repeat flag

This is a convenience property for specifying several properties of the background all at once. It is recommended that you specify the properties individually unless you plan to replace all of them with this property value.

The individual value are space separated from one another and are specified individually as they would be for their specific properties.

The following properties are collected into this convenience property:

- `style.backgroundAttachment`
- `style.backgroundColor`
- `style.backgroundImage`
- `style.backgroundPosition`
- `style.backgroundRepeat`

Note that the `style.backgroundPosition` value itself is composed of two values; the X coordinate followed by the Y coordinate.

If, when you define this set of properties, you omit a keyword in the namespace of any particular property, that property will be set to its default initial value.

See also:	`Background.src`, `style.backgroundAttachment`, `style.backgroundColor`, `style.backgroundImage`, `style.backgroundPosition`, `style.backgroundPositionX`, `style.backgroundPositionY`, `style.backgroundRepeat`

style.backgroundAttachment (Property)

The means of attachment for the style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myStyle*.backgroundAttachment
CSS syntax:	background-attachment: *aSwitch*	
Argument list:	*aSwitch*	A switch setting for fixed or scrolling

This property determines how a background image, if you have one, is attached to the document on display. The following values are appropriate for this property:

- `fixed`
- `scroll`

Fixing the image allows the document content to slide over it as if the two were on separate layers.

Warnings:

- This property may be named `background-Attachment` according to some documentation.

See also:	`style.background`, `style.backgroundImage`

style.backgroundColor (Property)

A color of the styled object's background.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.backgroundColor
CSS syntax:	background-color: *acolor*	
HTML syntax:	<BODY BGCOLOR="...">	
Argument list:	*acolor*	A valid color specifier

This background color is applied to the element before any background image is drawn. You can define both a background image and a background color. If you do, and if the background image contains any pixels that are set to a transparent color, then the background color will show through.

There are several ways in which you can access the background color of a document or element. Depending on how you do this, you may affect the entire document or just a part of it.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="ONE" STYLE="background-color:RED">
The DIV block ONE
</DIV>
<DIV ID="TWO" STYLE="background-color:BLUE">
The DIV block TWO
</DIV>
<FORM>
<INPUT TYPE="button" VALUE="CLICK ME" onClick="clickMe()">
</FORM>
<SCRIPT>
//MSIE Only
function clickMe()
{
   myStyle1 = document.all.ONE.style.backgroundColor;
   myStyle2 = document.all.TWO.style.backgroundColor;

   document.all.ONE.style.backgroundColor = myStyle2;
   document.all.TWO.style.backgroundColor = myStyle1;
}
</SCRIPT>
</BODY>
</HTML>
```

See also:	`color names`, `color value`, `Document.bgColor`, `JSSTag.backgroundColor`, `rgb()`, `style.background`

style.backgroundImage (Property)

The image displayed as a background to the object.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.backgroundImage
CSS syntax:	background-image: *aURL*	
HTML syntax:	<BODY BACKGROUND="...">	
Argument list:	*aURL*	A reference to an image asset

If a background image is available, then its URL is contained in this property. Changing the value in this property will replace the background with a new one, however there may be a perceptible delay while the new image is fetched from the web server.

The background image will be stationary or move with the document when it is scrolled according to the setting of the `style.backgroundAttachment` property.

See also:	`JSSTag.backgroundImage, style.background, style.backgroundAttachment`

style.backgroundPosition (Property)

The grid offset position for the background image.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.backgroundPosition`
CSS syntax:	`background-position:` *anX* `*` *aY*	
Argument list:	*anX*	A value describing the X coordinate position
	aY	A value describing the Y coordinate position

This property defines the reference position for the background image relative to the top left corner of the extent rectangle containing the styled element.

Like the `background` property, this is a convenience property which can be used instead of specifying the X and Y values separately.

This value should have both a top and a left position specified with a space character in between them. If you omit the second value, the first and only value will be assumed to apply to the horizontal axis while the value `50%` will be used by default for the vertical axis.

The positioning of the image includes the padding space around the styled element.

Oddly enough, the default measurement units for this property are percentages. You will achieve a more accurate positioning effect if you specify the value in pixels.

You can use the following keywords for vertical positioning:

- `top`
- `center`
- `bottom`

These keywords can be used for horizontal positioning:

- `left`
- `center`
- `right`

Warnings:

- Some versions of MSIE for the Macintosh do not use this value correctly and the image positioning may be unpredictable.

Example code:

```
// Example background position assignments
myStyle.backgroundPosition = "top left";
myStyle.backgroundPosition = "10 left";
myStyle.backgroundPosition = "top 20";
myStyle.backgroundPosition = "50% 50%";
myStyle.backgroundPosition = "25% 0";
```

See also:	Measurement units, `style.background`

style.backgroundPositionX (Property)

The X-coordinate of the background image grid position.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.backgroundPositionX`
CSS syntax:	`background-position-x:` *aValue*	
Argument list:	*aValue*	An X coordinate value

This property defines the horizontal coordinate of the reference position for the background image relative to the left edge of the extent rectangle containing the styled element. The positioning of the image includes the padding space around the styled element.

Unlike the `backgroundPosition` property, the default measurement units for this property are pixels. This is the most accurate means of positioning background images. You can also use the value `"left"` to equate symbolically to the value `0`.

Example code:

```
// Example background positionX assignments
myStyle.backgroundPositionX = "left";
myStyle.backgroundPositionX = "20";
myStyle.backgroundPositionX = "50%";
myStyle.backgroundPositionX = "0";
```

See also:	Measurement units, `style.background`

style.backgroundPositionY (Property)

The Y-coordinate of the background image grid position.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.backgroundPositionY`
CSS syntax:	`background-position-y:` *aValue*	
Argument list:	*aValue*	An Y-coordinate value

This property defines the vertical coordinate of the reference position for the background image relative to the top edge of the extent rectangle containing the styled element. The positioning of the image includes the padding space around the styled element.

Unlike the `backgroundPosition` property, the default measurement units for this property are pixels. This is the most accurate means of positioning background images. You can also use the value `"top"` to equate symbolically to the value `0`.

Example code:

```
// Example background positionY assignments
myStyle.backgroundPosition = "top";
myStyle.backgroundPosition = "10";
myStyle.backgroundPosition = "50%";
myStyle.backgroundPosition = "0";
```

See also:	Measurement units, `style.background`

style.backgroundRepeat (Property)

A property that controls the background step and repeat behavior.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.backgroundRepeat
CSS syntax:	background-repeat: *aValue*	
Argument list:	*aValue*	A selector for the kind of tiling algorithm

Depending on how you have designed the background image, you can use this property to control how it is step repeated across or down the page. The following values are appropriate:

- `repeat`
- `repeat-x`
- `repeat-y`
- `no-repeat`

See also:	`style.background`

style.behavior (Property)

Defines the URL location of a behavior HTC file.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.behavior

The behavior value may be specified as a file to be requested from the server or as a locally available behavior object. There are also built-in behaviors that the MSIE browser makes available.

Web-references:

http://msdn.microsoft.com/workshop/author/dhtml/reference/properties/behavior_1.asp#behavior

style.border (Property)

A border round the styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.border
CSS syntax:	border: *aWidth aStyle aColor*	
Argument list:	*aWidth*	A border width value
	aStyle	A border style selector
	aColor	A color value

This property provides a way to set all four borders in one assignment. It takes three values. However, you must specify the border style value for it to have any effect. The three values to define are:

- `borderStyle`
- `borderColor`
- `borderWidth`

Of course, you can specify them individually if you prefer, but this property may provide a cleaner display transition.

The three items should be space separated and defined as they would be for the specific properties that operate on them individually. Because the properties use distinctly different namespaces, the values can be defined in any order so long as the style value is always present.

You should include the `width` attribute. In fact unless you are specifying all three values, this shortcut isn't much of a saving over the discrete property setting mechanisms.

Borders and outlines are similar but not the same. An outline is like a border but it is drawn within the extent of the object. A border is drawn outside the object. The width of a border is measured outwards from the edge of element while the outline width is measured inwards.

See also:	color names, color value, Measurement units, `style.borderColor`, `style.borderStyle`, `style.borderWidth`, `style.margin`, `style.outline`, `style.padding`

style.borderBottom (Property)

Set the color, width and style of the bottom edge of the style border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderBottom
CSS syntax:	`border-bottom:` *aWidth aStyle aColor*	
Argument list:	*aWidth*	A border width value
	aStyle	A border style selector
	aColor	A color value

See also:	color names, color value, Measurement units, `style.borderColor`, `style.borderStyle`, `style.borderWidth`, `style.border`

style.borderBottomColor (Property)

The color of the bottom edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderBottomColor
CSS syntax:	`border-bottom-color:` *aColor*	
Argument list:	*aColor*	A color value

See also:	color names, color value, Measurement units, `rgb()`, `style.borderColor`

style.borderBottomStyle (Property)

The type of line for the bottom edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderBottomStyle
CSS syntax:	border-bottom-style: *aStyle*	
Argument list:	*aStyle*	A border style selector

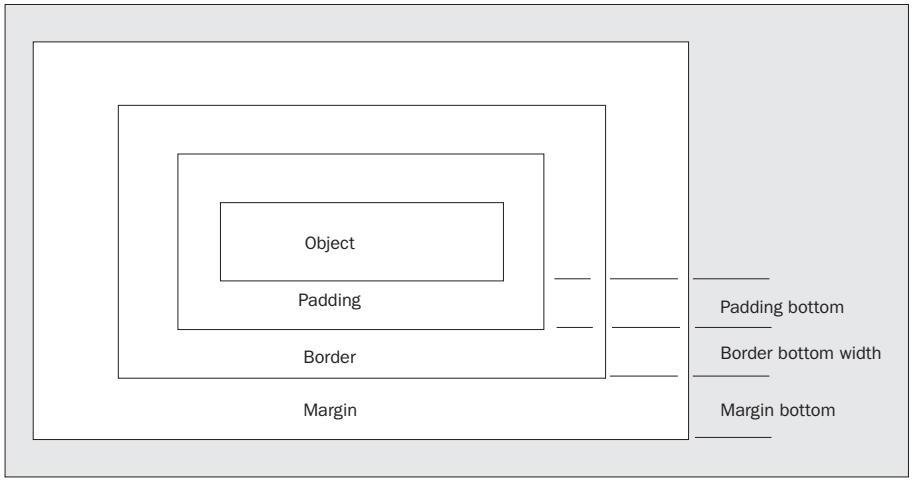
Refer to:

`style.borderStyle`

style.borderBottomWidth (Property)

The width of the bottom edge of the object's border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderBottomWidth
CSS syntax:	border-bottom-width: *aWidth*	
Argument list:	*aWidth*	A border width value



See also:	`JSSTag.borderBottomWidth`, Measurement units, `style.borderWidth`

style.borderCollapse (Property)

A switch that determines whether borders of adjacent elements are drawn independently of one another or shared between the two items.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.borderCollapse`
CSS syntax:	`border-collapse:` *`aSwitch`*	
Argument list:	*`aSwitch`*	A switching parameter value

Collapsing borders gives adjacent objects the same appearance as table cells. Cells in a table share common borders. The downside of this is that it is sometimes hard to see which object a border belongs to. You might turn off all the borders on an object that is surrounded by objects that have active borders. Then collapsing the borders for all the objects would look no different than if the middle object had its borders all active as well.

These keywords are appropriate for use with this property:

- `collapse`
- `separate`

Warnings:

- This style property appears to be inoperable in the Netscape 6.0 release. However it can be simulated by setting the border width to `0` for the edge that adjoins another bordered element. That should work across all CSS-compliant browsers.

See also:	`style.borderSpacing`

style.borderColor (Property)

The color of the border around an element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.borderColor`
CSS syntax:	`border-color:` *aColor*	
Argument list:	*aColor*	A color value

This property lets you change the color of one or more of the borders around an object.

If you specify only one value, all four borders are set. Two values define the top and bottom with the first and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Color values can be specified using symbolic names, `rgb()` functions, or hash delimited hex values.

This property might be used to control the border color around a frame or in fact with style sheet controls, you can control the border color around any object that can have a style associated with it.

See also:	color names, color value, `JSSTag.borderColor`, `rgb()`, `style.border`, `style.outlineColor`

style.borderLeft (Property)

Sets the color, width and style of the left edge of the style border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderLeft
CSS syntax:	`border-left:` *aWidth* `aStyle acolor`	
Argument list:	*aWidth*	A border width value
	aStyle	A border style selector
	acolor	A color value

See also:	color names, color value, Measurement units, `style.borderColor`, `style.borderStyle`, `style.borderWidth`, `style.border`

style.borderLeftColor (Property)

The color of the left edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderLeftColor
CSS syntax:	`border-left-color:` *aColor*	
Argument list:	*aColor*	A color value

See also:	color names, color value, rgb(), style.borderColor

style.borderLeftStyle (Property)

The type of line used for the left edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.borderLeftStyle`
CSS syntax:	`border-left-style:` *aStyle*	
Argument list:	*aStyle*	A border style selector

Refer to:

`style.borderStyle`

style.borderLeftWidth (Property)

The width of the border to the left of an element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.borderLeftWidth`
CSS syntax:	`border-left-width:` *aWidth*	
Argument list:	*aWidth*	A border width value

See also:	`JSSTag.borderLeftWidth`, Measurement units, style.borderWidth

style.borderRight (Property)

Sets the color, width, and style of the right edge of the style border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderRight
CSS syntax:	`border-right:` *aWidth aStyle acolor*	
Argument list:	*aWidth*	A border width value
	aStyle	A border style selector
	acolor	A color value

See also:	color names, color value, Measurement units, `style.borderColor`, `style.borderStyle`, `style.borderWidth`, `style.border`

style.borderRightColor (Property)

The color of the right edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderRightColor
CSS syntax:	`border-right-color:` *aColor*	
Argument list:	*aColor*	A color value

See also:	color names, color value, `rgb()`,`style.borderColor`

style.borderRightStyle (Property)

The kind of line used for the right edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderRightStyle
CSS syntax:	`border-right-style: aStyle`	
Argument list:	*aStyle*	A border style selector

Refer to:

`style.borderStyle`

style.borderRightWidth (Property)

The width of the border to the right of an element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderRightWidth
CSS syntax:	`border-right-width: aWidth`	
Argument list:	*aWidth*	A border width value

See also:	`JSSTag.borderRightWidth`, Measurement units, `style.borderWidth`

style.borderSpacing (Property)

This defines the spacing between the adjacent bordered edges of the two elements.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderSpacing
CSS syntax:	`border-spacing:` *aValue*	
Argument list:	*aValue*	A border spacing value

If borders are not collapsed and hence elements have borders that are independent of one another, this defines the spacing between the adjacent bordered edges of the two elements.

You can space elements apart, taking into account the fact that they have borders; this interposes some space between the objects so that you can clearly see the border around each one.

Warnings:

- Because the `borderCollapse` style property is not yet working correctly in Netscape 6.0, this one may also not work properly in all situations.

See also:	`style.borderCollapse`

style.borderStyle (Property)

The style of border that is drawn round a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderStyle
CSS syntax:	`border-style:` *aStyle*	
Argument list:	*aStyle*	A border style selector

This property lets you change the style of one or more of the borders around an object.

If you specify only one value, all four borders are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Style values can be specified using symbolic names as follows:

- `solid`
- `dashed`
- `dotted`
- `double`
- `inset`
- `outset`
- `groove`
- `ridge`
- `hidden`
- `none`

This property might be used to control the border style around a frame, or in fact with stylesheet controls you can control the border style around any object that can have a style associated with it.

Warnings:

- There may be some differences in the way that browsers draw these border styles. In particular, MSIE version 4 on Windows may not draw the dashed and dotted borders correctly.

See also:	`JSSTag.borderStyle`, `style.border`, `style.outlineStyle`

style.borderTop (Property)

Set the color, width and style of the top edge of the style border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderTop
CSS syntax:	border-top: *aWidth aStyle aColor*	

Argument list:	*aWidth*	A border width value
	aStyle	A border style selector
	acolor	A color value

See also:	color names, color value, Measurement units, `style.borderColor`, `style.borderStyle`, `style.borderWidth`, `style.border`

style.borderTopColor (Property)

The color of the top edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderTopColor
CSS syntax:	`border-top-color:` *aColor*	
Argument list:	*aColor*	A color value

See also:	color names, color value, `rgb()`, `style.borderColor`

style.borderTopStyle (Property)

The kind of line used for the top edge of the style border.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.borderTopStyle
CSS syntax:	`border-top-style:` *aStyle*	
Argument list:	*aStyle*	A border style selector

Refer to:

`style.borderStyle`

style.borderTopWidth (Property)

The width of the border along the top edge of an element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.borderTopWidth`
CSS syntax:	`border-top-width:` *aWidth*	
Argument list:	*aWidth*	A border width value

See also:	`JSSTag.borderTopWidth`, Measurement units, `style.borderWidth`

style.borderWidth (Property)

The thickness of the style border.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.borderWidth`
CSS syntax:	`border-width:` *aWidth*	
Argument list:	*aWidth*	A border width value

This property lets you change the width of one or more of the borders around an object.

If you specify only one value, all four borders are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Width values can be specified using symbolic names or pixel values. The following symbolic names are available:

- `thin`
- `medium`
- `thick`

This property might be used to control the border width around a frame or in fact, with style sheet controls you can control the border width around any object that can have a style associated with it.

See also:	`JSSTag.borderWidths()`, Measurement units, `style.border`, `style.margin`, `style.outlineWidth`

style.bottom (Property)

A positioning reference point.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.bottom`
CSS syntax:	`bottom: `*`aValue`*	
Argument list:	*`aValue`*	A positioning value

A CSS-P positioning style attribute that controls the location of an element relative to its containing parent element. The bottom edges of the two elements are used as the reference points.

The value can be specified in the usual pixel or fractional em-dash measurement units or the `auto` keyword can be used to let the browser do the positioning itself.

The exact positioning is affected by settings for `padding`, `border`, `margin`, and (particularly the mode of) the `position` property.

See also:	Measurement units, `style.left`, `style.pixelBottom`, `style.posBottom`, `style.right`, `style.top`

style.boxSizing (Property)

A special style supported by MSIE to control the way that elements are boxed.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.boxSizing
CSS syntax:	box-sizing: *aControl*	
Argument list:	*aControl*	The box sizing control value

Although the property is present as an enumerable property, searching the Microsoft documentation base yielded no useful information. Some very sparse web search results suggested this was some kind of layout control facility.

style.captionSide (Property)

An attribute that controls the positioning of a caption with respect to its owning object.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.captionSide
CSS syntax:	caption-side: *aSwitch*	
Argument list:	*aSwitch*	A switching value

This property would normally be used on a style that is used with tables. It allows the caption position relative to the owning element to be controlled.

The following keywords can be used with this property:

- `top`
- `bottom`

This is intended to replace the deprecated alignment controls that were formerly available with the `<CAPTION>` HTML tag.

See also:	`CAPTION` object, `CAPTION.align`, `CAPTION.vAlign`, `TABLE` object

style.cellSpacing (Property)

Defines the cell spacing of items in a table.

Availability:	CSS level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.cellSpacing
CSS syntax:	`cell-spacing: aValue`	
Argument list:	*aValue*	A spacing value

This property is intended to provide control over the cell spacing for tables. The property is able to accept one or two length values specified in the normal measurement units.

If you specify just one value it is used for both horizontal and vertical cell spacing. If you specify both values, the horizontal is taken to be first and the vertical spacing uses the second.

Assigning the `none` keyword to the property resets the cell spacing to the browser default value.

Warnings:

- This CSS 2 property is not yet supported by MSIE.

See also:	Measurement units, `TABLE` object

style.clear (Property)

A means of controlling text flow and positioning of objects adjacent to one another to allow them to coexist on the same horizontal line or to force a line break before or after them.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.clear
CSS syntax:	`clear: aValue`	
Argument list:	*aValue*	An alignment control value

This property is useful for giving fine control over the text flow around images or other objects. You can use it to clear alignment settings either side of the object, making it behave like a block structured item as far as the text flow is concerned. The following values can be assigned to this property:

- `none`
- `left`
- `right`
- `both`

The exact behavior depends on the presence of adjacent elements and the settings of their `style.float` properties being defined as either `left` or `right`.

See also:	`JSSTag.clear`, `style.float`

style.clip (Property)

A clip region for a style.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.clip`
CSS syntax:	`clip:` *aValue*	
Argument list:	*aValue*	Either a rectangle object or a keyword value

Positionable objects can have a clipping region defined for them. This defines the area of the styled object that is visible. At present you can only clip to a rectangular shape. You can specify either a clipping region measured in pixels, or use the symbolic name "`auto`" to use the extent rectangle surrounding the object as its clip region. The coordinates should be specified in the order: top, right, bottom and left and need to be enclosed in a `rect()` constructor function to instantiate a `rect` object to be assigned to the property.

You should be careful not to exceed the extent rectangle of the containing parent element. This should not cause a problem and the clipping regions should be clipped one within the other, but MSIE does not handle this very gracefully sometimes.

If you access the `left`, `right`, `top` and `bottom` properties of the `style.clip` `rect` object individually, you can specify a single numeric value for each as need be.

Warnings:

- This does not work in all versions of MSIE for Macintosh.

See also:	`Clip` object, `Rect` object

style.clip.bottom (Property)

The bottom edge of an element object's clip region.

Availability:	CSS level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.clip.bottom`

Refer to:

`style.clip`

style.clip.left (Property)

The left edge of an element object's clip region.

Availability:	CSS level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.clip.left`

Refer to:

`style.clip`

style.clip.right (Property)

The right edge of an element object's clip region.

Availability:	CSS level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.clip.right`

Refer to:

`style.clip`

style.clip.top (Property)

The top edge of an element object's clip region.

Availability:	CSS level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.clip.top`

Refer to:

`style.clip`

style.color (Property)

Defines the foreground color of any text drawn in the content of the styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0

Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.color
CSS syntax:	color: *aColor*	
Argument list:	*aColor*	A valid color value

The color of foreground text affected by this style object will be defined in this property.

The color can be specified in the normal way according to the HTML color specifiers.

See also:	color names, color value, `JSSTag.color, rgb(), String.fontcolor(),style.renderingIntent`

style.colorProfile (Property)

This is an extension to the style model that allows for accurate color models to be used for improved color fidelity of the displayed image.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.colorProfile
CSS syntax:	color-profile: *aProfile*	
Argument list:	*aProfile*	A color profile selector

This is related to the ICC color profiling support in the browser and platform. See also the Apple ColorSync technologies.

See also:	`style.renderingIntent`

style.columnSpan (Property)

Defines the number of columns to span when displaying a table cell.

Availability:	CSS level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.columnSpan

CSS syntax:	column-span: *aCount*	
Argument list:	*aCount*	A number of columns to span

The columnSpan property is used to define how many columns a table cell should span. There are other alternative ways to access the cell spanning controls for a table cell via the DOM representation of tables through the TABLE, TD and TH objects.

You should specify a numeric value to indicate how many columns the table cell should span. This can also be used with the COL and COLGROUP objects.

Warnings:

- This style property is not yet supported by MSIE.

See also:	COL object, COLGROUP object, TABLE object, TABLE.cols, TD.colSpan, TH.colSpan

style.content (Property)

A means of adding small fragments of HTML before and after an element without that HTML needing to be coded into the document source with the styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.content
CSS syntax:	content: *someContentRef*	
Argument list:	*someContentRef*	A URL, string or value to be placed before or after an element

If you have a generic effect you want to achieve that goes beyond what is possible with a simple property or style attribute and can only be accomplished by additional fragments of HTML, this property provides a way to add fragments of HTML before and after an element.

The string to be assigned to this should be a valid fragment of CSS text that uses the before: and after: pseudo elements to define leading and trailing fragments of HTML.

This is a relatively new part of the CSS standard and does not yet have a well defined JavaScript binding.

style.counterIncrement (Property)

A means of controlling the way that counters in enumerated items are to be incremented when they are used in the document.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.counterIncrement
CSS syntax:	counter-increment: *aValue*	
Argument list:	*aValue*	An incrementing value for the counter

The value specified in this property is added to the counter as it is enumerated in an ordered list.

See also:	style.listStyle,style.listStyleType

style.counterReset (Property)

A way to reset a counter at the start of a section.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.counterReset
CSS syntax:	counter-reset: *aValue*	
Argument list:	*aValue*	A new initial value for the counter

If you are building complex ordered list structures, you may want to force a counter to be reset to a specific value. This property provides a means of assigning a new value to the list at the start of the enumeration loop.

style.cssFloat (Property)

An extension to the `float` attribute that is a standard CSS attribute. `cssFloat` is an MSIE-only attribute and is not standardized. It appears to simply be another name for the `float` property.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.cssFloat
CSS syntax:	`css-float: anAlignment`	
Argument list:	*anAlignment*	A float control word

See also:	`style.styleFloat,style.float`

style.cssText (Property)

The CSS style sheet specification source text for this style object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.cssText

This property returns the contents of the entire style sheet rule that this style object belongs to. You can also assign a new CSS text value to this property in accordance with the style sheet syntax rules.

Property attributes:

`ReadOnly`.

style.cue (Property)

Part of the aural style control suite that defines the aural icon sound before and after an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.cue
CSS syntax:	cue: *aBefore anAfter*	
Argument list:	*aBefore*	A cue sound before the speech
	anAfter	A cue sound after the speech

This property is part of the audible style sheet property set. It is used as a shortcut for defining the value of the `style.cueBefore` and `style.cueAfter` properties in a single assignment.

Warnings:

- This style property is not yet supported by any browsers.

See also:	Aural style sheets, `style.cueAfter`, `style.cueBefore`

style.cueAfter (Property)

Part of the aural style control suite that defines the aural icon sound after an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.cueAfter
CSS syntax:	cue-after: *aSound*	
Argument list:	*aSound*	A sound to be played after speech

The `cueAfter` property provides a way to define a short audible sound after a spoken phrase. You can specify the URI for an audio clip or define the value `none` to inhibit the audible cue following the phrase.

The URI may be relative to the document or a fully specified URL value. It should locate an audio file having a MIME type that the browser supports for playback.

Warnings:

- This style property is not yet supported by any browsers.

See also:	Aural style sheets, MIME types, `style.cue`

style.cueBefore (Property)

Part of the aural style control suite that defines the aural icon sound before an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.cueBefore`
CSS syntax:	`cue-before:` *aSound*	
Argument list:	*aSound*	A sound to be played after speech

The `cueBefore` property provides a way to define a short audible sound before a spoken phrase. You can specify the URI for an audio clip or define the value `none` to inhibit the audible cue preceding the phrase.

The URI may be relative to the document or a fully specified URL value. It should locate an audio file having a MIME type that the browser supports for playback.

Warnings:

- This style property is not yet supported by any browsers.

See also:	Aural style sheets, MIME types, `style.cue`

style.cursor (Property)

A cursor shape to display when the pointer hovers over the element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myStyle*.cursor
CSS syntax:	cursor: *aShape*	
Argument list:	*aShape*	One of the available cursor shapes

You can define the shape of the cursor when the mouse pointer moves over the element. This is far more sensible than defining a onMouseOver and onMouseOut handler to set and reset the cursor shape.

The following cursor names can be specified:

- default
- auto
- crosshair
- help
- move
- pointer
- text
- wait
- hand
- resize
- n-resize
- ne-resize
- e-resize
- se-resize
- s-resize
- sw-resize
- w-resize
- nw-resize

The CSS standard suggests that a URI value could be specified to allow for a downloadable cursor shape to be defined although this is not currently supported in any browser.

style.direction (Property)

Controls the direction of flow of inline content such as text and table cells.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.direction
CSS syntax:	direction: *aDirection*	
Argument list:	*aDirection*	One of the available text directions

The direction property may be set to indicate a left to right or right to left parsing direction.

This is part of the localization support and represents the contents of the `DIR="..."` tag attribute.

If you assign a value to this property it is case-sensitive and must be one of the following:

- `ltr`
- `rtl`
- `ltr-override`
- `rtl-override`

This property works in conjunction with the `lang` property to control the direction of text flow.

The variations with the `override` modifier keyword are intended to force the direction even when the underlying language does not support it natively according to the Unicode rules.

style.display (Property)

A control attribute that defines how an element should be rendered into the display window.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myStyle*.display
CSS syntax:	display: *aType*	
Argument list:	*aType*	One of the supported display types

This is currently implemented as a simple visibility switch. If the property is set to the value "none", then the object is hidden. To reveal the object again, set this property to its default value which is an empty string ("").

When the object is hidden, the surrounding objects close up the space. This means you cannot use the property to accomplish a blinking effect, because everything will dance around the screen as the object appears and disappears.

The full CSS specification for this property allows for it to control the display of an object as either an inline or block level element in the page.

The following keywords are defined for use with this property:

- none
- block
- compact
- inline
- inline-table
- list-item
- run-in
- table
- table-caption
- table-cell
- table-column-group
- table-footer-group
- table-header-group
- table-row
- table-row-group

See also:	JSSTag.display

style.elevation (Property)

Part of the aural style control suite that defines the height of a sound source within a 3D space.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*`myStyle`*`.elevation`
CSS syntax:	`elevation: `*`aValue`*	
Argument list:	*`aValue`*	One of the available elevation values

The sound source can be located in the vertical direction giving a full 3D spatial system around the surface of a sphere when combined with the `azimuth` property.

The following values are appropriate:

value	elevation
`level`	On the same horizontal plane as the listener
`above`	Directly overhead
`below`	Directly underneath
`higher`	Approximately 10 degrees higher than the previous value
`lower`	Approximately 10 degrees lower than the previous value

Values can be specified in degrees with the `deg` suffix. The values `+90deg` and `-90deg` correspond to the `above` and `below` keywords.

Warnings:

- This style property is not yet supported by any browsers.

See also:	Aural style sheets, `style.azimuth`

style.emptyCells (Property)

An indication of how empty cells in a table should be displayed.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.emptyCells
CSS syntax:	empty-cells: *aControl*	
Argument list:	*aControl*	What to do with empty cells in a table

This property controls how the empty cells in a table are displayed. It can accommodate the following values:

- show
- hide

Arguably it might be useful to be able to specify some alternatives to simply hiding or showing the cells. Refer to the URL for an informative discussion on empty cells in tables.

See also:	TABLE object

Web-references:

http://www.hut.fi/u/jkorpela/HTML/emptycells.html

style.filter (Property)

Defines the visual, reveal or blend filter for the object.

Availability:	CSS level – Proposed JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myStyle*.filter
CSS syntax:	filter: *aFilter*(*aParam*=*aValue*, ...) ...	
Argument list:	*aFilter*	A filter name
	aParam	A filter parameter name
	aValue	A filter parameter value

This property defines a visual effect that is used when the display is updated as the result of a change to the content of an element.

There are three kinds of filters that can be applied to an object.

- `Visual`
- `Reveal`
- `Blend`

A visual filter is used to enhance the visual appearance of objects. For example, to flip them over, add a glow effect or a drop shadow.

A reveal filter is used to apply a transition effect as the appearance changes.

A blend filter controls the speed at which a reveal filter is applied.

You can define more than one filter, they just need to be space-separated from one another.

Here is a list of the procedural filter function names:

- `AlphaImageLoader()`
- `Gradient()`

Here is a list of the static filters supported at version 5.5 of the MSIE browser:

- `Alpha()`
- `BasicImage()`
- `Blur()`
- `Chroma()`
- `Compositor()`
- `DropShadow()`
- `Emboss()`
- `Engrave()`
- `Glow()`
- `Light()`
- `MaskFilter()`
- `Matrix()`
- `MotionBlur()`
- `Pixelate()`
- `Shadow()`
- `Wave()`

The old `blendTrans()` and `revealTrans()` filters are now replaced by these transition filters:

- `Barn()`
- `Blinds()`
- `CheckerBoard()`
- `Fade()`
- `GradientWipe()`
- `Inset()`
- `Iris()`
- `Pixelate()`
- `RadialWipe()`
- `RandomBars()`
- `RandomDissolve()`
- `Slide()`
- `Spiral()`
- `Stretch()`
- `Strips()`
- `Wheel()`
- `Zigzag()`

Filters are defined as if they were a sequence of space delimited function calls. They aren't really functions because their argument passing mechanism is not truly JavaScript based. Arguments to each filter function are defined as `name=value` pairs. These correspond to the properties and method invocations of the underlying filter object.

Refer to the specific topics on each filter function for details of what it does and how you can control it.

When using the filters in the context of the `Style` object, the function name for each filter must be preceded by this string:

"`progid:DXImageTransform.Microsoft.`"

You can apply the filters directly as properties of the `filter` object that belongs to HTML element objects themselves.

Visual filters require that the target objects have enough layout information to enable the filter to work. This means they require height and width to be defined using absolute positioning or setting the `contentEditable` property flag to `true`.

Warnings:

- Filters are not supported in all versions of MSIE on the Macintosh. In fact, they are not really well supported outside of the MSIE browser on the Win32 platform.
- There are various sources of documentation about these filters. There is some difference between them regarding the spelling of the filters' names and the availability of the filters. The naming conventions are sometimes all lower case and at others a mixed upper and lower case. This suggests that the filter name parser may be case-insensitive. This also applies to the `name=value` pairs that are passed as arguments to the filter functions.
- Certain filter functions are no longer included in the MSDN reference material and so they may be considered to be deprecated.
- We have conformed to the case style of the MSDN reference and have included all the filters that were encountered in our source material. Those that appear not to be in the current MSDN reference are marked as deprecated as follows:

```
FlipH()
FlipV()
Grayscale()
Invert()
Mask()
XRay()
```

- These are deprecated filters that used to provide blends and reveals:

```
BlendTrans()
RevealTrans()
```

- Note that the functionality and availability of the filters has changed significantly from version 4.0 to version 5.5 of the MSIE browser.
- The old functionality has not been lost. Instead, it has been reorganized and factored into the new filter suite. Nothing that you could have done before has been taken away but you will have to address the filters differently.

See also:	`Element.filters[]`, `onFilterChange`, Procedural surfaces, Static filters, `style.textShadow`, Transition, Visual filters

style.float (Property)

An alignment control that indicates how text is to be flowed round the object that the style is applied to.

Availability:	CSS level – 1 JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`String primitive`

JavaScript syntax:	IE	*myStyle*.float
CSS syntax:	float: *anAlignment*	
Argument list:	*anAlignment*	A float control word

This property defines which side is used for the reference alignment so that text can flow round the other.

Setting the property value to `none` allows the object to be placed inline according to where it appears in the document source.

The following keywords can be used with this property:

- `left`
- `right`
- `none`

Warnings:

- `IMG` elements in Netscape Navigator 4 do not align in the same way as MSIE browser `IMG` elements. Since you can't access the style model in the same way, this is maybe a moot point but there are alternative ways to control alignment in each browser. So, assuming you could define the float attribute in both, Netscape Navigator 4 would still not position the `IMG` objects in the same way.
- The JavaScript language reserves the `float` keyword and so it is dangerous to use it as a property on any object. Because of this, a more consistent control of alignment for `IMG` objects can be achieved with the `align` property instead.
- Netscape 6.0 supports the `cssFloat` property which is preferred and which avoids the conflict with the `float` keyword.

See also:	style.clear, style.styleFloat

style.floatStyle (Property)

An MSIE extension to the normal float style attributes. All the indications are that this is simply another name for the `styleFloat` property.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myStyle*.floatStyle
CSS syntax:	float-style: *anAlignment*	
Argument list:	*anAlignment*	A floating alignment control value

See also:	style.styleFloat

Refer to:

style.styleFloat

style.font (Property)

A special shortcut styling control that provides a way to define several font styling attributes in a single assignment.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.font
CSS syntax:	font: *aStyle aVariant aWeight aSize aLineHeight aFamily*font: *aConstant*	
Argument list:	*aStyle*	A font style value
	aVariant	A font variant
	aWeight	A font weight
	aSize	A font size
	aLineHeight	A line height value
	aFamily	A font family
	aConstant	A CSS font constant

This property can be assigned with a string containing space-separated keywords and values. The values are then unpacked and assigned to individual font styling properties.

The following font styling properties are collected together into this item:

- style.fontFamily
- style.fontSize
- style.fontStyle
- style.fontVariant
- style.fontWeight
- style.lineHeight

Refer to the individual topics for these properties for details of the range of suitable values. For the style.font property, the values can be presented in any order since their namespaces do not collide.

As an alternative the CSS font constant values can be used to define font appearance according to a browser and platform specific macro. The following macros are supported:

- `caption`
- `icon`
- `menu`
- `messagebox`
- `smallcaption`
- `statusbar`

These appearance of fonts styled according to these values are not defined in any standard but they will be consistent with text presented in the appropriate contexts on the client platform.

See also:	`style.fontFamily`, `style.fontSize`, `style.fontStyle`, `style.fontVariant`, `style.fontWeight`, `style.lineHeight`

style.fontFamily (Property)

A list of fonts to be used for the element. The first one in the list that is available will be used.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.fontFamily
CSS syntax:	font-family: *aFamily* ...	
Argument list:	*aFamily*	A font family list

The ordering of the font family names dictates the priority with which they are used. The names should be separated from one another by spaces but some font names may have spaces in them, so if you use font names containing spaces, they should be enclosed inside quotes. Make sure that you use a different kind of string delimiter quote for indicating font names to that which you use to enclose the string of font names.

As well as the names of any font families that you think may be installed in the target client browser, you can specify generic font families with the following keywords:

- `serif`
- `sans-serif`
- `cursive`
- `fantasy`
- `monospace`

See also:	JSSTag.fontFamily, String.fixed(), style.font, style.voiceFamily

style.fontSize (Property)

Controls the size of the text drawn with the current font. Note that different browsers support a text-imaging model at varying resolutions, and it is difficult to obtain consistent results when older browsers are used.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.fontSize
CSS syntax:	font-size: *aSize*	
Argument list:	*aSize*	A font size

Font sizes can be specified in a variety of measurement units.

There are some issues to do with font sizes that make fonts very difficult to control across platforms. This is affected by several factors:

- Font digitizing
- Font design (x-height)
- Bitmap vs. Adobe vs. TrueType
- Pixel DPI settings
- Different defaults for symbolic sizes

There are differences between the way that fonts are rendered. Considering that the Macintosh supports at least three simultaneous font rendering models at a time and historically there have been several radically different font management schemes, it is amazing that fonts ever appear in the way they were intended. The Windows platform must provide at least half as many again while the X-Windows support on the Linux platform supports a completely different font rendering model.

Certain font families appear to render larger than others for the same point size. This difference is due to the different x-height for the characters.

The differences between the Macintosh and the Windows environment are due to the 72 DPI vs. 96 DPI default pixel resolution of the screen displays. The latest versions of MSIE for the Macintosh provide a 96 DPI switch to work round this.

The symbolic names for font sizes do not render identically across platforms nor do they render the same across browsers within the same platform. These are the symbolic font size names for absolute sizes:

- `xx-small`
- `x-small`
- `small`
- `medium`
- `large`
- `x-large`
- `xx-large`

You can use numeric values with suffixes to indicate the units of measure:

- `px`
- `em`
- `percentage`

The `px` suffix means pixels while the `em` value means the width of an em-dash in the current font. You can use floating point values for measurements in `em` units. You can also use floating point values for percentage values. The percentage relates to the containing parent object's font settings.

Two additional symbolic names are reserved for relative font sizes:

- `larger`
- `smaller`

The larger and smaller keywords index up and down the scale defined by the absolute size keywords.

Warnings:

- Be very careful when defining styles with relative settings. This can cascade recursively in some cases and you will end up with text that reduces or increases in size as it goes down the page.

See also:	`JSSTag.fontSize,String.big(),String.fontsize(), String.small(),String.sub(), String.sup(), style.font`

style.fontSizeAdjust (Property)

A means of compensating for the differences in browser font rendering models.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.fontSizeAdjust
CSS syntax:	font-size-adjust: *aValue*	
Argument list:	*aValue*	An adjustment factor

This is a mechanism that is intended to help with adjustments for the x-height differences between fonts. It provides a compensation effect that reduces fonts with large x-heights so that they appear to be the same size as other fonts with small x-heights.

The following values can be assigned to this property:

- z
- none

style.fontStretch (Property)

A means of extending the font in the horizontal direction only.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.fontStretch
CSS syntax:	font-stretch: *aValue*	
Argument list:	*aValue*	A font stretch control value

This styling property is used to change the horizontal span of the text by expanding or contracting it. The property can accept the following keywords:

- normal
- wider
- narrower
- ultra-condensed
- extra-condensed
- condensed
- semi-condensed
- semi-expanded
- expanded
- extra-expanded
- ultra-expanded
- inherit

style.fontStyle (Property)

Controls the italicization of a font. The oblique and italic styles affect the displayed font in different ways.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.fontStyle
CSS syntax:	font-style: *aStyle*	
Argument list:	*aStyle*	A font style value

Fonts can be styled to present themselves in a slanted appearance. It is not commonly realized that an italic and oblique font are not the same. A fully featured font engine provides both oblique and italic font styles. A less well featured font engine will simulate the effect by slanting the upright characters to make them appear to be italic. Other systems may simulate italic with oblique and vice versa.

The differences between the italic and oblique faces is in the treatment of certain characters such as a small letter a. In one model the same letter form as is used for the upright font is drawn with its verticals tilted at an angle. In the other the letter form is still drawn tilted but an alternative shape is used. In a properly supported system with all the special font renderings available, the characters will be specially drawn so they look clean when slanted. Simply skewing the upright characters does not preserve the character shape as accurately.

The following keywords can be applied to this property:

- `normal`
- `italic`
- `oblique`

Warnings:

- Netscape Navigator does not understand the `oblique` keyword when defining style values for `fontStyle` properties.
- The MSIE browser understands both `italic` and `oblique` keywords but assumes that they both mean `italic`.

See also:	`JSSTag.fontStyle,String.italics(),String.sub(), String.sup(),style.font`

style.fontVariant (Property)

The small-caps variant of a font for a style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.fontVariant
CSS syntax:	font-variant: *aVariant*	
Argument list:	*aVariant*	A font variant

This is a popular design trick which renders lower-case letters in upper-case but in a smaller font size. This is often called small-caps.

The following keywords can be applied to this property:

- `normal`
- `small-caps`

See also:	`style.font`

style.fontWeight (Property)

The boldness of text drawn in the current font.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.fontWeight
CSS syntax:	font-weight: *aWeight*	
Argument list:	*aWeight*	A font weight

The font weight is a continuous scale from 100 to 900. Printers can resolve the font weights to a finer granular accuracy than a screen display. Screen displays can generally cope with discriminating a difference between 100 and 200 but cannot manage any better than that due to the screen resolution.

The value can also be specified with the following keywords:

- `bold`
- `bolder`
- `lighter`
- `normal`

See also:	`JSSTag.fontWeight`, `String.bold()`, `style.font`

style.getAttribute() (Method)

A method to extract attributes from a style.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.getAttribute(`*anAttribName*`)`
	-	*myStyle*`.getAttribute(`*anAttribName*`, `*aCaseSense*`)`
Argument list:	*aCaseSense*	A flag to indicate a case-sensitive lookup
	anAttribName	An attribute of a style object

This is an accessor method which is used to access named attributes of an `Element` object. Attributes are not properties in the strict sense of the word but may be accessible as if they were in some implementations.

This accessor is intended to provide a means of managing custom attributes.

You need to know the names of the attributes you want to access. If you do, then you can pass the attribute name as an argument to this method call.

The value of that attribute is returned by the method.

It would be logical to assume that attributes are named uniquely but if several share the same name, differing only in case-sensitivity, then if a case-insensitive search is used you may not retrieve the one you expect. It is likely that you'll be given the last one that occurs but this may be implementation dependent.

The case sensitive flag should be set to the Boolean `true` value to force a case-sensitive search and `false` to ignore the case of letters in the attribute name.

The following values can be passed in the optional case-sensitive flag argument:

- `0` – A case-insensitive search of property values is carried out by default. If several instances are located, then only the last is returned.
- `1` – A case-sensitive search is carried out.
- `2` – The value is returned exactly as was originally defined in the document source regardless of subsequent `setAttribute()` calls.

The result will be the value of the attribute. If the element does not have an attribute of the specified name, a `null` value is returned.

Warnings:

- If a case-sensitive search is carried out using a property name stored in a variable, you should make sure that the same setting was defined for a corresponding `setAttribute()` call. If you don't, then it is possible that the name may have a case change if the `0` value was used in the `setAttribute()` call. After that case change, the value in the variable will no longer match the property defined for the receiving object.

See also:	`Element.getAttribute(), style.setAttribute()`

style.getExpression() (Method)

An MSIE extension for managing style controls.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.getExpression(`*`aProperty`*`)`
Argument list:	*`aProperty`*	The name of a property whose expression is to be retrieved

This is part of the MSIE support for managing behaviors. With this method, you can access the value of an expression that was previously defined with the `setExpression()` method or which is defined within a style rule.

The rules that are used to construct a style are comprised of multiple expressions. You can use this method to extract the value of an expression from a style item.

Given the rule might contain a line such as:

```
width:200px
```

The `getExpression()` method can be applied to the style object containing the rule with that expression like this:

```
myStyle.getExpression("width:")
```

The value `200px` would be returned.

See also:	`Element.getExpression()`, `Element.removeExpression()`, `Element.setExpression()`, `style.removeExpression()`,`style.setExpression()`

style.height (Property)

The height of a sizing style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.height
CSS syntax:	`height: aHeight`	
Argument list:	*aHeight*	An object height

The object space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

When used to read the height on an object, this returns a value in pixel units with the `px` suffix.

You can also use this property to change the height of a styled element.

The normal range of values specified in measurement units can be used. You can also assign the `auto` keyword to let the browser deduce the height of an object from the document source.

Warnings:

- Note that not all styled elements can be resized by assigning a new value to this property.

See also:	`JSSTag.height`, Measurement units, `style.pixelHeight`, `style.posHeight`,`style.width`

style.imeMode (Property)

An Input Method Editor mode specifier.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0

Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`style`*`.imeMode`
CSS syntax:	`ime-mode:` *`aControl`*	
Argument list:	*`aControl`*	One of the available control keywords

Input Method Editors are provided to support Asian languages such as Chinese, Korean and Japanese.

This property maintains an IME specifier value.

The following keywords are valid:

- `auto`
- `active`
- `inactive`
- `disabled`

style.important (Property)

A means of adding emphasis to an object.

Availability:	CSS level – 1 JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.important`
CSS syntax:	`!important`	

Although the `!important` style attribute is supported in CSS style sheets used by MSIE and Netscape 6.0, there is apparently no access to it from JScript at this time. If there were, then syntax rules for JavaScript would preclude the use of the exclamation mark as a part of the identifier name for the property so it would most likely be called simply `style.important`.

Although there are no values assigned to this style attribute in the CSS style sheet, it is likely that it would be a Boolean value if it were accessible from JScript.

style.item() (Method)

When the style is treated as if it were a collection, objects belonging to it can be referenced by their item numbers.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`style object`	
JavaScript syntax:	IE	`myStyle.item(anIndex)`
	IE	*`myStyle`*`.item(`*`aSelector`*`)`
	IE	*`myStyle`*`.item(`*`aSelector, anIndex`*`)`
Argument list:	*`anIndex`*	A zero based value in accordance with the `length` attribute of the style object.
	`aSelector`	A textual value that selects all matching objects

You will have to use some JavaScript to inspect the values presented by this mechanism. The following lines both yield a `FONT-SIZE` object:

```
document.all.tags("HTML")[0].currentStyle.item(0)

document.all.tags("TITLE")[0].currentStyle.item(0)
```

The style object in both cases only has a single item in its collection and so the length values for these expressions always yield `1` for a simple document:

```
document.all.tags("HTML")[0].currentStyle.length

document.all.tags("TITLE")[0].currentStyle.length
```

If you begin to explore the MSIE browser in this way, there are many undocumented properties and object references which are reasonably easy to figure out because of their names. However some are quite obscure. We have tried to cover as many as we can. Discovering undocumented method calls is far more difficult and you may need to reverse engineer the JScript interpreter to discover the names of the methods that are implemented.

See also:	`Collection.Item()`

style.layoutGrid (Property)

An MSIE extension that provides a means of laying out objects on a grid.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0
Property/method value type:	`String primitive`

JavaScript syntax:	IE	*myStyle*.layoutGrid
CSS syntax:	layout-grid: *aLayout*	
Argument list:	*aLayout*	One of the available layout grid control keywords

The layout grid is especially useful when presenting Asian text. This uses ideographic characters where each single character represents a word on its own. They need to be arranged in an orderly manner but it is quite inconvenient to build a table with one cell for each character. A layout grid accomplishes the lining up and justification of each column and row in a much more convenient manner.

This is a convenience method for specifying all of the grid control values in a single assignment.

The values for the following related properties should be used to specify this value:

- layoutGridChar
- layoutGridLine
- layoutGridMode
- layoutGridType

Only the style.layoutGridCharSpacing is not supported by this short cut.

Since the namespaces for the values that can be used in these properties clash with one another, they should be presented in the following order:

<mode> <type> <line> <char>

Refer to the topics for these individual properties for details of the available values you can use.

See also:	style.layoutGridChar, style.layoutGridCharSpacing, style.layoutGridLine, style.layoutGridMode, style.layoutGridType

style.layoutGridChar (Property)

Part of the MSIE grid layout control.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	String primitive	
JavaScript syntax:	IE	*myStyle*.layoutGridChar
CSS syntax:	layout-grid-char: *aSize*	
Argument list:	*aSize*	A size specifier for the layout grid

The grid is defined according to various metrics associated with the font or can be explicitly specified. The following keyword values can be used:

- `none`
- `auto`

When set to `auto`, the largest character in the current font is used to define the height and width of each grid cell.

The value can also be specified in measurement units or as a percentage of the parent containing object.

See also:	Measurement units, `style.layoutGrid`

style.layoutGridCharSpacing (Property)

Spacing control for the MSIE grid layout extensions.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.layoutGridCharSpacing`
CSS syntax:	`layout-grid-char-spacing:` *aValue*	
Argument list:	*aValue*	Character spacing value within the grid

This is an additional parameter to control spacing between characters in the grid.

See also:	`style.layoutGrid`

style.layoutGridLine (Property)

Additional control for the MSIE grid layout extensions.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.layoutGridLine`
CSS syntax:	`layout-grid-line:` *aControl*	
Argument list:	*aControl*	A control value

This provides a fine level of control for adjusting the spacing between lines in the grid. The values available for use can be one of the following keywords:

- `none`
- `auto`

You can also specify a value in length units or as a percentage.

See also:	Measurement units, `style.layoutGrid`

style.layoutGridMode (Property)

Mode settings for the MSIE grid layout extensions.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.layoutGridMode`
CSS syntax:	`layout-grid-mode:` *aControl*	
Argument list:	*aControl*	A specifier for the mode of operation of the layout grid

This property defines whether the layout grid uses one or two axes or neither for positioning characters. The following keywords can be used:

- `both`
- `none`
- `line`
- `char`

The default is for both the line and character spacing to be used. Using the `line` or `char` keywords signifies that only one axis is to be used for the grid.

See also:	`style.layoutGrid`

style.layoutGridType (Property)

A type selector for the MSIE grid layout extensions.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.layoutGridType
CSS syntax:	layout-grid-type: *aType*	
Argument list:	*aType*	Select a type of layout grid

There are various kinds of grid supported. An appropriate grid type is selected with one of the following keywords:

- `loose`
- `strict`
- `fixed`

The kind of grid you would select will depend on the language and kind of ideographic font being used.

See also:	`style.layoutGrid`

style.left (Property)

A positioning reference point.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.left
CSS syntax:	left: *aPosition*	
Argument list:	*aPosition*	A left coordinate value

A CSS-P positioning style attribute that controls the location of an element relative to its containing parent element. The left edges of the two elements are used as the reference points.

The value can be specified in the usual pixel or fractional em-dash measurement units or the `auto` keyword can be used to let the browser do the positioning itself.

The exact positioning is affected by settings for padding, border, margin, and whether the position property is set to absolute or relative.

See also:	Measurement units, `style.bottom`, `style.pixelLeft`, `style.posLeft`, `style.right`, `style.top`

style.length (Property)

The `style` object can be treated as if it were a collection. This property indicates the number of objects that are in the collection.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.length`

Property attributes:

`ReadOnly`.

Refer to:

`Collection.length`

style.letterSpacing (Property)

The letter spacing of text in a style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.letterSpacing`
CSS syntax:	`letter-spacing:` *`aValue`*	
Argument list:	*`aValue`*	A letter spacing factor

The text can be spaced out to fill a larger space or provide some emphasis. This property may also condense the spacing by specifying a negative value. The value specified is added to the normal spacing between characters.

You can use the pixel or em-dash length values and a floating point value can be specified for the em-dash measurement units. The `normal` keyword is reserved for restoring the value back to its default setting.

The `auto` keyword is also defined in the CSS specification and can be assigned to the property to let the browser assume control.

See also:	Measurement units

style.lineBreak (Property)

Line breaking control style for Japanese text layouts.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.lineBreak`
CSS syntax:	`line-break: aControl`	
Argument list:	*`aControl`*	One of the available keywords

This property controls the way that line breaks are handled for Japanese text.

The following keywords are supported:

- `normal`
- `strict`

style.lineHeight (Property)

Defines the height of a box that contains a line of text. This is the distance between the base lines of two adjacent lines of text.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.lineHeight
CSS syntax:	line-height: *aLineHeight*	
Argument list:	*aLineHeight*	A line height value

This property provides a way to adjust the leading or spacing between the lines of text. The value in this property describes the height of a bounding box that surrounds a single line of text.

This property can have a length value specified in pixels or floating point multiples of an em-dash in the current font. The `normal` keyword can also be used to restore the default behavior.

See also:	`JSSTag.lineHeight,style.font`

style.listStyle (Property)

A shortcut property for defining several list style attributes in a single assignment.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.listStyle
CSS syntax:	list-style: *aType aPosition anImage*	
Argument list:	*aType*	A list type
	aPosition	A bullet position control
	anImage	A bullet image URL

This property supports the assignment of values to the following properties in one single operation:

- `style.listStyleImage`
- `style.listStylePosition`
- `style.listStyleType`

Refer to the topics discussing each individual property for details of the values you can use.

The values can be specified in any order or combination because their namespaces do not collide.

See also:	`style.counterIncrement,style.listStyleImage, style.listStylePosition,style.listStyleType`

style.listStyleImage (Property)

A URL for an image resource to be used for bullets in a list style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.listStyleImage`
CSS syntax:	`list-style-image:` *anImage*	
Argument list:	*anImage*	A bullet image URL

You can modify the image used as a leading bullet in a list by defining a URL here. The image will be fetched by the browser and then placed into the page at the front of each list item.

Note that this property is cascaded down and inherited by other elements so if you want to create sub-lists you will need to redefine it in child list styles.

The `none` keyword will restore the list bullet to its default appearance.

See also:	`style.listStyle,style.listStyleType`

style.listStylePosition (Property)

A position control for a list marker.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.listStylePosition`
CSS syntax:	`list-style-position:` *aPosition*	
Argument list:	*aPosition*	A bullet position control

The list item marker can be positioned inside or outside the extent rectangle for the list item. The following keywords can be used with this property:

- `inside`
- `outside`

The bullet placement and indentation of the list item are left-justified differently according to the value of this property.

Note that there is some relationship between the behavior of this property and the alignment settings for the element in the list item.

See also:	Measurement units, `style.listStyle`

style.listStyleType (Property)

The type of list presentation marker for an ordered (`<OL>`) or unordered (`<UL>`) list.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.listStyleType`
CSS syntax:	`list-style-stype:` *`aType`*	
Argument list:	*`aType`*	A list type

You can define the way that list items are enumerated on the page. The specific details depend on whether the list item is a member of an ordered list (`<OL>`) or an unordered list (`<UL>`).

The following keywords are appropriate for use with unordered lists:

- `circle`
- `disc`
- `square`

The default setting for an unordered list will be a disc.

The following keywords are appropriate for an ordered list:

- `decimal`
- `lower-alpha`
- `lower-roman`
- `upper-alpha`
- `upper-roman`

The default setting for an ordered list is decimal.

The keywords for this property correspond with the values defined in `UL.type` and `OL.type` object properties. Although the notation is different the displayed artefacts will be the same.

This display control property is completely overridden if the `listStyleImage` property is set to a URL for an image. As long as the `listStyleImage` property is set to "`none`" or an empty ("") string this property comes into play.

See also:	`JSSTag.listStyleType`, `OL.type`, `style.counterIncrement`, `style.listStyle`, `style.listStyleImage`, `UL.type`

style.margin (Property)

The margin around a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.margin
CSS syntax:	margin: *aWidth* ...	
Argument list:	*aWidth*	Up to four width values can be specified

This property lets you change the width of one or more of the margins around an object.

If you specify only one value, all four margins are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right,while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Width values can be specified using pixel values, em-dash units or percentages of the next outermost parent object. The `auto` keyword lets the browser decide for itself.

Warnings:

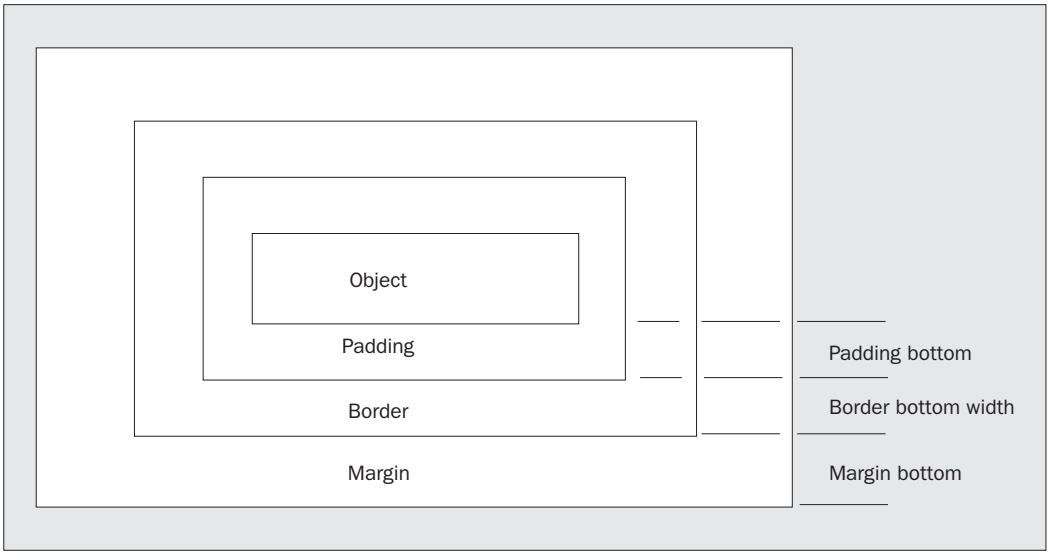
- Although both Netscape Navigator and MSIE support padding and margin control properties. It is not clear from the documentation sources whether they are simply different names for the same thing. Padding is a space that is placed outside the content rectangle of the element's extent. Margins also are not calculated as part of the element's width and height so they appear to be the same thing, although functionally they should be contained inside the extent rectangle if they behave in a manner consistent with the way that margins are generally assumed to work.
- Be wary of using margins and padding in case they undergo a functional change in the future.

See also:	`JSSTag.margins()`, Measurement units, `style.border`, `style.borderWidth`, `style.padding`

style.marginBottom (Property)

The thickness of the bottom margin of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.marginBottom
CSS syntax:	margin-bottom: *aWidth*	
Argument list:	*aWidth*	A margin width value



See also:	BODY.bottomMargin, JSSTag.marginBottom, style.margin

style.marginLeft (Property)

The thickness of the left margin of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.marginLeft
CSS syntax:	margin-left: *aWidth*	
Argument list:	*aWidth*	A margin width value
See also:	`BODY.leftMargin,JSSTag.marginLeft,style.margin`	

style.marginRight (Property)

The thickness of the right margin of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.marginRight
CSS syntax:	margin-right: *aWidth*	
Argument list:	*aWidth*	A margin width value
See also:	`BODY.rightMargin,JSSTag.marginRight,style.margin`	

style.marginTop (Property)

The thickness of the top margin of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.marginTop
CSS syntax:	margin-top: *aWidth*	
Argument list:	*aWidth*	A margin width value

See also:	`BODY.topMargin`, `JSSTag.marginTop`, `style.margin`

style.markerOffset (Property)

A spacing distance between the list item marker and the list item content.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.markerOffset
CSS syntax:	marker-offset: *aValue*	
Argument list:	*aValue*	A control for marker offsets

The distance between the marker and the text it is marking can be specified in length units. That is pixels or proportions of an em-dash. The `auto` keyword can be used to indicate default behavior, or the `inherit` keyword can indicate that the value should be defined in a parent element object.

See also:	Measurement units

style.marks (Property)

A control attribute that determines whether crop marks should be added to the page when it is printed.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.marks
CSS syntax:	marks: *aType*	
Argument list:	*aType*	A marker type

This is usually functionality that is reserved for printed pages. It is applied within the `@page` rule which is a special rule in the style sheet for laying out pages.

The following mark types are supported:

- `crop`
- `cross`

Crop marks are used for trimming while cross marks are used for aligning each print color in the press.

style.maxHeight (Property)

Defines the maximum height of a styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.maxHeight
CSS syntax:	max-height: *aValue*	
Argument list:	*aValue*	A maximum height value

This property provides a means of specifying the maximum height of an element so that it cannot get any bigger, regardless of the implications of the document flow and automatic browser formatting.

The value is expressed in the usual measurement units (either pixels or fractions of an em-dash). You can also use the percentage of the containing element as a maximum size.

The size of an element can be constrained using the minimum/maximum extents for the height and width. This ensures that the element's size will fall within the permitted bounds but yet still have some flexibility to allow the document flow to respond to window sizing.

See also:	Measurement units, `style.maxWidth`, `style.minHeight`

style.maxWidth (Property)

Defines the maximum width of a styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.maxWidth`
CSS syntax:	`max-width: `*`aValue`*	
Argument list:	*`aValue`*	A maximum width value

This property provides a means of specifying the maximum width of an element so that it cannot get any bigger, regardless of the implications of the document flow and automatic browser formatting.

The value is expressed in the usual measurement units (either pixels or fractions of an em-dash). You can also use the percentage of the containing element as a maximum size.

The size of an element can be constrained using the minimum/maximum extents for the height and width. This ensures that the element's size will fall within the permitted bounds, but yet still have some flexibility to allow the document flow to respond to window sizing.

See also:	Measurement units, `style.maxHeight`, `style.minWidth`

style.minHeight (Property)

Defines the minimum height of a styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.minHeight
CSS syntax:	min-height: *aValue*	
Argument list:	*aValue*	A minimum height value

This property provides a means of specifying the minimum height of an element so that it cannot get any smaller, regardless of the implications of the document flow and automatic browser formatting.

The value is expressed in the usual measurement units (either pixels or fractions of an em-dash). You can also use the percentage of the containing element as a maximum size.

The size of an element can be constrained using the minimum/maximum extents for the height and width. This ensures that the element's size will fall within the permitted bounds, but yet still have some flexibility to allow the document flow to respond to window sizing.

See also:	Measurement units, `style.maxHeight`, `style.minWidth`

style.minWidth (Property)

Defines the minimum width of a styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.minWidth
CSS syntax:	min-width: *aValue*	
Argument list:	*aValue*	A minimum width value

This property provides a means of specifying the minimum width of an element so that it cannot get any smaller, regardless of the implications of the document flow and automatic browser formatting.

The value is expressed in the usual measurement units (either pixels or fractions of an em-dash). You can also use the percentage of the containing element as a maximum size.

The size of an element can be constrained using the minimum/maximum extents for the height and width. This ensures that the element's size will fall within the permitted bounds but yet still have some flexibility to allow the document flow to respond to window sizing.

See also:	Measurement units, `style.maxWidth`, `style.minHeight`

style.orphans (Property)

Defines the minimum number of lines of a paragraph of text that must be visible at the bottom of a page when a page break is present. This is most likely to occur when printing documents.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.orphans
CSS syntax:	orphans: *aCount*	
Argument list:	*aCount*	A number of lines for an orphan count

Widows and orphans are fragments of text that appear to be formatted incorrectly when a paragraph of text spans a page break.

Windows and orphans are usually controlled together and the usual technique is to specify that an entire paragraph should be kept on the same page. This forces the paragraph to be taken over to the next page in its entirety, even if the flow requires just a single word to be taken over.

The CSS styling controls allow a finer level of control in that you can allow for a paragraph to be split across a page boundary, but specify a lower limit on the number of lines that must be kept on a single page.

This is fine in principle, but there can be some contention for the right layout when a very short paragraph is spanning a page break. This will generally be solved simply by forcing the page break to happen before the paragraph causing the whole paragraph to be carried over to the next page.

An orphan is that fragment of text that is left at the bottom of a page when a paragraph encloses a page break. It is the topmost few lines of the paragraph. The integer value in this property controls the minimum number of lines that must be present, otherwise the paragraph will be taken over entirely to the next page.

See also:	`style.pageBreakAfter`, `style.size`, `style.widows`

style.outline (Property)

A shortcut attribute for defining all the outline settings together.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.outline
CSS syntax:	outline: *aColour aStyle aWidth* outline: aControl	
Argument list:	*aColour*	An outline color value
	aStyle	A style of outlining
	aWidth	A thickness of the outline
	aControl	A control over inheritance

An outline is like a border but it is drawn within the extent of the object. It is intended to be drawn and then removed and is useful for those times when you want to border something without the border taking up any space. Its width is measured inwards from the outer edge of an object.

This property is a means of defining the following style properties with a single assignment:

- `style.outlineColor`
- `style.outlineStyle`
- `style.outlineWidth`

Because the namespaces do not collide, they can be specified in any order.

See also:	`style.border,style.outlineColor, style.outlineStyle,style.outlineWidth`

style.outlineColor (Property)

The color of a border outline around the styled element.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myStyle*.outlineColor
CSS syntax:	outline-color: *aColor*	
Argument list:	*aColor*	An outline color value

This property lets you change the color of one or more of the outlines around an object.

If you specify only one value, all four outlines are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Color values can be specified using symbolic names, `rgb()` functions or hash delimited hex values.

See also:	Color names, Color value, `rgb()`, `style.borderColor`, `style.outline`

style.outlineStyle (Property)

The border style for an outline around a styled element.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.outlineStyle
CSS syntax:	outline-style: *aStyle*	
Argument list:	*aStyle*	A style of outlining

This property lets you change the style of one or more of the outlines around an object.

If you specify only one value, all four outlines are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Style values can be specified using symbolic names as follows:

- `solid`
- `dashed`
- `dotted`

- double
- inset
- outset
- groove
- ridge
- hidden
- none

See also:	style.borderStyle, style.outline

style.outlineWidth (Property)

The width of a border that outlines a styled element.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.outlineWidth
CSS syntax:	outline-width: *aWidth*	
Argument list:	*aWidth*	A thickness of the outline

This property lets you change the width of one or more of the outlines around an object.

If you specify only one value, all four outlines are set. Two values define the top and bottom with the first, and the second then applies to the left and right. If three values are specified, the first controls the top, the second controls both left and right, while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order: top, right, bottom and left.

Width values can be specified using symbolic names or pixel values. The following symbolic names are available:

- thin
- medium
- thick

See also:	style.borderWidth, style.outline

style.overflow (Property)

The overflow style that defines how to display content that is too large to fix the element's stated box size.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.overflow
CSS syntax:	overflow: *aType*	
Argument list:	*aType*	An overflow type specifier

Sometimes you may add content to an element and cause the element to overflow its bounding extent rectangle. This property helps the browser determine what it should do with that overflowed content.

The following keywords may be applied to this property:

- `auto`
- `hidden`
- `scroll`
- `visible`

The general approach to handling overflow is to wrap the content within the width and increase the height to accommodate the flow. This may not be appropriate for some objects whose width formatting is fixed. This would be the case with a `PRE` object for example.

The `visible` setting allows the width to be expanded to accommodate the object in attempt to keep it all visible at once.

The `hidden` setting preserves the settings for the height and width. It may rearrange the content to better fill the extent rectangle, but it may clip the content within the extent rectangle so that the object retains the size it had already been defined to be presented with.

The `scroll` setting allows for scroll bars to be placed within the extent rectangle of the object itself if the content exceeds the present settings of the height and width extent rectangle. This behavior is not consistent across all platforms.

The `auto` setting displays scrollbars within the extent rectangle of the object if necessary, but appears to be functionally identical to the scroll value being defined. Again, this is not consistently supported across the platforms.

The workings of this property may be affected by the value defined for the `position` property. That is, this overflow technique is applicable to absolutely positioned elements.

Warnings:

- Some versions of the MSIE browser on the Macintosh platform cannot cope with a `scroll` or `auto` attribute in this property. The scrollbars simply don't appear.

See also:	`PRE` object, `style.position`

style.overflowX (Property)

A definition of how to handle horizontally overflowing content.

Availability:	JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.overflowX
CSS syntax:	`overflow-x:` *aType*	
Argument list:	*aType*	An overflow type specifier

Refer to:

`style.overflow`

style.overflowY (Property)

A definition of how to handle vertically overflowing content.

Availability:	JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.overflowY
CSS syntax:	`overflow-y:` *aType*	
Argument list:	*aType*	An overflow type specifier

Refer to:

`style.overflow`

style.padding (Property)

A shortcut means of specifying all the padding attributes for a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.padding
CSS syntax:	padding: *aWidth* ...	
Argument list:	*aWidth*	Up to four padding widths

This property lets you change the width of one or more of the padding regions around an object.

If you specify only one value, all four padding regions are set. Two values define the top and bottom with the first, and the second then applies to the left and right,. If three values are specified, the first controls the top, the second controls both left and right while the third controls the bottom edge. When all four values are specified, they are assumed to be in the order, top, right, bottom and left.

Width values can be specified using pixel values, em-dash units or percentages of the next outermost parent object. The `auto` keyword lets the browser decide for itself.

You can also specify the values independently with the following properties:

- `style.paddingBottom`
- `style.paddingLeft`
- `style.paddingRight`
- `style.paddingTop`

Warnings:

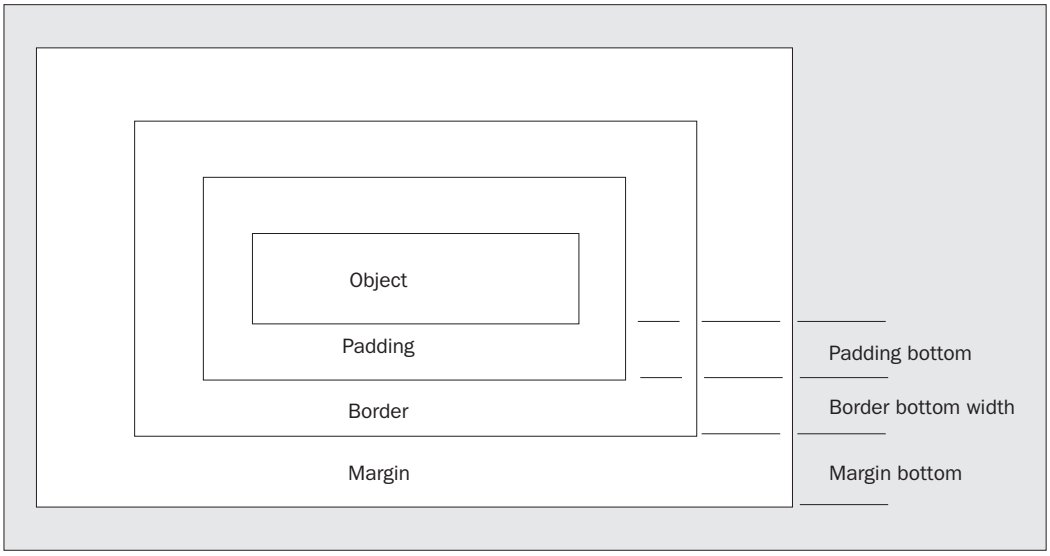
- Although both Netscape Navigator and MSIE support padding and margin control properties, it is not clear from the documentation sources whether they are simply different names for the same thing. Padding is a space that is placed outside the content rectangle of the element's extent. Margins also are not calculated as part of the element's width and height so they appear to be the same thing, although functionally they should be contained inside the extent rectangle, if they behave in a manner consistent with the way that margins are generally assumed to work.
- Be wary of using margins and padding in case the way they are implemented undergoes a functional change in the future.

See also:	`JSSTag.paddings()`, Measurement units, style.border, `style.margin`

style.paddingBottom (Property)

A value for the thickness of the padding space at the bottom of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.paddingBottom
CSS syntax:	padding-bottom: *aWidth*	
Argument list:	*aWidth*	A padding width value



See also:	`JSSTag.paddingBottom`, Measurement units, `style.padding`, `style.margin`

style.paddingLeft (Property)

A value for the thickness of the padding space to the left of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.paddingLeft
CSS syntax:	padding-left: *aWidth*	
Argument list:	*aWidth*	A padding width value
See also:	`JSSTag.paddingLeft`, Measurement units, `style.padding`, `style.margin`	

style.paddingRight (Property)

A value for the thickness of the padding space to the right of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.paddingRight
CSS syntax:	padding-right: *aWidth*	
Argument list:	*aWidth*	A padding width value
See also:	`JSSTag.paddingRight`, Measurement units, `style.padding`, `style.margin`	

style.paddingTop (Property)

A value for the thickness of the padding space at the top of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.paddingTop
CSS syntax:	padding-top: *aWidth*	
Argument list:	*aWidth*	A padding width value

See also:	`JSSTag.paddingTop`, Measurement units, `style.padding`, `style.margin`

Refer to:

style.page (Property)

A means of placing a styled element onto a particular page. If necessary a page break will be created to accommodate the required location.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.page
CSS syntax:	page: *aValue*	
Argument list:	*aValue*	A page identifier

This is part of the printing support in CSS. The property can accept either the `auto` keyword, which allows the element to be printed on the current page. It can also have a named page layout cited as an identifier value. That named layout must have been created earlier in the style sheet.

When this style is deployed, one of two possibilities pertains. It names a page layout which is the current layout being rendered or some other layout that is currently being written on. If the identifier corresponds to the layout currently being rendered, then the element is simply added to the page unless the page is full and then a new page is created in the normal way. If the page currently being rendered is of another type, that is its layout is different, then a new page is started and the element is the first item placed on it.

See also:	`style.size`

style.pageBreakAfter (Property)

The placement of a page break after the styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyle`*`.pageBreakAfter`
CSS syntax:	`page-break-after:` *`aSwitch`*	
Argument list:	*`aSwitch`*	A page break control value

This is part of the support for printing pages. A browser doesn't need to mark the breaks between pages because its pages are of unlimited length and width when the scrollbars are present. You need this for printouts, though, because the paper has a finite size.

The following keywords can be applied to this property:

- `auto`
- `left`
- `right`
- `always`
- `avoid`
- `inherit`

These attributes are part of the CSS level 2 specification, which is not yet fully supported in most browsers.

The `auto` setting allows the browser to use its best opinion on whether to place a page break after the element.

The `left` and `right` keywords provide a swinging format capability based on whether the page is an odd or even page (by implication odd number pages are rightwards). This allows page breaks to be placed depending on whether element flows onto a right or leftwards facing page.

The `always` value requires that a page break happens after this element on every occasion regardless of whether the page is odd or even.

The CSS level 2 standard allows for the property to contain the `avoid` value. This is not yet supported in all browsers and simply inhibits page breaks after the element.

The above all applies equally to the `pageBreakBefore` property apart from noting that the page break is placed prior to the object rather than after it.

The `pageBreakInside` property only honors the `auto`, `avoid` and `inherit` keywords.

Warnings:

- This property does not work consistently across browsers and platforms. Unusually, it works better in MSIE for Macintosh than Windows.

See also:	`style.orphans`, `style.size`, `style.widows`

style.pageBreakBefore (Property)

The placement of a page break before the styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.pageBreakBefore`
CSS syntax:	`page-break-before:` *aSwitch*	
Argument list:	*aSwitch*	A page break control value

See also:	`style.size`, `style.pageBreakAfter`

style.pageBreakInside (Property)

Indicates whether a page break can occur inside the element if necessary.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.pageBreakInside
CSS syntax:	page-break-inside: *aSwitch*	
Argument list:	*aSwitch*	A page break control value

See also:	style.page, style.size, style.pageBreakAfter

style.pause (Property)

Part of the aural style control suite that defines a momentary pause before or after an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.pause
CSS syntax:	pause: *aTime*	
Argument list:	*aTime*	A pause duration between speeches

This is a shortcut property for defining the `pauseBefore` and `pauseAfter` values in a single assignment. The two values should be space separated. If you only specify one, it will be assigned to both properties. If you specify two values, the first is used as `pauseBefore` and the second as `pauseAfter`.

The values are specified as time units. These are a floating point value with either the `ms` or `s` suffix to denote the unit of measure.

You can specify a percentage value which is used to calculate a proportion of the time taken to speak a single word at the words-per-minute rate defined in the `speechRate` property.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, Measurement units, `style.pauseAfter`, `style.pauseBefore`, `style.speechRate`

style.pauseAfter (Property)

Part of the aural style control suite that defines a momentary pause after an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	`myStyle.pauseAfter`
CSS syntax:	`pause-after: aTime`	
Argument list:	*`aTime`*	A pause duration after speech

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.pause`

style.pauseBefore (Property)

Part of the aural style control suite that defines a momentary pause before an item is spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*`myStyle`*`.pauseBefore`
CSS syntax:	`pause-before: aTime`	
Argument list:	*`aTime`*	A pause duration before speech

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.pause`

style.pitch (Property)

Part of the aural style control suite that defines the average pitch frequency of the voice used to speak the text.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.pitch
CSS syntax:	pitch: *aFrequency*	
Argument list:	*aFrequency*	A frequency to pitch the voice

You can specify the value in hertz or kilohertz. The measurement units specifier for these would be `Hz` or `kHz`. The numeric values would normally be an integer for the Hz units and a floating point value for the kHz units. If you prefer, the following keywords can be used:

- `x-low`
- `low`
- `medium`
- `high`
- `x-high`

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, Measurement units

style.pitchRange (Property)

Part of the aural style control suite that defines the variance of the spoken voice pitch when it is capable of rendering emphasis by changing its average pitch.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.pitchRange
CSS syntax:	pitch-range: *aRange*	
Argument list:	*aRange*	A range of pitch variation

The pitch range allows for the voice to raise and fall during speech to make it sound more interesting.

The value of `0` can be used to prevent any pitch change during speech. This would cause speech to use a monotone and sound very dull. A value of `50` would sound normal while a value of `100` would sound somewhat excited.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.richness`

style.pixelBottom (Property)

The location of the styled element measured in pixel units within the page.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.pixelBottom`
CSS syntax:	`pixel-bottom:` *aValue*	
Argument list:	*aValue*	A positioning value

This object was added in version 5 of MSIE to complete the set of positioning properties already available with the `style` object in earlier versions of MSIE.

Objects can be positioned on screen with this property. This value defines the location of the bottom edge of a styled element. The bottom edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.bottom` property which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posBottom` property for a more generalized value that can be operated on with different measurement units.

See also:	Measurement units, `style.bottom`, `style.posBottom`

style.pixelHeight (Property)

The pixel height of the styled element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.pixelHeight`
CSS syntax:	`pixel-height:` *aHeight*	
Argument list:	*aHeight*	A sizing value

Although this is a read and write property, it is most likely to be useful for measuring the height of an object to get a numeric value without the trailing `px` suffix that you get when enquiring the `style.height` value.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posHeight` property for a more generalized value that can be operated on with different measurement units.

See also:	Measurement units, `style.height`, `style.pixelWidth`, `style.posHeight`

style.pixelLeft (Property)

The pixel position of the left edge of the styled element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.pixelLeft`
CSS syntax:	`pixel-left:` *aValue*	
Argument list:	*aValue*	A positioning value

Objects can be positioned on screen with this property. This value defines the location of the left edge of a styled element. The left edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

The value in this property should be reflected in the `Element.offsetLeft` property.

This property will be useful as an alternative to the `style.left` property which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posLeft` property for a more generalized value that can be operated on with different measurement units.

See also:	`Element.offsetLeft`, `Layer.left`, Measurement units, `style.left`, `style.posLeft`

style.pixelRight (Property)

The pixel position of the right edge of the styled element.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.pixelRight`
CSS syntax:	`pixel-right:` *aValue*	
Argument list:	*aValue*	A positioning value

This object was added in version 5 of MSIE to complete the set of positioning properties already available with the `style` object in earlier versions of MSIE.

Objects can be positioned on screen with this property. This value defines the location of the right edge of a styled element. The right edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.right` property, which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posRight` property for a more generalized value that can be operated on with different measurement units.

See also:	Measurement units, `style.posRight`, `style.right`

style.pixelTop (Property)

The pixel position of the top edge of the styled element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.pixelTop
CSS syntax:	pixel-top: *aValue*	
Argument list:	*aValue*	A positioning value

Objects can be positioned on screen with this property. This value defines the location of the top edge of a styled element. The top edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

The value in this property should be reflected in the `Element.offsetTop` property.

This property will be useful as an alternative to the `style.top` property which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posTop` property for a more generalized value that can be operated on with different measurement units.

See also:	`Element.offsetTop`, `Layer.top`, Measurement units, `style.posTop`, `style.top`

style.pixelWidth (Property)

The pixel width of the styled element.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	myStyle.pixelWidth
CSS syntax:	pixel-width: *aWidth*	
Argument list:	*aWidth*	A sizing value

Although this is a read and write property, it is most likely to be useful for measuring the width of an object to get a numeric value without the trailing `px` suffix that you get when enquiring the `style.width` value.

The value in this property will be an integer defined in pixel measurement units only. This is regardless of the settings of the measurement units in the CSS attribute. Refer to the `style.posWidth` property for a more generalized value that can be operated on with different measurement units.

See also:	Measurement units, `style.pixelHeight`, `style.posHeight`, `style.posWidth`, `style.width`

style.playDuring (Property)

Part of the aural style control suite that controls the mix between foreground and background sound effects.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.playDuring`
CSS syntax:	`play-during:` *aControl*	
Argument list:	*aControl*	A mix control for background sounds

Foreground and background sound effects need to be controlled carefully and blended properly, so that background noises such as music and sound effects do not distract from the speech.

The values for this comprise a URI value and an optional controlling parameter. The value should be space-separated.

The URI specifies an audio file to be downloaded and played in the background.

The following keywords control how the background sound is mixed with any parent object's sound effects:

- `mix`
- `repeat`
- `auto`
- `none`

The `mix` keyword combines any sounds already playing as defined by parent elements.

The `repeat` keyword allows for the background sound to be looped as required to extend it to the same length as the spoken content.

The `auto` value allows the parent elements sound effects to be played without being interrupted by this elements sounds.

The `none` value turns off any sound effects inherited from parent objects only playing sounds controlled by this object.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.posBottom (Property)

A measurement unit independent positioning control property.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.posBottom`
CSS syntax:	`pos-bottom: aValue`	
Argument list:	*aValue*	A positioning value

This object was added in version 5 of MSIE to complete the set of positioning properties already available with the `style` object in earlier versions of MSIE.

Objects can be positioned on screen with this property. This value defines the location of the bottom edge of a styled element. The bottom edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.bottom` property, which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in the measurement units defined by the CSS attribute. Refer to the `style.pixelBottom` property for a more specialized value that can be operated on unambiguously in pixel measurement units.

See also:	Measurement units, `style.bottom`, `style.pixelBottom`

style.posHeight (Property)

A measurement unit independent size control property.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.posHeight`
CSS syntax:	`pos-height:` *aHeight*	
Argument list:	*aHeight*	A sizing value

Although this is a read and write property, it is most likely to be useful for measuring the height of an object to get a numeric value without the trailing measurement unit suffix that you get when enquiring the `style.width` value.

The value in this property will be an integer defined in CSS attribute defined measurement units only. Refer to the `style.pixelHeight` property for a more specialized value that can be operated on unambiguously using pixel values.

See also:	Measurement units, `style.height`, `style.pixelHeight`, `style.pixelWidth`, `style.posWidth`

style.position (Property)

A flag to indicate relative or absolute positioning of an element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.position = "absolute"`
	-	*myStyle*`.position = "relative"`
CSS syntax:	`position:` *aControl*	
Argument list:	*aControl*	A positioning control

In MSIE, this value returns a floating point value reflecting the current value of the position attribute for the `styleSheet` object.

You can define other values for this according to the available keywords:

- `absolute`
- `relative`
- `fixed`
- `normal`
- `static`

The `absolute` keyword applies to element objects that are positioned with respect to the document boundaries.

The `relative` keyword applies to element objects that are positioned with respect to a parent or containing element object.

The `fixed` keyword is defined in the CSS standard to mean that an element object should be positioned with respect to the display window.

The `normal` keyword is equivalent to the CSS defined static keyword and applies to objects whose position is controlled by the text flow. These can be block or inline structured objects.

Warnings:

- `Element` objects in Netscape Navigator 4 are positioned by means of the layer capabilities of that version of the browser. Any object that has its position property set to the absolute value will need to be managed in a layer of its own, so that it can be positioned independently of any other objects in the page. These layers are accessible via the `layers[]` property of the document.
- As of Netscape 6.0, layers are completely deprecated and have not been implemented. If you use layers at all, your pages are going to break.
- The `style.position` property is not supported consistently across browsers. Nor is it supported according to the defined default values in the CSS standard.
- The fixed keyword is not yet properly supported in MSIE.
- Netscape 6.0 does not support the `normal` keyword although it supports the functionally identical `static` keyword.

See also:	`Document.layers[]`, Dynamic positioning, Measurement units, `style.overflow`

Property attributes:

`ReadOnly`.

style.posLeft (Property)

A measurement unit independent positioning control property.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.posLeft`
CSS syntax:	`pos-left:` *`aValue`*	
Argument list:	*`aValue`*	A positioning value

Objects can be positioned on screen with this property. This value defines the location of the left edge of a styled element. The left edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.left` property which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in the measurement units defined by the CSS attribute. Refer to the `style.pixelLeft` property for a more specialized value that can be operated on unambiguously in pixel measurement units.

See also:	`Element.offsetLeft`, `Layer.left`, Measurement units, `style.left`, `style.pixelLeft`

style.posRight (Property)

A measurement unit independent positioning control property.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.posRight`
CSS syntax:	`pos-right:` *aValue*	
Argument list:	*aValue*	A positioning value

This object was added in version 5 of MSIE to complete the set of positioning properties already available with the `style` object in earlier versions of MSIE.

Objects can be positioned on screen with this property. This value defines the location of the right edge of a styled element. The right edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.right` property which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in the measurement units defined by the CSS attribute. Refer to the `style.pixelRight` property for a more specialized value that can be operated on unambiguously in pixel measurement units.

See also:	Measurement units, `style.pixelRight`, `style.right`

style.posTop (Property)

A measurement unit independent positioning control property.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.posTop`

CSS syntax:	pos-top: *aValue*	
Argument list:	*aValue*	A positioning value

Objects can be positioned on screen with this property. This value defines the location of the top edge of a styled element. The top edge includes padding, borders and margins around the object as well as its content. The position is located with reference to the next outermost (parent) container.

This property will be useful as an alternative to the `style.top` property, which includes the measurement units when a value is read back from it.

The value in this property will be an integer defined in the measurement units defined by the CSS attribute. Refer to the `style.pixelTop` property for a more specialized value that can be operated on unambiguously in pixel measurement units.

See also:	`Element.offsetTop`, `Layer.top`, Measurement units, `style.pixelTop`, `style.top`

style.posWidth (Property)

A measurement unit independent size control property.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.posWidth
CSS syntax:	pos-width: *aWidth*	
Argument list:	*aWidth*	A sizing value

Although this is a read and write property, it is most likely to be useful for measuring the width of an object to get a numeric value without the trailing measurement unit suffix that you get when enquiring the `style.width` value.

The value in this property will be an integer defined in CSS attribute defined measurement units only. Refer to the `style.pixelWidth` property for a more specialized value that can be operated on unambiguously using pixel values.

See also:	Measurement units, `style.pixelWidth`, `style.posHeight`, `style.width`

style.quotes (Property)

A list of quotation marks to use for progressively quoted content that may have nested quotation marks.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.quotes
CSS syntax:	`quotes: aValue`	
Argument list:	*aValue*	A string to use for quoting text

If you specify quotes, you should indicate pairs of quotes. Each quote should be enclosed it its own set of delimiters, which then allows multiple characters to be used for each quotation symbol.

You can alternatively use the value `none` or `inherit`.

style.removeExpression() (Method)

An MSIE extension for managing style controls.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myStyle*.removeExpression(*aProperty*)
Argument list:	*aProperty*	The name of the property whose expression is to be removed

This is part of the MSIE support for managing style expressions. With this method, you can remove an expression that was previously defined with the `setExpression()` method.

See also:	`Element.getExpression(),`
	`Element.removeExpression(),`
	`Element.setExpression(),style.getExpression(),`
	`style.setExpression()`

style.renderingIntent (Property)

An MSIE extension to control the rendering of the page. This is part of the color modeling and preservation of true color representations.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.renderingIntent`
CSS syntax:	`rendering-intent:` *aControl*	
Argument list:	*aControl*	A rendering intent specifier value

As yet, this is still being worked on. Early drafts suggest the following keywords will be available:

- `auto`
- `perceptual`
- `relative-colorimetric`
- `saturation`
- `absolute-colorimetric`

See also:	Color names, Color value, `style.color`, `style.colorProfile`

style.richness (Property)

Part of the aural style control suite that defines the forcefulness of the spoken voice.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.richness`
CSS syntax:	`richness:` *aValue*	
Argument list:	*aValue*	A voice quality control value

This control affects the animation, sometimes called brightness or stridency, in the voice.

The value `50` is used as the default and with this setting the voice will sound as if it's normal.

Reducing this value makes the voice more mellow and soft. Extremely low values might almost be whispered.

Increasing value to `100` makes the voice very forceful, almost shouting.

The value can be specified as a floating point value to control the richness very finely.

The behavior of the spoken voice when controlled by the aural style properties does very much depend on the in-built speech capabilities of the platform. The Macintosh already supports a very versatile and realistic voice synthesizer as an integral component of its operating system. It would be interesting to experiment with this if it were integrated with a usable browser.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.pitchRange`

style.right (Property)

A positioning reference point.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.right`
CSS syntax:	`right:` *aPosition*	
Argument list:	*aPosition*	A right coordinate value

A CSS-P positioning style attribute that controls the location of an element relative to its containing parent element. The right edges of the two elements are used as the reference points.

The value can specified in the usual pixel or fractional em-dash measurement units or the `auto` keyword can be used to let the browser do the positioning itself.

The exact positioning is affected by settings for padding, border, margin and the position property.

See also:	Measurement units, `style.bottom`, `style.left`, `style.pixelRight`, `style.posRight`, `style.top`

style.rowSpan (Property)

An indication of how many rows a table cell should span.

Availability:	CSS level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.rowSpan
CSS syntax:	row-span: *aRowCount*	
Argument list:	*aRowCount*	A number of rows to span in a table

This is used when you want to create complex tables, and can be used as an alternative to nesting a table. Avoiding nested tables is good because they can be quite unwieldy.

This is related somewhat to the `rowSpan` property of the `TD` and `TH` objects and controls the same behavior.

See also:	`TABLE` object, `TD.rowSpan`, `TH.rowSpan`

style.rubyAlign (Property)

An MSIE extension to support the alignment of ruby elements.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.rubyAlign
CSS syntax:	ruby-align: *aControl*	
Argument list:	*aControl*	An alignment control keyword

This controls the alignment of the ruby text with respect to the base text.

The following keywords are supported:

- `auto`
- `left`
- `center`
- `right`
- `distribute-letter`
- `distribute-space`
- `line-edge`

See also:	`RUBY` object

style.rubyOverhang (Property)

An MSIE extension to support the alignment of styled elements.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.rubyOverhang`
CSS syntax:	`ruby-overhang: `*`aControl`*	
Argument list:	*`aControl`*	A definition of the kind of overhang to display

This defines the overhang of the ruby text with respect to its base text.

The following keywords are accepted:

- `auto`
- `whitespace`
- `none`

See also:	`RUBY` object

style.rubyPosition (Property)

An MSIE extension to support the alignment of styled elements.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.rubyPosition`
CSS syntax:	`ruby-position: `*`aPosition`*	
Argument list:	*`aPosition`*	A specifier for where the ruby is to be placed

This defines the position of the ruby text with respect to its base text.

The following keywords are accepted:

- `above`
- `inline`

See also:	`RUBY` object

style.scrollbar3dLightColor (Property)

Access to the scrollbar colors.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbar3dLightColor`
CSS syntax:	`scrollbar-3d-light-color : aColor`	
Argument list:	*`aColor`*	A color value

This provides a means of reading or writing the color value for a scroll box and its scrollbar.

The value is one of the usual color values.

See also:	Color names, Color value

style.scrollbarArrowColor (Property)

Defines the arrow color of a scrollbar.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarArrowColor`
CSS syntax:	`scrollbar-arrow-color: aColor`	
Argument list:	*`aColor`*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.scrollbarBaseColor (Property)

Defines the base color of a scrollbar.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarBaseColor`
CSS syntax:	`scrollbar-base-color: aColor`	
Argument list:	*`aColor`*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.scrollbarDarkShadowColor (Property)

Defines the dark shadow color of a scrollbar.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarDarkShadowColor`
CSS syntax:	`scrollbar-dark-shadow-color: aColor`	
Argument list:	*`aColor`*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.scrollbarFaceColor (Property)

Defines the face color of a scrollbar.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarFaceColor`

CSS syntax:	`scrollbar-face-color: aColor`	
Argument list:	*aColor*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.scrollbarHighlightColor (Property)

Defines the highlight color of a scrollbar

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarHighlightColor`
CSS syntax:	`scrollbar-highlight-color: aColor`	
Argument list:	*aColor*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.scrollbarShadowColor (Property)

Defines the shadow color of a scrollbar.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.scrollbarShadowColor`
CSS syntax:	`scrollbar-shadow-color: aColor`	
Argument list:	*aColor*	A color value

This is a color value specified in the normal way.

See also:	Color names, Color value

style.setAttribute() (Method)

A method for setting attributes in styles.

Availability:	JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myStyle*.setAttribute(*aName*, *aValue*)
Argument list:	*aName*	The name of an attribute to set
	aValue	The value to be stored in the attribute

This method is used to define attribute values that can be accessed or redefined later on.

See also:	style.getAttribute()

style.setExpression() (Method)

An MSIE extension for managing style controls.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myStyle*.setExpression(*aName*, *anExpression*, *aLanguage*)
Argument list:	*aName*	The name of the property
	anExpression	The expression to be evaluated
	aLanguage	The language to use when evaluating the expression

This is used to set the values for expressions within the style handling complex. You can later retrieve the value of these expressions with the `getExpression()` method or delete them with the `removeExpression()` method.

The rules that are used to construct a style are comprised of multiple expressions. You can use this method to assign a new value to an expression within a style item with that value being generated by a callback to a script function.

Given the rule might contain a line such as:

```
width:200px
```

the `setExpression()` method can be applied to the style object containing the rule with that expression like this:

```
myStyle.setExpression("width:", "callBack()", "JavaScript")
```

The value of the width parameter would then be defined by the result of calling the `callBack()` function in the JavaScript context.

The expressions are attached to style properties and can be executed in a variety of languages. The language argument can be one of the following:

- `JavaScript`
- `JScript`
- `VBScript`

See also:	`Element.getExpression(), Element.removeExpression(), Element.setExpression(),style.getExpression(), style.removeExpression()`

Style.size (Property)

Defines the size and orientation of a bounding box on a printed page.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.size`
CSS syntax:	`size:` *anAspect*`size:` *aSize anAspect*`size:` *aWidth aHeight anAspect*	
Argument list:	*aSize*	When only one length value is specified, the page is square
	anAspect	An aspect ration control
	aWidth	A page width
	aHeight	A page height

This is part of the printing control mechanism in the CSS level 2 specification.

It provides a way to set the page size and aspect ration of the printed output. This should not affect the display of the page on the screen.

There are three parameter values expected. The first two are numeric values describing the page size. These are expressed in measurement units. You can optionally only include one because the third parameter is a keyword. If you omit both of the numeric values, the page size is assumed to be that of the printer by default. If only one is specified, then a square printable area is defined. Two values control the page width and page height respectively.

Printers may apply a non-printable margin area to the page, and the value you specify here must fit within it otherwise the content may be cropped when it is printed.

The last parameter value is specified using one of the following keywords:

- `auto`
- `portrait`
- `landscape`

See also:	`STYLE.media`, `style.orphans`, `style.page`, `style.pageBreakAfter`, `style.widows`

style.speak (Property)

Part of the aural style control suite that defines whether the content should be spoken out loud or not.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.speak`
CSS syntax:	`speak:` *aType*	
Argument list:	*aType*	A speech type

If the browser is equipped to utilize the platform's text to speech capabilities, this will cause the content of the element to be spoken out.

Realistically, the element must have some textual content to speak. The element is not going to make for a very interesting spoken phrase if it is an image, although the `ALT` text of the image might be used if it is defined.

The kind of speech is controlled with these keywords:

- `none`
- `normal`
- `spell-out`

The `none` keyword inhibits the text to speech capabilities.

The `normal` keyword reads the word as best it can. Sometimes this might use phonetic rules to pronounce the word and this may sound strange.

The `spell-out` keyword forces the content to be read out one letter at a time. This may be more helpful if there are complex words that the phonetic rules don't cope with very well, or if the content is a formula or other kind of algebraic expression. This may also be useful for abbreviations or acronyms.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speakDate (Property)

A format control that dictates the order in which date items are spoken.

Availability:	CSS level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.speakDate
CSS syntax:	speak-date: *aFormat*	
Argument list:	*aFormat*	A date format to speak

Date values may need to be spoken in a manner appropriate to the context of the listener.

This for example may require the order in which the date components should be spoken to manage the regional differences. Typically the American English and UK English language variants exchange the day and month values for example.

The following keywords are supported to select an order for reading out the Day, Month and Year components of a date value:

- `mdy`
- `dmy`
- `ymd`

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speakHeader (Property)

Part of the aural style control suite that defines whether a table cell's header description is spoken before the content of the cell itself.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.speakHeader
CSS syntax:	speak-header: *aSwitch*	
Argument list:	*aSwitch*	A control for how often to speak table headers

When the contents of a table are being read out, it can become confusing if the table content is simply read out cell by cell. This property indicates how often the column headings should be read out prior to reading the contents of each cell. It supports the keywords `once` and `always`.

The `once` keyword dictates that table column headings should be spoken once at the start of reading out the table.

The `always` keyword mandates that the column heading be spoken immediately prior to each cell in the row.

Other keywords may be added to this property in due course to allow more flexible ways of reading out table headings.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speakNumeral (Property)

Part of the aural style control suite that defines whether numbers are spoken individually or in a compounded form.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.speakNumeral
CSS syntax:	speak-numeral: *aType*	
Argument list:	*aType*	A manner in which to read numeric values

This property controls how numeric values are read out. Long numeric values would normally be read out one digit at a time, but a year number might be read out as a compound string.

The CSS2 standard dictates that the language for reading the numbers should be defined with the `LANG="..."` HTML tag attribute for the HTML tag that instantiates the object that this style applies to.

The following keywords can be used with this property:

- `none`
- `digits`
- `continuous`

The `none` keyword inhibits the reading out of numbers.

The `digits` keyword forces numeric values to be read out one digit at a time. For example, 2000 would be pronounced as "Two zero zero zero" if the spoken language is English.

The `continuous` keyword forces numeric values to be read out as a word or string of words compounded together. For example, 2000 would be pronounced as "Two thousand" if the spoken language is English.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speakPunctuation (Property)

Part of the aural style control suite that defines whether punctuation is spoken, or whether it affects the phrasing and delivery of the speech.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	`myStyle.speakPunctuation`
CSS syntax:	`speak-punctuation: aType`	
Argument list:	*`aType`*	A manner in which to speak punctuation characters

For some textual content, it may be important that the punctuation is spelled out one punctuation symbol at a time. In other contexts it may be appropriate for the text-to-speech handler to use the punctuation to control the phasing and intonation of the voice.

The `none` and `code` keywords can be used with this property.

The `none` keyword means that punctuation is interpreted and should affect the phasing of the spoken text.

The `code` keyword forces the text-to-speech output to enumerate each punctuation symbol as it is encountered. How this might affect the inflection and enunciation of the voice may be platform dependant.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speakTime (Property)

Part of the aural style control suite that defines the format of time values and whether they are spoken in 12 or 24 hour format.

Availability:	CSS level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	`myStyle.speakTime`
CSS syntax:	`speak-time: aFormat`	
Argument list:	*`aFormat`*	A format according to which time values should be spoken

Spoken time values may be controlled with some very minimal keywords to determine whether to use a 12 hour or 24 hour clock for the basis of the spoken time. The following keyword values are appropriate:

- `none`
- `12`
- `24`

The `none` keyword inhibits time speaking, while the other two select an appropriate time pronunciation.

There is scope for more control over the way this property is used in future versions of the CSS standard.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.speechRate (Property)

Part of the aural style control suite that defines the rate at which the text is spoken out loud.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*`myStyle`*`.speechRate`
CSS syntax:	`speech-rate:` *`aSpeed`*	
Argument list:	*`aSpeed`*	A speed at which the text should be spoken

The speech rate may be adjusted to provide a fast talking voice or a slower voice for more complex spoken content.

The property may have a numeric value assigned to indicate how many words should be read per minute. This would be an average value on the grounds that some words may take longer to pronounce than others. The speech rate can be specified as a floating point value for very fine control over the speech rate.

There are also a set of keywords so you can specify a generic absolute value. These are the keywords that are supported:

- `x-slow`
- `slow`
- `medium`
- `fast`
- `x-fast`

Speech rates can be adjusted relative to a parent or containing element object. Assuming a speech rate is defined for a parent object, then you can use the relative speech rate keywords `slower` and `faster`.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.pause`

style.stress (Property)

Part of the aural style control suite that defines the amount of inflection in the voice as items are spoken.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*`.stress`
CSS syntax:	`stress:` *aValue*	
Argument list:	*aValue*	A stress level for the speech

To make the spoken voice sound more interesting (and human-like), this property provides some control over the stress or inflection in the voice as it reads the text contained in the element object.

This property takes a numeric value, either integer or floating point with the value `50` being the normal default. Increasing the stress value of the voice will provide a greater variation in the way that words are enunciated. A value of `zero` would make the voice sound dull and unexciting.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.styleFloat (Property)

A property that allows styled elements to float.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.styleFloat
CSS syntax:	style-float: *anAlignment*	
Argument list:	*anAlignment*	A floating alignment control value

If you are flowing text around block-structured elements, this property provides some control over which side the block-structured element is aligned on.

The following values can be assigned to this property:

- `none`
- `left`
- `right`

When the property is set to "`none`", the element will appear inline with the text at the position determined by its location in the document source. For small objects this means they will appear to be symbols within the text without casing any line break.

The `style.float` and `style.floatStyle` properties are related.

See also:	`style.float`

style.tableLayout (Property)

Controls how the browser primarily works out table sizing and layout from the content or the sizing HTML tag attributes.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.tableLayout`
CSS syntax:	`table-layout:` *aType*	
Argument list:	*aType*	A kind of table layout to use

When you have a table in a document, it can take some time before the page content first appears. This is because the browser needs to traverse the entire table and load all its content, so that it can work out the width and height of each cell and then sum them together to determine the overall size of the table.

This property provides a switch that enables the browser to use this normal technique or to use an accelerated method, whereby it takes the attributes that are specified with HTML tag attributes and immediately draws the table using those values.

This property accepts the `auto` and `fixed` keywords.

The `auto` keyword selects the normal table sizing and drawing method.

The `fixed` keyword allows the HTML tag attributes controlling the size to be used to draw the table outline, and the widths of the first row of cells are used to set the width of each columns. From there, the table can be lengthened to accommodate any textual content. You should make sure that there is enough size information in the first row of the table to allow it to establish realistic column widths. This means the columns in the first row should have a width equal to or greater than the width of any other cell in the remaining rows for optimum performance. This is less important when the table only contains text, but may be a problem for tables that partially use graphical content.

See also:	`TABLE` object

style.textAlign (Property)

Controls the horizontal alignment of text within the styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.textAlign
CSS syntax:	text-align: *anAlignment*	
Argument list:	*anAlignment*	A style of text alignment to use

Text alignment in the horizontal axis can be controlled with this property. The `style.verticalAlign` property can be used to align objects vertically with respect to their parents.

The following values are appropriate for this property:

- `left`
- `center`
- `right`
- `justify`

Assigning the `center` value is equivalent to placing the `<CENTER>` tags around the text to be center justified. This aligns the text about the center of its width, but leaves the left and right hand sides of the text looking ragged.

The `left` value lines up the left edge of the text but leaves the right side ragged.

The `right` value lines up the right side of the text and leaves the left side ragged.

The `justify` keyword is intended to line up both the left and right sides nice and neatly, using space expansion between words to use up the additional space.

Warnings:

- The `justify` keyword is not defined in the CSS standard but is inconsistently supported across browsers and platforms. In many cases, it may result in a left justified and ragged right appearance rather than the left and right justified effect you would have expected.

See also:	`CAPTION.align`, `JSSTag.textAlign`, `style.textJustify`, `style.verticalAlign`, `style.wordSpacing`

style.textAutospace (Property)

Support for spacing control in ideographic languages used in Asia.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.textAutospace`
CSS syntax:	`text-autospace:` *aControl*	
Argument list:	*aControl*	One of the available keywords

This property accepts the following keywords:

- `none`
- `ideograph-alpha`
- `ideograph-numeric`
- `ideograph-parenthesis`
- `ideograph-space`

style.textDecoration (Property)

Controls decorative additions to the text such as underlines and strike-throughs.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textDecoration`
CSS syntax:	`text-decoration:` *aStyle*	
Argument list:	*aStyle*	A set of decorative properties for the text

Text decoration is often confused with text style. In word processors you will commonly see italic and bold in the same menu as underline and strike-through. In the context of a web browser they are separated into `fontStyle` and text decoration.

The following decorations can be applied:

- `blink`
- `line-through`
- `overline`
- `underline`
- `none`

You can apply several of these decorations as long as they are space separated in the string being assigned.

To restore text decoration to its default state simply assign an empty string, "". It is also likely that the value "`none`" will cancel the text decoration too, at least on the MSIE browser.

There are individual properties for each of these styles that you can use if you prefer. Those properties are controlled with a Boolean primitive value.

Setting the properties to the value `true` will add that decoration to the text block.

Setting the `style.textDecorationNone` property to `true` will automatically set the others to `false` and cancel the text decoration effect.

See also:	`JSSTag.textDecoration`, `String.blink()`, `String.strike()`, `style.textDecorationBlink`, `style.textDecorationLineThrough`, `style.textDecorationNone`, `style.textDecorationOverline`, `style.textDecorationUnderline`

style.textDecorationBlink (Property)

The blink attribute of the styled element.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textDecorationBlink`
CSS syntax:	`text-decoration-blink:` *aSwitch*	
Argument list:	*aSwitch*	A Boolean switch for the text decoration

This is a Boolean value that needs to be set to `true` or `false` to activate the styled appearance.

Warnings:

- The MSIE browser does not support text blinking so even though the property is provided and supported, its effects are ignored.
- This property does not work on some versions of MSIE on the Macintosh platform.

See also:	`String.blink()`,`style.textDecoration`, `style.textDecorationNone`

style.textDecorationLineThrough (Property)

A text decoration style.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textDecorationLineThrough`
CSS syntax:	`text-decoration-line-through:` *aSwitch*	
Argument list:	*aSwitch*	A Boolean switch for the text decoration

This is a Boolean value that needs to be set to `true` or `false` to activate the styled appearance.

Warnings:

- This property does not work on some versions of MSIE on the Macintosh platform.

See also:	`String.strike()`,`style.textDecoration`, `style.textDecorationNone`

style.textDecorationNone (Property)

A text decoration style.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myStyle*.textDecorationNone
CSS syntax:	text-decoration-none: *aSwitch*	
Argument list:	*aSwitch*	A Boolean switch for the text decoration

This is a Boolean value that needs to be set to `true` or `false` to activate the styled appearance.

Warnings:

- This property does not work on some versions of MSIE on the Macintosh platform.

See also:	style.textDecoration, style.textDecorationBlink, style.textDecorationLineThrough, style.textDecorationOverline, style.textDecorationUnderline

style.textDecorationOverline (Property)

A text decoration style.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	String primitive
JavaScript syntax:	- *myStyle*.textDecorationOverline
CSS syntax:	text-decoration-overline: *aSwitch*
Argument list:	*aSwitch* A Boolean switch for the text decoration

This is a Boolean value that needs to be set to `true` or `false` to activate the styled appearance.

Warnings:

- This property does not work on some versions of MSIE on the Macintosh platform.

See also:	style.textDecoration, style.textDecorationNone

style.textDecorationUnderline (Property)

A text decoration style.

Availability:	CSS level – Proposed JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textDecorationUnderline`
CSS syntax:	`text-decoration-underline:` *aSwitch*	
Argument list:	*aSwitch*	A Boolean switch for the text decoration

This is a Boolean value that needs to be set to `true` or `false` to activate the styled appearance.

Warnings:

- This property does not work on some versions of MSIE on the Macintosh platform.

See also:	`style.textDecoration`, `style.textDecorationNone`

style.textIndent (Property)

Controls the indentation of text within the styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textIndent`
CSS syntax:	`text-indent:` *aValue*	
Argument list:	*aValue*	An amount of text indentation

Text blocks can have the first line indented. This might be applied to an element that is instantiated by a `<P>` tag for example.

The value is specified using the normal measurement units such as pixels or floating point fractional em-dash values.

If you want to create a hanging indent effect, the first line can be moved leftwards by specifying a negative value in this property.

Assigning a value of zero to this property restores it to its default condition with all lines being left justified identically.

Warnings:

- Negative indents (sometimes called outdents or hanging indents) may not be supported correctly on all browsers on all platforms. You may need to perform some experiments and platform testing to verify it works on your target user's browsers.
- Some versions of MSIE on Macintosh do not properly support this feature.

See also:	`JSSTag.textIndent,Measurement units`

style.textJustify (Property)

Controls the justification layout of textual content within the styled element.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.textJustify`
CSS syntax:	`text-justify: `*`aControl`*	
Argument list:	*`aControl`*	One of the available control keywords

The text justification can accommodate any of the following keywords:

- `auto`
- `distribute`
- `distribute-all-lines`
- `distribute-center-last`
- `inter-cluster`
- `inter-ideograph`
- `inter-word`
- `kashida`
- `newspaper`

See also:	`style.textAlign`

style.textKashidaSpace (Property)

A means of controlling the Kashida expansion of an Asian font.

Availability:	CSS level – Proposed JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.textKashidaSpace
CSS syntax:	text-kashida-space: *aValue*	
Argument list:	*aValue*	A space scaling value

The value for this property can be specified as a percentage value or with the `inherit` keyword.

style.textShadow (Property)

Controls artistic shadow effects for text in the styled element.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.textShadow
CSS syntax:	text-shadow: *aValueH aValueV aRadius*, ...text-shadow: *aColor aValueH aValueV aRadius*, ...	
Argument list:	*aColor*	A color for the blur
	aValueH	A horizontal blur factor
	aValueV	A vertical blur factor
	aRadius	A blur radius

This is an alternative to using the visual filter effects in MSIE. With this, you can add several shadows to the text, each one having a different color. The shadows can be vertically and horizontally offset from the text on an individual basis. This simulates the effect of the text being lit from several angles with different light sources.

Although the text shadows are layered with the text itself, when the Z order of the text is changed with respect to other elements in the page, the shadows move with it as if they were in some kind of layer group.

The values for the one particular shadow are space separated and should be specified in the correct order since several of them are length values and therefore they share the same namespace.

Each set of arguments for a shadow layer should be separated from the previous one by a comma so there are two levels of delimiting going on.

As an alternative, the keyword value `none` can be assigned to the property to deactivate shadows altogether.

The arguments for each shadow layer are as follows and should be defined in this order:

- A color value (optional and may be omitted).
- The horizontal offset value in spatial coordinates
- The vertical offset value in spatial coordinates
- The blur radius value in spatial coordinates

If the color value is omitted, the color of the element object itself will be used. This value may not have been defined for the element object and may have been inherited from a parent containing element object.

Negative values can be used for the horizontal and vertical offset values.

See also:	Filter – `Shadow()`, Filter object, `style.filter`, `style.zIndex`

style.textTransform (Property)

Controls capitalization of the text within the styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.textTransform`
CSS syntax:	`text-transform:` *aControl*	
Argument list:	*aControl*	A text transformation to apply

Sometimes you may want to format a block of text for a heading. It's likely you will want to modify the capitalization as well as the appearance.

Regardless of the actual upper/lower case combination of letters in the text block, they can be forced to be displayed according to the case rules defined by this attribute.

The following values can be assigned to this property:

- `capitalize`
- `lowercase`
- `uppercase`
- `none`

See also:	`JSSTag.textTransform`

style.textUnderlinePosition (Property)

A means of controlling whether the underline is placed above or below the text.

Availability:	CSS level – Proposed JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*`.textUnderlinePosition`
CSS syntax:	`text-underline-position:` *aControl*	
Argument list:	*aControl*	One of the available keywords

This style property accepts the `above` and `below` keywords.

style.top (Property)

A positioning reference point.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.top`
	-	*myStyle*`.top = `*yCoordinate*
CSS syntax:	`top:` *aValue*	
Argument list:	*aValue*	A positioning value

A CSS-P positioning style attribute that controls the location of an element relative to its containing parent element. The top edges of the two elements are used as the reference points.

The value can be specified in the usual pixel or fractional em-dash measurement units or the `auto` keyword can be used to let the browser do the positioning itself.

The exact positioning is affected by settings for padding, border, margin and the position property.

See also:	Measurement units, `style.bottom`, `style.left`, `style.pixelTop`, `style.posTop`, `style.right`

style.unicodeBidi (Property)

Controls the bi-directionality of Unicode text within the styled element.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*`.unicodeBidi`
CSS syntax:	`unicode-bidi:` *aControl*	
Argument list:	*aControl*	A setting for bi-directional Unicode text

This sets or returns the level of embedding within the bi-directional text drawing mechanism.

The property can accept the following keywords:

- `normal`
- `embed`
- `bidi-override`

style.verticalAlign (Property)

The vertical alignment of the style.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.verticalAlign
CSS syntax:	vertical-align: *anAlignment*	
Argument list:	*anAlignment*	An alignment control value

The `textAlign` property controls the horizontal alignment, this property controls the vertical alignment.

The following values can be assigned to this property to control text alignment within the element's extent rectangle:

- `bottom`
- `top`

These keywords can be assigned to control the way the box is aligned with respect to its surrounding elements in the document content flow:

- `baseline`
- `middle`
- `sub`
- `super`
- `text-bottom`
- `text-top`

You can also define a value with measurement units or as a percentage relative to the next outermost containing parent element.

These alignment values work as you would expect and as are commonly used in the HTML document source.

See also:	`CAPTION.align`, `JSSTag.verticalAlign`, `style.textAlign`

style.visibility (Property)

The visibility of elements in this style.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Opera – 5.0

Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.visibility = *aSwitch*
CSS syntax:	visibility: *aSwitch*	
Argument list:	*aSwitch*	A visibility switch value

This controls the visibility of a DOM or HTML `Element` object. It corresponds to the visibility property of the Netscape Navigator Layer object but uses different keywords.

The following keywords are appropriate for use with this property:

- `inherit`
- `hide`
- `hidden`
- `show`
- `visible`

The `inherit` keyword allows a child element to be visible only when its parent is visible.

If the child element is made explicitly visible or hidden then its visibility will be unaffected by its parent element object. The parent can be invisible, possibly being used for positioning control while the child is on display.

The `hide` and `show` keywords are considered Netscape Navigator 4 and are deprecated. Since `hidden` and `visible` work even for layers, there is no need to ever use `hide` and `show`.

The `hidden` and `visible` keywords mean the same thing as `hide` and `show` but are more portable across browsers and the CSS standard.

See also:	`Layer.visibility`

style.voiceFamily (Property)

Part of the aural style control suite that defines which one of an available set of predefined voices is used to speak the text.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*myStyle*.voiceFamily
CSS syntax:	voice-family: *aFamilyName* ...	
Argument list:	*aFamilyName*	A list of voice family names

Most platforms that support spoken text will provide the facility to speak in a variety of alternative voices. This is somewhat similar to text being displayed on different fonts.

However, the available voices are not likely to be platform independent.

Generic and portable family names have not yet been defined.

You can stack these in the same way that fonts are defined using a left to right precedence rule. The first matching voice family will be used for the spoken text.

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets, `style.fontFamily`

style.volume (Property)

Part of the aural style control suite that defines the dynamic range from soft to loud that the spoken voice will use.

Availability:	CSS level – 2 DOM level – 2	
Property/method value type:	`String primitive`	
JavaScript syntax:	none	*`myStyle`*`.volume`
CSS syntax:	`volume:` *`aValue`*	
Argument list:	*`aValue`*	A volume setting for speech

This controls the loudness of the spoken text. It can be specified with a numeric value which is assumed to be an absolute volume level in the range 0 to 100 and is assumed to be the percentage of the volume range for the platform.

If a percent sign is added, the value inherited from the parent containing element object is multiplied by that percentage for the child element's volume setting.

In addition, these keywords are also supported for defining absolute values:

- `silent`
- `x-soft`
- `soft`
- `medium`
- `loud`
- `x-loud`

Warnings:

- This is not yet supported by any of the browsers.

See also:	Aural style sheets

style.whiteSpace (Property)

Controls how the browser should treat whitespace characters within the document source when it is rendered on the page.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 5.5 Internet Explorer – 5.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.whiteSpace
CSS syntax:	white-space: *aControl*	
Argument list:	*aControl*	A whitespace control value

When the HTML document source is authored, the browser by default will ignore any text formatting within the document apart from that enclosed in <PRE> tags. Between words, multiple spaces are collapsed to single spaces and carriage returns are ignored.

The following keywords can be used to control whitespace handling in the browser:

- `normal`
- `nowrap`
- `pre`

With the `normal` keyword, the browser behaves as it normally would.

The `nowrap` keyword forces the browser to ignore line breaks. There is an implication that whitespace should be preserved, otherwise this setting is no different to the normal keyword.

The `pre` keyword honors all line breaks and whitespace in the text. Setting the `pre` keyword in this property retains the proportional font and simply leaves linebreaks and whitespace intact, unlike text that is enclosed in <PRE> tags, which will be rendered in a monospace font. This means that whitespace used for alignment may still not do what you expect although it may be a way of indenting text. It is not clear from the available documentation whether <BR> tags are honored inside a block styled with the `pre` keyword, but it is likely that they are which is also not the case when enclosing the text inside <PRE> tags. Netscape 6.0 does in fact honor <BR> tags inside an element styled with the `pre` value.

Warnings:

- There are reports that the CSS syntax for this property does not work correctly on Netscape Navigator (even in version 6).
- MSIE 5 meanwhile has problems with the `pre` value when it is applied to this property.

See also:	`JSSTag.whiteSpace`

style.widows (Property)

Defines the minimum number of lines of a paragraph of text that must be visible at the top of a page when a page break is present. This is most likely to occur when printing documents.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.widows
CSS syntax:	windows: *aCount*	
Argument list:	*aCount*	A count of widow lines

Widows and orphans are fragments of text that appear to be formatted incorrectly when a paragraph of text spans a page break.

Windows and orphans are usually controlled together and the usual technique is to specify that an entire paragraph should be kept on the same page. This forces the paragraph to be taken over to the next page in its entirety, even if the flow requires just a single word to be taken over.

The CSS styling controls allow a finer level of control in that you can allow for a paragraph to be split across a page boundary, but specify a lower limit on the number of lines that must be kept on a single page.

This is fine in principle but there can be some contention for the right layout when a very short paragraph is spanning a page break. This will generally be solved simply by forcing the page break to happen before the paragraph causing the whole paragraph to be carried over to the next page.

A widow is that fragment of text that is left at the top of a page when a paragraph encloses a page break. It is the bottom few lines of the paragraph. The integer value in this property controls the minimum number of lines that must be present. This has the effect of moving the page break earlier in the paragraph to satisfy the requirements of the window setting. However, that itself may transgress the setting for the orphan property, leading to the whole paragraph being taken onwards.

See also:	`style.orphans`, `style.pageBreakAfter`, `style.size`

style.width (Property)

The width of a styled element.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.width
CSS syntax:	width: *aWidth*	
Argument list:	*aWidth*	An object width

The object space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

When used to read the width of an object, this returns a value in pixel units with the `px` suffix.

You can also use this property to change the width of a styled element.

The normal range of values specified in measurement units can be used. You can also assign the `auto` keyword to let the browser deduce the width of an object from the document source.

Warnings:

- Note that not all styled elements can be resized by assigning a new value to this property.

See also:	`JSSTag.width`, Measurement units, `style.height`, `style.pixelWidth`, `style.posWidth`

style.wordBreak (Property)

A means of controlling line breaking behavior within words.

Availability:	CSS level – Proposed JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyle*.wordBreak

CSS syntax:	word-break: *aControl*	
Argument list:	*aControl*	One of the available keywords

This is especially useful for controlling line breaking behavior when multiple languages are used.

The following keywords can be used:

- normal
- break-all
- keep-all

style.wordSpacing (Property)

Controls the spacing between words on the page.

Availability:	CSS level – 1 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.01 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myStyle*.wordSpacing
CSS syntax:	word-spacing: *aSwitch*	
Argument list:	*aSwitch*	A control value for word spacing

When the textAlign attribute is set to the justify keyword, this spacing may come into play.

A length value in measurement units can be specified to adjust the spacing between words or the normal keyword can be assigned to let the browser calculate spacing on its own.

Warnings:

- As of MSIE 4.01, this is only available on the Macintosh platform.

See also:	Measurement units, style.textAlign

style.wordWrap (Property)

Controls the word wrapping behavior when the content exceeds the bound of its containing element object.

Availability:	CSS level – Proposed JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myStyle`*`.wordWrap`
CSS syntax:	`word-wrap: `*`aControl`*	
Argument list:	*`aControl`*	One of the available keywords

This property accepts the `normal` and `break-word` keywords.

style.writingMode (Property)

A typographic control for use with Asian fonts.

Availability:	CSS level – Proposed JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.writingMode`
CSS syntax:	`writing-mode: `*`aControl`*	
Argument list:	*`aControl`*	One of the available keywords

This controls the direction that characters are written into the display.

The following keywords are accepted:

- `lr-tb`
- `tb-rl`

style.zIndex (Property)

A value for the position of the element in a Z stacking order.

Availability:	CSS level – 2 DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0 Opera – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyle*.zIndex
	-	*myStyle*.zIndex = *aZValue*
CSS syntax:	z-index: *aZValue*	
Argument list:	*aZValue*	A position in the Z order

Elements can be placed in front of or behind other elements according to the Z index value.

The value should be defined with an integer or can be replaced by the `auto` keyword. The `auto` value is the same as setting this property to zero.

Any elements that share the same `zIndex` value will be stacked in the display using their order as presented in the document source.

Warnings:

- The CSS-P standard name for the property is `z-index` so this property may be accessible with a different name on some implementations.

See also:	`Layer.zIndex`, `style.textShadow`, `style.zOrder`

style.zoom (Property)

Reads and writes a zoom scaling factor for the receiving element object.

Availability:	JScript – 5.5 Internet Explorer – 5.5	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`style.zoom`
CSS syntax:	zoom: *aScaleFactor*	
Argument list:	*aScaleFactor*	A zooming control value

This controls a magnification effect that is applied to an object. The value can be one of the following:

- `normal`
- A floating point multiplier
- A percentage scalar

style.zOrder (Pitfall)

In some documentation, this property is described as an alternative way of controlling the Z ordered location of the styled object.

Warnings:

- So far, no examples of this property have been located. Use the `zIndex` property.

See also:	`style.zIndex`

<STYLE> (HTML Tag)

Style controls can be effected from JavaScript code.

The style mechanisms allow the content and the appearance of the document to be separated. The style sheet can now define the appearance of the page. This also means that styles can be shared and if your server is up to the task, you can serve a different style sheet according to the user agent value defined by the requesting browser.

Currently, CSS1 styling is widely used and CSS2 is gaining acceptance.

As far as we are concerned with JavaScript, we either need to create a style or apply it to part of a document. To create a style in Netscape Navigator 4 we use JSSS (JavaScript Style Sheets), which is functionally equivalent to CSS1. However JSSS is completely unavailable in any other browser, including Netscape Navigator 6.0 and its use for scripts is discouraged.

See also:	`.htc`, `<META>`, `<STYLE TYPE="...">`, CSS, CSS level 1, CSS level 2, `Document.attachEvent()`, `Document.detachEvent()`, `JavaScript Style Sheets`, `Window.attachEvent()`, `Window.detachEvent()`

Cross-references:

Wrox *Instant JavaScript* – page 50

<STYLE TYPE="..."> (HTML Tag Attribute)

The MIME type for a block of JSSS style code.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
Deprecated:	Yes	
HTML syntax:	`<STYLE TYPE="..."> some JSSS Code </STYLE>`	
Argument list:	`...`	A MIME type that signifies JavaScript source text.
	`someCode`	Some script based style text

The same MIME type values that apply to the `<SCRIPT>` tag are also used for the `<STYLE>` tag when this attribute is applied.

When this JavaScript style sheet is evaluated, the interpreter adds the document to the scope chain so that the `tags`, `classes` and `ids` properties of the document object can be accessed directly as if they were global values. This saves accessing them with the `document` object prefix. Thus:

`document.tags` becomes `tags`

`document.classes` becomes `classes`

`document.ids` becomes `ids`

Warnings:

- This functionality is removed from Netscape Navigator 6.0.

See also:	`<META>`, `<SCRIPT TYPE="...">`, `<SCRIPT>`, `<STYLE>`, Adding JavaScript to HTML, JavaScript Style Sheets, MIME types, `SCRIPT.type`, `StyleSheet.type`, `text/JavaScript`

Cross-references:

Wrox *Instant JavaScript* – page 50

StyleSheet object (Object/DOM)

An object that represents a style sheet.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

JavaScript syntax:	-	*myStyleSheet* = *myDocument*.styleSheets[*anIndex*]
	IE	*myStyleSheet* = *myDocument*.createStyleSheet()
Argument list:	*anIndex*	A valid reference to an item in the collection
Object properties:	cssText, disabled, href, id, media, ownerNode, owningElement, owningNode, parentStyleSheet, readOnly, title, type	
Object methods:	addImport(), addRule(), removeRule()	
Collections:	cssRules[], imports[], rules[]	

A style sheet contains many individual style objects which are managed as a collection. These style sheet objects are created by means of the <STYLE> HTML tag or are imported with the <LINK> tag. They can also be created by means of the @import statement inside a style definition.

The Document.styleSheets[] collection contains a reference for every styleSheet object in the document.

Beware that a STYLE object and a style object are different things. A STYLE object is instantiated by the <STYLE> HTML tag and contains properties that reflect its attributes.

This is quite different to a style object which is a member of a styleSheet and describes the rules for a particular style.

DOM level 2 adds the following properties:

- title
- media
- ownerRule

It also adds the following methods:

- insertRule()
- deleteRule()

Warnings:

- Note that MSIE 5 incorrectly names this object class as styleSheet instead of StyleSheet (note the capitalization).

See also:	Document.createStyleSheet(),Document.styleSheets[], Element.style,rule object,Style sheet, StyleSheetList object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
cssText	-	5.0 +	-	5.0 +	-	-	-
disabled	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	-

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
Href	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	ReadOnly.
id	-	5.0 +	-	5.0 +	-	-	ReadOnly.
media	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	Warning, ReadOnly.
ownerNode	1.5 +	-	6.0 +	-	-	2 +	ReadOnly.
owningElement	-	3.0 +	-	4.0 +	-	-	ReadOnly.
owningNode	-	5.0 +	-	5.0 +	-	-	Warning, ReadOnly.
parentStyleSheet	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	ReadOnly.
readOnly	1.5 +	3.0 +	6.0 +	4.0 +	-	-	ReadOnly.
title	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	Warning, ReadOnly.
type	1.5 +	3.0 +	6.0 +	4.0 +	-	2 +	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
addImport()	-	3.0 +	-	4.0 +	-	-	-
addRule()	-	3.0 +	-	4.0 +	-	-	-
removeRule()	-	5.0 +	-	5.0 +	-	-	-

StyleSheet.addImport() (Method)

A method for importing to style sheets.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myStyleSheet*.addImport(*aUrl*)
	IE	*myStyleSheet*.addImport(*aUrl*, *anIndex*)
Argument list:	*anIndex*	An index position within the collection where the new style sheet should be inserted
	aUrl	A URL value that points at a CSS documents

This method provides a way to import an external style sheet so its rules become part of the current style sheet.

This is another example of how to build a document hierarchy in a web browser.

If you omit the index location for the style sheet that is being imported, it will be appended to the end of the current collection of style sheets belonging to the document.

See also:	Hierarchy of objects

StyleSheet.addRule() (Method)

A method for adding a rule to a style sheet.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myStyleSheet*.addRule(*aSelector*, *aStyle*)
	IE	*myStyleSheet*.addRule(*aSelector*, *aStyle*, *anIndex*)
Argument list:	*anIndex*	A index in the collection where the new rule should be inserted
	aSelector	The style rule selector string
	aStyle	A series of style settings for this rule

This method allows individual rules to be added to a style sheet. You may want to control the precedence of the rules and so the optional index value can be used to determine where in the collection of rules the new rule is to be inserted.

If the index is omitted, the new rule is simply appended to the style sheet.

You can override rules as long as you are not changing the type of rule being defined. Positional rules must always be overridden by a new positioning rule and cannot be changed to an appearance rule and vice versa.

See also:	Document.createStyleSheet(),Hierarchy of objects, StyleSheet.removeRule(),StyleSheet.rules[]

StyleSheet.cssRules[] (Collection)

A collection of CSS rules belonging to a style sheet. This is another name for the rules[] collection.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myStyleSheet*.cssRules

Property attributes:

ReadOnly.

Refer to:

StyleSheet.rules[]

StyleSheet.cssText (Property)

The CSS text belonging to a style sheet.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myStyleSheet*.cssText

This is the source text of the entire CSS text for the whole style sheet. This is not the same as the `cssText` property for individual style rules. It is equivalent to all of those individual `cssText` values concatenated together.

StyleSheet.disabled (Property)

A property that disables a style sheet.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myStyleSheet*.disabled

This is a Boolean primitive value that enables and disables the rules in a style sheet.

The `DISABLED="..."` HTML tag attribute does not work in all versions of MSIE even though the `styleSheet.disabled` property does.

StyleSheet.href (Property)

The HREF location of a style sheet for download from a server.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myStyleSheet*.href

The path to a document on the server where a style sheet can be loaded from. This will likely correspond to an `HREF="..."` or `SRC="..."` HTML tag attribute in a `<LINK>` HTML tag.

Property attributes:

`ReadOnly`.

StyleSheet.id (Property)

The value of the `ID="..."` HTML tag attribute.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myStyleSheet.id`
HTML syntax:	`<LINK ID="anIDValue"><STYLE ID="anIDValue">`	
Argument list:	*`anIDValue`*	A unique `ID` value within the document

This property is initially defined by the `ID="..."` HTML tag attribute of the `<LINK>` or `<STYLE>` tag that instantiates the `styleSheet` object.

Property attributes:

`ReadOnly`.

StyleSheet.imports[] (Collection)

A collection of all the imported style sheets defined for this style sheet object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`styleSheets object`	
JavaScript syntax:	IE	*`myStyleSheet`*`.imports`

See also:	`StyleSheetList` object, `Collection` object

Property attributes:

`ReadOnly`.

StyleSheet.media (Property)

A description of the target media.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`MediaList object`	
JavaScript syntax:	-	*`myStyleSheet`*`.media`

Warnings:

- DOM level 2 style specification details cover the use of style sheets for several different media. This acts as a selector for one of several alternative appearances depending on the resolution and color capabilities of the target medium the document will be presented on.
- Typically that might be print or video screen.

Property attributes:

`ReadOnly`.

StyleSheet.ownerNode (Property)

The DOM node that owns the style sheet.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`Node object`	
JavaScript syntax:	N	`myStyleSheet.ownerNode`

This is part of the internal node structured hierarchy maintained by the browser as a foundation for its implementation of the DOM model. In many cases this is likely to be the same object as that returned by the `owningElement` property. This property is in preparation for the DOM level 2 styling support.

Note that this property is named incorrectly in MSIE 5 where it is called `owningNode`.

See also:	`StyleSheet.owningNode`

Property attributes:

`ReadOnly`.

StyleSheet.owningElement (Property)

The element that owns the style sheet.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`An object`	
JavaScript syntax:	IE	*`myStyleSheet`*`.owningElement`

This property refers to the owning `LINK` or `STYLE` object that is the parent for the style sheet. From that you can establish a collection of sibling style sheets.

See also:	Hierarchy of objects

Property attributes:

`ReadOnly`.

StyleSheet.owningNode (Property)

The DOM node that owns the style sheet.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Node object`	
JavaScript syntax:	IE	`myStyleSheet.owningNode`

This is part of the internal node structured hierarchy maintained by the MSIE browser as a foundation for its implementation of the DOM model. In many cases this is likely to be the same object as that returned by the `owningElement` property. This property is in preparation for DOM level 2 styling support.

Warnings:

- Note that this property is named incorrectly in MSIE 5 and should be called `ownerNode` according to the DOM level 2 style specification.

See also:	Hierarchy of objects, `StyleSheet.ownerNode`

Property attributes:

`ReadOnly`.

StyleSheet.parentStyleSheet (Property)

The parent stylesheet that styles are cascaded from.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`StyleSheet object`	
JavaScript syntax:	-	*`myStyleSheet`*`.parentStyleSheet`

Where style sheets are imported and if the object reference is a `StyleSheet` object that was the result of an import, then that `StyleSheet` object will have a parent. The value returned by this property is another `StyleSheet` object.

See also:	Hierarchy of objects

Property attributes:

`ReadOnly`.

StyleSheet.readOnly (Property)

The read-only property of a style sheet.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`myStyleSheet`*`.readOnly`

In the same way that you can lock a rule and make it read-only, you can also use this property to lock an entire style sheet to prevent it from being changed in the browser by JavaScript.

See also:	`rule.readOnly`

Property attributes:

`ReadOnly`.

StyleSheet.removeRule() (Method)

An accessor for removing rules belonging to a style sheet's rules collection.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	`myStyleSheet.removeRule(anIndex)`
Argument list:	*`anIndex`*	The index number of the rule to be removed

If you used the `addRule()` method to create new rules, then this method operates as a complementary tool to remove rules from the style sheet.

See also:	`StyleSheet.addRule()`

StyleSheet.rules[] (Collection)

An array of rules contained within this style sheet.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`SelectorArray` object	
JavaScript syntax:	IE	*`myStyleSheet`*`.rules`

The object class of the rule collection is called a `SelectorArray`.

See also:	`rule` object, `SelectorArray` object, `StyleSheet.addRule()`

Property attributes:

`ReadOnly`.

StyleSheet.title (Property)

This is an advisory title text.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myStyleSheet`*`.title`

Warnings:

- The DOM standard notes that the title value is often specified in the `ownerNode`. That would be the `TITLE="..."` HTML tag attribute for a `<LINK>` tag. It also relates to the pseudo-attribute for the XML style sheet processing instruction.

Property attributes:

`ReadOnly`.

StyleSheet.type (Property)

What sort of style sheet the object represents.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- `myStyleSheet.type`
HTML syntax:	`<STYLE TYPE="...">`

This value returns a string that describes the MIME type for the style sheet document that was used to instantiate the `StyleSheet` object.

Normally, you would see the value "`text/css`" in this property.

See also:	`<SCRIPT TYPE="...">`,`<STYLE TYPE="...">`, `SCRIPT.type`

Property attributes:

`ReadOnly`.

Style sheet (Definition)

A means of abstracting presentation style out of the content in a web page.

The style sheet support is now standardized around the CSS standards and provides a way to make the HTML document relate to the content of the page, while the style sheet contains a definition of how it should look. This has great benefits for the maintenance of a web site and allows you to significantly change the appearance of the whole site simply by specifying a new style sheet.

See also:	`StyleSheet` object

StyleSheetList object (Object/DOM)

An array of style sheet objects provided by MSIE.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myStyleSheets* = *myDocument*.styleSheets
Object properties:	length	
Object methods:	item()	

Warnings:

- MSIE inconsistently names this as a `styleSheets` object rather than a `StyleSheets`, `StyleSheetCollection` or `StyleSheetArray` object.
- DOM level 2 describes this as a `StyleSheetList` which is more consistent. Because this is a collection, DOM allows for the `item()` method to be supported.

See also:	Collection object, Document.styleSheets[], StyleSheet object

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
length	1.5 +	5.0 +	6.0 +	5.0 +	-	2 +	ReadOnly.

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
item()	1.5 +	5.0 +	6.0 +	5.0 +	-	2 +	-

StyleSheetList.item() (Method)

An accessor for objects in the `StyleSheetList` collection.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	StyleSheet object	
JavaScript syntax:	-	*myStyleSheetList*.item(*anIndex*)
	-	*myStyleSheetList*[*anIndex*]
Argument list:	*anIndex*	The numeric index of the required style sheet

Calling this method with a numeric value that can range from `0` to `1` less than the `length` value selects the required `StyleSheet` object from the collection.

Note that the array like square bracket notation can be used as well.

StyleSheetList.length (Property)

The number of style sheets currently supported by the document.

Availability:	DOM level – 2 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myStyleSheetList*.length

See also:	`Collection.length`

Property attributes:

`ReadOnly`.

SUB object (Object/HTML)

An object that encapsulates the contents of a `<SUB>` tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	<classname relation="parent">Element object</classname>	
JavaScript syntax:	IE	*mySUB* = *myDocument*.all.*anElementID*
	IE	*mySUB* = *myDocument*.all.tags("SUB")[*anIndex*]
	IE	*mySUB* = *myDocument*.all[*aName*]
	-	*mySUB* = *myDocument*.getElementById(*anElementID*)
	-	*mySUB* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySUB* = *myDocument*.getElementsByTagName ("SUB")[*anIndex*]
HTML syntax:	`<SUB> ... </SUB>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object

Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDblClick	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onDragStart	-	3.0 +	-	4.0 +	-	-	-	-
onFilterChange	-	3.0 +	-	4.0 +	-	-	-	-
onHelp	-	3.0 +	-	4.0 +	-	-	-	Warning
onKeyDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyPress	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onKeyUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseDown	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseMove	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOut	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseOver	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onMouseUp	-	3.0 +	-	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

Refer to:

`Element` object

Subclasses (Definition)

Subclasses inherit the behavior from their superclass.

When you create a subclass in JavaScript, it is done by building a constructor function. To be completely correct, the constructor should be linked by the constructor property of the prototype property. We overwrite the prototype as an object is created, however the constructor is inherited from the object that was cloned. We need to set the constructor manually. That is done like this:

```
MyNewClass.prototype.constructor = MyNewClass;
```

Warnings:

- There are some versions of Netscape Navigator that set the constructor property to be read-only and this prohibits a script from changing it.
- In Navigator 4, a non-portable low level internal variable can be 'hacked' to fix up the prototype rather than the constructor. This uses the `__proto__` internal property.

See also:	__proto__, Anchor object, Superclasses

SubmitButton object (Object/DOM)

A button in a form that submits the form to the server.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera browser – 3.0	
Inherits from:	<classname relation="parent">Input object</classname>	
JavaScript syntax:	-	*mySubmitButton* = *myDocument*.*aFormName*.*anElementName*
	-	*mySubmitButton* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*mySubmitButton* = *myDocument*.all.*anElementID*
	IE	*mySubmitButton* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*mySubmitButton* = *myDocument*.all[*aName*]
	-	*mySubmitButton* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*mySubmitButton* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*mySubmitButton* = *myDocument*.getElementById(*anElementID*)
	-	*mySubmitButton* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySubmitButton* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	<INPUT TYPE="submit">	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The name attribute of an element
	anElementID	The ID attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the forms collection
Object properties:	type, value	
Object methods:	handleEvent()	
Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDblClick, onFilterChange, onFocus, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onRowEnter, onRowExit	

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all subclasses of the `Input` object superclass.

There isn't really a `SubmitButton` object class, but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a submit button. In actual fact, the object is represented as an item of the `Input` object class.

Event handling support via properties containing function objects was added to `SubmitButton` objects at version 1.1 of JavaScript.

Unlike MSIE, Netscape Navigator does not support the `select()` method or `defaultValue` property for this subclass of the `Input` object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<FORM>
<SELECT ID="IN1">
<OPTION VALUE="-1">Please select an item
<OPTION VALUE="0">Sunday
<OPTION VALUE="1">Monday
<OPTION VALUE="2">Tuesday
<OPTION VALUE="3">Wednesday
<OPTION VALUE="4">Thursday
<OPTION VALUE="5">Friday
<OPTION VALUE="6">Saturday
</SELECT>
<INPUT ID="SUBMIT" TYPE="Submit" VALUE="CLICK ME" onClick="clickMe()">
</FORM>
<SCRIPT>
//MSIE only
function clickMe()
{
   selectedValue  = document.all.IN1.value;

   if(selectedValue == -1)
   {
      alert("You must select an item first!");
   }
   else
   {
      document.all.SUBMIT.click()
   }
}
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

Element object, Input object, Node object

SubmitButton.handleEvent() (Method)

Passes an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*mySubmitButton*`.handleEvent(`*anEvent*`)`
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape Navigator prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`SubmitButton` object, `Window.handleEvent()`

SubmitButton.type (Property)

The subclass type of this `Input` object.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*mySubmitButton*`.type`

The type value for a `SubmitButton` is always "`submit`". This value is necessary to determine the type of form element, because this object is really an instance of the `Input` class. There is actually no `SubmitButton` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

SubmitButton.value (Property)

The text string in the button.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`mySubmitButton`*`.value`

Although this value may be sent back to the web server when the form is submitted, the main purpose of a Submit button is to trigger the form submission. This property provides a convenient means of labelling the button.

Warnings:

- This may be changed in some platforms but not others.

See also:	`Input.value,ResetButton.value`

Subtract (-) (Operator/additive)

Subtracts the right operand from the left operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera browser – 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`anOperand1 - anOperand2`*
Argument list:	*`anOperand1`*	A numeric value to be subtracted from
	`anOperand2`	A numeric value to be subtracted

Subtraction is indicated when two operands are separated by a minus sign.

The value on the right is subtracted from the value on the left. The result is the difference between the two values.

Subtraction behaves identically to addition, as if the formula:

```
a - b
```

had become:

```
a + (-b)
```

The associativity is left to right.

Refer to the operator precedence topic for details of execution order.

See also:	Add (+), Additive operator, Arithmetic operator, Assign value (=), Assignment expression, Associativity, Negation operator (–), Operator Precedence, Subtract then assign (-=)

Cross-references:

ECMA 262 edition 2 – section 11.6.3

ECMA 262 edition 3 – section 11.6.2

Subtract then assign (-=) (Operator/assignment)

Subtracts the right value from the left, modifying the left-hand value.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	`-`	*`anLValue -= anOperand`*
Argument list:	*`anLValue`*	An operand that can be assigned into
	`anOperand`	A value to subtract

Subtracts the right operand from the left operand and assigns the result to the left operand.

This is functionally equivalent to the expression:

```
anOperand1 = anOperand1 - anOperand2;
```

Although this is classified as an assignment operator it is really a compound of an assignment and an additive operator.

The associativity is right to left.

Refer to the operator precedence topic for details of execution order.

The new value of *`anOperand1`* is returned as a result of the expression.

Warnings:

- The operand to the left of the operator must be an LValue. That is, it should be able to take an assignment and store the value.

See also:	Add then assign (+=), Additive operator, Arithmetic operator, Assignment operator, Associativity, Operator Precedence, Subtract (–)

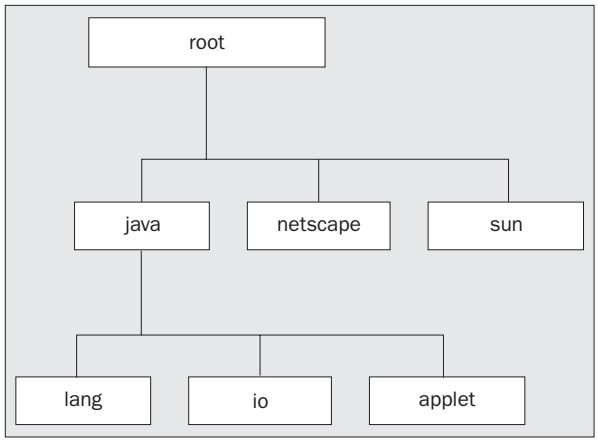
sun (Java package)

A short cut reference to the `Packages.sun` object.

Availability:	JavaScript – 1.1 Netscape – 3.0	
Property/method value type:	`JavaPackage sun`	
JavaScript syntax:	N	*myWindow*`.Packages.sun`
	N	*myWindow*`.sun`
	N	`Packages.sun`
	N	`sun`



See also:	`Window.java`, `Window.sun`, `Window.Packages`

Property attributes:

`ReadOnly`.

SUP object (Object/HTML)

An object that encapsulates the contents of a `<SUP>` tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*mySUP* = *myDocument*.all.*anElementID*
	IE	*mySUP* = *myDocument*.all.tags("SUP")[*anIndex*]
	IE	*mySUP* = *myDocument*.all[*aName*]
	-	*mySUP* = *myDocument*.getElementById(*anElementID*)
	-	*mySUP* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*mySUP* = *myDocument*.getElementsByTagName("SUP")[*anIndex*]
HTML syntax:	`<SUP> ... </SUP>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
OnClick	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
OnDblClick	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning
OnDragStart	-	3.0 +	-	4.0 +	-	-	-	-
OnFilterChange	-	3.0 +	-	4.0 +	-	-	-	-

Superclasses (Definition)

Superclasses are the parent class of subclassed objects.

Superclass mechanisms are used in true object oriented systems to provide a means of generalizing object descriptions and capturing common behaviors into a shared parent class.

A superclass of an object may also have a superclass of its own. Eventually, by walking up the class hierarchy, you should arrive at the topmost class. That is probably the `Object` class but it can be implementation dependent.

See also:	`Anchor` object, Subclasses

switch(...) ... case: ... default: ... (Selector)

Selects one of a set of cases according to a switch value.

Availability:	ECMAScript edition – 3 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 3.0	
JavaScript syntax:	-	`switch(`*`aValue`*`) { `*`aCaseTree`*` }`
Argument list:	*`aCaseTree`*	A set of case statements to be selected.
	`aValue`	An integer value used as a selector

The `switch` statement evaluates its expression and selects a labeled statement block for execution according to the value resulting from the expression.

If there is no match, then a `default` case is used.

Each labeled case should be terminated by a `break` keyword to avoid the execution dropping down through into the handler for the next case in the script source. On the other hand, this may be what you intend and so omitting the `break` keyword allows several cases to be matched and handled with a common fragment of code.

The use of `switch` is illustrated in the example. The value enclosed in parentheses is evaluated and its result is used as a selector. It looks for a matching `case` label and executes the code in that block. If it does not match, it uses the `default` block (if there is one).

Unlike the ANSI C version of `switch`, the JavaScript one will match strings as well as integers.

The `break;` statements prevent the code from dropping down into the next block.

The following are all legal case labels:

```
case 0:

case 100*23:

case "abc":

case "aaa" + "bbb":

case Number.NaN:
```

The C language environment dictates that a `switch` statement must be capable of supporting at least 256 individual cases. The ECMAScript standard does not define a limit.

You need to be careful when nesting `switch` statements. The `case` labels will be subordinate to the closest enclosing `switch` given the rules of precedence and block structuring of the code. Case labels must be unique within a single `switch` mechanism, but can duplicate `case` values in other `switch` structures within the same or an enclosing code block.

Warnings:

- Primitive values are allowed as selectors but objects, arrays and functions are not. You could wrap them with `toString()` or `valueOf()` functions though. However the results may be slightly unpredictable unless you thoroughly test the effects of those functions in all your target implementations.
- The value `document.forms.length` is valid for use in a `case` label at JavaScript version 1.2 but may not be later. The values really do have to be constant, and it's possible that a later version of the interpreter may check the `ReadOnly` attribute of any property value that is used in this context.

Example code:

```
// An example switch statement
switch(myValue){
     case 1:      document.write("one");
     break;
     case 'too':
     document.write("two");
     break;
     default:
     document.write("unknown");
     break;
}
```

SyntaxError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 Netscape – 6.0	
Inherits from:	`Error object`	
JavaScript syntax:	N	*myError* `= new SyntaxError()`
	N	*myError* `= new SyntaxError(`*aNumber*`)`
	N	*myError* `= new SyntaxError(`*aNumber*`, `*aText*`)`
Argument list:	*aNumber*	An error number
	aText	A text describing the error

This subclass of the `Error` object is used when an exception is caused by a script source text parsing error.

See also:	`catch( ... )`, `Error` object, `EvalError` object, `RangeError` object, `ReferenceError` object, `throw`, `try ... catch ... finally`, `TypeError` object, `URIError` object

TABLE object (Object/HTML)

An object that represents a table within a document.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape –6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTABLE* = *myDocument*.all.*anElementID*
	IE	*myTABLE* = *myDocument*.all.*aTableID*
	IE	*myTABLE* = *myDocument*.all.tags("TABLE")[*anIndex*]
	IE	*myTABLE* = *myDocument*.all[*aName*]
	-	*myTABLE* = *myDocument*.getElementById(*anElementID*)
	-	*myTABLE* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myTABLE* = *myDocument*.getElementsByTagName ("TABLE")[*anIndex*]
HTML syntax:	`<TABLE> ... </TABLE>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`, `background`, `bgColor`, `border`, `borderColor`, `borderColorDark`, `borderColorLight`, `caption`, `cellPadding`, `cellSpacing`, `cols`, `dataFld`, `dataPageSize`, `dataSrc`, `frame`, `height`, `rules`, `summary`, `tabIndex`, `tFoot`, `tHead`, `width`	

Object methods:	`createCaption()`, `createTFoot()`, `createTHead()`, `deleteCaption()`, `deleteRow()`, `deleteTFoot()`, `deleteTHead()`, `insertRow()`, `nextPage()`, `previousPage()`, `refresh()`
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onBlur`, `onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onResize`, `onRowEnter`, `onRowExit`, `onScroll`, `onSelectStart`
Collections:	`cells[]`, `rows[]`, `tBodies[]`

Tables are a hierarchical means of describing a two dimensional array of cells containing HTML.

Generally speaking the DOM compliant browsers provide a more sophisticated model of the table for access under control of a JavaScript program.

There are a set of related object types that need to be understood to utilize tables most effectively:

- `CAPTION`
- `COL`
- `COLGROUP`
- `TBODY`
- `TD`
- `TFOOT`
- `TH`
- `THEAD`
- `TR`

The following style object properties should also be considered:

- `style.captionSide`
- `style.cellSpacing`
- `style.columnSpan`
- `style.emptyCells`
- `style.rowSpan`
- `style.tableLayout`

See also:	`CAPTION` object, `COL` object, `COLGROUP` object, `Element` object, `Element.offsetParent`, `style.captionSide`, `style.cellSpacing`, `style.columnSpan`, `style.emptyCells`, `style.rowSpan`, `style.tableLayout`

Inheritance chain:

`Element` object, `Node` object

TABLE.align (Property)

A controlling property for the alignment of table cells within a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*.align

The horizontal alignment of the `TABLE` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TBODY.align`, `TD.align`, `TFOOT.align`, `TH.align`, `THEAD.align`, `TR.align`

TABLE.background (Property)

A URL of an image to be used as the background for a table.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTABLE*`.background`

If a background image is available, then its URL is contained in this property. Changing the value in this property will replace the background with a new one. However, there may be a perceptible delay while the new image is fetched from the web server.

TABLE.bgColor (Property)

The background color value for a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value

TABLE.border (Property)

The width of the border around cells in a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*.border

The thickness of the border around the table should be specified as an integer value describing a value measured in pixels. This describes the table border drawn with a 3D effect. If you add borders around any elements with the style properties, those describe a different border.

See also:	`TABLE.frame`

TABLE.borderColor (Property)

The color of the border around the cells in a table.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTABLE*.borderColor

You can use this property to determine the color of a border surrounding a table. Note that there are additional properties to determine the highlights and lowlights of the table border coloring.

TABLE.borderColorDark (Property)

The color value of the shadowed edge of the table border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTABLE*.borderColorDark

Table borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the shadowed part of the table border.

TABLE.borderColorLight (Property)

The color value of the highlighted edge of the table border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTABLE*`.borderColorLight`

Table borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the highlighted part of the table border.

TABLE.caption (Property)

The caption text contained in a `CAPTION` object belonging to the `TABLE` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`CAPTION` object	
JavaScript syntax:	-	*myTABLE*`.caption`

This property yields a reference to a `CAPTION` object belonging to the table. That is if you have defined a caption with the `<CAPTION>` HTML tag.

Warnings:

- This property is not fully supported on all versions of the MSIE browser or across all platforms.

See also:	`CAPTION` object

Property attributes:

`ReadOnly`.

TABLE.cellPadding (Property)

The width of the cell padding around the cell contents within a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*`.cellPadding`

The cell padding describes the space allowed inside the cell but around the cell content. The table grows larger but the border thicknesses stay the same. The growth takes place inside the cells.

TABLE.cells[] (Collection)

A collection of all the cells in a `<TABLE>`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	IE	*myTABLE*`.rows`

This collection includes any cells inside objects instantiated by `<TBODY>`, `<TFOOT>` and `<THEAD>` tags.

This is not necessarily the same as the `cells` collection returned from a `TBODY` object.

Addressing the table by means of its `cells[]` collection allows you to visit all the cells in a single enumeration loop rather than having to nest a loop for each axis of the table.

The columns and rows are different axes of the table. However, they are described in different ways. The `cols` value is simply an integer that is set to the number of columns. The `rows` property is a reference to a collection of objects, one `row` object for each row in the table. Therefore to establish how many cells there are in the table, you need to multiply the `table.cols` value by the `table.rows.length` value.

The `table.cols` value should also be equivalent to `table.rows.cells.length` value as well.

See also:	`Collection` object, `TABLE.cols`, `TABLE.rows[]`, `TBODY.rows[]`, `TFOOT.rows[]`, `THEAD.rows[]`, `TR.rowIndex`

Property attributes:

`ReadOnly`.

TABLE.cellSpacing (Property)

The width of the cell spacing between cells in a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*`.cellSpacing`

The cell spacing describes the space allowed between adjacent table cells. This moves the cells apart by introducing a few pixels outside the cell border. It has the effect of thickening the border lines between cells.

TABLE.cols (Property)

The number of columns in a table.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myTABLE*`.cols`

The columns and rows are different axes of the table. However, they are described in different ways. The `cols` value is simply an integer that is set to the number of columns. The `rows` property is a reference to a collection of objects, one `row` object for each row in the table. Therefore to establish how many cells there are in the table, you need to multiply the `table.cols` value by the `table.rows.length` value.

The `table.cols` value should also be equivalent to the `table.rows.cells.length` value.

See also:	`style.columnSpan`, `TABLE.cells[]`, `TABLE.rows[]`, `TBODY.rows[]`, `TFOOT.rows[]`, `THEAD.rows[]`, `TR.cells[]`

TABLE.createCaption() (Method)

Creates a new `CAPTION` object for use with the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Property/method value type:	CAPTION object	
JavaScript syntax:	-	*myTABLE*.createCaption()

You can modify a caption by accessing its innerHTML property in MSIE and Netscape 6.0.

See also:	CAPTION object

TABLE.createTFoot() (Method)

Creates a new TFOOT object for use with the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	TFOOT object	
JavaScript syntax:	-	*myTABLE*.createTFoot()

See also:	TFOOT object

TABLE.createTHead() (Method)

Creates a new THEAD object for use with the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	THEAD object	
JavaScript syntax:	-	*myTABLE*.createTHead()

See also:	THEAD object

TABLE.dataPageSize (Property)

Part of the data-binding model in MSIE that maps table rows to database rows.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myTABLE*`.dataPageSize`

This is used in MSIE when the contents of a table are instantiated from a database fetch. Each row corresponds to a record and the columns correspond to a field in the record structure.

This property determines how many records are assumed to be in each page full of data. That way the table can be traversed one full page at a time.

The `nextPage()` and `previousPage()` methods are used to aid navigation of a table that is paged in this manner.

See also:	`TABLE.nextPage(),TABLE.previousPage(), TABLE.refresh()`

TABLE.deleteCaption() (Method)

Deletes the `CAPTION` object currently belonging to the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTABLE*`.deleteCaption()`

See also:	`CAPTION` object

TABLE.deleteRow() (Method)

Deletes a specified row within the `TABLE` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTABLE*`.deleteRow(`*anIndex*`)`
Argument list:	*anIndex*	The row to delete

See also:	`TR` object

TABLE.deleteTFoot() (Method)

Deletes the table footer from the owning table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTABLE*.deleteTFoot()

See also:	TFOOT object

TABLE.deleteTHead() (Method)

Deletes the table header from the owning table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTABLE*.deleteTHead()

See also:	THEAD object

TABLE.frame (Property)

A control over which of the table cells sides are controlled by the BORDER tag attribute and border property of the TABLE object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTABLE*.frame

This property controls which parts of a table's outer framing border are rendered into the display. The following keywords are supported by this property:

Keyword	Description
above	The top edge only
below	The bottom edge only
border	All four sides
box	Same as border
hsides	Top and bottom edges
lhs	Left edge
rhs	Right edge
void	No sides framed at all
vsides	Left and right sides

The `frame` property affects the outer border around the whole table. You should use the `border` property to control the ruled edges between cells.

See also:	`TABLE.border`, `TABLE.rules`

TABLE.height (Property)

The height of the `TABLE` in pixels.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*.height

A table will be sized according to the content within it. The HTML tags for a table allow the table height to be specified as a percentage of the height of the containing HTML element. When the table is rendered, an extent rectangle can be drawn round it. An extent rectangle is the smallest rectangle that will completely enclose the table. This `height` property returns the vertical size of that extent rectangle.

Including height and width information on tables is optional, but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the table content has all been fetched before reserving sufficient space for it in the display.

See also:	`TABLE.width`

TABLE.insertRow() (Method)

Insert a new row into the table at a specified row index.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`TR object`	
JavaScript syntax:	-	*myTABLE*`.insertRow(`*anIndex*`)`
Argument list:	*anIndex*	The row at which to insert a new row

See also:	`TR` object

TABLE.nextPage() (Method)

Part of the data binding mechanism that pages the table according to the contents of a database selection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTABLE*`.nextPage()`

When this method is called from your script, the data handler will load the next group of records from the data source and display them in the table cells. The number of records fetched from the database corresponds to the `dataPageSize` property.

See also:	`TABLE.dataPageSize`, `TABLE.previousPage()`, `TABLE.refresh()`

TABLE.previousPage() (Method)

Part of the data binding mechanism that pages the table according to the contents of a database selection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTABLE*`.previousPage()`

When this method is called from your script, the data handler will load the previous group of records from the data source and display them in the table cells. The number of records fetched from the database corresponds to the `dataPageSize` property.

See also:	`TABLE.dataPageSize`, `TABLE.nextPage()`, `TABLE.refresh()`

TABLE.refresh() (Method)

Part of the data binding mechanism that refreshes the table according to the contents of a database selection.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTABLE*.refresh()

When this method is called from your script, the data handler will load the current group of records from the data source and display them in the table cells. The number of records fetched from the database corresponds to the dataPageSize property.

This might be useful if the database is a means of communicating between several users who are accessing the data at the same time. You might set up some means of refreshing automatically with a timeout loop.

See also:	TABLE.dataPageSize, TABLE.nextPage(), TABLE.previousPage()

TABLE.rows[] (Collection)

A collection of all the rows in a <TABLE>.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Collection object	
JavaScript syntax:	-	*myTABLE*.rows

This collection includes any rows inside objects instantiated by <TBODY>, <TFOOT> and <THEAD> tags.

This is not necessarily the same as the rows collection returned from a TBODY object.

The columns and rows are different axes of the table. However they are described in different ways. The cols value is simply an integer that is set to the number of columns. The rows property is a reference to a collection of objects, one row object for each row in the table. Therefore to establish how many cells there are in the table, you need to multiply the table.cols value by the table.rows.length value.

The table.cols value should also be equivalent to table.rows.cells.length value.

See also:	Collection object, TABLE.cells[], TABLE.cols, TBODY.rows[], TFOOT.rows[], THEAD.rows[], TR.rowIndex

Property attributes:

ReadOnly.

TABLE.rules (Property)

Controls the drawing of border rules around table cells.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTABLE*`.rules`

This property controls which parts of a table's inner borders are rendered into the display. The following keywords are supported by this property:

Keyword	Description
all	All borders are placed around all cells
cols	Borders only delimit columns of cells
groups	Borders are placed between cell groups
none	No borders between cells are displayed at all
rows	Borders only delimit rows

Where borders are used to delimit groups of cells, the groups are established with the `<THEAD>`, `<TBODY>`, `<TFOOT>`, `<COLGROUP>` or `<COL>` HTML tags.

The `rules` property affects the inner borders around the cells in the table. The `frame` property controls the ruled edges around the outside of the table. Table ruling and bordering is quite complex and some time spent messing around with the property values is worthwhile.

Warnings:

- Be careful not to confuse this with the `rules[]` collection of a StyleSheet. These rules are ruled borders not style sheet rules.

See also:	`COL` object, `COLGROUP` object, `TABLE.frame`, `TBODY` object, `TFOOT` object, `THEAD` object

TABLE.summary (Property)

Adds a summary text object to the table.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTABLE*.summary

This is a textual summary of the table for presentation where the table cannot be rendered out. Braille browsers or speaking browsers for the sight impaired would utilize this and it might be useful as a mouse rollover tooltip text.

TABLE.tBodies[] (Collection)

A collection of all `TBODY` objects within a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	-	*myTABLE*.tBodies

If a table has any `<TBODY>` HTML tags defined within its extent, then the `TBODY` objects instantiated by those tags will become members of this collection.

See also:	`TABLE` object, `TBODY` object

Property attributes:

`ReadOnly`.

TABLE.tFoot (Property)

A reference to a `TFOOT` object for the table if there is one defined.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`TFOOT object`	
JavaScript syntax:	-	*myTABLE*.tFoot

If a table has a <TFOOT> HTML tag defined within its extent, then the TFOOT object instantiated by those tags can be accessed via this property. Note that a table can own only one TFOOT object.

See also:	TABLE object, TFOOT object

Property attributes:

ReadOnly.

TABLE.tHead (Property)

A reference to a THEAD object for the table if there is one defined.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	THEAD object	
JavaScript syntax:	-	*myTABLE*.tHead

If a table has a <THEAD> HTML tag defined within its extent, then the THEAD object instantiated by those tags can be accessed via this property. Note that a table can own only one THEAD object.

See also:	TABLE object, THEAD object

Property attributes:

ReadOnly.

TABLE.width (Property)

The width of the TABLE in pixels.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTABLE*.width

A table will be sized according to the content within it. The HTML tags for the table allow the table width to be specified as a percentage of the width of the containing HTML element. When the table is rendered, an extent rectangle can be drawn round it. An extent rectangle is the smallest rectangle that will completely enclose the table. This `width` property returns the horizontal size of that extent rectangle.

Including height and width information on tables is optional but it can significantly improve the performance of the layout engine as it renders the web page. This is because the layout engine does not need to wait until the table content has all been fetched before reserving sufficient space for it in the display.

See also:	`TABLE.height`

TableColElement object (Object/HTML)

A means of accessing cells in a particular column of the table without needing to traverse the rows.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0
Inherits from:	`Element object`
JavaScript syntax:	- *`myTableColElement`* `= new TableColElement()`
Object properties:	`align`, `ch`, `chOff`, `span`, `vAlign`, `width`
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`

See also:	`COL` object, `COLGROUP` object, `TABLE` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`align`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`ch`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`chOff`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`span`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`vAlign`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-
`width`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
`onDblClick`	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onHelp	-	5.0 +	-	5.0 +	-	-	-	Warning
onKeyDown	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning
onKeyPress	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning

onMouseUp	1.5 +	5.0 +	6.0 +	5.0 +	-	-	4.0 +	Warning

Inheritance chain

`Element` object, `Node` object

TableColElement.align (Property)

The alignment settings for a column or column group in the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myTableColElement`*`.align`
See also:	`COL` object, `COLGROUP` object, `TABLE` object	

TableColElement.ch (Property)

The alignment character for cells in the column.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myTableColElement`*`.ch`
See also:	`COL` object, `COLGROUP` object, `TABLE` object	

TableColElement.chOff (Property)

The offset of the alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myTableColElement`*`.chOff`
See also:	`COL` object, `COLGROUP` object, `TABLE` object	

TableColElement.span (Property)

The number of columns that a column group should span.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*`myTableColElement`*`.span`
See also:	`COL` object, `COLGROUP` object, `TABLE` object	

TableColElement.vAlign (Property)

The vertical alignment setting for a column within the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myTableColElement`*`.vAlign`
See also:	`COL` object, `COLGROUP` object, `TABLE` object	

TableColElement.width (Property)

The width of a column within the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTableColElement*.width

See also:	`COL` object, `COLGROUP` object, `TABLE` object

TableSectionElement object (Object/DOM)

DOM level 1 specifies a single object that MSIE implements as `TFOOT` and `THEAD` objects.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myTableSectionElement* = new TableSectionElement()

See also:	`THEAD` object, `TFOOT` object

tags (Property)

An alternative reference to the `document.tags` property in JSS.

Availability:	JavaScript – 1.2 Netscape – 4.0 Deprecated in Netscape 6.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	N	*myDocument*.tags

Warnings:

- This functionality is removed from Netscape 6.0.

See also:	JavaScript Style Sheets, `Document.tags[]`

taint() (Function/global)

A method for controlling secure access to data values.

Availability:	JavaScript – 1.1 Netscape – 3.0 Deprecated

This was removed at version 1.2 of JavaScript. If you encounter it in a script you are maintaining, it is probably wise to seek how it can be removed, otherwise it is likely to cause a run-time error.

Warnings:

- DO NOT USE THIS FUNCTION!

See also:	`Navigator.taintEnabled()`,`untaint()`

TBODY object (Object/HTML)

An object that encapsulates a `<TBODY>` tag within a `<TABLE>` block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTBODY* = *myDocument*.all.*anElementID*
	IE	*myTBODY* = *myDocument*.all.tags("TBODY")[*anIndex*]
	IE	*myTBODY* = *myDocument*.all[*aName*]
	-	*myTBODY* = *myDocument*.getElementById(*anElementID*)
	-	*myTBODY* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myTBODY* = *myTable*.tBodies[*anIndex*]
	-	*myTBODY* = *myDocument*.getElementsByTagName ("TBODY")[*anIndex*]
HTML syntax:	`<TBODY> ... </TBODY>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey`,`align`,`bgColor`,`chOff`,`rows`,`tabIndex`,`vAlign`	

Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`
Collections:	`rows[]`

Each table owns at least one `TBODY` object which is created by default even if you don't enclose some rows within `<TBODY>` tags. Additional `TBODY` objects can be created to break the table into sections if you need to.

The `TBODY` object represents that part of the table which excludes any footer or header cells.

You can access `TBODY` objects by their `ID` HTML tag attribute in the DOM hierarchy or by selecting them from the `tBodies[]` collection belonging to their parent `TABLE` object.

Warnings:

- Note that on some versions of the MSIE browser on the Macintosh platform, you cannot access the `innerHTML`, `innerText`, `outerHTML` or `outerText` properties of a `TBODY` object.

See also:	`Element` object, `Input.accessKey`, `TABLE` object, `TABLE.rules`, `TABLE.tBodies[]`, `TD` object, `TR` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`accessKey`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`align`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`bgColor`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`chOff`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`rows`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`tabIndex`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	Warning
`vAlign`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

Table continued on following page

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onMouseOut	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseOver	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onMouseUp	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

TBODY.align (Property)

A control for the alignment of cells within the `TBODY` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTBODY*.align

The alignment of the `TBODY` object with respect to its containing parent object is defined in this property. The available set of alignment specifiers include:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TABLE.align`, `TD.align`, `TFOOT.align`, `TH.align`, `THEAD.align`, `TR.align`

TBODY.bgColor (Property)

The background color of a `TBODY` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	-	*myTBODY*.bgColor

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value

TBODY.rows[] (Collection)

A collection of objects, each one containing a description of a row described by a <TR> tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTBODY*.rows

This is not necessarily the same as the rows collection returned from a TABLE object. That is because the rows[] collection belonging to a TBODY object can only list those TR objects that are contained within the <TBODY> tags.

See also:	Collection object, TABLE.cells[], TABLE.cols, TABLE.rows[], TFOOT.rows[], THEAD.rows[], TR.rowIndex

Property attributes:

ReadOnly.

TBODY.vAlign (Property)

A control for the vertical alignment of cells within the TBODY object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTBODY*.vAlign

The vertical alignment of the content within the table cells can be controlled across an entire TBODY extent with this property. The following keywords can be assigned to it:

- baseline
- bottom
- middle
- top

These may be also available on some implementations:

- absbottom
- absmiddle
- baseline
- texttop

See also:	TD.vAlign, TFOOT.vAlign, TH.vAlign, THEAD.vAlign, TR.vAlign

TD object (Object/HTML)

An object that encapsulates a single cell described by a <TD> tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	Element object	
JavaScript syntax:	IE	*myTD* = *myDocument*.all.*anElementID*
	IE	*myTD* = *myDocument*.all.tags("TD")[*anIndex*]
	IE	*myTD* = *myDocument*.all[*aName*]
	-	*myTD* = *myDocument*.getElementById(*anElementID*)
	-	*myTD* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myTD* = *myDocument*.getElementsByTagName ("TD")[*anIndex*]
HTML syntax:	<TD> ... </TD>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	abbr, accessKey, align, axis, background, bgColor, borderColor, borderColorDark, borderColorLight, cellIndex, ch, chOff, colSpan, headers, height, noWrap, rowSpan, scope, tabIndex, vAlign, width	

Event handlers:	onAfterUpdate, onBeforeUpdate, onBlur, onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onSelectStart

This object is instantiated by a <TD> tag that encloses the content of a single data cell.

Some of the property values in this object may be inherited from parent objects such as TABLE, TR and TBODY.

Warnings:

- Note that on some versions of the MSIE browser on the Macintosh platform, you cannot access the innerHTML, innerText, outerHTML or outerText properties of a TD object.

See also:	Element object, Input.accessKey, TABLE object, TBODY object, TH object, TR object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

onRowExit	-	3.0 +	-	4.0 +	-	-	-	-
onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

TD.abbr (Property)

An abbreviation value to be used for header cells in the column where the data cell resides.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTD*.abbr

See also:	`TH.abbr`

TD.align (Property)

A control for the alignment of content within the table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTD*`.align`

The alignment of the `TD` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TABLE.align`, `TBODY.align`, `TFOOT.align`, `TH.align`, `THEAD.align`, `TR.align`

TD.axis (Property)

The names group of related header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTD*`.axis`

See also:	`TH.axis`

TD.background (Property)

A URL for an image to be loaded into the background of the table cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTD*`.background`

If a background image is available, then its URL is contained in this property. Changing the value in this property will replace the background with a new one. However there may be a perceptible delay while the new image is fetched from the web server. You might be able to work around that by preloading the image and keeping a reference to it in a variable.

See also:	`TH.background`

TD.bgColor (Property)

The background color for this table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTD*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value, `TH.bgColor`

TD.borderColor (Property)

The color of the border around this table cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTD*`.borderColor`

You can use this property to determine the color of a border surrounding a table data cell. Note that there are additional properties to determine the highlights and lowlights of the table data cell border coloring.

See also:	`TH.borderColor`

TD.borderColorDark (Property)

The color value of the shadowed edge of the table cell border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTD*`.borderColorDark`

Table data cell borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the shadowed part of the table data cell border.

See also:	`TH.borderColorDark`

TD.borderColorLight (Property)

The color value of the highlighted edge of the table cell border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTD*`.borderColorLight`

Table data cell borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the highlighted part of the table data cell border.

See also:	`TH.borderColorLight`

TD.cellIndex (Property)

A zero-based integer value that indicates the position of this cell within the row. This is the horizontal coordinate position of the cell within the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTD*`.cellIndex`

You can access cells by means of the `rows[]` and `cells[]` collections belonging to the `TABLE` and `TR` objects respectively. This property provides the horizontal coordinate to use in the `TR.cells[]` collection to access the object describing this table cell.

Warnings:

- This is not supported on some versions of MSIE running on the Macintosh platform.

See also:	`TH.cellIndex`

Property attributes:

`ReadOnly`.

TD.ch (Property)

The alignment character for cells in a column arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTD*`.ch`

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR="..."` HTML tag attribute is reflected in this property and is active when the `CHAROFF="..."` HTML tag attribute is present.

See also:	`COL.ch`, `COLGROUP.ch`, `TH.ch`, `THEAD.ch`, `TR.ch`

TD.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTD*.chOff

The CHAR alignment style requires that an alignment character be specified with the `ch` property and that an offset measured in pixels be defined as its value. The offset value can be defined with the `CHAROFF` HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	`COL.chOff`, `COLGROUP.chOff`, `TH.chOff`, `THEAD.chOff`, `TR.chOff`

TD.colSpan (Property)

The number of columns that the table cell spans.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTD*.colSpan

This corresponds to the `COLSPAN` attribute within a `<TD>` HTML tag for a table cell description. It defines how many table columns this column is to span.

Warnings:

- Note that this may affect the value of the `cellIndex` property for subsequent cells within the same row. Although you cannot alter the `cellIndex` value directly, operations that affect the way the table is addressed may move cells around in the collection that represents all cells in the table.

See also:	`COL.span`, `COLGROUP.span`, `style.columnSpan`, `TH.colSpan`

TD.headers (Property)

A list of `ID` attribute values for header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTD*`.headers`

See also:	`TH.headers`

TD.height (Property)

The height in pixels of the table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTD*`.height`

The table cell space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

See also:	`TH.height`

TD.noWrap (Property)

Controls whether textual content is allowed to wrap within the table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*myTD*`.noWrap`

This is a Boolean value that controls whether the textual content is wrapped at the right hand window border or not.

If the value `false` is assigned to this property, then words will wrap as the page is drawn. This is good and is the way you would expect a browser to behave. The text will flow according to the space available.

If the value `true` is assigned to this property, the line of text will continue to the right until a `<BR>` or other block level tag is encountered. This will force the horizontal width of the page to be extremely large and the user will need to scroll furiously to be able to see the text and then scroll back again for the start of the next line.

Warnings:

- Only use this if you plan to place line breaks at frequent intervals yourself and really do need to control the line breaks manually. The effect is as if you had placed `<PRE>` tags around the content of the cell, although the font may still be a proportional font rather than the monospaced font that `<PRE>` sets up by default.

See also:	`TH.noWrap`

TD.rowSpan (Property)

Indicates how many rows the table cell is intended to span.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`Number primitive`
JavaScript syntax:	- *myTD*`.rowSpan`

This is used when you want to create complex tables. This technique may be an alternative to nesting a table. That is always good because sometimes nested tables can become very unwieldy.

See also:	`style.rowSpan`, `TH.rowSpan`

TD.scope (Property)

The scope covered by header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0

Property/method value type:	String primitive	
JavaScript syntax:	N	*myTD*.scope

See also:	TH.scope

TD.vAlign (Property)

The vertical alignment of content within the table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTD*.vAlign

The vertical alignment of the content within the table cells can be controlled for a single table cell with this property. The following keywords can be assigned to it:

- baseline
- bottom
- middle
- top

These may be also available on some implementations:

- absbottom
- absmiddle
- baseline
- texttop

This value will override the setting for a row or TBODY extent.

See also:	TBODY.vAlign, TFOOT.vAlign, TH.vAlign, THEAD.vAlign, TR.vAlign

TD.width (Property)

The width in pixels of the table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myTD*`.width`

The table cell space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

See also:	`TH.width`

telnet: URL (Request method)

Opens up a telnet client to do terminal mode access.

Open a telnet application and connect to the telnet port on the target server. You should be asked for a username and password. This will then give you access to a command line interface on the target host as long as you are validated.

See also:	`javascript:` URL, `mailbox:` URL, Security policy, URL

Ternary operator (Definition)

An operator that requires three arguments.

There is only one ternary operator in JavaScript. It is the `?:` conditional execution operator.

See also:	Binary operator, Conditionally execute (?:), Unary operator

Wrox *Instant JavaScript* – page – 21

Text object (Object/DOM)

The DOM level 1 specification describes a `Text` object which MSIE and Netscape 6.0 implement as a `textNode` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
JavaScript syntax:	-	*myText* = new Text()

Refer to:

`textNode` object

text/JavaScript (MIME type)

A MIME type that indicates the content is a JavaScript source text.

This is otherwise known as `application/x-javascript`, although `text/JavaScript` should be used.

See also:	`<SCRIPT TYPE="...">`, `<STYLE TYPE="...">`, MIME types

TEXTAREA object (Object/DOM)

A multiple line text cell in a form.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Inherits from:	`Input` object	
JavaScript syntax:	IE	*myTEXTAREA* = *myDocument*.all.*anElementID*
	IE	*myTEXTAREA* = *myDocument*.all.tags ("TEXTAREA")[*anIndex*]
	IE	*myTEXTAREA* = *myDocument*.all[*aName*]
	-	*myTEXTAREA* = *myDocument*.getElementById(*anElementID*)
	-	*myTEXTAREA* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myTEXTAREA* = *myDocument*.getElementsByTagName ("TEXTAREA")[*anIndex*]

HTML syntax:	`<TEXTAREA> ... </TEXTAREA>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`cols`, `readOnly`, `rows`, `type`, `value`, `wrap`	
Object methods:	`handleEvent()`, `select()`	
Event handlers:	`onAfterUpdate`, `onBeforeUnload`, `onBeforeUpdate`, `onBlur`, `onChange`, `onDragStart`, `onErrorUpdate`, `onFilterChange`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onRowEnter`, `onRowEnter?`, `onRowExit`, `onScroll`, `onSelect`, `onSelectStart`	

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

Untypically, there actually is a `TEXTAREA` class supported by MSIE. Most other kinds of input are simply an instance of the `Input` object class. Netscape prior to version 6.0 internally represents this object as a sub-class of the `Input` object even though it is created by a different HTML tag.

Event handling support via properties containing function objects was added to `TEXTAREA` objects at version 1.1 of JavaScript, but this will have changed to reflect the new DOM event model for Netscape 6.0.

Unlike MSIE, the Netscape 4 implementation of this sub-class of the `Input` object does not support the `click()` method or the `onSelect` event.

The example below seems to be supported by all browsers apart from Netscape 6.0. On this browser, the escape sequence `\x0D` needs to be changed to `\n` in order for the example to work.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<FORM>
Type some lines of text into the text area, click the button and they will be
sorted.<BR><BR>
<TEXTAREA VALUE="" NAME="BOX_A" ROWS=15 COLS=39></TEXTAREA><BR>
<INPUT TYPE="button" VALUE="Reveal" onClick="handleClick()">
</FORM>
<SCRIPT>
function handleClick()
{
   myString = document.forms[0].BOX_A.value;
   myArray = myString.split("\x0d");
   myArray.sort();
   document.forms[0].BOX_A.value = myArray.join("\x0d");
}
</SCRIPT>
</BODY>
</HTML>
```

`onRowExit`	-	3.0 +	-	4.0 +	-	-	-	-
`onScroll`	-	3.0 +	-	4.0 +	-	-	-	-
`onSelect`	1.0 +	3.0 +	2.0 +	4.0 +	3.0 +	-	-	-
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Input` object, `Node` object

TEXTAREA.cols (Property)

The number of columns that a `TextArea` may contain.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTEXTAREA*`.cols`

The text area in a form is sized by columns and rows in the default font used for input items. This property reflects the `COLS` HTML tag attribute in the `<TEXTAREA>` HTML tag that instantiates this object.

Style sheets are about the only way you can control the appearance of these cells because it is the only way the default input font can be changed. If the font size changes then the size of the `TEXTAREA` extent rectangle must change too. This might affect the layout of the page.

TEXTAREA.handleEvent() (Method)

Passes an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myTEXTAREA*`.handleEvent(`*anEvent*`)`
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`TEXTAREA` object, `Window.handleEvent()`

TEXTAREA.readOnly (Property)

When set to `true`, the `TextArea` cannot be modified.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Boolean value`	
JavaScript syntax:	-	*myTEXTAREA*`.readOnly`

The `TextArea` content is defined but cannot be changed by the user. You may want to control this property based on JavaScript code. If the property is set `true` from the HTML document source, you will have to unlock the field before the user can modify the field content.

See also:	`Input.readOnly`, `Password.readOnly`, `TextCell.readOnly`

Property attributes:

`ReadOnly`.

TEXTAREA.rows (Property)

The number of rows in a text area.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTEXTAREA*`.rows`

The text area in a form is sized by columns and rows in the default font used for input items. This property reflects the `ROWS` HTML tag attribute in the `<TEXTAREA>` HTML tag that instantiates this object.

Style sheets are about the only practical way you can control the appearance of these cells because it is the only way the default input font can be changed. If the font size changes then the size of the `TEXTAREA` extent rectangle must change too. This might affect the layout of the page.

TEXTAREA.select() (Method)

Selects all the text within the <TEXTAREA> cell allowing it to be cut and pasted by the user.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera browser – 3.0	
JavaScript syntax:	-	*myTEXTAREA*.select()

If the browser supports a Selection object or TextRange objects, you may then be able to access the selected text using JavaScript. Of course in a form object, the text of the whole object can also be accessed, but this may not be what was selected because the user may select all or part of a page, and that selection may span several form elements or be only part of a form element.

See also:	Input.select()

TEXTAREA.type (Property)

The type indicator for this Input object.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTEXTAREA*.type

This property is supported to remain consistent with all other form elements. The value returned by a TEXTAREA object should always be "textarea".

This allows you to determine the input type when the form elements array is traversed. Then you can select appropriate handling based on the type value for the element.

See also:	Input.type

Property attributes:

ReadOnly.

TEXTAREA.value (Property)

The text string that has been entered into the text area.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTEXTAREA*`.value`

This may be the same as the `defaultValue` if the user has not yet entered any text into the `TEXTAREA`.

See also:	`Input.value`, `TextCell.value`

TEXTAREA.wrap (Property)

Controls the kind of word wrapping effect within the text area.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTEXTAREA*`.wrap`

You would normally want the text to wrap within a text area field so that you could see it all. However there may be times when other text wrapping regimes could be useful.

This property will accept the following keywords:

- `off`
- `physical`
- `virtual`

The `off` keyword switches word wrapping off altogether.

The `physical` keyword wraps text as it reaches the right border. It will also send the carriage returns back to the server when the form data is submitted.

The `virtual` keyword shows the word wrapping effect on the screen but the carriage returns are not sent back to the server which remains unaware that any wrapping has occurred. This is probably the most useful setting.

TextCell object (Object/DOM)

A single line text cell in a form.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Inherits from:	`Input object`	
JavaScript syntax:	-	*myTextCell* = *myDocument*.*aFormName*.*anElementName*
	-	*myTextCell* = *myDocument*.*aFormName*.elements[*anItemIndex*]
	IE	*myTextCell* = *myDocument*.all.*anElementID*
	IE	*myTextCell* = *myDocument*.all.tags("INPUT")[*anIndex*]
	IE	*myTextCell* = *myDocument*.all[*aName*]
	-	*myTextCell* = *myDocument*.forms[*aFormIndex*].*anElementName*
	-	*myTextCell* = *myDocument*.forms[*aFormIndex*].elements[*anItemIndex*]
	-	*myTextCell* = *myDocument*.getElementById(*anElementID*)
	-	*myTextCell* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTextCell* = *myDocument*.getElementsByTagName("INPUT")[*anIndex*]
HTML syntax:	`<INPUT TYPE="text">`	
Argument list:	*anIndex*	A valid reference to an item in the collection
	aName	The `NAME` attribute of an element
	anElementID	The `ID` attribute of an element
	anItemIndex	A valid reference to an item in the collection
	aFormIndex	A reference to a particular form in the `forms` collection
Object properties:	`maxLength`, `readOnly`, `size`, `type`, `value`	
Object methods:	`handleEvent()`, `select()`	
Event handlers:	`onAfterUpdate`, `onBeforeUpdate`, `onBlur`, `onChange`, `onFilterChange`, `onFocus`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onRowEnter`, `onRowExit`, `onSelect`	

Many properties, methods and event handlers are inherited from the `Input` object class. Refer to topics grouped with the "Input" prefix for details of common functionality across all sub-classes of the `Input` object super-class.

There isn't really a `TextCell` object class, but it is helpful when trying to understand the wide variety of input element types if we can reduce the complexity by discussing only the properties and methods of a text cell. In actual fact, the object is represented as an item of the `Input` object class.

Event handling support via properties containing function objects was added to `TextCell` objects at version 1.1 of JavaScript.

The Netscape implementation of this sub-class of the `Input` object does not support as wide a variety of events as the MSIE implementation. In particular, the keyboard events are not supported.

The WebTV set-top box does not support the `onkeypress` event handler for this object type prior to the Summer 2000 release.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<DIV ID="RESULT">?</DIV>
<FORM>
<INPUT TYPE="text" VALUE="" NAME="BOX_A"><BR>
<INPUT TYPE="text" VALUE="" NAME="BOX_B"><BR>
<INPUT TYPE="text" VALUE="" NAME="BOX_C"><BR>
<INPUT TYPE="text" VALUE="" NAME="BOX_D"><BR><BR>
<INPUT TYPE="button" VALUE="Reveal" onClick="handleClick()">
</FORM>
<SCRIPT>
function handleClick()
{
   myString  = "[";
   myString += document.forms[0].elements.BOX_A.value;
   myString += "] [";
   myString += document.forms[0].elements.BOX_B.value;
   myString += "] [";
   myString += document.forms[0].elements.BOX_C.value;
   myString += "] [";
   myString += document.forms[0].elements.BOX_D.value;
   myString += "]";
   document.all.RESULT.innerText = myString;
}
</SCRIPT>
</BODY>
</HTML>
```

Inheritance chain:

`Element` object, `Input` object, `Node` object

TextCell.handleEvent() (Method)

Pass an event to the appropriate handler for this object.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*`myTextCell`*`.handleEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event to be handled by this object

This applies to Netscape prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 3 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an `Event` object that contains information about the event.

See also:	`TextCell` object, `Window.handleEvent()`

TextCell.maxLength (Property)

The maximum length of values to be entered into the text cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myTextCell*`.maxLength`

This defines the maximum number of characters that are allowed to be entered into the text field. The browsers differ in how they handle this value. Some will warn the user with a beep or flash on the screen, others simply stop accepting keystrokes when this number of characters have been entered.

See also:	`Input.maxLength`, `Password.maxLength`

TextCell.readOnly (Property)

When set to `true`, the text cell contents cannot be changed.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextCell*`.readOnly`

The `TextCell` content is defined but cannot be changed by the user. You may want to control this property based on JavaScript code. If the property is set `true` from the HTML document source, you will have to unlock the field before the user can modify the field content.

See also:	`Input.disabled`, `Input.readOnly`, `Password.readOnly`, `TEXTAREA.readOnly`

Property attributes:

`ReadOnly`.

TextCell.select() (Method)

Selects all the textual content of a `<INPUT>` text cell allowing the user to cut and paste it if they so wish.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
JavaScript syntax:	-	*myTextCell*.select()

If the browser supports a `Selection` object or `TextRange` objects, you may then be able to access the selected text using JavaScript. Of course in a `form` object, the text of the whole object can also be accessed, but this may not be what was selected because the user may select all or part of a page and that selection may span several form elements or only part of a form element.

See also:	`Input.select()`

TextCell.size (Property)

The number of characters that have been typed into the text cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextCell*.size

This is an approximate measure at best. You cannot be sure how wide this box really needs to be when using a proportionally spaced font in it. The browser will size the box close to an optimal size to cope with the specified number of characters.

Warnings:

- It can be quite distracting if the box size is too small to accommodate the `maxLength` number of characters. This can leave the user having to do some cumbersome select actions with the mouse or use arrow keys to reveal the hidden parts of the textual content of the box.

See also:	`Input.size`, `Password.size`

TextCell.type (Property)

The type of this `Input` object.

Availability:	DOM level – 1 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTextCell*.type

The value of this property for a `TextCell` object must always be "`text`".

This value is necessary to determine the type of form element because this object is really an instance of the `Input` class and not the `TextCell` class. There is actually no `TextCell` class.

See also:	`Input.type`

Property attributes:

`ReadOnly`.

TextCell.value (Property)

The text string that has been entered into the text cell.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTextCell*.value

This may be the same as the `defaultValue` if the user has not yet entered any text into the `TextCell`.

See also:	`Input.value`, `TEXTAREA.value`

textNode object (Object/DOM)

A string of text represented as a node within the document hierarchy.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Inherits from:	`CharacterData object`	
JavaScript syntax:	IE	*myTextNode* = *myDocument*.all.tags("TEXT")[*anIndex*]
	-	*myTextNode* = *myDocument*.createTextNode(*someData*)
Argument list:	*someData*	Textual content for the text node
	anIndex	A selector within a collection of text nodes
Object properties:	`data, length`	
Object methods:	`splitText()`	

The MSIE browser models the document as a collection of nodes. Clearly, an HTML tag corresponds to an object. However, what isn't so obvious is that the text in between HTML tags is collected together and represented by a `textNode` object.

These `textNodes` are generally accessible as child objects belonging to an object instantiated by an HTML tag.

For example:

```
AAA<P>BBB<P>CCC
```

can be accessed as follows:

The `<P>` tags are objects which are members of the `document.getElementsByTagName("P")` collection. The text "BBB" is referenced through the `firstChild` property of the `P` object instantiated by the first `<P>` tag. The text "CCC" is a `textNode` object referenced via the `firstChild` property of the second `<P>` tag.

The DOM level 3 specification is expected to add the following method to the `textNode` object:

- `isWhitespaceInElementContent()`

See also:	`Attribute.nodeName, Document.createTextNode()`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`data`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-
`length`	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
splitText()	1.5 +	5.0 +	6.0 +	5.0 +	-	1 +	-

Inheritance chain:

CharacterData object, Node object

textNode.data (Property)

The data associated with a text node within the document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTextNode*.data

A text node is that textual content in between objects that represent HTML tags. If the HTML tags are bricks in a wall, then the text is the mortar joining them all together. The text nodes could also be called interstitial nodes because they exist in the cracks between HTML Elements.

textNode.length (Property)

The length of the text in a textNode object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	Number primitive	
JavaScript syntax:	-	*myTextNode*.length

The text enclosed in a text node can be measured for length by this property. However it is still stored as a string value in the data property and you should not assume that it is an array simply because it has a length property.

Property attributes:

ReadOnly.

textNode.splitText() (Method)

A means of splitting the text in a text node into two so that HTML can be placed in between them.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0	
Property/method value type:	`textNode object`	
JavaScript syntax:	-	*myTextNode*`.splitText(`*anOffset*`)`
Argument list:	*anOffset*	The location within the text data to split the text at

This is functionally similar to splitting a `String` object. The character index, using a zero-based counting scheme where the split is to occur, should be passed as an argument.

The method returns the text to the right of the split. The receiving object is truncated at the split point. You can then append some HTML to the receiving object and then append the text object that was returned by the method.

TextRange object (Object/JScript)

An object that represents part of the text stream of an HTML document.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTextRange* `=` *myElement*`.createTextRange()`
Object properties:	`boundingHeight,boundingLeft,boundingTop, boundingWidth,htmlText,text`	
Object methods:	`collapse(),compareEndPoints(),duplicate(), execCommand(),expand(),findText(),getBookmark(), getBoundingClientRect(),getClientRects(), inRange(),isEqual(),move(),moveEnd(),moveStart(), moveToBookmark(),moveToElementText(), moveToPoint(),parentElement(),pasteHTML(), queryCommandEnabled(),queryCommandIndeterm(), queryCommandState(),queryCommandSupported(), queryCommandText(),queryCommandValue(),select(), setEndPoint()`	

The main purpose of a `TextRange` object is to encapsulate that part of the document text that depends on the user having used the mouse to select a portion of text. A `TextRange` object can also encapsulate an insertion point in the text of a document.

An insertion point is encapsulated by creating a TextRange object that is of zero length.

A new TextRange object is instantiated with the createTextRange() method which can be applied to the following object types which can contain selectable text:

- BODY
- TextCell
- TEXTAREA

The TextCell and TEXTAREA objects are members of the Form Element category, sometimes called Input Elements.

When you have created a TextRange object, you can then manipulate its properties to select just that portion of text in the document that you want.

Once you have marked the text you want within the start and end points, you can replace the content of the TextRange with the pasteHTML() method to operate on the text in the document. However, there may be limitations on when and how you can do this depending on the extent of the TextRange object's boundaries.

Warnings:

- There are platform limitations to the TextRange object that mean it is only functional on the Windows platform within MSIE. This limits the audience for your ingenuity in using it, but within a captive environment, this capability can still be useful.

See also:	BODY.createTextRange(), Button object, BUTTON object, Element.isTextEdit, Element.parentTextEdit, Input.createTextRange(), Selection object, selection.createRange(), TEXTAREA object, TextCell object

Inheritance chain:

`Element` object, `Node` object

TextRange.boundingHeight (Property)

The height of the extent rectangle around selected text on the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRange`*`.boundingHeight`

`TextRange` objects use the start and end points to map into the physical display of the text on the screen. Although it may not be visible, the text range nevertheless corresponds to a spatial extent rectangle that can be described using pixel coordinates. The value of this property is the height of the extent rectangle that currently encloses the text encapsulated by the `TextRange` object.

See also:	`TextRange.boundingWidth`

Property attributes:

`ReadOnly`.

TextRange.boundingLeft (Property)

The left edge of a selected text on the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRange`*`.boundingLeft`

`TextRange` objects use their start and end points to map into the physical display of the text on the screen. Although it may not be visible, the text range nevertheless corresponds to a spatial extent rectangle that can be described using pixel coordinates. This property's value is the X coordinate of the left edge of the extent rectangle that currently encloses the text encapsulated by the `TextRange` object.

Property attributes:

`ReadOnly`.

TextRange.boundingTop (Property)

The top edge of a selected text on the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRange`*`.boundingTop`

`TextRange` objects use their start and end points to map into the physical display of the text on the screen. Although it may not be visible, the text range nevertheless corresponds to a spatial extent rectangle that can be described using pixel coordinates. This property's value is the Y coordinate of the top edge of the extent rectangle that currently encloses the text encapsulated by the `TextRange` object.

Property attributes:

`ReadOnly`.

TextRange.boundingWidth (Property)

The width of a selected text on the page.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRange`*`.boundingWidth`

`TextRange` objects use their start and end points to map into the physical display of the text on the screen. Although it may not be visible, the text range nevertheless corresponds to a spatial extent rectangle that can be described using pixel coordinates. The value of this property is the width of the extent rectangle that currently encloses the text encapsulated by the `TextRange` object.

See also:	`TextRange.boundingHeight`

Property attributes:

`ReadOnly`.

TextRange.collapse() (Method)

A method that shrinks a text range to an insertion point.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*`myTextRange`*`.collapse()`
	IE	*`myTextRange`*`.collapse(`*`aFlag`*`)`
Argument list:	*`aFlag`*	A Boolean value to indicate which end of the text range should become the insertion point

You can call this method to shrink the `TextRange` to an insertion point either at the start or end of the text range.

If no value is passed as an argument, then the insertion point is taken from the start of the text range.

A Boolean `true` value also uses the startpoint as the new insertion point.

A Boolean value of `false` selects the endpoint as the new insertion point.

TextRange.compareEndPoints() (Method)

Compare two `TextRange` objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.compareEndPoints (*anOperator*, *aTextRange*)
Argument list:	*anOperator*	A selector for the kind of comparison
	aTextRange	A reference to another `TextRange` object

The typical means of comparing two objects is to pass a reference to one object as an argument to a method invoked on the other. This method performs such a comparison. The first keyword is an operator to indicate the kind of comparison to be carried out. The second argument is a reference to the second `TextRange` object that it is to be compared with.

The following keywords can be passed in the first argument as string values:

- `StartToEnd`
- `StartToStart`
- `EndToStart`
- `EndToEnd`

The values returned by this method are -1, 0 or 1. These indicate whether the first value is before, coincident with or after the second value. The operator dictates which values are to be tested.

See also:	`TextRange.isEqual()`,`TextRange.setEndPoint()`

TextRange.duplicate() (Method)

Duplicate a `TextRange` object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`TextRange object`	
JavaScript syntax:	IE	*myTextRange*.duplicate()

This is a deep copy of a `TextRange` object. Simply assigning the value of one variable copies only the reference to the same object. You need to call this method to create a new object whose properties are set to the same values as its parent.

TextRange.execCommand() (Method)

Part of an MSIE special document command handling mechanism. Execute a command across the text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*.execCommand(*aCommand*)
	IE	*myTextRange*.execCommand(*aCommand*, *aUIFlag*)
	IE	*myTextRange*.execCommand(*aCommand*, *aUIFlag*, *aParameter*)
Argument list:	*aCommand*	An MSIE command to execute
	aParameter	Parameter value to the command
	aUIFlag	Display or inhibit UI appearance

The MSIE browser supports a special command handling interface that hooks through the browser's user interface. It allows you to automate user actions in a way that other browsers and non-Windows platform users cannot take advantage of. It is another example of the Microsoft Embrace, Enhance and Eliminate approach to dominating the browser marketplace.

Although this is a method that can be applied to a `document` object, many of the commands that are executed through this mechanism will require that a `TextRange` object is created and available first.

The result returned by this method is a Boolean `true` if the action succeeded and a Boolean `false` if it failed in some way.

The flag parameter provides a way to suppress any user interface changes that may appear as a result of executing the command.

Name	Description
2D-Position	Absolutely positioned elements can be moved by dragging.
AbsolutePosition	Sets an element's position property to "absolute".
BackColor	The background color for the current selection is set to the color value passed in the parameter argument.
Bold	The selected text has `<B>` and `</B>` tags placed at either end.
Copy	The `TextRange` is copied to the clipboard.
CreateBookmark	Carries out modifications to an existing `<A>` tag or creates one, then adds the item to the bookmarks list. The parameter provides the `NAME` value. The `<A>` tag is removed if there is no parameter.
CreateLink	Wraps an `<A HREF="...">` tag around the selected text. The parameter contains the URL value for the HREF.
Cut	Performs a cut to clipboard.
Delete	The text range is deleted. This is not the same as a Cut command.

Table continued on following page

Name	Description
FontName	Wraps <FONT> tags round the selection. The required font face is passed in the parameter.
FontSize	Wraps <FONT> tags round the selection and defines the font's size from the parameter value.
ForeColor	Redefines the foreground text color for the selection taking the color value from the parameter.
FormatBlock	Wraps a <BLOCK> tag round the TextRange.
Indent	The TextRange is indented.
InsertButton	A <BUTTON> tag is placed at the current insertion point in the document. Its ID value is defined by the parameter.
InsertFieldset	A <FIELDSET> tag is inserted with the ID value being taken from the parameter.
InsertHorizontalRule	An <HR> tag is added at the current insertion point.
InsertIFrame	A new <IFRAME> is inserted with the content URL being provided in the parameter.
InsertImage	Overwrites an image on the current selection.
InsertInputButton	An <INPUT TYPE="Button"> is added with its ID value coming from the parameter.
InsertInputCheckbox	An <INPUT TYPE="Checkbox"> tag is added with its ID value coming from the parameter.
InsertInputFileUpload	An <INPUT TYPE="FileUpload"> is added with its ID value coming from the parameter.
InsertInputHidden	An <INPUT TYPE="Hidden"> is added with its ID value coming from the parameter.
InsertInputImage	An <INPUT TYPE="Image"> is added with its ID value coming from the parameter.
InsertInputPassword	An <INPUT TYPE="Password"> is added with its ID value coming from the parameter.
InsertInputRadio	An <INPUT TYPE="Radio"> is added with its ID value coming from the parameter.
InsertInputReset	An <INPUT TYPE="Reset"> is added with its ID value coming from the parameter.
InsertInputSubmit	An <INPUT TYPE="Submit"> is added with its ID value coming from the parameter.
InsertInputText	An <INPUT TYPE="Text"> is added with its ID value coming from the parameter.
InsertMarquee	A new <MARQUEE> is added with the ID being taken from the parameter.
InsertOrderedList	A new <OL> is added with the ID being taken from the parameter.
InsertParagraph	A new <P> is added with the ID being taken from the parameter.
InsertSelectDropdown	A new <SELECT TYPE="select-one"> is added with the ID being taken from the parameter.
InsertSelectListbox	A new <SELECT TYPE="select-multiple"> is added with the ID being taken from the parameter.

Table continued on following page

Name	Description
InsertTextArea	A new <TEXTAREA> is added with the ID being taken from the parameter.
InsertUnorderedList	A new <UL> is added with the ID being taken from the parameter.
Italic	The TextRange is enclosed with <I> tags.
JustifyCenter	The TextRange is centered within its parent object.
JustifyFull	The TextRange is fully justified.
JustifyLeft	The TextRange is left justified.
JustifyRight	The TextRange is right justified.
LiveResize	Causes the MSHTML Editor to update an element's appearance continuously during a resizing or moving operation, rather than updating only at the completion of the move or resize.
MultipleSelection	Allows for the selection of more than one site selectable element at a time when the user holds down the SHIFT or CTRL keys.
Outdent	The complement of the Indent command.
OverWrite	The input-typing mode is set to overwrite if the parameter value is true and insert if it is false.
Paste	The contents of the clipboard are pasted into the TextRange.
PlayImage	If an image represents a video clip, then it starts playing.
Refresh	The document is reloaded.
RemoveFormat	The complement of the FormatBlock command.
SaveAs	Saves the current web page to a file.
SelectAll	The entire document text is selected.
StopImage	The complement of the PlayImage command.
UnBookmark	The complement of the CreateBookmark command.
Underline	Places <U> tags around the TextRange.
Unlink	The complement of the CreateLink command.
Unselect	Unselects whatever was selected to create the TextRange. Many commands are now inappropriate until a new TextRange has been created.

None of these commands provides any greatly significant functionality as far as dynamic HTML is concerned. A few of them allow you to manage the clipboard and bookmark lists. It is probably best to avoid using these commands and use the more usual ways of accessing the document internals.

See also:	Document.execCommand(),FileUpload.select(), TextRange.queryCommandEnabled(), TextRange.queryCommandIndeterm(), TextRange.queryCommandState(), TextRange.queryCommandSupported(), TextRange.queryCommandText(), TextRange.queryCommandValue()

TextRange.expand() (Method)

Expands a `TextRange` by a character, word, sentence or story.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.expand(*aSelector*)
Argument list:	*aSelector*	Indicates what to expand the `TextRange` by

This method has a single argument. The argument indicates what to look for when expanding the `TextRange` object. The end point is modified according to the rules determined by this keyword. The following keywords can be applied:

- `character`
- `word`
- `sentence`
- `textedit`

The `character` keyword causes the endpoint to be indexed onwards by a single character position.

The `word` keyword looks for the next word break in the document text. It also moves the start point to he beginning of the word.

The `sentence` keyword looks for the next full stop at the end of a sentence. It also looks onwards from this to move the start point to the beginning of the sentence.

The `textedit` keyword restores the `TextRange` so it encapsulates only the original selection.

This method returns a Boolean `true` if the range expansion succeeded and a Boolean `false` if it didn't.

See also:	`TextRange.move()`

TextRange.findText() (Method)

Defines a text range according to a search.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`TextRange object`	
JavaScript syntax:	IE	*myTextRange*.findText(*aString*)
Argument list:	*aString*	A string to find in the `TextRange` object

This is a case-insensitive search for a matching text. If the text is located, then the start and end points of the `TextRange` object are adjusted to encapsulate the found text chunk.

The `TextRange` needs to be collapsed for this to work. It could be collapsed and made to point at the start of the document if you want to search the whole text, otherwise the search commences at the current insertion point.

This method returns a Boolean `true` if it found a match and a Boolean `false` if it didn't.

TextRange.getBookmark() (Method)

Bookmarks a position in a text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`TextRange bookmark`	
JavaScript syntax:	IE	*`myTextRange`*`.getBookmmark()`

These are not user bookmarks that are stored in the favorites menu but are special bookmarks for remembering access points in `TextRange` objects.

This method generates a special value that can be stored in a variable and can later be passed to the `moveToBookmark()` method to restore the start and end points of the `TextRange` to the current values. It's a simple way to store and restore the settings of a `TextRange`.

See also:	`TextRange.moveToBookmark()`

TextRange.getBoundingClientRect() (Method)

A method that returns a rectangle measured in pixels within the client display surface.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Rect object`	
JavaScript syntax:	IE	*`myTextRange`*`.getBoundingClientRect()`

This method evaluates the current start and end points of the text range and works out the pixel locations of a bounding rectangle in the display screen. These are then used to instantiate a `textRectangle` object which is returned with the extent rectangle of the `TextRange` object as its values.

A `TextRange` may describe several discontinuous blocks of text. Each one of these would be bounded by a separate client rectangle. This extent rectangle bounds the entire set.

See also:	`Rect` object, `textRectangle` object

TextRange.getClientRects() (Method)

A collection of `textRectangle` objects within the client display surface.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Collection` object	
JavaScript syntax:	IE	*myTextRange*`.getClientRects()`

A `TextRange` may describe several discontinuous blocks of text. Each one of these would be bounded by a separate client rectangle.

This method evaluates the current start and end points of the text range and works out the pixel locations of a bounding rectangle in the display screen for each of the different text areas. These are then used to instantiate a `textRectangle` object which is added to a collection.

The collection of individual client `textRectangle` objects is then returned to the caller.

See also:	`textRectangle` object

TextRange.htmlText (Property)

Returns a text range as HTML source.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextRange*`.htmlText`

This is somewhat similar to the `innerHTML` of an `Element` object. In this case the start and end points of the `TextRange` are taken as the delimiting boundaries. The HTML contained within those boundaries can be returned to your script when the property is read.

Because this property is read-only, you will need to use the `pasteHTML()` method to replace the HTML bounded by a `TextRange` object.

See also:	`TextRange.pasteHTML()`,`TextRange.text`

Property attributes:

`ReadOnly`.

TextRange.inRange() (Method)

Tests for one text range within another.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*`.inRange(`*aTextRange*`)`
Argument list:	*aTextRange*	Another `TextRange` to test against

Given that you have two distinctly separate `TextRange` objects, you can test whether one is contained within the other by passing it as an argument to this method.

TextRange.isEqual() (Method)

Tests two text ranges for equality.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*`.isEqual(aTextRange)`
Argument list:	*aTextRange*	Another `TextRange` to compare against

Given that you have two distinctly separate `TextRange` objects, you can test whether they are both equivalent to one another by passing one as an argument to this method being called on the other. You may accomplish the same thing less conveniently with the `compareEndPoints()` method.

See also:	`TextRange.compareEndPoints()`

TextRange.move() (Method)

Relocates the insertion point of a `TextRange`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*`.move(`*aSelector*`)`
	IE	*myTextRange*`.move(`*aSelector*`, `*aCount*`)`
Argument list:	*aCount*	Indicates how many times to iterate
	aSelector	A rule selector

The `TextRange` is collapsed to an insertion point at the end of the current bounded range. Then the keyword determines how the insertion point is indexed onwards or backwards.

This method has two arguments. The first argument indicates what to look for when moving the `TextRange` object. The second indicates how many times to apply that location search. A negative value indicates a backwards search. The insertion point is modified according to the rules determined by this keyword. If the second argument is omitted, it is assumed to be the value 1. The following keywords can be applied:

- `character`
- `word`
- `sentence`
- `textedit`

The `character` keyword causes the insertion point to be indexed onwards by a single character position.

The `word` keyword looks for the next word break in the document text.

The `sentence` keyword looks for the next full stop at the end of a sentence.

The `textedit` keyword moves the insertion point either to the beginning or end of the original selection.

This method returns an integer describing how many times it was able to move the insertion pointer.

See also:	`TextRange.expand()`

TextRange.moveEnd() (Method)

Relocates the end point of a `TextRange`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.moveEnd(*aSelector*)
	IE	*myTextRange*.moveEnd(*aSelector*, *aCount*)
Argument list:	*aCount*	Indicates how many times to iterate
	aSelector	A rule selector

This works in almost the same way as the `move()` method but instead of collapsing the `TextRange` first, it just operates on the end point of the current text range. Then the keyword determines how the end point is indexed onwards or backwards.

This method has two arguments. The first argument indicates what to look for when adjusting the `TextRange` object. The second indicates how many times to apply that location search. A negative value indicates a backwards search. The end point is modified according to the rules determined by this keyword. If the second argument is omitted, it is assumed to be the value 1. The following keywords can be applied:

- `character`
- `word`
- `sentence`
- `textedit`

The `character` keyword causes the endpoint to be indexed onwards by a single character position.

The `word` keyword looks for the next word break in the document text.

The `sentence` keyword looks for the next full stop at the end of a sentence.

The `textedit` keyword moves the end point either to the beginning or end of the original selection.

This method returns an integer describing how many times it was able to move the end point.

Warnings:

- Be careful that the start and end points do not get crossed over. It is possible that the internal logic of the browser would cope with this and fix things up, but it is a likely area where the browser may be expected to fail.

TextRange.moveStart() (Method)

Relocates the start point of a `TextRange`.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.moveStart(*aSelector*)
	IE	*myTextRange*.moveStart(*aSelector*, *aCount*)
Argument list:	*aCount*	Indicates how many times to iterate
	aSelector	A rule selector

This works in almost the same way as the `move()` method but instead of collapsing the `TextRange` first, it just operates on the start point of the current text range. Then the keyword determines how the start point is indexed onwards or backwards.

This method has two arguments. The first argument indicates what to look for when adjusting the `TextRange` object. The second indicates how many times to apply that location search. A negative value indicates a backwards search. The start point is modified according to the rules determined by this keyword. If the second argument is omitted, it is assumed to be the value 1. The following keywords can be applied:

- `character`
- `word`
- `sentence`
- `textedit`

The `character` keyword causes the startpoint to be indexed onwards by a single character position.

The `word` keyword looks for the next word break in the document text.

The `sentence` keyword looks for the next full stop at the end of a sentence.

The `textedit` keyword moves the start point either to the beginning or end of the original selection.

This method returns an integer describing how many times it was able to move the start point.

Warnings:

- Be careful that the start and end points do not get crossed over. It is possible that the internal logic of the browser would cope with this and fix things up, but it is a likely area where the browser may be expected to fail.

TextRange.moveToBookmark() (Method)

Restores a bookmarked TextRange.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.moveToBookmark(*aBookmark*)
Argument list:	*aBookmark*	A bookmark obtained from a `getBookmark()` method call

This is the complement of the `getBookmark()` method. It takes the result of the `getBookmark()` method that would have been stored in a variable. The `TextRange` start and end points are then reset to the value that was originally defined when the bookmark was recorded.

The Boolean value `true` is returned if the bookmarked locations could be restored and a Boolean `false` value if they couldn't. It really depends on what has happened since the bookmark was captured as to whether it can realistically be restored or not.

See also:	`TextRange.getBookmark()`

TextRange.moveToElementText() (Method)

Expands the text range to encompass an HTML element.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.moveToElementText(*anObject*)
Argument list:	*anObject*	A reference to an object in the document

By passing an HTML `Element` object to this method, you can set the start and end points of the `TextRange` object to neatly bound the text of the HTML `Element` object.

TextRange.moveToPoint() (Method)

Expand the text range to include an x, y location.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.moveToPoint(*anX*, *aY*)
Argument list:	*anX*	An X coordinate value
	aY	A Y coordinate value

The `TextRange` can be set to create an insertion point in the text that corresponds with the X-Y coordinate point of an onscreen location. This is smart stuff indeed because it would be very difficult to compute the text flow and correlate it with screen coordinates.

The result is that the `TextRange` is set to an insertion point.

TextRange.parentElement() (Method)

A reference to an object that is the next outermost item in the document hierarchy.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Element object`	
JavaScript syntax:	IE	*myTextRange*.parentElement()

Having established that a `TextRange` may correspond to some block of text within the document, this returns a reference to an HTML `Element` object that fully encloses the `TextRange`.

For example, if a `TextRange` was set to bound a couple of `Input` elements within a Form, this method might return the `Form` object because that is the next outermost logical object. Of course you could get a `TABLE` object if the form contained a table with the input elements inside it.

TextRange.pasteHTML() (Method)

Pastes HTML or plain text into the text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*.pasteHTML(*someHTML*)
Argument list:	*someHTML*	A string containing valid HTML

Because the `htmlText` property is a read-only value, you will need to use this method to replace the HTML bounded by the `TextRange` or to insert HTML if the `TextRange` describes an insertion point.

See also:	`TextRange.htmlText`

TextRange.queryCommandEnabled() (Method)

Part of an MSIE special document command handling mechanism. Indicates the disposition of the specified command.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*.queryCommandEnabled (*aCommandName*)
Argument list:	*aCommandName*	An MSIE command name

This method returns a Boolean value that indicates whether the named command is enabled. Many factors can affect the result of this command. It may depend on the ready state of the document or whether a selection is in force.

Refer to the `TextRange.execCommand()` method for a list of the available commands.

See also:	`Document` object, `Document.queryCommandEnabled()`, `TextRange.execCommand()`

TextRange.queryCommandIndeterm() (Method)

Part of an MSIE special document command handling mechanism. Indicates whether the command is in an indeterminate state.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*.queryCommandIndeterm (*aCommandName*)
Argument list:	*aCommandName*	An MSIE command name

If the document is not fully loaded (you can check the `readyState`), or if a command might not be available due to some of its prerequisites not being set (such a selection creating a `TextRange`), this method will return a Boolean `true` value. If it returns a Boolean `false`, then the command may be available as determined by the enabled test.

See also:	`Document` object, `Document.queryCommandIndeterm()`, `TextRange.execCommand()`

TextRange.queryCommandState() (Method)

Part of an MSIE special document command handling mechanism. Returns the current state of a command.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive` or `Null`	
JavaScript syntax:	IE	*myTextRange*`.queryCommandState(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

This will return one of the following values:

- Boolean `true` if the command has completed.
- Boolean `false` if it is still in progress.
- `Null` if the state cannot be determined.

See also:	`Document` object, `Document.queryCommandState()`, `TextRange.execCommand()`

TextRange.queryCommandSupported() (Method)

Part of an MSIE special document command handling mechanism. Checks to see if a command is supported.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextRange*`.queryCommandSupported(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

Some commands are not supported by the `TextRange` object but may be supported by the `document` object.

This method returns a Boolean `true` value if the command is supported by the `TextRange` object.

See also:	`Document` object, `Document.queryCommandSupported()`, `TextRange.execCommand()`

TextRange.queryCommandText() (Method)

Part of an MSIE special document command handling mechanism. Returns the string associated with a command.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextRange*`.queryCommandText(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

Some commands support the extraction of text from the `document` or `TextRange`. If the command does support the extraction of text, it will be returned by this method.

See also:	`Document` object, `Document.queryCommandText()`, `TextRange.execCommand()`

TextRange.queryCommandValue() (Method)

Part of an MSIE special document command handling mechanism. Returns the value of the command.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextRange*`.queryCommandValue(`*aCommandName*`)`
Argument list:	*aCommandName*	An MSIE command name

The value of a command depends on the command itself and what is selected. This method returns a value according to those criteria.

See also:	`Document` object, `Document.queryCommandValue()`, `TextRange.execCommand()`

TextRange.select() (Method)

Select the text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*`.select()`

If the browser supports a `Selection` object or `TextRange` objects, you may then be able to access the selected text using JavaScript. Of course in a form object, the text of the whole object can also be accessed, but this may not be what was selected because the user may select all or part of a page, and that selection may span several form elements or only part of a form element.

Unless you call this method, the bounded area of the `TextRange` object will not be visible to the user.

TextRange.setEndPoint() (Method)

Set the end point of a text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextRange*`.setEndPoint(`*anOperator*`, `*aTextRange*`)`
Argument list:	*anOperator*	A selector for the kind of copy
	aTextRange	A reference to another `TextRange` object

This method provides a way to copy start and end points between distinctly different `TextRange` objects. The first keyword is an operator to indicate the kind of copy to be carried out. The second argument is a reference to the second `TextRange` object that is to act as a source for the new values. Although this method is called `setEndPoint()`, it will allow both start and end points to be modified.

The following keywords can be passed in the first argument as string values:

- `StartToEnd`
- `StartToStart`
- `EndToStart`
- `EndToEnd`

There are no values returned by this method. The indicated end points are simply copied from the source range to the target range.

See also:	`TextRange.compareEndPoints()`

TextRange.text (Property)

Extract the text of a text range.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextRange*`.text`

This is somewhat similar to the `innerText` of an `Element` object. In this case the start and end points of the `TextRange` are taken as the delimiting boundaries. The text contained within those boundaries can be returned to your script when the property is read. If there are any HTML tags within the bounded extent of the `TextRange`, they will be filtered out so that the method yields pure text only values.

Because this property is read-only, you will need to use the `pasteHTML()` method to replace the HTML bounded by a `TextRange` object. However, because there appears not to be a `pasteText()` method, you may need to do some complex reconstructive work if there was embedded HTML and you only requested the text.

See also:	`TextRange.htmlText`

textRectangle object (Object/JScript)

The extent rectangle that encloses a `TextRange` object.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
JavaScript syntax:	IE	*myTextRectangle* = *myTextRange*.getBoundingClientRect()
Object properties:	bottom, left, right, top	

This is a close relation to the `rect` object. This is a special case, used for describing rectangles on the screen which are the bounding extent rectangles for `TextRange` objects.

You shouldn't try to modify the properties of this object directly. It's intended for you to read to establish where on the screen the `TextRange` is located.

See also:	`Clip` object, `Rect` object, `TextRange.getBoundingClientRect()`, `TextRange.getClientRects()`

Property	JavaScript	JScript	N	IE	Opera	Notes
bottom	-	5.0 +	-	5.0 +	-	-
left	-	5.0 +	-	5.0 +	-	-
right	-	5.0 +	-	5.0 +	-	-
top	-	5.0 +	-	5.0 +	-	-

textRectangle.bottom (Property)

The bottom of a `textRectangle`.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	Number primitive	
JavaScript syntax:	IE	*myTextRectangle*.bottom

See also:	`Rect.bottom`, `textRectangle` object

textRectangle.left (Property)

The left edge of a `textRectangle`.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRectangle`*`.left`

See also:	`Rect.left`, `textRectangle` object

textRectangle.right (Property)

The right edge of a text rectangle.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRectangle`*`.right`

See also:	`Rect.right`, `textRectangle` object

textRectangle.top (Property)

The top edge of a `textRectangle`.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myTextRectangle`*`.top`

See also:	`Rect.top`, `textRectangle` object

TextStream object (Object/JScript)

An object that represent an I/O text stream. Very useful in a server-side context.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream* = *myFile*.OpenAsTextStream()
	IE	*myTextStream* = *myFileSystem*.OpenTextFile (*aName*, *aMode*, *aFlag*, *aFormat*)
Argument list:	*aName*	The name of the file to be created
	aFlag	A flag indicating whether the file can be created if necessary
	aMode	An access mode for the file
	aFormat	A format control for the file
Object properties:	AtEndOfLine, AtEndOfStream, Column, Line	
Object methods:	Close(), Read(), ReadAll(), ReadLine(), Skip(), SkipLine(), Write(), WriteBlankLines(), WriteLine()	

This object is a wrapper for a file when opened for I/O. With this object you can read and write to the file.

Files can be opened via methods belonging to the `File` object or by requesting that the `FileSystem` object open a named file. Both techniques yield the same kind of `TextStream` object.

See also:	Active Server Pages, File.OpenAsTextStream(), FileSystem.OpenTextFile()

Property	JavaScript	JScript	N	IE	Opera	Notes
AtEndOfLine	-	2.0 +	-	4.0 +	-	-
AtEndOfStream	-	2.0 +	-	4.0 +	-	-
Column	-	2.0 +	-	4.0 +	-	-
Line	-	2.0 +	-	4.0 +	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
Close()	-	2.0 +	-	4.0 +	-	-
Read()	-	2.0 +	-	4.0 +	-	-
ReadAll()	-	2.0 +	-	4.0 +	-	-
ReadLine()	-	2.0 +	-	4.0 +	-	-
Skip()	-	2.0 +	-	4.0 +	-	-
SkipLine()	-	2.0 +	-	4.0 +	-	-
Write()	-	2.0 +	-	4.0 +	-	-
WriteBlankLines()	-	2.0 +	-	4.0 +	-	-
WriteLine()	-	2.0 +	-	4.0 +	-	-

TextStream.AtEndOfLine (Property)

A Boolean value that indicates the status of the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextStream*`.AtEndOfLIne`

This property returns a value `true` if the file pointer is immediately preceding an end of line character.

TextStream.AtEndOfStream (Property)

A Boolean value that indicates the status of the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	*myTextStream*`.AtEndOfStream`

This property returns the Boolean value `true` if the file pointer is at the end of the text stream.

TextStream.Close() (Method)

A method that closes a text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*`.Close()`

The text stream is closed and any subsequent access will generate an error. You will need to re-open the text stream to gain access to it again.

TextStream.Column (Property)

The column number within the file.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myTextStream*`.Column`

This property facilitates the use of fixed length record structured files via a stream.

It yields the character column number within the current line.

TextStream.Line (Property)

The line number within the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myTextStream*.Line

The line number property is incremented for every newline character that is encountered within the file. This is effectively the record number within the file.

TextStream.Read() (Method)

A method that reads text from the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextStream*.Read(*aCount*)
Argument list:	*aCount*	A count of characters to read

This will read the specified number of characters from the file. Note that this may span a line break and is intended for reading fixed length records.

TextStream.ReadAll() (Method)

A method that reads the entire text stream in one go.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextStream*.ReadAll()

The entire text stream is returned in a single read. Be careful if you are dealing with extraordinarily large files. You may get back more data than you expected.

TextStream.ReadLine() (Method)

A method that reads a line from the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTextStream*`.ReadLine()`

This method will read the remainder of a line up to but not including the newline character.

TextStream.Skip() (Method)

A method that skips a specified number of characters through the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*`.Skip(`*aCount*`)`
Argument list:	*aCount*	The number of characters to skip through the file

Refer to:

`TextStream.Read()`

TextStream.SkipLine() (Method)

A method that skips a line of the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*`.SkipLine()`

Refer to:

`TextStream.ReadLine()`

TextStream.Write() (Method)

A method that writes to the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*.Write(*aString*)
Argument list:	*aString*	Some text to write to the file

This writes exactly (and only) the text passed in its string argument.

See also:	TextStream.WriteLine()

TextStream.WriteBlankLines() (Method)

A method that writes a specified number of blank lines to the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*.WriteBlankLines(*aCount*)
Argument list:	*aCount*	The number of blank lines to write to the file

This writes just the newline characters. The count value specifies just how many.

See also:	TextStream.WriteLine()

TextStream.WriteLine() (Method)

A method that writes a line to the text stream.

Availability:	JScript – 2.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	*myTextStream*.WriteLine()
	IE	*myTextStream*.WriteLine(*aString*)
Argument list:	*aString*	A string to be written to the file

This is similar to the Write() method except that it automatically places a newline character after the string that has been written. In addition, the string value is optional in which case this is functionally identical to calling WriteBlankLines(1).

See also:	TextStream.Write(),TextStream.WriteBlankLines()

TFOOT object (Object/HTML)

An object that encapsulates a <TFOOT> tag within a <TABLE> block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myTFOOT* = *myDocument*.all.*anElementID*
	IE	*myTFOOT* = *myDocument*.all.tags("TFOOT")[*anIndex*]
	IE	*myTFOOT* = *myDocument*.all[*aName*]
	-	*myTFOOT* = *myDocument*.getElementById(*anElementID*)
	-	*myTFOOT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTFOOT* = *myDocument*.getElementsByTagName ("TFOOT")[*anIndex*]
HTML syntax:	<TFOOT> ... </TFOOT>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`, `bgColor`, `ch`, `chOff`, `vAlign`	
Object methods:	`deleteRow()`, `insertRow()`	
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	
Collections:	`rows[]`	

A table must contain one and only one `TFOOT` object. If you don't create one automatically, the `TABLE` object instantiates one for you but it would be empty.

The `TFOOT` object is instantiated by a <TFOOT> HTML tag. This is a means of marking off a section at the bottom of the table so that the rows can be grouped together and operated on separately to the table body.

The DOM level 1 standard calls for the implementation of a `TableSectionElement` object which includes both `TFOOT` and `THEAD` in its capabilities.

Warnings:

- Some earlier versions of MSIE for Macintosh have very limited capabilities implemented for this object. You cannot access any of the HTML or text contained in the object, nor the `rows` collection.

See also:	`Element` object, `TABLE` object, `TABLE.createTFoot()`, `TABLE.deleteTFoot()`, `TABLE.rules`, `TABLE.tFoot`, `THEAD` object, `TR` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes

`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

TFOOT.align (Property)

The kind of horizontal alignment applied to items within the `<TFOOT>` block of a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTFOOT*`.align`

The horizontal alignment of the `TFOOT` object with respect to its containing parent object is defined in this property. The available set of alignment specifiers are:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TABLE.align`, `TBODY.align`, `TD.align`, `TH.align`, `THEAD.align`, `TR.align`

TFOOT.bgColor (Property)

The background color for items in the `<TFOOT>` block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTFOOT*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value, `THEAD.bgColor`

TFOOT.ch (Property)

The character used for alignment of columns within the table.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTFOOT*.ch

TFOOT.chOff (Property)

The offset of character alignments within a column.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTFOOT*.chOff

TFOOT.deleteRow() (Method)

In a multiple row footer, you can delete a particular row with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTFOOT*.deleteRow(*anIndex*)
Argument list:	*anIndex*	The row to delete

See also:	THEAD.deleteRow()

TFOOT.insertRow() (Method)

You can insert additional rows into a table footer with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`TR object`	
JavaScript syntax:	-	*myTFOOT*`.insertRow(`*anIndex*`)`
Argument list:	*anIndex*	The row at which to place the new inserted `TR` object

See also:	`THEAD.insertRow()`

TFOOT.rows[] (Collection)

A collection of rows within a `<TFOOT>` block belonging to a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	-	*myTFOOT*`.rows`

This is not the same as the `rows` collection returned from a `TABLE` object. That is because the `rows[]` collection belonging to a `TFOOT` object can only list those `TR` objects that are contained within the `<TFOOT>` tags.

See also:	Collection object, `TABLE.cells[]`, `TABLE.cols`, `TABLE.rows[]`, `TBODY.rows[]`, `THEAD.rows[]`, `TR.rowIndex`

Property attributes:

`ReadOnly`.

TFOOT.vAlign (Property)

The vertical alignment applied to items within the <TFOOT> block of a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTFOOT*.vAlign

The vertical alignment of the content within the table cells can be controlled across an entire TFOOT extent with this property. The following keywords can be assigned to it:

- baseline
- bottom
- middle
- top

These may be also available on some implementations:

- absbottom
- absmiddle
- baseline
- texttop

See also:	TBODY.vAlign, TD.vAlign, TH.vAlign, THEAD.vAlign, TR.vAlign

TH object (Object/HTML)

An object that encapsulates a <TH> table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Inherits from:	Element object

JavaScript syntax:	IE	*myTH* = *myDocument*.all.*anElementID*
	IE	*myTH* = *myDocument*.all.tags("TH")[*anIndex*]
	IE	*myTH* = *myDocument*.all[*aName*]
	-	*myTH* = *myDocument*.getElementById(*anElementID*)
	-	*myTH* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTH* = *myDocument*.getElementsByTagName("TH")[*anIndex*]
HTML syntax:	<TH> ... </TH>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
Object properties:	abbr, align, axis, background, bgColor, borderColor, borderColorDark, borderColorLight, cellIndex, ch, chOff, colSpan, headers, height, noWrap, rowSpan, scope, vAlign, width	
Event handlers:	onAfterUpdate, onBeforeUnload, onBlur, onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onResize, onRowEnter, onRowExit, onSelectStart	

This object is instantiated by a <TH> tag that encloses the content of a single data cell. This cell is formatted differently to a TD cell because a TH cell is considered to be a table header cell whereas a TD cell is a table data cell.

Some of the property values in this object may be inherited from parent objects such as TABLE, TR and TBODY.

See also:	Element object, TABLE object, TD object

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

TH.abbr (Property)

An abbreviation value to be used for header cells in the column where the data cell resides.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*.abbr

See also:	`TD.abbr`

TH.align (Property)

The alignment of content within a `<TH>` table cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTH*.align

The alignment of the `TH` object with respect to its containing parent object is defined in this property. The available set of alignment specifiers are:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TABLE.align`, `TBODY.align`, `TD.align`, `TFOOT.align`, `THEAD.align`, `TR.align`

TH.axis (Property)

The names group of related header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*`.axis`

See also:	`TD.axis`

TH.background (Property)

A URL for an image to load as the background for a table header cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTH*`.background`

If a background image is available, then its URL is contained in this property. Changing the value in this property will replace the background with a new one. However there may be a perceptible delay while the new image is fetched from the web server.

See also:	`TD.background`

TH.bgColor (Property)

The background color for a table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTH*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value, `TD.bgColor`

TH.borderColor (Property)

The border color around a table header cell.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTH*`.borderColor`

You can use this property to determine the color of a border surrounding a table header cell. Note that there are additional properties to determine the highlights and lowlights of the table header cell border coloring.

See also:	`TD.borderColor`

TH.borderColorDark (Property)

The color value of the shadowed edge of the table cell border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTH*`.borderColorDark`

Table header cell borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the shadowed part of the table header cell border.

See also:	`TD.borderColorDark`

TH.borderColorLight (Property)

The color value of the highlighted edge of the table cell border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTH*`.borderColorLight`

Table header cell borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the highlighted part of the table header cell border.

See also:	`TD.borderColorLight`

TH.cellIndex (Property)

A zero-based integer number that indicates the position of a `<TH>` cell within a `<TR>` row. This is effectively the horizontal column coordinate of a table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTH*`.cellIndex`

You can access cells by means of the `rows[]` and `cells[]` collections belonging to the `TABLE` and `TR` objects respectively. This property provides the horizontal coordinate to use in the `TR.cells[]` collection to access the object describing this table cell.

See also:	`TD.cellIndex`

Property attributes:

`ReadOnly`.

TH.ch (Property)

The alignment character for cells in a column arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*.ch

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR` HTML tag attribute is reflected in this property and is active when the `CHAROFF` HTML tag attribute is present.

See also:	`COL.ch`, `COLGROUP.ch`, `TD.ch`, `THEAD.ch`, `TR.ch`

TH.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*.chOff

The `CHAR` alignment style requires that an alignment character be specified with the `ch` property and that an offset measured in pixels be defined as its value. The offset value can be defined with the `CHAROFF` HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	`COL.chOff`, `COLGROUP.chOff`, `TD.chOff`, `THEAD.chOff`, `TR.chOff`

TH.colSpan (Property)

The number of columns that a header cell spans.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTH*`.colSpan`

This corresponds to the `COLSPAN` attribute within a `<TH>` HTML tag for a table header cell description. It defines how many table columns this column is to span.

Warnings:

- Note that this may affect the value of the `cellIndex` property for subsequent cells within the same row.

See also:	`COL.span`, `COLGROUP.span`, `style.columnSpan`, `TD.colSpan`

TH.headers (Property)

A list of `ID` attribute values for header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*`.headers`

See also:	`TD.headers`

TH.height (Property)

The height in pixels of the table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`String primitive`
JavaScript syntax:	- *myTH*`.height`

The table header cell space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the height of that extent rectangle.

See also:	`TD.height`

TH.noWrap (Property)

Controls whether text in the table header cell is allowed to wrap.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0
Property/method value type:	`Boolean primitive`
JavaScript syntax:	- *myTH*`.noWrap`

This is a Boolean value that controls whether the textual content is wrapped at the right hand window border or not.

If the value `false` is assigned to this property, then words will wrap as the page is drawn. This is good and is the way you would expect a browser to behave. The text will flow according to the space available.

If the value `true` is assigned to this property, the line of text will continue to the right until a `<BR>` or other block level tag is encountered. This will force the horizontal width of the page to be extremely large and the user will need to scroll furiously to be able to see the text and then scroll back again for the start of the next line.

Warnings:

- Only use this if you plan to place line breaks at frequent intervals yourself and really do need to control the line breaks manually.

See also:	`TD.noWrap`

TH.rowSpan (Property)

The number of rows that the table header will span.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTH*`.rowSpan`

This is used when you want to create complex tables. This technique may be an alternative to nesting a table. That is always good because sometimes nested tables can become very unwieldy.

See also:	`style.rowSpan`, `TD.rowSpan`

TH.scope (Property)

The scope covered by header cells.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTH*`.scope`

See also:	`TD.scope`

TH.vAlign (Property)

The vertical alignment of content within the table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTH*.vAlign

The vertical alignment of the content within the table cells can be controlled for a single table cell with this property. The following keywords can be assigned to it:

- `baseline`
- `bottom`
- `middle`
- `top`

These may be also available on some implementations:

- `absbottom`
- `absmiddle`
- `baseline`
- `texttop`

This value will override the setting for a row or `TBODY` extent.

See also:	`TBODY.vAlign`, `TD.vAlign`, `TFOOT.vAlign`, `THEAD.vAlign`, `TR.vAlign`

TH.width (Property)

The width in pixels of the table header cell.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTH*.width

The table header cell space is defined by an extent rectangle that surrounds the space occupied by it on the screen. An extent rectangle is that smallest rectangle that completely encloses the item. This property specifies the width of that extent rectangle.

See also:	`TD.width`

THEAD object (Object/HTML)

An object that encapsulates a `<THEAD>` tag within a `<TABLE>` block.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTHEAD* = *myDocument*.all.*anElementID*
	IE	*myTHEAD* = *myDocument*.all.tags("THEAD")[*anIndex*]
	IE	*myTHEAD* = *myDocument*.all[*aName*]
	-	*myTHEAD* = *myDocument*.getElementById(*anElementID*)
	-	*myTHEAD* = *myDocument*.getElementsByName (*aName*)[*anIndex*]
	-	*myTHEAD* = *myDocument*.getElementsByTagName ("THEAD")[*anIndex*]
HTML syntax:	`<THEAD> ... </THEAD>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`, `bgColor`, `ch`, `chOff`, `vAlign`	
Object methods:	`deleteRow()`, `insertRow()`	
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	
Collections:	`rows[]`	

A table must contain one and only one `THEAD` object. If you don't create one automatically, the `TABLE` object instantiates one for you, but it will be empty.

The `THEAD` object is instantiated by a `<THEAD>` HTML tag. This is a means of marking off a section at the top of the table so that the rows can be grouped together and operated on separately to the table body.

The DOM level 1 standard calls for the implementation of a `TableSectionElement` object which includes both `TFOOT` and `THEAD` in its capabilities.

See also:	`Element` object, `TABLE` object, `TABLE.createTHead()`, `TABLE.deleteTHead()`, `TABLE.rules`, `TABLE.tHead`, `TFOOT` object, `TR` object

Inheritance chain:

`Element` object, `Node` object

THEAD.align (Property)

The alignment of items within the <THEAD> block of a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTHEAD*.align

The alignment of the THEAD object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- center
- left
- right
- char
- justify

See also:	TABLE.align, TBODY.align, TD.align, TFOOT.align, TH.align, TR.align

THEAD.bgColor (Property)

The background color of items in the <THEAD> block of a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	String primitive	
JavaScript syntax:	-	*myTHEAD*.bgColor

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value, TFOOT.bgColor

THEAD.ch (Property)

The alignment character for cells in a column arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTHEAD*.ch

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR` HTML tag attribute is reflected in this property and is active when the `CHAROFF` HTML tag attribute is present.

See also:	`COL.ch`, `COLGROUP.ch`, `TD.ch`, `TH.ch`, `TR.ch`

THEAD.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTHEAD*.chOff

The CHAR alignment style requires that an alignment character be specified with the `ch` property and that an offset measured in pixels be defined as its value. The offset value can be defined with the `CHAROFF` HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	`COL.chOff`, `COLGROUP.chOff`, `TD.chOff`, `TH.chOff`, `TR.chOff`

THEAD.deleteRow() (Method)

In a multiple row footer, you can delete a particular row with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTHEAD*.deleteRow(*anIndex*)
Argument list:	*anIndex*	The row to be deleted

See also:	TFOOT.deleteRow(),TR.deleteCell()

THEAD.insertRow() (Method)

You can insert additional rows into a table footer with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTHEAD*.insertRow(*anIndex*)
Argument list:	*anIndex*	The row at which to insert the new TR object

See also:	TFOOT.insertRow()

THEAD.rows[] (Collection)

A collection of rows within a <THEAD> block of a table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	Collection object	
JavaScript syntax:	-	*myTHEAD*.rows

This is not the same as the `rows` collection returned from a `TABLE` object. That is because the `rows[]` collection belonging to a `THEAD` object can only list those `TR` objects that are contained within the `<THEAD>` tags.

See also:	Collection object, `TABLE.cells[]`, `TABLE.cols`, `TABLE.rows[]`, `TBODY.rows[]`, `TFOOT.rows[]`, `TR.rowIndex`

Property attributes:

`ReadOnly`.

THEAD.vAlign (Property)

A control for the vertical alignment of cells within the `THEAD` object.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTHEAD*`.vAlign`

The vertical alignment of the content within the table cells can be controlled across an entire `THEAD` extent with this property. The following keywords can be assigned to it:

- `baseline`
- `bottom`
- `middle`
- `top`

These may be also available on some implementations:

- `absbottom`
- `absmiddle`
- `baseline`
- `texttop`

See also:	`TBODY.vAlign`, `TD.vAlign`, `TFOOT.vAlign`, `TH.vAlign`, `TR.vAlign`

this (Keyword)

A reference to the receiving object.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	An object	
JavaScript syntax:	-	this

Every active execution context owns a this value. It is used for self-referring script statements.

The specific this value of an execution context depends on the caller and the type of code being executed. This is determined on entry to an execution context. The this value associated with an execution context is immutable and therefore cannot be changed from a script.

A this value is considered to be a primary expression.

The this keyword is often used inside function bodies that are registered with a prototype. When it is executed, the function can refer to its owning object without having to know what sort of object it is. We can use this to write a function that can be used with several kinds of object.

If the this keyword is used inside an event handler, it refers to the object that the event belongs to. We can exploit this to build event handlers that support many objects and can be called by different event types.

If the this keyword is used outside of all functions (in global code) it refers to the Global object. A this property used in a script will therefore return that global object. In fact it will return an object of type Window.

Other object types will be returned according the context in which the property is applied.

The example shows how the this keyword can be used to enhance the prototype of an object.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// See what the scope rules define for 'this'
document.write(this);
document.write("<BR>");
```

```
document.write(typeof this);
document.write("<BR>");

// Create a user defined prototype
function AnimalClass()
{
   return "Animal";
}

function Animal(aSpecies, aHabitat)
{
   this.species  = aSpecies;
   this.habitat  = aHabitat;
   this.toString = AnimalClass;
}

// Instantiate an animal
myAnimal = new Animal("Cow", "Field");
document.write("Object: "  + myAnimal + "<BR>");
document.write("Species: " + myAnimal.species + "<BR>");
document.write("Habitat: " + myAnimal.habitat + "<BR>");
</SCRIPT>
</BODY>
</HTML>
```

Wrox *Instant JavaScript* – page – 53

Thousands separator (Definition)

A special locale specific character for indicating groups of digits.

See also:	Decimal point (.), Localization

throw (Statement)

Throw a custom exception in the hope it will be caught by an error handler.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

The `throw` statement provides a way to create an exception which will be passed to an associated `catch()` handler in a `try ... catch` structure. It is really intended to be used in that context, but you can use it outside of a `try ... catch` structure and trap the exception with the normal `onError` event handling support.

You can use this mechanism to generate an error, perhaps as a result of testing some value. Placing a `throw` statement into your code will force the error handling to be invoked. However if you use it outside of a `try ... catch` block, the browser error handling will generate an error due to there being no way of catching the thrown event. It forces an error dialog, but not the one you wanted. You need to use a `throw` with a `try ... catch` block to force the `catch` code to be called.

You can work around this by assigning an error handler function to the `onerror` property and making sure that the error handler returns a Boolean `true` value to signify that the error has no further processing required.

Warnings:

- This is not supported by Netscape Enterprise Server 3, and so its error handling capabilities are not available server -side.
- When using MSIE version 5 on the Macintosh platform, if you set the `LANGUAGE` HTML tag attribute of the enclosing `<SCRIPT>` tag to JScript 1.3, this handler will not be invoked properly.
- The example below, while supported on Netscape 6.0, does not seem to be supported on Internet Explorer 5.0 or 5.5.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
// Define an error handler function
function myErrHandler(anException)
{
   alert("An error happened and was caught by this handler.");
   return true;
}

// Register the error handler
onerror = myErrHandler;
```

```
// Throw an exception
throw "ERR";
</SCRIPT>
</BODY>
</HTML>
```

Time from year (Time calculation)

A date and time algorithm defined by ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

To calculate any time values relative to the start of a year, we need to know what instant the year began.

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non leap years to adjust the day numbers and yield the day number of the first day of the given year and then use that to work out the time in milliseconds when the year started:

```
DayFromYear(y) = 365 * (y - 1970) + floor((y - 1969) / 4) - floor((y - 1901) /
100) + floor((y - 1601) / 400)

msPerDay = 86400000TimeFromYear(y) = msPerDay * DayFromYear(y)
```

Subtracting this value from any absolute time value gives you a millisecond accurate offset from the beginning of the specified year.

Example code:

```
// Work out days and milliseconds at start of a year
var msPerDay = 86400000;

// Test day from year
document.write("<TABLE BORDER=1>");
for(var ii=1980; ii<2009; ii++)
{
   document.write("<TR>");
   document.write("<TD>");
   document.write(ii);
   document.write("</TD>");
   document.write("<TD>");
   document.write(dayFromYear(ii));
   document.write("</TD>");
   document.write("<TD>");
   document.write(timeFromYear(ii));
   document.write("</TD>");
   document.write("</TR>");
}
document.write("</TABLE>");

// Work out milliseconds at start of year
function timeFromYear(aYear)
{
   var myTime = msPerDay * dayFromYear(aYear);
   return myTime;
}

// Day from year function
function dayFromYear(aYear)
{
   var myDay = 365 * (aYear - 1970)  +
      Math.floor((aYear - 1969) / 4) -
      Math.floor((aYear - 1901) / 100)  +
      Math.floor((aYear - 1601) / 400);
   return myDay;
}
```

Time range (Definition)

ECMAScript measures time in milliseconds since 01-01-1970 UTC.

Availability:	ECMAScript edition – 2

In ECMA compliant implementations, time is measured in milliseconds since the first of January 1970 UTC.

In ECMA compliant implementations, leap seconds are ignored and it is assumed that there are exactly 86,400,000 milliseconds per day. The available range of number values is 18 quadrillion, which is sufficient to measure, to millisecond accuracy, over a time period of nearly 286,000 years forwards or backwards from 01-January-1970 UTC.

`Date` objects don't use this entire range of values and only cope with 100 million days either side of 01-January-1970 UTC. Still, that is a time period that covers just over half a million years. So, no Y2K crisis there (probably).

The exact moment of midnight at the beginning of 01-January-1970 UTC is represented by the value 0.

The time range may not be the same as that provided by the underlying host environment. For example, Macintosh dates and times are based on a start time of the first of January 1904 measured in seconds. The adjustment is trivial in computational terms but may be missing in some implementations.

Time value (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

The ECMA standard defines some useful methods for decomposing time values.

Some constant values need to be defined first:

- HoursPerDay = 24
- MinutesPerHour = 60
- SecondsPerMinute = 60
- msPerSecond = 1000

From these we can derive some other values:

- msPerMinute = msPerSecond * SecondsPerMinute = 60000
- msPerHour = msPerMinute * MinutesPerHour = 3600000

Now the methods can be defined in terms of these constants and their derivatives.

- HourFromTime(t) = floor(t / msPerHour) modulo HoursPerDay
- MinFromTime(t) = floor(t / msPerMinute) modulo MinutesPerHour
- SecFromTime(t) = floor(t / msPerSecond) modulo SecondsPerMinute
- msFromTime(t) = t modulo msPerSecond

Example code:

```
// Define some constants
HoursPerDay      =   24;
MinutesPerHour   =   60;
SecondsPerMinute =   60;
msPerSecond      = 1000;

// Derived values
msPerMinute = msPerSecond * SecondsPerMinute;
msPerHour   = msPerMinute * MinutesPerHour;

// Grab the time now in milliseconds
myMilliseconds = Number(new Date());
document.write("Hours ...: ");
document.write(HourFromTime(myMilliseconds));
document.write("<BR>");
document.write("Minutes ...: ");
document.write(MinFromTime(myMilliseconds));
document.write("<BR>");
document.write("Seconds ...: ");
document.write(SecFromTime(myMilliseconds));
document.write("<BR>");
document.write("Milliseconds ...: ");
document.write(msFromTime(myMilliseconds));
document.write("<BR>");

// Work out the hour number (Add 1 hour for BST)
function HourFromTime(aMillisecondTime)
{
```

```
   return (Math.floor(aMillisecondTime/msPerHour) % HoursPerDay);
}

// Work out the minutes of the hour
function MinFromTime(aMillisecondTime)
{
   return (Math.floor(aMillisecondTime/msPerMinute) % MinutesPerHour);
}

// Work out the seconds of the minute
function SecFromTime(aMillisecondTime)
{
   return (Math.floor(aMillisecondTime/msPerSecond) % SecondsPerMinute);
}

// Work out the millisecond time value
function msFromTime(aMillisecondTime)
{
   return (aMillisecondTime % msPerSecond);
}
```

Time within day (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

Calculating the time within a day uses modulo arithmetic to find the remainder after calculating the day number.

The formula for calculating time within the day is shown here:

- t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.
- msPerDay = 86400000
- TimeWithinDay(t) = t modulo msPerDay

Example code:

```
// Define some constants
HoursPerDay      =   24;
MinutesPerHour   =   60;
SecondsPerMinute =   60;
msPerSecond      = 1000;

// Derived values
msPerMinute = msPerSecond * SecondsPerMinute;
msPerHour   = msPerMinute * MinutesPerHour;
msPerDay    = msPerHour   * HoursPerDay;

// Grab the time now in milliseconds
myMilliseconds = Number(new Date());
document.write("Time within day ...: ");
document.write(TimeWithinDay(myMilliseconds));
document.write("<BR>");

// Work out the millisecond time value
function TimeWithinDay(aMillisecondTime)
{
   return (aMillisecondTime % msPerDay);
}
```

ECMA 262 edition 3 – section – 15.9.1.2

TimeClip() (Time calculation)

A date and time algorithm.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

The `TimeClip()` operator is provided internally to convert implementation dependent numeric values to millisecond time values with a bounds check and sign handling fix up. Any date value is trimmed off and discarded, hence the name `TimeClip()`.

Implementations may represent number values internally in many ways. Time computations need the millisecond value to be presented in a particular way. This operator does all the cleaning and conversion necessary.

Although this is called an operator in the standard, its behavior is more like that of a function. It is not part of the formal language implementation and is probably not useful to have simulated in script form. It is documented in the standard to assist in the algorithmic breakdown of the `Date` method handlers and is covered here for the sake of completeness.

The result is a time value in milliseconds.

See also:	Broken down time, `Date` object, `Date()`, `Date.setTime()`, `Date.UTC()`

Cross-references:

ECMA 262 edition 2 – section – 15.9.1.14

ECMA 262 edition 3 – section – 15.9.1.14

Timeout handlers (Definition)

You can set event handlers to be called when a timeout expires.

This is a mechanism for scheduling the execution of a script at some time in the future. The delay is measured from the moment the `setTimeout()` method is invoked.

See also:	`Window.clearInterval()`, `Window.clearTimeout()`, `Window.setInterval()`, `Window.setTimeout()`

Timer events (Definition)

Events that are triggered after a delay time.

Timer events are created by calling a timer set-up function and giving it a delay value. You can also cancel timeouts, but this can lead to problems because cancelling a timeout that has already been processed is prone to crashing the browser. Managing timeouts is tricky and exposes you to an area where the browser is somewhat less reliable than mainstream functionality.

Nevertheless, timer events are useful for managing refreshes and animation. You can interlock a refresh with some animation or scrolling so that the refresh exhibits as few screen redrawing artifacts as possible.

If you are really careful about memory leaks, you can build a ticker display with JavaScript. Making this clickable with an anchor is useful, but also exposes some cross-platform shortcomings and there are several ways to do this and each only works in one browser/platform combination and crashes on the others.

Because `setTimeout()` defines a delay from the time of execution to the time when the event is triggered, a cyclic mechanism takes no account of the processing time between `setTimeout()` calls. This means that the animation can become jerky. You can smooth that out by calculating how much time is left before you want the next scheduled event to occur. You need to access some kind of tick count to establish a reference time. You can do this by extracting values from a `Date` object and using its millisecond value. A modulo of that with the result subtracted from your ideal schedule frequency should yield a value that takes account of any processing jitter.

Automatic refreshing is sometimes called client pull.

If you want to execute something on a regular basis, then `setInterval()/clearInterval()` may be what you are looking for. These two methods manage an interval timer that you can set up to execute a function periodically. Because this doesn't disappear, there is less likelihood of crashing the browser if you try to clear one of these timers.

Warnings:

- Timer related crashes seem to be able to lock up a desktop system comprehensively enough that it requires a reboot to recover. This applies equally to Macintosh and Windows based systems and both MSIE and Netscape. There are many different causes, usually to do with runaway events, trying to kill timers that don't exist, or handling mouse rollovers that cross from one object to another. Multiple frames (especially `<IFRAME>` handling in MSIE on Macintosh) are especially prone to rollover crashes when combined with timer events. The crashing is all to do with timer events disposing of an object that the mouse has rolled over and triggered an interaction event for dispatch. In the meantime the object has gone and the browser follows it.

Cross-references:

Wrox *Instant JavaScript* – page – 55

<TITLE> (HTML Tag)

A tag that encloses the title block in a document header. It corresponds to the MSIE `TITLE` object.

The `<TITLE>` tag conveys no apparent visible effect on the document. It is considered to be an invisible tag, although its value does appear in the window heading bar.

Warnings:

- Be careful not to confuse this with the `TITLE` attribute of an HTML tag and its corresponding `Element` object's `title` property. They are just a means of naming objects and associating specific tags with specific objects.

See also:	`Document.title`, `TITLE` object

TITLE object (Object/HTML)

An MSIE object that represents the `<TITLE>` block of a document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0

Inherits from:	`Element` object	
JavaScript syntax:	IE	*myTITLE* = document.all.tags("TITLE")[0]
	IE	*myTITLE* = document.all[*anIndex*]
	IE	*myTITLE* = *myDocument*.all.*anElementID*
	IE	*myTITLE* = *myDocument*.all.tags("TITLE")[*anIndex*]
	IE	*myTITLE* = *myDocument*.all[*aName*]
	-	*myTITLE* = *myDocument*.getElementById(*anElementID*)
	-	*myTITLE* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTITLE* = *myDocument*.getElementsByTagName ("TITLE")[*anIndex*]
HTML syntax:	<TITLE> ... </TITLE>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`text`	
Event handlers:	`onClick`, `onDblClick`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`	

The <TITLE> tag conveys no apparent visible effect on the document. It is considered to be an invisible tag although its value does appear in the window heading bar.

See also:	<TITLE>, `Document.title`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`text`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	ReadOnly

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

TITLE.text (Property)

The text contained inside the `<TITLE>` block for the current document.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTITLE*`.text`

This yields the text of the title block. This is the same as the `document.title` property. Because it is read-only, you cannot modify the value from script. You can't get at the content of the `<TITLE>` tag with the `innerHTML` property either.

See also:	`Document.title`

Property attributes:

`ReadOnly`.

ToBoolean (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts the public types to Boolean values.

The `ToBoolean` operator converts its argument to a value of type Boolean according to the following table:

Input Type	Result
Undefined	Always false.
Null	Always false.
Boolean	No conversion, the input value is returned unchanged.
Number	The result is `false` if the argument is 0 or `NaN` otherwise it is `true`.
String	Zero length strings return `false` otherwise the result is `true`.
Object	Always `true`.

See also:	`Cast` operator, Conversion, Implicit conversion, Logical operator, Number, Type conversion

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 – section – 9.2

ECMA 262 edition 3 – section – 9.2

ToInt32 (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts its input value to a 32 bit signed integer value.

See also:	`Cast` operator, Conversion, Implicit conversion, Number, Type conversion

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 – section – 9.5

ECMA 262 edition 3 – section – 9.5

ToInteger (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts values to integers.

See also:	`Cast` operator, Conversion, Implicit conversion, Type conversion

Property attributes:

`Internal`.

Cross-references:

ECMA 262 edition 2 – section – 9.4

Token (Definition)

Tokens are the fundamental components that an executable script is built from.

Availability:	ECMAScript edition – 2

A token is the smallest component of a source script text that can be interpreted.

Tokens are the actual components that an executable script is built from. They may be reserved words, identifiers, punctuator symbols or literals.

You cannot use reserved words as identifier names.

The reserved word set is comprised of the structural statements that you use to make a script work.

The `null` literal is simply the keyword `null`.

The Boolean literals are the keywords `true` and `false`.

See the reserved words topic for a list of all currently defined reserved words.

See also:	Boolean literal, `Cast` operator, Identifier, Keyword, Lexical convention, Lexical element, Literal, Null literal, Punctuator, Reserved word, Reserved Word

Cross-references:

ECMA 262 edition 2 – section – 7.4

ECMA 262 edition 3 – section – 7.5

ToNumber (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts its argument to an appropriate numeric value.

The `ToNumber` operator converts its input values according to the following table:

Input Type	Result
Undefined	Returns `NaN`
Null	0
Boolean	1 if `true`, 0 if `false`.
Number	No conversion, the input value is returned unchanged.
String	The value of a sequence of characters that can reasonably be converted to a number, and if not then `NaN` is returned.
Object	Internally, a conversion to one of the primitive types happens followed by a conversion from that type to a number. Some objects will return a number that is readily usable. Others will return something that cannot be converted and `NaN` will result.

The string scanning algorithm copes with spelled out special values such as Infinity, exponential values and can scan integers in Octal and Hexadecimal notation as well as decimal.

Cross-references:

ECMA 262 edition 2 – section – 9.3

ECMA 262 edition 3 – section – 9.3

ToObject (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts its input argument into an object.

The `ToObject` operator converts its input arguments according to the following table:

Input Type	Result
Undefined	Generates a run-time error.
Null	Generates a run-time error.
Boolean	Create a new `Boolean` object whose default value is the input value.
Number	Create a new `Number` object whose default value is the input value.
String	Create a new `String` object whose default value is the input value.
Object	No conversion, the input value is returned unchanged.

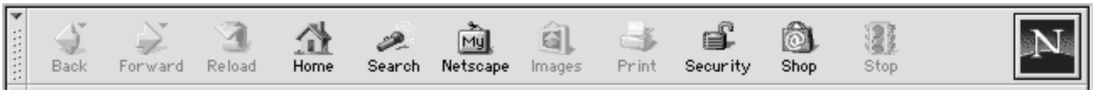
toolbar (Property)

An alias for the `window.toolbar` property.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	*myWindow*`.toolbar`
	-	`toolbar`



See also:	`Bar` object, `Window.toolbar`

Property attributes:

`ReadOnly`.

top (Property)

An alias for the `window.top` property.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*`.top`
	-	`top`

Property attributes:

`ReadOnly`.

`Window.top`

Topic classification (Overview)

Descriptions of topic classifications.

The various classifications of topics in this manual are listed in this table:

Classification	Description
Accessor method	A means of accessing properties
Additive operator	An operator that sums values
Arithmetic operator	An operator that works with numeric values
`Array`	A kind of object that is compounded from several others
ASP tag	A tag that is only available in Microsoft ASP
Assignment operator	An operator that assigns values
Attribute	Attributes define how properties behave
Background	Background information
Bitwise operator	An operator that works with bit patterns
Blend filter	A transition filter available only in MSIE
Boolean literal	A Boolean constant value
Browser object	An object only available in a browser
Built-in function	A function provided by the implementation
Built-in object	An object provided by the implementation
Collection	A sub-class of the `Array` object that supports additional methods
Comma operator	An expression delimiter
Conditional operator	An operator that yields a Boolean result
Constant	A fixed literal value
Constructor	An object instance factory
Core object	An object that is part of the core language
Declaration	A specification of an identifier
Definition	A specification of an identifier with storage
Delimiter	A token separator
DOM object	An object that belongs to the DOM specification
Environment variable	Part of the implementation that an interpreter runs in
Escape sequence	A means of generating non-typable characters
Event	Events need to be considered a separate kind of language entity

Table continued on following page

Classification	Description
Event handler	Event handlers are many and various, each covered in its own topic
External code call	Some environments support the calling of external code
File extension	File types are identified by different file extensions
`Function` object attribute	An attribute of a `function` object
Function property	An object property that can be called as a method
Global function	A function that belongs to the `global` object
Global variable	Some variables are available as member properties of the `global` object
Host object	Objects not defined as part of the core language
HTML tag	A part of an HTML document
HTML Tag	Some JavaScript language needs to be described in terms of its underlying HTML tags
HTML Tag Attribute	An attribute added to an HTML tag
Identifier	The name of a function or variable
Idiom	A familiar form or expression
Instance	A copy of a built-in object
Internal function	A function that cannot be called from a script
Internal method	A method that cannot be invoked from a script
Internal object	An object maintained internally by the interpreter and not generally available to the script writer
Internal object	An object that cannot be accessed from a script
Internal operator	An operator that cannot be used in expressions contained in a script
Internal property	A property that cannot be accessed from a script
Internal type	A data type that cannot be created from a script
Interpreter	There is now a wide choice of JavaScript interpreters available
Iterator	Certain control structures that can be used to create loops
Java class	Access to `Java` objects is via the wrappers that let you access the classes
Java method	A method belonging to a `Java` object accessible via a JavaScript wrapper
Java package	A collection of Java classes enclosed in a JavaScript wrapper
Java static method	A method belonging to a Java class accessible via a JavaScript wrapper
`JScript` object	An object only available in Microsoft JScript
Keyword	A reserved word in the language
Label	Code can be labelled with entry points
Logical operator	An operator that works with Boolean values
Method	A message sent to a method performs an action inside the object
MIME type	A means of telling the browser what kind of data is being supplied
Mobile communicator	Web access is also possible from mobile devices
MSIE method	A method that is only available in MSIE even though the object may be more widely available

Table continued on following page

Classification	Description
MSIE object	An object only available in MSIE
MSIE property	A property that is only available in MSIE even though the object may be more widely available
Native object	A built-in object defined by the standard
NES result value	A result value that a Netscape Enterprise Server method call returns
NES server method	A method that is only available in Netscape Enterprise Server even though the object may be more widely available
NES server object	An object only available in Netscape Enterprise Server
NES server property	A property that is only available in Netscape Enterprise Server even though the object may be more widely available
Netscape object	An object that is only available in the Netscape scripting environment
Null literal	A `null` constant value
Object	An object of no particular type
Object	An object that can be instantiated
Object model	There are several object models that describe various parts of the JavaScript object space
Operator	An operator that can be used to create expressions
Overview	A descriptive outline text
Pitfall	Some topics describe ways in which JavaScript can catch you out
Portable Documents	JavaScript is used to handle forms in PDF
Postfix operator	An operator that can be appended to an LValue
Pre-processor directive	The Microsoft interpreters support a pre-processor rather like that in the C language
Primitive value	A fundamental value built-in to the implementation
Product	Some JavaScript interpreters are available as part of a commercial product
Property	A named attribute of an object
Proxy.pac support	Part of the Netscape proxy handler
References	Sources of additional information
Relational operator	An operator that yields the result of a comparison
Request method	Several types of request method can be used in a URL
Reserved word	Reserved functionality
Reveal filter	A transition filter available only in MSIE
Script container	Scripts may be carried in a variety of containers other than HTML documents
Security model	A particular way of implementing security
Security policy	A policy regarding the way security is managed
Security privilege	A privilege level in the security mechanism
Selector	A means of choosing one of several possible outcomes

Table continued on following page

Classification	Description
Server object	An object that is only available server-side
Server-side file	Special files accessible only to the web server
Server-side method	Some methods are available only on the server-side
Server-side object	Some objects are only available on the server-side
Simulated functionality	Some script that emulates capabilities of other languages
Special file	JavaScript is implemented in a variety of ways and in some cases special files are necessary
Standard	Several standards affect the way that JavaScript works
Statement	A single executable unit of code
Static method	A method belonging to a class, not an object
Static property	These properties belong to the class (or rather they would in a truly object oriented system)
String operator	An operator for working with string data
Summary	A brief description of a subject
Support for preferences	Preference handling requires a number of different topics to describe it
Symbol	A special character
Time calculation	A process of working out time values
Time operator	An operator for time value expressions
Transition filter	A transition filter available only in MSIE
TV Set-top Box	Web access is now becoming more widely available in TV applications
Type	A data value classification
Unary operator	An operator that only requires one operand
Useful tip	Some topics provide useful advice
Value	A value of a variable or object
Value property	A property of an object that yields a value and cannot be called as a function
Visual filter	A transition filter available only in MSIE
Web browser	Each of the commonplace web browsers is described in its own topic
Web server	Server-side code needs to be executed under control of a web server

See also:	ECMA

ToPrimitive (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This operator converts objects to primitive values.

The `ToPrimitive` operator takes a value argument and an optional preferred type argument and converts its input to a primitive type from an object representation.

Input Type	Result
Undefined	No conversion, the input value is returned unchanged.
Null	No conversion, the input value is returned unchanged.
Boolean	No conversion, the input value is returned unchanged.
Number	No conversion, the input value is returned unchanged.
String	No conversion, the input value is returned unchanged.
Object	The default value defined by the object's internal `DefaultValue` method is returned. A coercion to the preferred type happens and is context dependent on where the result is being assigned.

See also:	`Cast` operator, Conversion, Implicit conversion, Number, Type conversion

Cross-references:

ECMA 262 edition 2 – section – 8.6.2.6

ECMA 262 edition 2 – section – 9.1

ECMA 262 edition 3 – section – 8.6.2.6

ECMA 262 edition 3 – section – 9.1

ToString (Operator/internal)

Returns a string primitive version of an object.

Availability:	ECMAScript edition – 2

This internal operator converts its input argument to a string.

The `ToString` operator converts its input arguments according to the following table:

Input Type	Result
Undefined	"`undefined`"
Null	"`null`"
Boolean	If the argument is true, then the result is "`true`" otherwise the result is "`false`"
Number	Special cases are provided for NaN and Infinity where "`NaN`" and "`Infinity`" will be returned. Otherwise the string is a textual representation of the value. The string is formatted into decimal or exponential formats as determined by the magnitude of the value.

Table continued on following page

Input Type	Result
String	No conversion, the input value is returned unchanged.
Object	An internal conversion to a primitive takes place followed by a conversion from that primitive to a string. Some objects will return a string value that is immediately useful.

Warnings:

- In Microsoft environments, this is available most of the time but does not work for certain objects. In particular, there may some objects in WSH for which it is not supported.

See also:	`Cast` operator, Conversion, Implicit conversion, `JSObject.toString()`, String concatenate (+), `toString()`, Type conversion

Cross-references:

ECMA 262 edition 2 – section – 9.8

ECMA 262 edition 3 – section – 9.8

toString() (Function/global)

Returns a string representation of the receiving object.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myObject*`.toString()`
	-	*myObject*`.toString(`*aRadix*`)`
Argument list:	*aRadix*	Radix conversion can be applied when the receiver is a number

The generic behavior of this method is to return a String primitive representation of the receiving object. It is generally overridden on a class by class basis due to objects containing such different properties and values.

The `ToString` internal operator is called. This doesn't usually tell you very much. The default `toString()` handlers may be different for the built-in classes, but all you'll likely get from a class you create yourself will be the string "`[object Object]`".

You will need to override the `toString()` function that is provided by default and add your own. This should be added to the prototype of your class.

The generic version of the `toString()` method may be useful when debugging. You can use the `apply()` method to force its use on objects you are trying to inspect and which may have overridden the `toString()` method themselves.

This method is supported by virtually every object by virtue of the fact that it is available as a method of the `Global` object in Netscape. Therefore it gets inherited into the scope chain for every script and function (method).

Warnings:

- At JavaScript version 1.2 in the Netscape version 4 browser, there is a slight difference in the way that `toString()` works. It will output all the nested objects that are joined by properties. This gave rise to a technique for deep copying objects. However, it wasn't ECMA compliant and it no longer works in Netscape as of JavaScript 1.3.
- It might still work if you set the language version to JavaScript 1.2, but it's unreliable, not portable and definitely not going to work in Netscape 6.0. If you are exploiting it, you need to find an alternative because your scripts are going to break.

See also:	`Array.toString()`, `Boolean.toString()`, Conversion, `Date.toString()`, `Error.toString()`, `Function.toString()`, `Number.toString()`, `Object.toString()`, `prototype.toString()`, `RegExp.toString()`, String, String concatenate (+), `String.toString()`, `ToString`

ToUint16 (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts its input argument into an unsigned 16 bit integer value.

See also:	`Cast` operator, Conversion, Implicit conversion, Number, `String.fromCharCode()`, Type conversion

Cross-references:

ECMA 262 edition 2 – section – 9.7

ECMA 262 edition 3 – section – 9.7

ToUint32 (Operator/internal)

An internal operator for converting values.

Availability:	ECMAScript edition – 2

This internal operator converts its input argument to an unsigned 32 bit integer.

See also:	`Cast` operator, Conversion, Implicit conversion, Number, Type conversion

Cross-references:

ECMA 262 edition 2 – section – 9.6

ECMA 262 edition 3 – section – 9.6

TR object (Object/HTML)

An object that encapsulates the row content of a table contained in a `<TR>` tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTR* = *myDocument*.all.*anElementID*
	IE	*myTR* = *myDocument*.all.tags("TR")[*anIndex*]
	IE	*myTR* = *myDocument*.all[*aName*]
	-	*myTR* = *myDocument*.getElementById(*anElementID*)
	-	*myTR* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTR* = *myDocument*.getElementsByTagName("TR")[*anIndex*]
HTML syntax:	`<TR> ... </TR>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`align`, `bgColor`, `borderColor`, `borderColorDark`, `borderColorLight`, `ch`, `chOff`, `rowIndex`, `sectionRowIndex`, `vAlign`	
Object methods:	`deleteCell()`, `insertCell()`	
Event handlers:	`onBlur`, `onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	
Collections:	`cells[]`	

Tables are a two dimensional array of cells divided first into rows and then into columns. To access a particular cell, you locate its row first and then index along the cells in a row to find the one you want.

Rows are enclosed in `<TR>` tags which instantiate a `TR` object. The `TR` objects in a table are available as members of the `rows[]` collection.

They are also available in the `rows[]` collections that belong to `TFOOT`, `TBODY` and `THEAD` objects if the rows have been grouped inside tags that instantiate those objects.

You can access the cells in a row by using the `cells[]` collection that belongs to the `TR` object for the row you are interested in.

Warnings:

- Some earlier versions of the MSIE browser did not support access to the `innerHTML` property and related content when used on the Macintosh platform.

See also:	`Element` object, `TABLE` object, `TABLE.deleteRow()`, `TABLE.insertRow()`, `TBODY` object, `TD` object, `TFOOT` object, `THEAD` object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`align`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`bgColor`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`borderColor`	-	3.0 +	-	4.0 +	-	-	-	-
`borderColorDark`	-	3.0 +	-	4.0 +	-	-	-	-
`borderColorLight`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

TR.align (Property)

The alignment of content within table cells in the row.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTR*`.align`

The alignment of the `TR` object with respect to its containing parent object is defined in this property. The following set of alignment specifiers are available:

- `center`
- `left`
- `right`
- `char`
- `justify`

See also:	`TABLE.align`, `TBODY.align`, `TD.align`, `TFOOT.align`, `TH.align`, `THEAD.align`

TR.bgColor (Property)

The background color of table cells within the row.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTR*`.bgColor`

The background can be colored independently of whether an image is loaded into the background of an object. In fact it may be advisable to set the background color to something similar to the average color of the background image in case the image takes a long time to load or the browser is unable to display a background image.

See also:	Color names, Color value

TR.borderColor (Property)

The color of the border around table cells in the row.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTR*`.borderColor`

You can use this property to determine the color of a border surrounding a table row. Note that there are additional properties to determine the highlights and lowlights of the table row border coloring.

TR.borderColorDark (Property)

The color value of the shadowed edge of the table row border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTR*`.borderColorDark`

Table row borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the shadowed part of the table row border.

TR.borderColorLight (Property)

The color value of the highlighted edge of the table cell border (assuming the table is lit from the top left).

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myTR*`.borderColorLight`

Table row borders are presented as having an engraved appearance. This means you may need to control the highlights and lowlights. This property defines the color of the highlighted part of the table row border.

TR.cells[] (Collection)

A collection of cells within this row of the table.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	-	*myTR*`.cells`

The `table.cols` value should also be equivalent to `table.rows.cells.length` value.

See also:	`TABLE.cols`

Property attributes:

`ReadOnly`.

TR.ch (Property)

The alignment character for cells in a column arrangement.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	*myTR*`.ch`

HTML 4.0 provides for text to be arranged in neat columns within table cells without the need to create additional tables within tables. This method of alignment is selected by setting the `ALIGN="CHAR"` HTML tag attribute. The `CHAR` HTML tag attribute is reflected in this property and is active when the `CHAROFF` HTML tag attribute is present.

See also:	`COL.ch`, `COLGROUP.ch`, `TD.ch`, `TH.ch`, `THEAD.ch`

TR.chOff (Property)

The offset of a column alignment character.

Availability:	DOM level – 1 JavaScript – 1.5 Netscape – 6.0
Property/method value type:	`String primitive`

JavaScript syntax:	N	*myTR*.chOff

The CHAR alignment style requires that an alignment character be specified with the `ch` property and that an offset measured in pixels be defined as its value. The offset value can be defined with the `CHAROFF` HTML tag attribute. The remainder of the string is offset by this distance from the alignment character.

See also:	`COL.chOff`, `COLGROUP.chOff`, `TD.chOff`, `TH.chOff`, `THEAD.chOff`

TR.deleteCell() (Method)

In a multiple column table, you can delete a particular cell within a row with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
JavaScript syntax:	-	*myTR*.deleteCell(*anIndex*)
Argument list:	*anIndex*	The horizontal cell address to be deleted

See also:	`THEAD.deleteRow()`

TR.insertCell() (Method)

You can insert an additional cell into the row within a table with this method.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`TD object`	
JavaScript syntax:	-	*myTR*.insertCell(*anIndex*)
Argument list:	*anIndex*	The horizontal index at which to insert a cell

TR.rowIndex (Property)

A zero-based integer that indicates which row of the table this <TR> block represents.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTR*`.rowIndex`

The `TR.rowIndex` property is the vertical coordinate for cells in this row measured across the entire table.

This property yields a zero-based index number for this table row within the `rows[]` collection belonging to the `TABLE` object the row is a member of.

Note that this index will not hold true for the `rows[]` collections belonging to `THEAD`, `TBODY` and `TFOOT` objects. For that, you should inspect the `sectionRowIndex` property.

See also:	`TABLE.cells[],TABLE.rows[],TBODY.rows[], TFOOT.rows[],THEAD.rows[],TR.sectionRowIndex`

Property attributes:

`ReadOnly`.

TR.sectionRowIndex (Property)

A zero-based integer that indicates which row of the table this <TR> block represents.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myTR*`.sectionRowIndex`

The `TR.sectionRowIndex` property is the vertical coordinate for cells in this row measured within a `THEAD`, `TBODY` or `TFOOT` group and is reset to zero at the start of each section of the table.

This property yields a zero-based index number for this table row within the `rows[]` collection belonging to the `THEAD`, `TBODY` or `TFOOT` object the row is a member of.

Note that this index will not hold true for the `rows[]` collections belonging to `TABLE` object. For that, you should inspect the `rowIndex` property.

See also:	`TR.rowIndex`

Property attributes:

`ReadOnly`.

TR.vAlign (Property)

The vertical alignment of content in the table cells in this row.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myTR*`.vAlign`

The vertical alignment of the content within the table cells can be controlled across an entire `TR` extent with this property. The following keywords can be assigned to it:

- `baseline`
- `bottom`
- `middle`
- `top`

These may be also available on some implementations:

- `absbottom`
- `absmiddle`
- `baseline`
- `texttop`

See also:	`TBODY.vAlign`, `TD.vAlign`, `TFOOT.vAlign`, `TH.vAlign`, `THEAD.vAlign`

transient (Reserved word)

Reserved for future language enhancements.

Refer to:

Reserved word

Transition (Definition)

A visual effect used during event handling in MSIE.

These are activated by means of the `apply()` and `play()` methods. When executed, the transition will reveal the new display content. This mechanism obviously requires the use of a second display buffer and so for large onscreen windows, you may find that MSIE requires much more memory to utilize these effects properly.

See also:	`Element.filters[]`, filter – `BlendTrans()`, filter – `RevealTrans()`, `Filter` object, `style.filter`

Translation (Definition)

The process of tokenizing and interpreting a script.

See also:	Error handling, Interpret

Trigonometric function (Definition)

Functions for calculating angular values.

The trigonometric functions are provided by the `Math` object.

The following trigonometric functions are defined by the ECMA standard:

Function	Description
`acos()`	Inverse cosine
`asin()`	Inverse sine
`atan()`	Inverse tangent
`atan2()`	Inverse tangent of two values
`cos()`	Cosine of an angle
`sin()`	Sine of an angle
`tan()`	Tangent of an angle

See also:	Exponent-log function, Integer-value-remainder, `Math` object, `Math.acos()`, `Math.asin()`, `Math.atan()`, `Math.atan2()`, `Math.cos()`, `Math.sin()`, `Math.tan()`, Mathematics, Power function

true (Primitive value)

The Boolean `true` value.

Availability:	ECMAScript edition – 2
Property/method value type:	`Boolean primitive`

This is a Boolean primitive value representing the logically true state.

Conditional code execution depends on this value to signify the execution of a block of script code.

See also:	Boolean, Boolean, Boolean literal, Definition, false

try ... catch ... finally (Statement)

A mechanism for attempting to execute some potentially problematic code with a means of catching the exception and continuing execution.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape – 6.0

This was introduced in JavaScript 1.4 and JScript version 5.0. The intention is to provide a way to execute a section of code in the `try` block and then if it has a problem, some recovery action can trap the error and handle it gracefully.

There are three basic sections.

The `try` statement is followed by a block of code enclosed in braces that may be problematic. Indeed, the problems may not be script-based errors but may be the result of testing for some condition. That may lead to a custom exception being thrown.

If an exception of any kind happens in the `try` block, execution is immediately passed to the `catch()` function following.

The `catch` function is passed an `Error` object containing details of the kind of exception that has occurred.

When the `catch` function completes, execution drops into the block of code associated with the `finally` statement. In the case of the `try` block not having any exceptional behavior, at the end of that block execution also drops into the `finally` code block, bypassing the `catch` function altogether. So the `finally` code gets executed always after the `try` block.

You might use the `finally` block to tidy up or discard some unwanted objects.

In the example, the `try` block makes sure two values are presented in the correct order. If they are not in the right order, an exception is thrown and during the exception handling, they are swapped over. We put up an alert and set a flag that is presented in the output just to be sure it really happened like that.

Warnings:

- The functionality is not supported in Netscape prior to version 6.0.
- This is not supported by Netscape Enterprise Server 3 and so its error handling capabilities are not available server-side.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
testThrow(100, 200);
testThrow(300, 100);
function testThrow(arg1, arg2)
{
   var switched = "NO";

   // Force an error condition
   try
   {
      if(arg1 < arg2)
      {
         throw "Wrong order";
      }
   }
   catch(myErr)
   {
      alert(myErr);
      var temp = arg1;
      arg1 = arg2;
      arg2 = temp;
      switched = "YES"
   }
   finally
   {
```

```
        document.write("Biggest : "  + arg1 + "<BR>");
        document.write("Smallest : " + arg2 + "<BR>");
        document.write("Switched : " + switched + "<BR>");
        document.write("<BR>");
    }
}
</SCRIPT>
</BODY>
</HTML>
```

TT object (Object/HTML)

An object that represents the font style controlled by the `<TT>` HTML tag.

Availability:	JScript – 3.0 Internet Explorer – 4.0 Deprecated	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myTT* = *myDocument*.all.*anElementID*
	IE	*myTT* = *myDocument*.all.tags("TT")[*anIndex*]
	IE	*myTT* = *myDocument*.all[*aName*]
	-	*myTT* = *myDocument*.getElementById(*anElementID*)
	-	*myTT* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myTT* = *myDocument*.getElementsByTagName("TT")[*anIndex*]
HTML syntax:	`<TT> ... </TT>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	`onClick`, `onDblClick`, `onDragStart`, `onFilterChange`, `onHelp`, `onKeyDown`, `onKeyPress`, `onKeyUp`, `onMouseDown`, `onMouseMove`, `onMouseOut`, `onMouseOver`, `onMouseUp`, `onSelectStart`	

`<TT>` tags and the objects that represent them are inline elements. Placing them into a document does not create a line break.

See also:	`Element` object

TV Set-top boxes (Definition)

The integration of TV and Web content is resulting in new kinds of hardware that displays web page content at TV resolution.

In the same way that we had a browser war, there is a similar activity going on with TV set-top boxes. These are generally a slightly lower than normal functionality browser burned into a ROM or upgradeable Flash PROM chip.

There are several varieties already available in various forms. From the MSIE tradition comes the WebTV box. This is a browser originally based on MSIE 3 but now enhanced somewhat. There are limitations due to the need for it to occupy as little memory as possible. For those who prefer the Netscape browser, the Liberate box comes from a company initially formed as a joint venture between Netscape Communications and Oracle. It now has significant backing from Cisco and all things considered may well become the dominant platform.

Other alternatives exist from Bush Electronics and Netgem.

Because of the hardware limitations, these 'browser in a box' systems tend to support a reduced functionality set when compared with the more recent desktop computer based browsers. Typically the HTML support would be at version 3.2 of HTML and if JavaScript is supported it would be based on JavaScript version 1.2 with some minor additions and a few features omitted or compromised. This is very much a generalization however, and you will likely find some products that exceed these specifications.

A good source of information about the progress and development of the whole area of Digital Interactive TV and set-top boxes can be found at the Ruel web site.

Type (Definition)

The ECMA 262 standard defines nine data types. A type is a set of data values.

Availability:	ECMAScript edition – 2

A value is an entity that can take on the personality of one of the implemented data types. Some types are reserved for internal use and are not generally made visible to the script developer although this may be implementation dependent and they might be visible with a debugger.

The ECMA 262 standard defines nine data types. The host environment may add others depending on what it needs. The various types are listed in the table, which indicates whether they are special internal types:

Type Name	Description
Aggregate	A collection of atomic types assembled collectively into an object.
Arithmetic	All types that yield a value that can be operated on numerically.
Array	Collections of objects and identifiers assembled into a sequence.
Basic	The fundamental simple, non-object types.
Boolean	This type can store and yield `true` or `false` values.
Completion	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
List	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Null	This has exactly one value, `null`, and is distinct from undefined.
Number	Integer and floating point values are all stored in a generic number type.
Object	An object is an unordered collection of properties. Each property consists of a name, a value and a set of attributes.
Reference	Used only as the intermediate result of expression evaluations and cannot be stored in object properties.
Scalar	The non-object types.
String	Strings are arrays of characters which are accessible individually by indexing their position in the sequence.
Undefined	This value is returned by variables that have not yet been assigned a value.

Warnings:

- You cannot access values of type Reference, List and Completion from your scripts and they cannot be stored as object properties.

See also:	Aggregate type, Boolean, `Cast` operator, Completion type, `const`, `enum`, Identifier, `int`, List type, Logical operator, `null`, Number, Object, Reference, Scalar type, String, undefined type

Type conversion (Definition)

Type conversion happens automatically as needed.

Availability:	ECMAScript edition – 2

JavaScript on the one hand is very good for the beginning programmer because it is very forgiving in regard to variable types. Other languages require that you define the type of a variable at the outset and only ever store the correct kind of data in it. JavaScript doesn't actually care and modifies the type of a variable on the fly according to the values being presented.

Type conversion happens automatically as needed. To support this, a set of polymorphic operators are provided to make the conversion.

The following internal operators are provided:

- `ToPrimitive`
- `ToBoolean`
- `ToNumber`
- `ToInteger`
- `ToInt32`
- `ToUint32`
- `ToUint16`
- `ToString`
- `ToObject`

From the script writers point of view, these functions are inaccessible. However, you can call the constructors to invoke these functions indirectly.

The items of data themselves are still strongly typed, but the variable containers are smart enough to cope. There are some subtle rules to this however and you can create some situations where a very hard to diagnose problem occurs that is based on data typing inside the variables.

Type conversion happens during expression evaluation. You can still get rounding errors with Unary operators but you only need to worry about converting a single type.

If you think there is some ambiguity in your expression, you should force a conversion to the most appropriate type. Generally, object values should be converted to Numbers or Strings. Objects will generally have a preferred type that they yield when converted. In most cases that will be a number although `Date` objects prefer to become Strings.

Binary operators require two values and some require that both are of the same type or can be converted to the same type. If the type of the two operands is different, then you can have problems with some operators in expressions. If both need to be numeric for example, and once is not a legal numeric value even after conversion, then an error will result. The arithmetic and bitwise operators fall into that category.

The rest of the binary operators are polymorphic. That means they can cope with values of different types. The assignment operators will change the LValue to whatever type the RValue is. There is still some requirement here that the LValue is legally convertible. The comma operator doesn't combine its two operands in any way whatsoever.

Occasionally the interpreter may generate an error message due to its inability to legally convert a value to an appropriate type to complete the expression evaluation.

The relational operators cause some confusion since the values need to be converted for comparison but the relational comparisons work for several types. It is difficult to know what type will be used for the relational test unless you explicitly force a type conversion yourself.

The concatenation operator is also ambiguous because you may have two numeric strings and want to add them but the concatenate operator may join them together to make a string composed of both.

The addition/concatenation operator looks at the arguments and if either is a String already or preferentially converts to one, then a concatenation occurs. If neither operator prefers to be a String then a Number conversion happens and the values are added.

Relational operators perform the same deductive test. However, the conversion to Strings is less likely since relational operators are concerned with magnitude. However, they will test for collation order if both arguments are Strings.

Relational operators will attempt to convert both arguments to a Number and if they cannot, then they will use a String based compare. If at least one argument can be converted to a Number then the other will be forced to be a Number for comparison purposes. So for a relation test to be String based, both arguments must be Strings, or string-like objects.

Tests for equality require further deductive reasoning on the part of the interpreter. The values are converted to their preferred types. If the types are the same then the values can be compared easily either as Numbers or Strings. If the types are different, then further conversion is necessary before the comparison can be completed. In that case, Boolean values become Numbers as do any other non-Numeric values and Numeric comparison predominates.

Comparing `null` with undefined values does not require any conversion and they will compare equal.

Warnings:

- The ECMAScript compliant interpreters are based on comparison rules that prevailed prior to ECMAScript being formalized. However, JavaScript version 1.2 incorrectly anticipated that the standard would rule that equality required the type of the two operators to be identical. This means that a number in quotes will not test equal to the numeric value itself. Therefore "10" != 10 yields a `true` value instead of a `false` value. This will only come into play if you specify JavaScript version 1.2 in the language attribute of the `<SCRIPT>` tag in your web page. Placing a `<SCRIPT LANGUAGE=JavaScript">` tag is sufficient to work around this. In Netscape version 4.0, if you don't explicitly ask for version 1.2 of JavaScript, you still have access to the JavaScript version 1.2 capabilities of the language except that this particular comparison works as per the pre-JavaScript version 1.2 rules. That is to say, it works correctly.
- Version 6 of Netscape and version 5 of MSIE claim to be ECMAScript compliant and this problem should go away. Other browsers strive for ECMA compliance too, so as long as you avoid specifying JavaScript version 1.2 in your `<SCRIPT>` tags, you shouldn't encounter this problem.
- New operators `===` and `!==` are introduced with the ECMA standard at edition 3 to provide a test that takes account of data typing. MSIE version 4.0 already supports them in anticipation of the third edition of the standard. Netscape supports them at version 6.0.
- Earlier versions of MSIE and Netscape exhibited bugs in the comparison logic where the results of comparisons involving `NaN`, `null` and 0 where type conversions led to inconsistent behavior.

Example code:

```
// String object scanned from numeric literal
a = String(50);          // Equivalent to "50"

// Number object scanned from string literal
b = Number("22.22");     // Equivalent to 22.22

// String literal coerced to numeric
c = +("0x00FF");         // Equivalent to 255

// String with number subtracted
d = "22.22" - 11.11;     // Equivalent to 11.11

// Logical operator on string and number
e = ("abcde" && 23);     // Equivalent to 23

// Bitwise operator on string and number
f = ("0xF0" & 255);      // Equivalent to 240

// Number coerced to string by concatenation
g = "100" + 10;          // Equivalent to "10010"

// Test for equality of value
h = ("100.1" == 100.1);  // Equivalent to true

// Test for identity of instantiation
i = ("100.1" === 100.1); // Equivalent to false

// Object coerced to string forcing number to be concatenated
j = (new Object) + 10;   // Equivalent to "[object Object]10"
```

TypeError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 Netscape – 6.0	
Inherits from:	`Error object`	
JavaScript syntax:	N	`myError = new TypeError()`
	N	`myError = new TypeError(aNumber)`
	N	`myError = new TypeError(aNumber, aText)`
Argument list:	*aNumber*	An error number
	aText	A text describing the error

This sub-class of the `Error` object is used when an exception is caused by an operand having an unexpected data type.

See also:	`catch( ... )`, `Error` object, `EvalError` object, `RangeError` object, `ReferenceError` object, `SyntaxError` object, `throw`, `try ... catch ... finally`, `URIError` object

Inheritance chain:

`Error` object

ECMA 262 edition 3 – section – 15.11.6.5

typeof (Operator/unary)

An operator that yields the type of an operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 1.0 Internet Explorer – 3.02 Netscape – 3.0 Opera – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`typeof` *`anOperand`*
	-	`typeof(anOperand)`
Argument list:	*`anOperand`*	An object or variable to check for type

This operator produces a string that contains the operand's type.

The `typeof` operator inspects the operand and returns a string representing its type. The operand is not evaluated. There are times when this is advantageous and can avoid a run-time error.

The string value returned depends on the operand type being evaluated. The `typeof` operator returns these values:

Type	Result
Undefined	"undefined"
Infinity	"number"
NaN	"number"
Null	"object"
Boolean primitive	"boolean"
Number primitive	"number"
String primitive	"string"
`Boolean()` constructor	"boolean"
`Date()` constructor	"string"
`Number()` constructor	"number"
`RegExp()` constructor	"undefined"
`String()` constructor	"string"
`Boolean` object instance	"object"
`Date` object instance	"object"
`Math` object instance	"object"
`Number` object instance	"object"
`RegExp` object instance	"object"

Table continued on following page

Type	Result
`String` object instance	"object"
Generic object instance	"object"
Object not supporting a call interface	"object"
Object that supports a call interface	"function"
Other host objects	Implementation defined
`typeof` any value	"string"

Note that the values returned are lowercase and are not an exact match for the class of the operand. String objects and primitive strings are both described as having a `typeof` "string" for instance.

In some documentation the `typeof` operator is referred to as a function. Since it has optional parentheses and the operand is passed as an argument, it behaves as if it were a function.

The `typeof` operator is one of few ways in which you can use the contents of a variable that is not yet defined. It will yield the undefined type for variables that have not yet had a value assigned to them. And thus you can determine if it is safe to use them as an RValue in an assignment expression.

The associativity is right to left.

Refer to the operator precedence topic for details of execution order.

In JavaScript version 1.1, you can determine the difference between the undefined and `null` values.

In JavaScript version 1.3, the `===` operator will detect the difference.

You cannot distinguish between different kinds of objects. To do that you can compare the object `constructor` property with one of the built-in types. You can ask the constructor property (if there is one) for its name. Sometimes a `toString()` conversion on the object will yield a function name and occasionally you may need to check prototype values or test for the existence of properties. If all else fails, you have to assume that it's just an object of arbitrary type.

Warnings:

- The `typeof` operator is not available in Netscape version 2.02.
- In Microsoft environments, this is available most of the time, but does not work for certain objects. In particular, there may some objects in WSH for which it is not supported.

Example code:

```
// Testing a string value
var aString = 'String text';
document.write(typeof(aString));     // Yields "string"

// Testing variables that exist but are not yet assigned
var aVar1;
document.write(typeof aVar1);     // Yields "undefined"

// Testing variables that do not yet exist
document.write(typeof aVar2 );     // Yields "undefined"
```

U object (Object/HTML)

An object that represents the font style controlled by the <U> HTML tag.

Availability:	DOM level –1 JavaScript –1.5 JScript –3.0 Internet Explorer –4.0 Netscape version –6.0 Deprecated	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myU* = *myDocument*.all.*anElementID*
	IE	*myU* = *myDocument*.all.tags("U")[*anIndex*]
	IE	*myU* = *myDocument*.all[*aName*]
	-	*myU* = *myDocument*.*getElementById*(*anElementID*)
	-	*myU* = *myDocument*.getElementsByName(*aName*)[*anIndex*]
	-	*myU* = *myDocument*.getElementsByTagName ("U")[*anIndex*]
HTML syntax:	<U> ... </U>	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

<U> tags and the objects that represent them are in-line elements. Placing them into a document does not create a line break.

See also:	`Element` object

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

onSelectStart	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object

UDI (Definition)

Universal Document Identifier.

This is another name for a URL. Arguably this is a sub-set of all the available URLs because it refers specifically to a document and not a sound effect for example.

See also:	URI, URL, URN

UIEvent object (Object/DOM)

This is part of the DOM level 2 user interface event set.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape version – 6.0	
Inherits from:	`Event object`	
JavaScript syntax:	N	*myUIEvent* = new UIEvent()
Object properties:	`detail, view`	
Object methods:	`initUIEvent()`	

The availability of the `UIEvent` object handling can be determined with the `Implementation.hasFeature()` method call.

The available set of events is defined by HTML 4.0 and DOM level 0 with some additional events added. These event types are enumerated in the DOM level 2 specification and are:

- DOMFocusIn
- DOMFocusOut
- DOMActivate

See also:	`AbstractView` object, `Event` object, `Implementation.hasFeature()`, `MouseEvent` object, `onBlur`, `onClick`, `onFocus`

Property	JavaScript	JScript	N	IE	Opera	DOM	Notes
`detail`	1.5 +	-	6.0 +	-	-	2 +	ReadOnly
`view`	1.5 +	-	6.0 +	-	-	2 +	ReadOnly

Method	JavaScript	JScript	N	IE	Opera	DOM	Notes
`initUIEvent()`	1.5 +	-	6.0 +	-	-	2 +	-

Inheritance chain:

`Event` object

UIEvent.detail (Property)

Some detailed information about the `Event` object is made available as a numeric value.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape version – 6.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myUIEvent*`.detail`

The value provided here depends on the `Event` type being inspected.

Property attributes:

`ReadOnly`.

UIEvent.initUIEvent() (Method)

After creating a `UIEvent` object with `document.createEvent()`, it must be initialized with this method call.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape version – 6.0	
JavaScript syntax:	N	*myUIEvent*.initUIEvent(*aType*, *canBubble*, *canCancel*, *aView*, *aDetail*)
Argument list:	*aType*	A string containing the event type
	canBubble	A boolean flag indicating whether the event can bubble
	canCancel	A boolean flag indicating whether the event can be cancelled
	aView	A reference to an `AbstractView` object
	aDetail	A numeric detail value

A new `event` object is manufactured by calling the `DocumentEvent.createEvent()` method. That event should have been defined with a type specified as "`UIEvent`". If it was, then it will support an `initUIEvent()` method. This must be called before the event is dispatched, otherwise the `event` object will not contain enough information for the event dispatcher/handler to make sense of it and route it to the correct target objects.

The two boolean argument values define whether the event will be allowed to be cancelled, and what type of propagation to use (`bubble` or `capture`).

The view argument refers to an `AbstractView` object which DOM level 2 describes and which may not yet be well supported by any browser.

The detail value can be used to pass context information into the event handling chain.

See also:	`DocumentEvent.createEvent()`, `MouseEvent.initMouseEvent()`

UIEvent.view (Property)

A reference to the `AbstractView` object that generated the event.

Availability:	DOM level – 2 JavaScript – 1.5 Netscape version – 6.0	
Property/method value type:	`AbstractView` object	
JavaScript syntax:	N	`myUIEvent.view`

A abstract view object is defined in the DOM level 2 views module. The support for this property in Netscape 6.0 should extend to it providing a `Window` object. The support may not extend to the complete view interface that allows you to select alternate document views.

Property attributes:

`ReadOnly`.

UL object (Object/HTML)

An object that encapsulates an unordered list in a `<UL>` tag.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	`myUL = myDocument.all.anElementID`
	IE	*myUL* `= myDocument.all.tags("UL")[`*anIndex*`]`
	IE	*myUL* `= myDocument.all[`*aName*`]`
	-	*myUL* `= myDocument.getElementById(`*anElementID*`)`
	-	*myUL* `= myDocument.getElementsByName (`*aName*`)[`*anIndex*`]`
	-	*myUL* `= myDocument.getElementsByTagName ("UL")[`*anIndex*`]`
HTML syntax:	`<UL> ... </UL>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an `Element` object
Object properties:	`compact, start, type`	
Event handlers:	`onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart`	

The `<UL>` tag is a block-level tag. That means that it forces a line break before and after itself.

The DOM level 1 standard describes this as a `UListElement` object.

See also:	DIR object, Element object, OL object

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`compact`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`start`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-
`type`	1.5 +	3.0 +	6.0 +	4.0 +	-	1 +	-	-

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`onClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDblClick`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onDragStart`	-	3.0 +	-	4.0 +	-	-	-	-
`onFilterChange`	-	3.0 +	-	4.0 +	-	-	-	-
`onHelp`	-	3.0 +	-	4.0 +	-	-	-	Warning
`onKeyDown`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onKeyPress`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onKeyUp`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseDown`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseMove`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOut`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseOver`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onMouseUp`	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning
`onSelectStart`	-	3.0 +	-	4.0 +	-	-	-	-

Inheritance chain:

`Element` object, `Node` object.

UL.compact (Property)

A switch that compacts the unordered list content to occupy less space on the screen.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`myUL.compact`

The collection of `LI` objects are presented in the normal spaced-out style when the compact property belonging to their owner `OL` object is set to `false`.

Setting the property to `true` should result in the list items being squeezed closer together. However, the functionality is rarely supported on web browsers.

It's more likely that you'll apply CSS style attributes to the list to achieve the same effect.

UL.type (Property)

A control for the type of listing style that is presented.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUL*`.type`

Although an unordered list does not support a sequence numbering scheme, they may be displayed in a variety of different formats selected by this property.

You can override this on an item by item basis and so this property is related to the `LI.type` property.

The following values are appropriate for this property:

- circle
- disc
- square

See also:	`LI.type`, `OL.type`, `style.listStyleType`

Unary expression (Definition)

An operator prefixing an operand.

Availability:	ECMAScript edition – 2

Unary expressions can also be considered to be prefix expressions and also operate on `LValues`.

See also:	Add (+), `delete`, Expression, Logical `NOT` – complement (!), Prefix decrement (--), Prefix increment (++), typeof, Unary operator, `void`

Cross-references:

ECMA 262 edition 2 – section – 11.4

ECMA 262 edition 3 – section – 11.4

Unary operator (Definition)

An operator that requires only one operand to create an expression.

Availability:	ECMAScript edition – 2

Unary operators are those that operate on a single value or expression result.

Some of the unary operators use keywords to convey their meaning. Others are sequences of punctuation characters. Here are the unary operators defined by ECMAScript:

Operator	Meaning
+	Convert the operand to a numeric value.
++	Increment the numeric value of the operand.
-	Convert the operand to a numeric value and negate it.
--	Decrement the numeric value of the operand.
~	Convert the operand to a 32 bit integer and perform a bitwise complement on it.
!	Convert the operand to a boolean value and reverse its value.
new	Invokes an object constructor
delete	Used to delete a property from an object if it can be deleted.
void	Regardless of the result of evaluating the expression that may be operated on, this will always yield the undefined value.

Some of these operators have a different meaning when used with more than one operand.

See also:	Add (+), Bitwise `NOT` – complement (~), delete, Expression, Logical `NOT` – complement (!), Negation operator (-), Operator, Operator Precedence, Positive value (+), Postfix operator, Prefix operator, Ternary operator, typeof, Unary expression, `void`

ECMA 262 edition 3 – section – 11.4

Wrox *Instant JavaScript* – page – 19

undefined (Constant/static)

A literal constant whose type is a built-in primitive value.

Availability:	ECMAScript edition – 2 JavaScript – 1.3 JScript – 5.5 Internet Explorer – 5.5 Netscape version – 4.06
Property/method value type:	`Undefined primitive`

The undefined value is a primitive value that is returned when a variable has not yet been assigned a value.

In some implementations this value compares equal to the `null` value. They are not actually the same, but this can sometimes provide a work-around for those implementations that do not provide a way to explicitly test for an undefined value.

If a variable is declared and no value is assigned to it, then it will contain the undefined value. It will exist and can be referred to in expressions and will affect them to the extent they can be affected by the value 'undefined'.

If a variable has never been declared and it is referred to, a run-time error will result. It does not exist let alone contain the 'undefined' value. There is one instance where referring to a non-existent variable does not generate an error, and that is to use it as an `LValue` in an assignment. Only the = operator can be used. The prefix and postfix increment/decrement operators should yield an error and so should the compound assignment operators, since the value to the left does not exist until after the assignment has taken place.

You cannot create an 'undefined' value explicitly in older interpreters since there is no keyword to yield it as a constant. This is more of a problem with MSIE which only supported the undefined keyword as of version 5.5 while Netscape has supported it since JavaScript 1.3. If you need to, you can manufacture one of your own with this expression:

```
undefined = (void 0);
```

This whole area is somewhat mysterious and the (`void 0`) simulation really creates a `null` value which some browsers cannot distinguish from the undefined value.

Warnings:

- Some implementations do not provide adequate protection against you corrupting this value. Be careful not to assign your own values to this variable. It will lead to unpredictable results if you do.
- This is not available for use server-side with Netscape Enterprise Server 3.

Example code:

```
// Assuming a or b has not been declared, this generates an error
a += 10;
// This doesn't
a = 10;
// This does
alert(b);
```

See also:	Exception, `Global` object, `null`, Null literal, Range error, `void`

ECMA 262 edition 2 – section – 4.3.9

ECMA 262 edition 3 – section – 4.3.9

O'Reilly *JavaScript Definitive Guide* – page – 47

Undefined behaviour (Definition)

Erroneous operations not described in the standard.

Undefined behavior is what happens when something goes wrong but the standard does not provide any suggested behavior. In many languages, an attempt to divide by zero would yield an undefined result. However JavaScript defines the `NaN` value for just such an occasion.

These situations generally manifest themselves as a run-time error which at the least would present an alert to the user. Sometimes the implementation can catch these errors and may offer the opportunity to stop executing scripts on that web page.

In some cases, the undefined behavior may degenerate to the worst case scenario where the hosting application or even the environment itself is compromized and the system crashes. An example of this is some versions of Netscape when presented with an `<OBJECT>` tag and some versions of MSIE when `onMouseover` events cross from one DOM object to another. In both cases, the browser crashes and does so in such a way that the underlying operating system is also stalled, necessitating a complete reboot.

A portable script should not depend on any undefined behavior performing in a predictable way, even if that behavior is benign. It is very likely that any undefined behavior will not survive between versions of the implementation and almost certainly will not be portable across platforms.

See also:	Behavior, Portability, Range error

undefined type (Type)

A native built-in type.

Availability:	ECMAScript edition – 2
Property/method value type:	`Undefined primitive`

The undefined type has exactly one value, called undefined. It is returned by variables that have not yet been assigned with a value.

This value is also returned in some browsers when referring to a part of the document object model that is non-existent.

Sending a subsequent message to values that are currently undefined results in a run-time error.

Wrox *Instant JavaScript* – page – 14

Undocumented features (Definition)

Aside from the features covered in official documentation, browsers support many other hidden capabilities.

Warnings:

- There have always been undocumented features in the web browsers. Some of these were uncovered during the preparation of this book and have been covered in their own topics.
- Generally, the undocumented features are methods and properties of objects that are not commonly used and maybe an extension to the object that is platform specific. There are also objects that are obscure and can only be discovered by inspection.
- Reading the standards documents, release notes, and manufacturer manuals, only reveals part of the picture.
- The most powerful tool for uncovering these undocumented features is JavaScript itself. In particular the `for( ... in ... )` enumerator which will scan an object for any enumerable properties. This won't reveal all the hidden features but it will uncover many of them.
- Armed with this knowledge, you can write inspection scripts to display the values of those properties. Often they point at an object and if the property is undocumented, then it's likely the object is as well.
- You can spend many hours examining a new browser release and learn much about how it's organized internally. This helps to better understand DOM navigation and how to do 'extreme JavaScript programming'.
- MSIE version 5.0 and 5.5 both introduce many interesting and undocumented features. Netscape version 6.0 builds on that, and adds many more, in particular the sidebar. A great deal of Netscape's user interface is written in JavaScript and by examining the Mozilla source code and the `.js` files that are installed with it, you can learn and possibly customize your browsing experience.

See also:	Netscape

unescape() (Function/global)

Un-URL-escape a string.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0 Deprecated	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`unescape(`*`anInputString`*`)`
Argument list:	*`anInputString`*	A string to be converted

This function is the complement of the `escape()` function described in its own topic elsewhere.

A string that might have been escaped with the `escape()` function either locally or remotely, can be converted back to a normal unescaped string with this function.

This function has Unicode support in MSIE version 4.

As far as ECMAScript is concerned, this is superceded in edition 3 with a set of generalized URI handling functions. The JScript 5.5 documentation refers to this as a deprecated feature.

See also:	Cast operator, `decodeURI()`, `decodeURIComponent()`, `encodeURI()`, `encodeURIComponent()`, `escape()`, `Function` property, `Global` object, URI handling functions

Property attributes:

`DontEnum`.

Cross-references:

ECMA 262 edition 3 – section – B.2.2

Unicode (Standard)

A character encoding standard.

Availability:	ECMAScript edition – 2

The Unicode standard is derived originally from ASCII. ASCII was an 8 bit coded character set with a limited number of individual character values. Unicode is a 16 bit coding that supports all the required characters for the major languages of the world, plus the technical symbols in common use.

Implementations of JavaScript that conform to the ECMA 262 standard must interpret character values in accordance with the Unicode Standard, version 2.0, and ISO/IEC 10646-1 with UCS-2 (Universal Character Set) as the adopted encoding form, implementation level 3. If the adopted 10646 subset is not indicated, then it should be assumed to be the BMP subset, collection 300.

For most usage, the character set will be the lower 128 characters that roughly correspond to the ASCII character table. However, internationalization and localization work in progress suggests that non-English speaking users should be able to declare identifiers in their own natural language with its particular character sets and special symbols. Internet web site domain name standards are undergoing some revision to support double byte characters. The ECMAScript edition 3 improves support for handling localized strings, numbers and dates.

The Unicode standard is due for updating to a new edition as the version 2.0 is somewhat old now and does not support Euro currency symbols among other things. A version 3.0 standard is reported to be on the way.

Unicode characters are more properly referred to as code points.

Universal coordinated time (Standard)

A universal standard time that is synchronized to GMT.

The universal coordinated time (AKA Universel Temps Cordonne – UTC) is a standard time value that is based on an atomic clock, measured and calibrated according to astronomical observations of pulsars.

UTC is synchronized to Greenwich Mean Time which is coincident with the location of the zero meridian.

Local time at any point on the earth's surface is computed relative to UTC by adding a positive or negative offset to UTC. In general, the offsets are measured in complete hours of 60 minutes duration.

However there are some locations in the world where the offset is a fractional offset in hours. As a general rule, each hour corresponds to a movement of 15 degrees further away from the meridian. This is not completely strict since China spans almost 4 hours in terms of distance but is entirely in one time-zone based on the time in Peking.

Some Islamic countries do not adopt the same time scale in any case, choosing instead to measure the time from sunrise to sunset as 12 hours. Since days wax and wane according to the season, this can cause some difficulty in converting local time to UTC and vice versa.

UniversalBrowserAccess (Security privilege)

A combination of both read and write access.

This is a combination of everything that `UniversalBrowserRead` and `UniversalBrowserWrite` provide access control for in a single privilege.

See also:	about: URL, `Event` object, `Event.data`, `History` object, `netscape.security.PrivilegeManager`, `onDragDrop`, `PrivilegeManager` object, `PrivilegeManager.disablePrivilege()`, `PrivilegeManager.enablePrivilege()`, Requesting privileges, Restricted access, Same origin, Security policy, self, `Window.close()`

UniversalBrowserRead (Security privilege)

A privilege to grant read access to browser internals.

Gives a script permission to read the properties of windows whose content comes from different origins. This also controls script access to the `history` object among other things. Other internal browser state information that is accessible via the `about:` URL is also controlled by this privilege.

This privilege is also necessary to read the `data` property of an `event` object that is passed to the `ondragdrop()` event handler.

See also:	about: URL, Event object, Event.data, History object, History.current, netscape.security.PrivilegeManager, onDragDrop, PrivilegeManager object, PrivilegeManager.disablePrivilege(), PrivilegeManager.enablePrivilege(), Requesting privileges, Restricted access, Same origin, Security policy

UniversalBrowserWrite (Security privilege)

A privilege that grants the ability to write to internal browser values.

This property allows scripts to close windows. Without this privilege, if a script opens a window, it cannot create a window that is smaller than 100 pixels square. Scripts without this privilege also cannot move a window off-screen, create one that is larger than the screen or create a window that lacks a title-bar. Conferring this privilege allows scripts to do all these things. Without it, scripts cannot hide from view or carry on running when the user thinks they have stopped.

This privilege grants the script permission to hide or show the various window furniture (menu-bar, status-line, scroll-bars, tool-bar, location-bar, directory-bar or personal-bar). Without it, scripts cannot change the visibility of these items.

It also affects event management. You cannot watch events in other windows if they come from different sources without this privilege and you cannot set event object properties without it either. The occasional bug in a browser lets you get round the security in odd ways.

This is how to put a toolbar back onto a window that didn't have one. You are supposed to require privileges to do it, but it sometimes works regardless:

```
open('', '_top', 'status=0,toolbar=1');
```

Putting a toolbar back lets you view source because the menu is reinstated too.

See also:	netscape.security.PrivilegeManager, PrivilegeManager object, PrivilegeManager.disablePrivilege(), PrivilegeManager.enablePrivilege(), Requesting privileges, Restricted access, Same origin, Security policy

UniversalFileRead (Security privilege)

A privilege to grant access to read a file in the file system.

If your script has this privilege, it can then select a file in the client file-system and upload it to the server by means of a FileUpload object. This is done by setting the value property of that FileUpload object.

If this capability is activated, the contents of any file on the local file-system can be presented to a CGI script running on a web server.

See also:	FileUpload object, FileUpload.value, netscape.security.PrivilegeManager, PrivilegeManager object, PrivilegeManager.disablePrivilege(), PrivilegeManager.enablePrivilege(), Requesting privileges, Restricted access, Security policy

UniversalPreferencesRead (Security privilege)

A privilege that allows access to preferences information.

This privilege controls read access to preference settings. Scripts without it cannot see user preference settings. It arbitrates the use of the `Navigator.preference()` method in read mode.

See also:	`History.next`, `History.previous`, `Navigator.preference()`, `netscape.security.PrivilegeManager`, `PrivilegeManager` object, `PrivilegeManager.disablePrivilege()`, `PrivilegeManager.enablePrivilege()`, Requesting privileges, Restricted access, Security policy

UniversalPreferencesWrite (Security privilege)

A privilege that grants the ability to change preferences settings.

This privilege controls whether scripts can change the current user preference settings. It controls the use of the `Navigator.preference()` method.

See also:	`Navigator.preference()`, `Navigator.savePreferences()`, `netscape.security.PrivilegeManager`, `PrivilegeManager` object, `PrivilegeManager.disablePrivilege()`, `PrivilegeManager.enablePrivilege()`, Requesting privileges, Restricted access, Security policy

UniversalSendMail (Security privilege)

A privilege that grants the permission to send mail.

This controls whether a `mailto:` or `news:` URL can be used when submitting a form. A confirmation dialog affirmative response is required if this privilege is not granted to the script.

The result of this is that an e-mail or Usenet news article is submitted that contains the user's e-mail address.

See also:	`mailto: URL`, `netscape.security.PrivilegeManager`, `news: URL`, `PrivilegeManager` object, `PrivilegeManager.disablePrivilege()`, `PrivilegeManager.enablePrivilege()`, Requesting privileges, Restricted access, Security policy

Unspecified behavior (Definition)

Correct behavior that is not specified in the standard.

Although the standard attempts to cover every possible eventuality, there will be parts of an implementation that are not described in the standard. For example, the standard may not define the order in which arguments to a function are to be processed. Some implementations may process them from left to right and others from right to left.

See also:	Behavior

untaint() (Function/global)

A deprecated method for controlling secure access to data values.

Availability:	JavaScript – 1.1 Netscape version – 3.0 Deprecated

This was removed at version 1.2 of JavaScript. If you encounter it in a script you are maintaining, it is probably wise to seek to have it removed, otherwise it is likely to cause a run-time error.

Warnings:

- DO NOT USE THIS FUNCTION!

See also:	`Navigator.taintEnabled()`, `taint()`

unwatch() (Function/global)

Un-set a watch-point for a named property of an object.

Availability:	JavaScript – 1.2 Netscape version – 4.0	
JavaScript syntax:	N	*myObject*`.unwatch(aProperty)`
Argument list:	*aProperty*	A property to cease watching

This method is provided to ease the task of debugging JavaScript.

It is provided to disconnect the watcher that was set up with the `watch()` method.

Its calling circumstances are identical and you simply need to provide a complementary `unwatch()` to deactivate the effects of a `watch()`.

The new event model supported by Netscape version 6.0 and that already available in MSIE 5.0 present a `propertyName` property that belongs to the `Event` object. You can inspect that during an `onPropertyChanged` event and achieve the same `watch()/unwatch()` behavior.

See also:	Event, Event handler, Event management, Event model, `Event` object, `onPropertyChange`, `watch()`

URI (Definition)

A Uniform Resource Identifier.

This is another name for a URL. Some commentators argue that a URI is different to a URL. One identifies the target while the other locates it. There may be several copies at different URLs but perhaps they would all be instances of the same URI.

A URI is composed like this (according to the ECMA standard):

```
scheme:first/second;third?fourth
```

See also:	UDI, URL, URN

Cross-references:

RFC 1738, 1808

URI handling functions (Definition)

ECMA edition 3 describes a set of functions it refers to as URI handling properties.

Availability:	ECMAScript edition – 3

According to the ECMA standard (edition 3), a URI is composed of component parts separated by special characters. The special characters are:

- Colon (:)
- Slash (/)
- Semi-colon (;)
- Question-mark (?)

Other characters are reserved for future use.

A URI will need to be encoded without damaging these characters. Normal `escape()` function techniques are not URI safe.

ECMA defines functions for encoding and decoding the entire URI and also functions for dealing with its components individually.

See also:	`decodeURI(),decodeURIComponent(),encodeURI(), encodeURIComponent(),escape(),unescape()`

Cross-references:

ECMA 262 edition 3 – section – 15.1.3

URIError object (Object/core)

A native error object based on the `Error` object.

Availability:	ECMAScript edition – 3 JavaScript – 1.5 Netscape version – 6.0	
JavaScript syntax:	N	*myError* = new URIError()
	N	*myError* = new URIError(*aNumber*)
	N	*myError* = new URIError(*aNumber*, *aText*)
Argument list:	*aNumber*	An error number
	aText	A text describing the error
Object properties:	description, message, name, number	
Object methods:	toString()	

This sub-class of the `Error` object is used when an exception is caused by one of the URI handler functions being used inappropriately.

See also:	`catch( ... )`, `Error` object, `EvalError` object, `RangeError` object, `ReferenceError` object, `SyntaxError` object, throw, try ... catch ... finally, `TypeError` object

Property	JavaScript	JScript	N	IE	Opera	NES	ECMA	Notes
description	1.5 +	-	6.0 +	-	-	-	3 +	-
message	1.5 +	-	6.0 +	-	-	-	3 +	-
name	1.5 +	-	6.0 +	-	-	-	3 +	-
number	1.5 +	-	6.0 +	-	-	-	3 +	-

Method	JavaScript	JScript	N	IE	Opera	NES	ECMA	Notes
toString()	1.5 +	-	6.0 +	-	-	-	3 +	-

ECMA 262 edition 3 – section – 15.11.6.6

URL (Definition)

A Uniform Resource Locator.

The URL is composed of several parts. The `http:` in the URL specifies a URL method, which is to be used for retrieving the document or performing the action. There are several alternatives.

The following URL methods may be found. Note that some of these are implementation dependent:

- http: – Hypertext Transfer Protocol. See RFC 2068
- https: – Secure Hypertext Transfer Protocol.
- ftp: – File Transfer Protocol. See RFC 1738
- news: – USENET news. See RFC 1738
- snews: – Secure USENET news.
- mailto: – Electronic mail address. See RFC 2368
- telnet: – Reference to interactive sessions. See RFC 1738
- file: – Host-specific file names. See RFC 1738

These are special Netscape URL request methods that invoke internal sub-systems. Some of these may not be fully functional or may need to be activated by configuration options in the prefs.js file:

- nethelp: – Help manager.
- about: – Internal browser resources.
- mailbox: – Mailbox manager.
- view-source: – Source viewer.
- javascript: – JavaScript interpreter.
- livescript: – JavaScript interpreter.
- mocha: – JavaScript interpreter.
- imap: – internet message access protocol. See RFC 2192
- pop3: – Post Office Protocol v3. See RFC 2384
- ldap: – Local Directory Access Protocol.
- ldaps: – Local Directory Access Protocol (secure).
- rlogin: – Remote login.
- tn3270: – Interactive 3270 emulation sessions.
- wais: – Wide Area Information Servers. See RFC 1738
- wysiwyg: – JavaScript generated page content.

The MSIE browser also uses the `clsid:` URL to locate registered ActiveX controls that are loaded with the `<OBJECT>` tag.

The IANA documention also lists these protocols:

- gopher: – The Gopher Protocol. See RFC 1738
- nntp: – USENET news using NNTP access. See RFC 1738
- prospero: – Prospero Directory Service. See RFC 1738

- z39.50s: – Z39.50 Session. See RFC 2056
- z39.50r: – Z39.50 Retrieval. See RFC 2056
- cid: – content identifier. See RFC 2392
- mid: – message identifier. See RFC 2392
- vemmi: – versatile multimedia interface. See RFC 2122
- service: – service location. See RFC 2609
- nfs: – network file system protocol. See RFC 2224
- acap: – application configuration access protocol. See RFC 2244
- rtsp: – real time streaming protocol. See RFC 2326
- tip: – Transaction Internet Protocol. See RFC 2371
- data: – data. See RFC 2397
- dav: – dav. See RFC 2518
- opaquelocktoken: – opaquelocktoken. See RFC 2518
- sip: – session initiation protocol. See RFC 2543
- tel: – telephone. See RFC 2806
- fax: – fax. See RFC 2806
- modem: – modem. See RFC 2806
- afs: – Andrew File System global file names.
- mailserver: – Access to data available from mail servers

These are specified as part of the ATVEF standard to provide support for TV set top boxes:

- tv: – Display a TV picture where you might use an image.
- lid: – Local identifier for accessing cached and carousel delivered assets.
- uhttp: – Unidirectional (broadcast) HTTP content.

Warnings:

- As of autumn 2000, there are changes afoot to allow characters other than the English letters and numbers to be used in URL values. The Verisign organisation will act as an arbiter of whether a URL is valid but it may be composed of arabic and Chinese characters for example.

See also:	about: URL, ATVEF, clsid: URL, file: URL, ftp: URL, http: URL, https: URL, javascript: URL, mailbox: URL, mailto: URL, nethelp: URL, news: URL, snews: URL, telnet: URL, UDI, URI, URN, view-source: URL

Url object (Object/HTML)

An object that represents URLs in Netscape but which has extensions in MSIE.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Inherits from:	`Element object`	
JavaScript syntax:	-	*myUrl* = *myDocument*.links[*anIndex*]
Argument list:	*anIndex*	A reference to an element in a collection
Object properties:	`charset, coords, hash, host, hostname, href, hreflang, Methods, mimeType, name, nameProp, pathname, port, protocol, protocolLong, rel, rev, search, shape, tabIndex, target, text, type, urn, x, y`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

Objects of this type are contained in the `document.links[]` array.

Event handling support via properties containing function objects was added to `Url` objects at version 1.1 of JavaScript.

See also:	Anchor object, Area object, Document.links[], HyperLink object, LINK object, LinkArray object, Location object, String.anchor(), String.link(), Url.hash, Url.host, Url.hostname, Url.href, Url.name, Url.pathname, Url.port, Url.protocol, Url.search, Url.target, Url.text

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
`charset`	-	-	-	-	-	-	-	-
`coords`	1.0 +	1.0 +	2.0 +	3.02 +	-	-	-	-
`hash`	1.0 +	1.0 +	2.0 +	3.02 +	3.0 +	-	-	Warning

onMouseOut	1.1 +	3.0 +	3.0 +	4.0 +	3.0 +	-	4.0 +	Warning
onMouseOver	1.0 +	1.0 +	2.0 +	3.0 +	3.0 +	-	4.0 +	Warning
onMouseUp	1.2 +	3.0 +	4.0 +	4.0 +	3.0 +	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

Url.charset (Property)

The character set of the document pointed at by the `HREF="…"` HTML tag attribute of an anchor.

Property/method value type:	String primitive	
JavaScript syntax:	none	*myUrl*.charset

This would contain the character set being used by the document referred to by the `HREF="..."` HTML tag attribute. For example the value "`iso-8859-1`" is likely to be returned but the local variant of the browser and OS may affect the value you get.

This property might contain a value such as:

```
csISO5427Cyrillic
```

Details of other aliases can be located at the IANA registry.

See also:	Anchor.charset, LINK.charset

Url.coords (Property)

The co-ordinates on screen where the object represented by the URL is located.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myUrl*.coords

When a shaped area is defined within an image map, the extent rectangle around the shape is defined with the co-ordinates property. The value is defined with the `COORDS="..."` HTML tag attribute.

See also:	Anchor.coords, Url.shape

Url.hash (Property)

The hash delimited item at the end of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*.hash
	-	*myUrl*.hash = *aLocation*
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*aLocation*	A new named location within the document

This property yields a text string that contains the hash suffix from the URL if there is one.

You can assign a new value to this property, which will become a new anchor location within the document.

Warnings:

- This attribute may not work correctly when URLs are accessed from one frame to another in some versions of MSIE. You should check your target platforms for compliance.
- If you assign a value to this property, you should omit the leading hash.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE" HREF="http://www.mydomain.com/folder/file.html#abcdef">Click
here</A><BR>
<SCRIPT>
//In testing, this did not work on Opera 5.0
document.write(document.links[0].hash);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, URL, `Url` object, `Url.href`, `Url.pathname`, `Url.port`, `Url.protocol`, `Url.search`, `Url.target`

Url.host (Property)

The hostname and port number of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*.host
	-	*myUrl*.host = aHost
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*aHost*	A new hostname and optional port value

This property yields the hostname and colon delimited port number of the HREF value in an `<A>` tag if there is one and an empty string if not.

You can redefine the host by assigning a new value to this property.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
document.write(document.links[0].host);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, `Anchor.host`, URL, `Url` object, `Url.href`, `Url.pathname`, `Url.port`, `Url.protocol`, `Url.search`, `Url.target`

Url.hostname (Property)

The hostname of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myUrl*.hostname
	-	*myUrl*.hostname = *aHostname*
HTML syntax:	<A HREF="..."><LINK HREF="...">	
Argument list:	*aHostname*	The name of a host

This property yields the host value of the HREF value in an <A> tag if there is one and an empty string if not.

You can redefine the hostname by assigning a new value to this property.

Warnings:

- Be careful not to assign a port number with the host name, otherwise your new URL may acquire two port numbers which makes it invalid.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
// In testing, this did not work on Opera 5.0
document.write(document.links[0].hostname);
</SCRIPT>
</BODY>
</HTML>
```

See also:	Anchor.hash, Anchor.hostname, URL, Url object, Url.href, Url.pathname, Url.port, Url.protocol, Url.search, Url.target

Url.href (Property)

The complete HREF of an HREF URL if there is one.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0
Property/method value type:	String primitive

JavaScript syntax:	-	*myUrl*.href
	-	*myUrl*.href = *aHREF*
HTML syntax:	<A HREF="..."><LINK HREF="...">	
Argument list:	*aHREF*	A valid HREF value

This property yields a text string that contains the complete HREF value from the URL if there is one and an empty string if not.

You can redefine the entire HREF content by assigning a new value to this property.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
document.write(document.links[0].href);
</SCRIPT>
</BODY>
</HTML>
```

See also:	Anchor.hash, Anchor.href, Location.href, URL, Url object, Url.hash, Url.host, Url.hostname, Url.pathname, Url.port, Url.protocol, Url.search, Url.target

Url.hreflang (Property)

The language that the document at the HREF location is coded in.

Property/method value type:	String primitive	
JavaScript syntax:	none	*myUrl*.hreflang

This property should contain values that use the international language two-letter abbreviation codes. These are not the same as the country codes, which are also two letter values.

Refer to the Language codes topic for a list of the available codes.

See also:	Language codes, LINK.hreflang

Url.Methods (Property)

A collection of methods belonging to the URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Collection object`	
JavaScript syntax:	IE	*myUrl*`.Methods`
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	

The values here would be one of the valid methods for the HTTP protocol. It would be one of the following:

- GET
- HEAD
- POST
- PUT
- DELETE
- OPTIONS
- TRACE

It is likely that only the `GET` and `POST` methods make any logical sense in this contents and on rare occasions, the `PUT` method may be referred to although it is unusual to find a web server that accepts documents with this request method.

See also:	`Anchor.Methods`

Url.mimeType (Property)

The MIME type used to access the document pointed at by the URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myUrl*`.mimeType`

The MSIE browser maps the file extension of the file belonging to the anchor to an extended description of the file format, which it makes available through the `mimeType` property. Here is a list of some `mimeType` values it pays special attention to.

File type	MSIE expanded Mime type
.css	Microsoft CSS1 Style Sheet (W3C would have been more appropriate)
.gif	GIF Image
.htc	Microsoft HTML Component file for behaviours
.htm	Microsoft HTML Document 4.0
.html	Microsoft HTML Document 4.0
.jpg	JPEG Image
.js	Microsoft JScript File (this is a bit presumptuous)
.txt	Text Document
.vbs	Microsoft VBScript File
.xxx	All unrecognized file types are returned as xxx File with no further expansion

Microsoft assert that `.htm` and `.html` files are "Microsoft HTML" and `.css` files are "Microsoft CSS1" style sheets. They also assert that `.js` files are "Microsoft JScript" files. This is not strictly true because they don't own those file extensions across all platforms, nor indeed do they even own them on the Windows platform.

See also:	`Anchor.mimeType`

Url.name (Property)

In MSIE, the `Url.name` property is another way to access the `anchor.name` property.

Availability:	JavaScript – 1.5 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.name`
HTML syntax:	`<A NAME="aName">`	
Argument list:	*aName*	A name for an anchor

The value of this property is defined by the `NAME="..."` tag attribute in the HTML that describes the document. Without the `NAME` attribute the anchor object does not get added to the `anchors[]` array.

Warnings:

- This only works on MSIE and not in Netscape. This is because Netscape maintains links and anchors as strictly different things altogether. MSIE treats them as the same class of object.
- Logically there is not much purpose in changing the name of a link anyway.
- Be aware in MSIE that assigning a new name will affect the length of the `document.anchors[]` array even though the item is rightly a `link` object.

See also:	`Anchor.name`, `Area.name`, `Document.links[]`, `LinkArray.length`, `Url` object

Url.nameProp (Property)

The filename portion of the URL value.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myUrl.nameProp`

This property extracts the filename portion of the `HREF="..."` value for this anchor object.

See also:	`Anchor.nameProp`

Url.pathname (Property)

The pathname portion of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.pathname`
	-	*myUrl*`.pathname = aPath`
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*aPath*	A new pathname value

This property yields a text string that contains the pathname value from the URL if there is one and an empty string if not.

MSIE and Netscape support the use of this property as an `LValue`. If you write to it, the pathname portion of the HREF value is modified. Be careful not to include a hash or search/query value.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
document.write(document.links[0].pathname);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, *`Anchor.pathname`*, URL, `Url` object, `Url.hash`, `Url.host`, `Url.hostname`, `Url.href`, `Url.port`, `Url.protocol`, `Url.search`, `Url.target`

Url.port (Property)

The port value of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myUrl`*`.port`
	-	*`myUrl`*`.port = `*`aPortNumber`
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*`aPortNumber`*	A numeric value to be used as a port number

This property yields the port number value of the HREF attribute in an `<A>` tag if there is one and an empty string if not.

You can assign a value to this property as if it was an `LValue`.

Warnings:

- Do not include the delimiting colon when you assign a value to this property.
- Make sure you assign a numeric value. Non-numeric values will be rejected. This is to avoid the possibility of a completely invalid port number being used.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
// In testing, this did not work in Opera 5.0
document.write(document.links[0].port);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, `Anchor.port`, URL, `Url` object, `Url.hash`, `Url.host`, `Url.hostname`, `Url.href`, `Url.pathname`, `Url.protocol`, `Url.search`, `Url.target`

Url.protocol (Property)

The protocol value of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.protocol`
	-	*myUrl*`.protocol = aProtocol`
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*aProtocol*	A valid protocol for the URL that the browser supports

This property yields text string that contains the protocol value from the URL if there is one and an empty string if not.

Using this property as an `LValue`, you can redefine the protocol for the link if it has an HREF. You might want to do this if you want to change the way you access a particular document.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
```

```
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
// In testing, this did not work in Opera 5.0
document.write(document.links[0].protocol);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, `Anchor.protocol`, `IMG.protocol`, URL, `Url` object, `Url.hash`, `Url.host`, `Url.hostname`, Url.href, `Url.pathname`, `Url.port`, `Url.search`, `Url.target`

Url.protocolLong (Property)

A long, human readable description of the protocol.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*`myUrl`*`.protocolLong`

Only the MSIE browser supports this, and it's of such limited use as to make one question its purpose.

See also:	`Anchor.protocolLong`

Url.rel (Property)

The relationship of this element to the document pointed at by the URL.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myUrl.rel`
HTML syntax:	`<LINK REL="...">`	

This is sometimes called a forward link. Although the `HREF="..."` HTML tag attribute is normally the only means used to identify a target document, the browser is permitted to use the `REL="..."` HTML tag attribute to decide whether to use the HREF value or how it should be used.

The following HTML version 4.0 standard link types are permitted in this property:

- alternate
- appendix
- bookmark
- chapter
- contents
- copyright
- glossary
- help
- index
- next
- prev
- section
- start
- stylesheet
- subsection

MSIE adds these as well:

- same
- next
- parent
- previous

When used or tested within a script, any comparisons should be case insensitive.

See also:	`LINK.rel`

Url.rev (Property)

The relationship of the document pointed at by the URL to this element.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.rev`

This is sometimes called a reverse link. It defines the relationship between a document and another that calls it. The linkage is defined from the destination document's viewpoint.

This property supports the same HTML version 4.0 standard link types as the `rel` property. Refer to that topic for details.

When used or tested within a script, any comparisons should be case insensitive.

Because `rel` and `rev` properties are complementary, the values in them are likely to be related. For example, if one contains the value "`next`" then the other is likely to contain "`previous`".

See also:	`LINK.rev`

Url.search (Property)

The query portion of an HREF URL if there is one.

Availability:	JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.search`
	-	*myUrl*`.search = `*aString*
HTML syntax:	`<A HREF="..."><LINK HREF="...">`	
Argument list:	*aString*	A new search string.

This property yields a text string that contains the query value from the URL if there is one and an empty string if not.

This should really be called the query portion of the URL instead of the search attribute.

You can assign a new value to this property. This might be useful if the user needs to specify some search parameters, which can be range checked at the client end. You will need to prefix the new value with a question mark otherwise the assignment won't work.

It is probably named 'search' due to it having been used by search engines, and that being the way people first noticed its widespread use when inspecting their web server's referrer logs.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE"
HREF="http://www.mydomain.com:8080/folder/file.html#abcdef">Click here</A><BR>
<SCRIPT>
// In testing, this did not work in Opera 5.0
document.write(document.links[0].search);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, `Anchor.search`, `request.<urlExtension>`, URL, `Url` object, `Url.hash`, `Url.host`, `Url.hostname`, `Url.href`, `Url.pathname`, `Url.port`, `Url.protocol`, `Url.target`

Url.shape (Property)

The shape of an area in an image map that this URL is associated with.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`myUrl.shape`

This property has a meaningful value when the Url object is instantiated via `<MAP>` and `<AREA>` tag. It defines the shape of the hotspot within the extent rectangle, defined by the `coords` property. It might contain one of the following values:

- default
- rect
- circle
- poly

See also:	`Anchor.shape`, `Area.shape`, `Url.coords`

Url.target (Property)

The target attribute of an <A> tag if there is one.

Availability:	DOM level – 1 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape version – 2.0 Opera browser – 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*.target
	-	*myUrl*.target = *aTarget*
HTML syntax:	<A TARGET="..."><LINK TARGET="...">	
Argument list:	*aTarget*	The name of a new target window or frame

This property yields the value of the TARGET attribute in an <A>, <AREA> or <MAP> tag if there is one and an empty string if not.

You can assign a new value to this property so that the URL will be directed to a different window or frame.

Here are some example target values:

- _parent
- _self
- _top
- _blank
- Window name
- Frame name

Netscape version 6.0 adds the _content target value for use within HTML that exists in the sidebar area. This ensures that the link is targeted at the main window and does not overwrite the sidebar.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<A NAME="EXAMPLE" HREF="http://www.mydomain.com:8080/folder/file.html#abcdef"
TARGET="_top">Click here</A><BR>
<SCRIPT>
document.write(document.links[0].target);
</SCRIPT>
</BODY>
</HTML>
```

See also:	`Anchor.hash`, `Anchor.target`, `BASE.target`, `Location.target`, `Map.target`, URL, `Url` object, `Url.hash`, `Url.host`, `Url.hostname`, `Url.href`, `Url.pathname`, `Url.port`, `Url.protocol`, `Url.search`

Url.text (Property)

The text that appears between the `<A>` and `</A>` tags.

Availability:	JavaScript – 1.2 Netscape version – 4.0	
Property/method value type:	`String primitive on Netscape` `Undefined value on MSIE`	
JavaScript syntax:	N	*myUrl*`.text`

This is equivalent to the `innerText` property that MSIE supports. On Netscape 4 `Url.text` is ReadOnly while the `Url.innerText` property on MSIE 4 allows `read` and `write` access.

Assigning to this property in MSIE simply creates a `text` property but does not affect the text of the anchor.

The value yielded by this property (when it does work) is the text between the `<A>` and `</A>` tags.

Warnings:

- You will need to detect the browser type before attempting to use this property.
- Does not work properly on Netscape on the Macintosh.
- Even if it does work, you may only extract a portion of the text from the anchor.

See also:	`Anchor.text`, `Url` object

Url.type (Property)

The MIME type of the document that the URL points at.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 3.0 Internet Explorer – 4.0 Netscape version – 6.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myUrl*`.type`

The MIME type of the document associated with the Url is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you are likely to see in this property.

See also:	`LINK.type`

Url.urn (Property)

A URN value derived from the URL.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	*myUrl*`.urn`

Refer to:

URN

Url.x (Property)

The X co-ordinate of a link.

Availability:	JavaScript – 1.2 Netscape version – 4.0 Deprecated	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myUrl*`.x`

The horizontal position of the object in the display measured in pixels. You can use the x and y co-ordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- This is withdrawn from Netscape 6.0 and no longer supported.

See also:	`Location.x`

Url.y (Property)

The Y co-ordinate of a link.

Availability:	JavaScript – 1.2 Netscape version – 4.0 Deprecated

Property/method value type:	Number primitive	
JavaScript syntax:	N	*myUrl*.y

The vertical position of the object in the display measured in pixels. You can use the x and y co-ordinates of the object as targets of the `scrollTo()` method for the window it lives in.

Warnings:

- This is withdrawn from Netscape 6.0 and no longer supported.

See also:	Location.y

URN (Definition)

A Uniform Resource Name.

The URN notation is an alternative means of formatting the URI portion of a URL. This is a standard which is in the process of being defined and deployed. Details are available in RFC 2141.

The format is somewhat different to that of a URL placed in an `HREF="..."` HTML tag attribute. It is not at present widely supported in browsers but may be in the future.

See also:	UDI, URI, URL

User-generated object (Definition)

An object created under script control.

JavaScript allows the user (or script developer really) to create their own objects, properties and methods. The prototypes for existing built-in objects can also be extended by the script developer.

This has generally been supported since the earliest versions of the main JavaScript interpreters. It was made available in the WebTV platform effective from the Summer 2000 release. This means that DHTML effects created by authoring tools such as DreamWeaver should work better in WebTV boxes that are shipped after this date or are upgraded in the field.

See also:	JellyScript

userDefined object (Object/DOM)

You can define your own objects in several different ways.

Availability:	DOM level – 1 JavaScript – 1.5 JScript – 5.0 Internet Explorer – 5.0 Netscape version – 6.0	
JavaScript syntax:	-	`myObject = new Function()`
	-	`myObject = new Object()`

Aside from the ways in which you can create custom objects with your own constructor functions, you can also create your own HTML tags to make custom document elements.

Objects are instantiated from HTML tags and assume a class name from the HTML tag names in the document. So you can invent your own tags that become objects in the document model in MSIE, and inherit some basic capabilities from the environment. Netscape version introduces this functionality at version 6.0.

See also:	`Object` object

userProfile object (Object/JScript)

An object that encapsulates a user's profile within the system.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`myUserProfile = navigator.userProfile`
Object methods:	`addReadRequest(), clearRequest(), doReadRequest(), getAttribute()`	

Through this object, a script can access details about the user from the profile that the system maintains.

This is accomplished by the arcane method of queueing requests for access. Then having queued all the requests, you can ask the user for permission with a single dialog.

If the user grants permission, you can then access the userProfile values, after which the request queue can be cleared.

Warnings:

- This is a not fully supported on some versions of MSIE for Macintosh.

See also:	`userProfile.addReadRequest(), userProfile.clearRequest(),userProfile.doReadRequest(), userProfile.getAttribute()`

Method	JavaScript	JScript	N	IE	Opera	Notes
`addReadRequest()`	-	3.0 +	-	4.0 +	-	-
`clearRequest()`	-	3.0 +	-	4.0 +	-	-
`doReadRequest()`	-	3.0 +	-	4.0 +	-	-
`getAttribute()`	-	3.0 +	-	4.0 +	-	?

userProfile.addReadRequest() (Method)

Adds a request to read a property of the user profile. These are queued up to have permission requested from the user.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`navigator.userProfile.addReadRequest (anAttribute)`
Argument list:	*`anAttribute`*	One of the valid vCard attribute names

This method adds a request to the queue. Each request denotes the parameters within the user profile that the script needs to access. You may call this method several times, each time asking for a different user preference. You won't initially be granted access to them until you have executed the `doReadRequest()` method. If the user affirms that you can access these values, then on its return, you can use the `getAttribute()` method to access the value you need. You can only access values you have requested and which the user has affirmed.

Here is a list of all the user preference attributes that you can request:

- vCard.Business.City
- vCard.Business.Country
- vCard.Business.Fax
- vCard.Business.Phone
- vCard.Business.State
- vCard.Business.StreetAddress
- vCard.Business.URL
- vCard.Business.Zipcode
- vCard.Cellular
- vCard.Company
- vCard.Department
- vCard.DisplayName
- vCard.Email
- vCard.FirstName
- vCard.Home.City
- vCard.Home.Country
- vCard.Home.Fax
- vCard.Home.Phone
- vCard.Home.State

- vCard.Home.StreetAddress
- vCard.Home.Zipcode
- vCard.Homepage
- vCard.JobTitle
- vCard.LastName
- vCard.MiddleName
- vCard.Notes
- vCard.Office
- vCard.Pager

See also:	`userProfile` object, `userProfile.clearRequest()`, `userProfile.doReadRequest()`,`userProfile.getAttribute()`, `vCard` object

userProfile.clearRequest() (Method)

Clear all read requests from the queue.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`navigator.userProfile.clearRequest()`

You should use this as soon as you have retrieved the necessary user information. It purges all pending requests. If you don't use this call, then if you made some more requests, next time you call the `doReadRequest()` method the user is asked for permission to access an ever increasing list of preferences.

See also:	`userProfile` object, `userProfile.addReadRequest()`

userProfile.doReadRequest() (Method)

Execute the current queue of read requests, asking the user for permission to access these properties of the profile.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`navigator.userProfile.doReadRequest(aCode)`
	IE	`navigator.userProfile.doReadRequest(aCode, aName)`
	IE	`navigator.userProfile.doReadRequest(aCode, aName, aDomain)`
	IE	`navigator.userProfile.doReadRequest(aCode, aName, aDomain, aPath)`
	IE	`navigator.userProfile.doReadRequest(aCode, aName, aDomain, aPath, anExpire)`

Argument list:		
	aCode	The use code selects an explanatory message
	aDomain	A server domain
	aName	A name denoting who is asking
	anExpire	An expiry date for the permissions
	aPath	A document path

Having queued some requests to read user preferences of course you would only request access to ones you genuinely needed. Then you should call this method. It presents the user with a dialog asking for permission to access the listed preference values. If the user decides to grant access, you will have access to the user preferences, but only to the ones you have requested.

There are a set of optional parameters for this method although the first argument is mandatory. These arguments are:

- A usage code. This is a numeric value but it is translated into an explanatory text in the dialog presented to the user. This argument must be present.
- The name argument is available so that you can say who you are, when you ask for the permission to access the user profile.
- You can specify a server domain, so that the permission granted can be recorded for that domain, to save requests from that domain interrupting the user to ask for the same permission more than once. This lasts for the session or until the expiry date if it is set.
- You can specify a document path within which permission granted will apply. This is much like the way that cookies are allowed to be returned only for documents within a path tree. This lasts for the session or until the expiry date if it is set.
- The last optional argument is an expiry date up to which time the permissions will be cached and can be used again subject to the domain and path criteria being satisfied.

Here is a list of the usage codes for use with the first argument:

Code	Description
0	System administrator request.
1	Research and development.
2	Complete current transaction.
3	Modify the site content.
4	Improve site content.
5	Notify about updates to the site.
6	Contacting for sales leads.
7	Linking to other information already collected.
8	Other unspecified purposes.
9	Disclosure to other parties for reasons of updating the site.
10	Disclosure to other parties for marketing purposes.
11	Disclosure to other parties for marketing purposes with your permission.
12	Disclosure to other parties for any other purposes.

See also:	`userProfile` object, `userProfile.addReadRequest()`

userProfile.getAttribute() (Method)

Get an attribute of the `vCard` object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`navigator.userProfile.getAttribute (attribName)`
Argument list:	*`attribName`*	The name of the required VCard attribute

If the user grants access to the `userProfile` data, this method will return the contents of the named attribute. The same attribute names that were used when the request was queued should be used here. These are all member attributes belonging to the `vCard` object.

You should call this method once for each attribute you need. If you have not been granted access to any attribute you will simply receive a `null` value.

Warnings:

- Some documentary sources suggest that this method is largely dysfunctional on a variety of platforms.

See also:	`userProfile` object, `userProfile.addReadRequest()`, `vCard` object

UTC (Standard)

Universel Temps Cordonne.

See also:	Broken down time, Calendar time, Date and time, Daylight savings time adjustment, Universal coordinated time

Utility objects (Definition)

Netscape Enterprise Server provides server-side utility objects to give assistance when running server-side JavaScript.

Refer to:

Netscape Enterprise Server

Value of an expression (Definition)

The result obtained by evaluating an expression.

See also:	LValue, RValue

Value preserving (Definition)

The act of converting values from one data type to another should preserve the value with no loss of resolution.

See also:	Integer promotion

Value property (Definition)

A property value of an object.

Availability:	ECMAScript edition –2
Property/method value type:	`Depends on value type`

A value property returns a generally constant value. Examples are the NaN and Infinity values returned by core objects.

Warnings:

- Do not create your own object properties with the same name as internal or core value properties. If you do, unpredictable behavior may result. Internal values should be protected against accidental damage in this way and they would be, if the interpreter designers were infallible. Unfortunately, to date, they have proven to everyone's dissatisfaction that infallibility is a lost art.

See also:	`Global` object, Infinity, Internal Property, `NaN`

Cross-references:

ECMA 262 edition 2 – section – 15.1.1

ECMA 262 edition 3 – section – 15.1.1

valueOf() (Method)

Returns the primitive equivalent value of the receiving object.

Availability:	JavaScript – 1.1 JScript – 3.0 Internet Explorer- 4.0 Netscape version – 3.0	
Property/method value type:	`Primitive value`	
JavaScript syntax:	-	*myObject*`.valueOf()`

The primitive value of the receiving object is returned by this method.

This method is supported by virtually all objects due to the fact that it is available as a method of the `Global` object in Netscape. Therefore it is inherited into the scope chain for every script and function (method).

Host implementations will generally override this inherited support and provide specialized output routines that yield a reasonable value.

Most likely the value will be a String primitive but it need not be. It could be any of the built-in core primitive data types as specified in the ECMA-262 standard.

See also:	`Array.valueOf()`, `Boolean.valueOf()`, `Date.valueOf()`, Number, `Number.valueOf()`, `Object.valueOf()`, `String.valueOf()`

var (Declaration)

A variable declarator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer- 3.02 Netscape version – 2.0 Netscape Enterprise Server version – 2.0 Opera browser – 3.0	
JavaScript syntax:	-	`var anIdentifier`
	-	`var anIdentifier = anInitialVaue`
	-	`var anIdentifier = anInitialVaue, anIdentifier = anInitialVaue, ...`
	-	`var anIdentifier, anIdentifier, ...`
Argument list:	*anIdentifier*	The name of a variable.
	anInitialVaue	An initial value for the variable

The `var` keyword prefaces a list of variable declarations. The list is terminated by a semi-colon.

Variables can be initialized in the declaration list that can declare a single variable or several at once.

If the `var` statement occurs inside a function declaration, the variables are defined with a scope that is local to that function body. Otherwise they are defined with global scope and are created as members of the `Global` object. When they are created as global variables, they take on the `DontDelete` property attributes.

Variables are created when an execution scope is entered. A block does not indicate a new execution scope, so variables cannot be created local to a code block unless it is a function body. That means they are not local to an `if(),while()` or `for()` block of compound statements.

When variables are created, they are initialized to contain the value undefined. If an initializer is added to the variable declaration, the value is assigned when the `var` statement is executed, which may be some time after the execution scope has caused the variable to be created.

Warnings:

- If you fail to declare a variable with the `var` keyword, you will end up creating a global variable automatically. If the variable should only have local scope and duration within a function, then you may want to avoid this.
- You should use local variables as often as possible to avoid unwanted side effects.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
var myGlobalVariable = 100;
function myLocalScope()
{
   var myLocalVariable = 200;
}

alert(myGlobalVariable);
alert(myLocalVariable);
</SCRIPT>
</BODY>
</HTML>
```

VAR object (Object/HTML)

An object representing the HTML content delimited by the `<VAR>` tags.

Availability:	JavaScript – 1.5 JScript – 3.0 Internet Explorer- 4.0 Netscape version – 6.0	
Inherits from:	`Element object`	
JavaScript syntax:	IE	*myVAR* = *myDocument*.all.*anElementID*
	IE	*myVAR* = *myDocument*.all.tags("VAR")[*anIndex*]
	IE	*myVAR* = *myDocument*.all[*aName]*
	-	*myVAR* = *myDocument*.getElementById(*anElementID*)
	-	*myVAR* = *myDocument*.getElementsByName(aName)[*anIndex*]
	-	*myVAR* = *myDocument*.getElementsByTagName("VAR")[*anIndex*]

HTML syntax:	<VAR> ... </VAR>	
Argument list:	*anElementID*	The ID value of the element required
	anIndex	A reference to an element in a collection
	aName	An associative array reference
Event handlers:	onClick, onDblClick, onDragStart, onFilterChange, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp, onSelectStart	

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	1.5 +	3.0 +	6.0 +	4.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

See also:	`Element` object

Variable (Definition)

A named storage receptacle for script accessible values.

Availability:	ECMAScript edition – 2

Variables are containers with names that you can manage from your JavaScript code. You can create new ones when you need to, and change the values that are stored in them whenever you want.

Some variables are available only within the function block that is currently executing while others are available all the time. The first kind are called local variables and the second are called global variables.

The availability of a variable is determined by the scope chain rules that are in force at any particular time.

When a primitive value is stored in the variable, a unique copy of that value is associated with the variable. However, when an object is stored in a variable, the variable contains only a reference to the object. The object's reference count is incremented and is only decremented when a reference to it is discarded. To discard the reference to an object that is contained in a variable, it must be deleted explicitly. This will not affect the object but will reduce its reference count by one. When its reference count is zero, the object can be purged from memory. Whether that happens or not depends on the way that garbage collection is managed. It is possible that simply replacing an object reference with some other value may not properly decrease the reference count in some implementations. This can lead to a memory leak.

Example code:

```
// Simple variable declaration.
var myVariable;

// Declare and initialise a variable to a null value.
var emptyVar = null;

// Declare and initialise to a floating point value.
var priceData = 11.50;

// Assign a string value to a variable.
someString = "23 The Irons, Cleethorpes";

// Assign a boolean value to a variable.
aBooleanValue = true;

// Assign an exponential value to a variable.
scientificValue = 1.34e+17;

// Assign a hex value to a variable.
aHexValue = 0xFF34;

// Assign an octal value to a variable.
AnOctalValue = 0177;

// Use an unusual variable identifier name.
$_funnyVarName = "Be careful with var names";

// Declare and initialise several variables on one line.
var aaa = 1, bbb = 2, ccc = 3;

// Store an object reference in a variable.
myObject = new Object();
```

Variable Declaration (Definition)

Variable declarations are stored as properties in an object.

Availability:	ECMAScript edition – 2

To create a variable called `myVariable`, you need to place a declaration like this in the script source text:

```
var myVariable;
```

You can optionally assign an initial value to the variable as it is declared. Like this:

```
var myVariable = "Initial value";
```

The semantics of the ECMAScript standard dictate that variable declarations must follow Function Declarations and Formal Parameter List processing.

The initial value of variables as they are declared is set to undefined. Any attributes of the property in the variable object are defined by the type of code. If a variable already exists and a declaration duplicates the same identifying name, the present value will not be replaced by the undefined value. In particular, a variable declaration cannot replace a previously declared function definition or formal parameter name.

Cross-references:

ECMA 262 edition 2 – section – 10.1.3

ECMA 262 edition 3 – section – 10.1.3

O'Reilly *JavaScript Definitive Guide* – page – 53

Variable instantiation (Definition)

Variables are local to one execution context.

Availability:	ECMAScript edition – 2

Every execution context has its own variable object associated with it. Variables declared in the source text are added as properties to the variable object.

This mechanism is a way of making sure that variables that are local to one execution context, do not affect the values of variables in another.

In the case of global and `eval()` code, any functions that are declared in the script source text are also added as properties of the variable object. JavaScript 1.3 and ECMAScript edition 3 introduces nested functions which means they will be added too.

For function, anonymous, and implementation-supplied code contexts, any passed in arguments (parameters) are also added as properties of the variable object.

Which particular variable object is used, and what attributes its properties take on depends on the type of code.

Cross-references:

ECMA 262 edition 2 – section – 10.1.3

ECMA 262 edition 3 – section – 10.1.3

Variable name (Definition)

The name of a variable that is unique within a block but not necessarily within the scope chain.

See also:	Variable, Identifier

Cross-references:

Wrox *Instant JavaScript* ISBN 1-861001-27-4 – page – 14

Variable statement (Definition)

A variable statement uses the `var` keyword to preface a list of variable declarations.

Availability:	ECMAScript edition – 2

A variable statement uses the `var` keyword to preface a list of variable declarations. The statement is terminated with a semi-colon.

You can declare the variables one at a time or several at once with the same `var` statement.

When the variables are declared, an initial value can be assigned to them at the outset.

Variables can be declared inside a function body. When they are declared there, they become local only to that function. When the function exits, the execution context is popped off the scope chain and the variables are discarded.

Variables can also be declared and assigned within a `for` loop header block.

VBArray object (Object/JScript)

A special JScript object for interacting with Visual Basic or VBScript array data.

Availability:	JScript – 3.0 Internet Explorer- 4.0	
JavaScript syntax:	IE	*myVBArray* = new VBArray()
	IE	*myVBArray* = new VBArray(*aVisBasArray*)
	IE	*myVBArray* = *VBArray*
Argument list:	*aVisBasArray*	An array created inside Visual Basic or VBScript
Object methods:	dimensions(), getItem(), lbound(), toArray(), ubound()	

Because VBScript is only available on the Windows platform, this object has limited use in portable applications.

You might find it useful in an intranet scenario where you have total control over which browsers are deployed to the users. In that case, you know that your pages will be viewed on a compatible platform and can happily use this object with impunity.

Warnings:

- Because the Visual BASIC interpreter is only available on a limited number of platforms, this functionality is likely to be limited only to those pages that need to work on the MSIE browser in a Windows environment. This technique is unlikely to work in any other context.

Example code:

```
<!-- An example taken from Wrox: Professional JavaScript -->

<SCRIPT LANGUAGE="VBScript">
function getArray()
dim arrVB(1)
arrVB(0) = 100
arrVB(1) = 250
getArray = arrVB
End function
</SCRIPT>

<SCRIPT LANGUAGE="JavaScript">
var vbArr = new VBArray(getArray());
alert(vbArr.dimensions());
</SCRIPT>
```

Method	JavaScript	JScript	N	IE	Opera	Notes
`dimensions()`	-	3.0 +	-	4.0 +	-	-
`getItem()`	-	3.0 +	-	4.0 +	-	-
`lbound()`	-	3.0 +	-	4.0 +	-	-
`toArray()`	-	3.0 +	-	4.0 +	-	-
`ubound()`	-	3.0 +	-	4.0 +	-	-

VBArray() (Constructor)

A constructor function for creating new VBArray objects.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`VBArray object`	
JavaScript syntax:	IE	*`new VBArray(aVisBasArray)`*
Argument list:	*`aVisBasArray`*	An array created inside Visual Basic or VBScript

This constructor would be useful if you are interacting with Visual Basic scripts or functions that need to have an array passed to them.

VBArray.dimensions() (Method)

A method for requesting the number of dimensions of the array.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myVBArray`*`.dimensions()`

This tells you the number of axes in the array; you can then determine the maximum size they are expected to occupy with the `lbounds()` and `ubounds()` methods.

VBArray.getItem() (Method)

An accessor method for retrieving items from the array.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	*`myVBArray`*`.getItem(anIndex)`
	IE	*`myVBArray`*`.getItem(`*`anIndex1, anIndex2, ...`*`)`
Argument list:	*`anIndex`*	A reference to an item in the array
	`anIndexN`	As many dimensions as are required to address the required item

This acessor method is used to extract the values from cells within the array. You cannot address the cells directly as you would with a native JavaScript, array although you can convert the VBArray to a native JavaScript array. Be careful though with multi-dimensional arrays.

You can use the `dimensions()` method to find out how many axes there are for addressing a multidimensional array. The `lbounds()` and `ubounds()` methods can be used to determine the extent of those axes.

VBArray.lbound() (Method)

A method that returns the index position of the first element in the VBArray.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myVBArray`*`.lbound(`*`aDimension`*`)`
Argument list:	*`aDimension`*	The dimension for which the lower bounds is required

This is the lower boundary value for the indicated dimension. You will need to measure this for each dimension individually if the array is multi-dimensional.

VBArray.toArray() (Method)

A conversion method for creating a JScript array object from a VBArray object.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Array object`	
JavaScript syntax:	IE	*`myVBArray.toArray()`*

You can convert an entire Visual Basic array to a JScript array. It is possible some data will get lost along the way but simple data formats should survive the translation.

Multi-dimensional arrays consume a great deal more memory than you anticipate. The compounded effect of adding each dimension usually increases storage by at least an order of magnitude each time.

See also:	`Array` object

VBArray.ubound() (Method)

A method that returns the index position of the last element in the VBArray.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*`myVBArray`*`.ubound(`*`aDimension`*`)`
Argument list:	*`aDimension`*	The dimension for which the upper bounds is required

This is the upper boundary value for the indicated dimension. You will need to measure this for each dimension individually if the array is multi-dimensional.

vCard object (Object/JScript)

This is an object accessible only through the user preferences interface in the MSIE browser.

Availability:	JScript – 3.0 Internet Explorer – 4.0

The `vCard` object is the parent object that contains all the user preferences settings.

There are basically three kinds of properties:

- Those that are members of the `vCard.Business` object
- Those that are members of the `vCard.Home` object
- Those that are members of the `vCard` object directly

Here is a list of all the user preference attributes that you can request:

- `vCard.Business.City`
- `vCard.Business.Country`
- `vCard.Business.Fax`
- `vCard.Business.Phone`
- `vCard.Business.State`
- `vCard.Business.StreetAddress`
- `vCard.Business.URL`
- `vCard.Business.Zipcode`
- `vCard.Cellular`
- `vCard.Company`
- `vCard.Department`
- `vCard.DisplayName`
- `vCard.Email`
- `vCard.FirstName`
- `vCard.Home.City`
- `vCard.Home.Country`
- `vCard.Home.Fax`
- `vCard.Home.Phone`
- `vCard.Home.State`
- `vCard.Home.StreetAddress`
- `vCard.Home.Zipcode`
- `vCard.Homepage`
- `vCard.JobTitle`
- `vCard.LastName`
- `vCard.MiddleName`
- `vCard.Notes`
- `vCard.Office`
- `vCard.Pager`

Version History (Background)

Historical details of JavaScript versions.

See also:	JavaScript version, JScript version, History

view-source: URL (Request method)

You can use this for debugging in both Netscape and MSIE.

This is a useful debugging aid in some circumstances. Sometimes it is hard to download a file and this may give you a workaround.

To display a window containing the HTMLized version of a directory in the client machine, try this:

```
view-source:/
```

It works at least on Netscape Navigator version 4.7 on a Macintosh. It likely works on other platforms and versions of Netscape too.

The top level directory is the folder in which Netscape lives.

On a Macintosh at least, you can append a disk volume name, like this:

```
view-source:/MacintoshHD/
```

Beyond that you can build a path to any document in the Macintosh system, including this, which is very interesting.

```
view-source:/MacintoshHD/System%20Folder/System
```

This displays a preferences file:

```
view-source:/MacintoshHD/System%20Folder/Preferences/Fetch%20Shortcuts
```

With this level of read access to your client machine, you might be able to browse various file content that normally you wouldn't have time to do. Point at a file and its data is visible right there on the screen in a browser window.

Warnings:

- Be very careful what you browse and how. This may void your warranty. Your mileage may vary. You may corrupt your system although read-only access is unlikely to cause any harm.

See also:	`file:` URL, `javascript:` URL, URL

Visual filters (Definition)

The MSIE browser in version 4.0 and upwards now supports visual transition effects to use when modifying page content or navigating from page to page.

These filters have been enhanced and added to at version 5.0 and 5.5 of JScript. As of version 5.5 of MSIE, the performance of these filters is also optimized and enhanced.

The following kinds of visual filters are supported:

- Procedural surfaces
- Static filters
- Transitions

See also:	Procedural surfaces, Static filters, `style.filter`

void (Operator/unary)

Force an undefined value to replace an operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 2.0 Internet Explorer – 4.0 Netscape version – 3.0 Opera browser – 3.0
Property/method value type:	`Undefined primitive`
JavaScript syntax:	- `void (anExpression)` - `void anExpression`
Argument list:	*`anExpression`* An expression to be evaluated

The `void` operator is used to allow the operand to be evaluated in the normal way (perhaps it is an expression or function call), but to force an undefined value to be returned in its place.

A very useful place for this is when you create JavaScript: URLs. Making sure the result of the expression is void helps the browser cope with the fact you are calling a script and not fetching a document. Don't use `void` however if you want the result of the JavaScript execution to be used as the content of a window.

This shows how to use void in a click handler:

```
<a HREF="javascript:void(callHandler('testString'));">
```

This shows how to force JavaScript result data into a window:

```
<a HREF="javascript:'<HR>Some text here</HR>'">
```

You can also use the `void` operator to manufacture an undefined value in older browsers that have no keyword already defined. The expression (`void 0`) is just such a value. This is unnecessary now that JScript 5.5 supports an undefined value in compliance with ECMA edition 2.

The associativity is from right to left.

Refer to the operator precedence topic for details of execution order.

This keyword also represents a Java data type and the void keyword allows for the potential extension of JavaScript interfaces to access Java applet parameters and return values.

This technique is also useful if you want to evaluate an expression merely for the benefit of its side effects and without any interest in the value it returns.

Warnings:

- The `void` keyword is not available in Netscape version 2.02, or MSIE version 3.02 or earlier versions of either.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
if(document.myUndefinedProperty == (void 0))
{
   document.write("An undefined property has been referenced");
}
else
{
   document.write("A defined property was used");
}
</SCRIPT>
</BODY>
</HTML>
```

See also: Assignment expression, Associativity, `javascript`: URL, LiveConnect, Operator, Operator Precedence, typeof, Unary expression, Unary operator, `undefined`

ECMA 262 edition 2 – section – 11.4.2

ECMA 262 edition 3 – section – 11.4.2

Wrox *Instant JavaScript* – page – 21

void expression (Definition)

An expression whose value is discarded and is evaluated purely for its side effects.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
function clickMe(aString)
{
   alert(aString);

   return "Some results to be ignored";
}
</SCRIPT>

<A HREF="javascript:clickMe('Test');">Test</A>
</BODY>
</HTML>
```

See also:	Constant expression, Conversion, Side effect

volatile (Reserved word)

Reserved for future language enhancements.

The addition of this operator suggests that volatile identifiers may be supported in a later version of the ECMAScript standard.

See also:	const, Reserved word

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.3

WAP (Standard)

Wireless Application Protocol.

This is a popular standard for use in mobile computing devices. It uses a derivative of the JavaScript standard language called WScript. This is constructed within a framework called WML, which is built around a structure organized like a stack of cards rather than pages, although the linkages between them are similar.

At the time of writing, this standard has become somewhat popular but there is already talk of it only being a transitory system. Future mobile computing devices may use something more sophisticated and therefore WAP may become less popular. Ultimately it will be made obsolete by a new standard.

See also:	Interpret, WML, WScript

watch() (Function/global)

Set a watch-point for a named property of an object.

Availability:	JavaScript - 1.2 Netscape - 4.0	
JavaScript syntax:	N	`myObject.watch(`*`aProperty`*`, `*`aHandler`*`)`
Argument list:	*`aHandler`*	A handler that gets called when the property changes
	`aProperty`	A property to watch

This method is provided to ease the task of debugging JavaScript.

It provides a general purpose way to call an unconnected function when a property value is changed. The function does not need to be called explicitly. The function that gets called has a particular API, which passes the following values:

- Property name
- Old value
- New value

It gets an opportunity to modify the new value or veto the change by returning the old value. Whatever value is returned is stored in the property. You can carry out other JavaScript tasks during this property call, although it is probably best to avoid making changes to other property values with watch-points that call the same handler, because you could set up a recursive loop.

If you invoke the `watch()` method without specifying a receiving object, as if it were a function, you are actually setting watch-points on global object properties. Since this is where global variables live, you can monitor them as easily as object properties.

The new event model supported by Netscape 6.0 and that already available in MSIE 5.0 present a `propertyName` property that belongs to the `Event` object. You can inspect that during an `onPropertyChanged` event and achieve the same `watch()/unwatch()` behavior.

Example code:

```
<HTML>
<HEAD></HEAD>
<BODY>
<SCRIPT>
// Code works with Netscape 4+ only
// Define initial value for property
var XXX = 10;
// Define watch handler function
function watchHandler(aProp, anOldVal, aNewVal)
{
   var myText = "";

   myText += "Property name ...: ";
   myText += aProp;
   myText += "\n";

   myText += "Old value .......: ";
   myText += anOldVal;
   myText += "\n";

   myText += "New value .......: ";
   myText += aNewVal;
   myText += "\n";

   alert(myText);
   return aNewVal;
}
// Register the watch handler
watch("XXX", watchHandler);
</SCRIPT>
Some body text
<SCRIPT>
// Modify the property to trigger the watch handler
XXX = 1000;
</SCRIPT>
</BODY>
</HTML>
```

See also:	Event, Event handler, Event management, Event model, `Event` object, `onPropertyChange`, `unwatch`(), Watchpoint handler

Cross-references:

Wrox *Instant JavaScript* –page - 56

Watchpoint handler (Interface)

The handler that is connected to a watch point has a special pre-defined API specification.

JavaScript syntax:	-	`function anId(aProp, oldVal, newVal) { someCode; return actualVal}`
Argument list:	`actualVal`	The value that will be placed into the property
	`anId`	A name for your handler function
	`aProp`	A formal parameter to pass the property name in
	`newVal`	A format parameter to pass the new value in
	`oldVal`	A formal parameter to pass the old value in

Your handler function is passed to the `watch()` method belonging to the object whose property you want to monitor.

When that property changes, your handler will be called.

You will be passed the following:

- The property name
- The old value
- The new value

Whatever you return from this handler will be stored in the property and will become its new value. This means you can return the old value, forcing the property to be read-only. You might change the new value to something else. Perhaps you would force the value to be all uppercase regardless of how it had been specified. You may even want to display an alert to warn the operator that the property is being changed.

See also:	`watch()`

Wave() (Filter/visual)

A visual filter for creating ripple effects.

Availability:	JScript - 3.0 Internet Explorer - 4.0

Refer to:

filter - `Wave()`

.web (File extension)

A compiled JavaScript and HTML application for Netscape Enterprise Server.

See also:	File extensions, Netscape Enterprise Server

Web browser (Definition)

A web browser can be used on a desktop computer, mobile device or TV set-top box to view web pages.

When JavaScript is built into a web browser, the interpreter is an integral part of the application. However, it is technically possible to separate the JavaScript interpreter and provide it as a service that is available to all applications in the system. This seems to be the way that JScript is going on the Windows platform. Whether the browser-based script environment is truly sharing the Windows Script Host facilities may depend on the browser version being used.

A web browser based interpreter will execute JavaScript that is provided in the following containers:

- An HTML page
- A JavaScript include (.js file)
- A Java archive (.jar file)

To add JavaScript to your HTML pages, you need to add `<SCRIPT>` tags as containers for the script source text.

See also:	.jar, .java, .js, `<SCRIPT>`, Host environment, HTML, HTML file, iCab, `Image` object, `Image()`, `Image.Class`, Internet Explorer, Netscape Navigator, OpenTV, Opera, Platform, WebTV

Cross-references:

Wrox *Instant JavaScript* – page - 5

Wrox *Instant JavaScript* – page - 41

Web scripting (Definition)

Web browsers provide a host environment for client-side computation.

Availability:	ECMAScript edition - 2

Web browsers provide a host environment in which to view a web page downloaded from a remote server or from a local file system. Scripts running in that browser use an object model representation of the browser and the presently viewed document. These are called the Browser Object Model and the Document Object Model respectively. There are objects to represent windows, dialog boxes, alerts, text areas, anchors, frames and all the functionality that the browser provides through its graphical user interface.

The host environment provides a means of connecting events to scripts and those scripts are then triggered when the user interacts with the document or browser. Because the entire complex provides a framework for execution and that execution is event driven, there is no `main()` function as you would have with the C language for example.

JavaScript that executes in the browser is called client-side script code. Similar script code can be executed in the web server as part of the web page request-response loop. That code would generally be executed in a more serial fashion in response to a single event (generate a page). This sort of activity is called server-side scripting.

A complete web-based application can be built with code distributed between the server and client environments.

Cross-references:

ECMA 262 edition 2 – section - 4.1

ECMA 262 edition 3 – section - 4.1

Web server (Definition)

An application that delivers web content on request from a browser.

There are many web server products available. Here are a few:

Server	Notes
Apache	At the time of writing it is currently at version 1.3.12 although minor updates happen all the time. The version 2.0 of Apache is now being seeded for beta testing.
Enterprise Server	A Netscape server product.
Fnord	A free web server that runs on Windows platforms
IIS	Internet Information Server. A Microsoft product
Intrabuilder	A Borland server product.
PWS	Personal Web Server. A Microsoft product
WebSite	A commercial PC-based web server.
WebStar	A Macintosh-based web server.

Cross-references:

Wrox *Instant JavaScript* – page - 5

WebTV (TV Set-top Box)

An analogue interactive TV set-top box.

Set-top boxes fall into several categories. From the point of view of a JavaScript developer, the most important category is the 'Browser in a box' model. This takes a basic Netscape Navigator or MSIE browser, places it inside a modest functionality PC and allows its page content to be overlaid on top of the video that is broadcast off-air. The video can also be placed into a cell within the page to allow the web page to be placed behind the video.

This is generally accomplished by allowing the `<IMG>` tag to take its source from a new URL type. Instead of an HTTP: protocol, the TV: protocol is used to trigger the video overlay hardware in place of a web request.

The WebTV boxes have been available for several years and are an analogue TV-set top box.

The JellyScript interpreter used in the WebTV box underwent an upgrade in late Spring 2000 and was released for public use during the Summer. It is generally referred to as the Summer 2000 release. You should be somewhat careful with releases of interpreters in set-top boxes, as a new release is likely to be presented for each manufacturing run. These will generally contain only minor changes. The set-top boxes are also designed to allow the interpreters to be upgraded remotely when they connect. This can lead to some interesting problems if you connect a UK PAL compatible box to an American NTSC service because the video hardware is reconfigured and is then rendered unusable.

The integration of the web content with the TV service is by means of crossover links that are URL values embedded into the video signal on a very low data rate channel that is part of the closed captioning signal.

The URL is encoded with a checksum and arrives at a rate of about 100 characters per second. Because the transfer is at such a low bit rate the URL values need to be short. When the box detects a cross-over link, it displays a small icon in the top right of the screen and the user can elect to request the associated page. The box then dials an ISP and the page is delivered in the normal way.

This is a quite good and workable enhancement to the TV service and although its deployment is limited mainly to the United States, boxes have been trialled in Europe and elsewhere.

There are a few limitations imposed on the JavaScript supported by the box and the embedded browser does not generally support extensions such as Java, plugins and ActiveX but nevertheless you can still accomplish quite a lot.

Week day (Time calculation)

A value between 0 and 6.

Availability:	ECMAScript edition - 2
Property/method value type:	`Number primitive`

Calculating weekdays is a simple modulo and offset of the day number derived from the time value.

The formula for calculating day number is shown here:

```
t = an instant in time measured in milliseconds relative to 01-January-1970 UTC.

msPerDay = 86400000

Day(t) = floor(t/msPerDay)

WeekDay(t) = (Day(t) + 4) modulo 7
```

The resulting values will be from 0 to 6 with Sunday being represented by 0 and Saturday by 6.

By way of proof, `WeekDay(0)` should yield 4 which represents Thursday, 01-January-1970.

Example code:

```
// Grab the time now in milliseconds
myMilliseconds = new Date().getTime();
document.write("Day number ...: ");
document.write(DayNumber(myMilliseconds));
document.write("<BR>");
document.write("Weekday number ...: ");
document.write(WeekDayNumber(myMilliseconds));
document.write("<BR>");
// Work out day number from milliseconds
function DayNumber(aMillisecondTime)
{
   msPerDay = 86400000
   myDay = Math.floor(aMillisecondTime/msPerDay);

   return myDay;
}
// Work out the week day number based on a thursday start
// This should be equivalent to Date.getDay().
function WeekDayNumber(aMillisecondTime)
{
  return ((DayNumber(aMillisecondTime) + 4) % 7);
}
```

Wheel() (Filter/transition)

Reveals the new image with a rotating wheel effect.

Availability:	JScript - 5.5 Internet Explorer - 5.5

Refer to:

filter - `Wheel()`

while(...) ... (Iterator)

An iterator mechanism – a loop construct.

Availability:	ECMAScript edition - 2 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Netscape Enterprise Server version - 2.0 Opera - 3.0	
JavaScript syntax:	-	`while ( aCondition ) { someCode }`
	-	`aLabel: while ( aCondition ) { someCode }`
Argument list:	*aCondition*	If true, the loop cycles once more
	aLabel	An optional identifier name for the loop
	someCode	The code that gets looped

Although the `while()` statement is an iterator, it is functionally related to the `if()` statement since it will execute the statement block only as long as the condition evaluates to `true`.

The difference between `if()` and `while()` is that `if()` only processes the statement block once whereas `while()` processes the statement block repeatedly until something causes the condition enclosed in parentheses to evaluate to `false`.

A while loop tests the condition before execution of each pass through the loop. If a do loop is supported by the implementations, it would test the condition after each pass through the loop.

A `break` statement can be used to terminate a `while()` iterator prematurely, perhaps within a conditional test that is supplementary to the one in the `while()` heading.

A `continue` statement can be used to initiate the next cycle of the `while()` iterator.

The unlabeled form is more commonly used and was available from earlier releases of the JavaScript and JScript interpreters. Labeling was added later at version 1.2 but is not often used.

If a labeled `continue` is used, the condition is tested again, and the loop will cycle if necessary.

Warnings:

- Make sure that something in the statement block will cause the test condition to change to `false` otherwise you will create an endless loop that can never exit. How this is dealt with depends on what you are doing in the loop and whether the implementation can detect an endless loop situation. It is likely the process containing the JavaScript interpreter will either stall and hang or a runtime error may result. In extreme cases, the hosting application may crash and on some platforms, the entire system may halt. At the very least, you could expect memory and CPU usage to go up while the loop runs. On a multi-user system, you may be able to use an administrator account to kill the offending process.

Example code:

```
// An enumerator built with a while statement
var a = 10;

while(a>0)
{
   document.write("*");
   a--;
}

document.write("<BR>");

// a labelled enumerator
a=0;

while(a<20)
{
   document.write(a);
   a++;
   if(a>10)
   {
      continue;
   }
   document.write("*<BR>");
}
```

Wrox *Instant JavaScript* – page - 23

Wrox *Instant JavaScript* – page - 25

Whitespace (Definition)

Whitespace is used to separate tokens from one another.

Availability:	ECMAScript edition - 2

Whitespace is used to improve the readability of the script and to separate tokens from one another where they could be misinterpreted if they were concatenated together.

Whitespace characters are insignificant to the script execution apart from how they may affect the interpretation of tokens. The placement of whitespace can affect the way an expression is evaluated. For example:

```
a = 10000;
```

Will assign the value 10000 to the variable `a`, whereas:

```
a = 10 000;
```

May assign the value 10 to variable `a` but will likely generate a syntax error unless the interpreter is especially forgiving. Strictly speaking the interpreter should reject this:

```
a = c ++;
```

Is also incorrect since the postfix operator is dissociated from the variable it operates on by the whitespace in between.

Actually, there are remarkably few places that whitespace cannot be introduced.

The following characters are considered to be whitespace in ECMAScript conforming JavaScript interpreters:

Escape Sequence	Unicode Value	Name	Symbol
\t	\u0009	Tab	<TAB>
-	\u000B	Vertical Tab	<VT>
\f	\u000C	Form Feed	<FF>
-	\u0020	Space	<SP>
-	\00A0	No-break space	<NBSP>
-	Other category "Zs"	Other Unicode space characters	<USP>

ECMA edition 3 adds a couple of new whitespace character definitions. One is the non-breaking space and the other refers generally to Unicode spacing characters.

O'Reilly *JavaScript Definitive Guide* – page - 28

window (Property)

The `window` object also known as `window.window`.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*.window
	-	window

See also:	`self,Window.frame,Window.window`

Property attributes:

`ReadOnly`.

Window adornments (Definition)

Another name for the furniture that surrounds a window.

Refer to:

Window furniture

Window events (Definition)

Some events within the event-handling complex relate to windows and their behaviors.

These events are generally triggered by clicking on a window adornment or executing a method call on a window that simulates the effect of clicking on a window border item.

See also:	`onBack`, `onForward`, `onLoad`, `onMove`, `onResize`, `onScroll`, `onUnload`

Window feature list (Definition)

The list of available features that a `window.open()` method can apply.

The feature list defines how the new window that is to be created will appear. For example, you can control the appearance of the various window adornments.

The features are generally presented as a name-value pair, thus:

```
name=value
```

The features are either available for use as simple switches and will control the functionality depending on whether they are present or not. Some also support an optional value while others require a mandatory value. Features requiring a mandatory value are generally numeric in nature.

The switching values may be "`yes`" or "`1`" to enable a feature and "`no`" or "`0`" to disable a feature. Switching features can be used with no associated value. This will generally default to "`yes`".

As you would expect, MSIE and Netscape Navigator support a completely different and incompatible set of features. Even controlling the same attribute of the window may require different feature names to be used (for example `width` in MSIE and `innerWidth/outerWidth` in Netscape Navigator).

The feature names are case insensitive but good style dictates that they are specified as shown in the table.

Here is a summary of the available features of a `window.open()` method:

Feature	Value	NNav	MSIE	Description
`alwaysLowered`	-	4	No	This dictates that a window should always be at the bottom of the stack of windows.
`alwaysRaised`	-	4	No	This dictates that a window should always be at the top of the stack of windows.
`channelMode`	-	No	4	Controls whether the window is presented in channel mode.
`dependent`	Yes/No	4	No	If a window is not dependent, it can survive after its creator has been closed.
`directories`	Yes/No	4	No	Controls the appearance of the Netscape Navigator personal toolbar.
`fullscreen`	-	No	4	On the Windows platform, MSIE will fill the screen with the window.
`height`	Number	2	4	This will set the window to the height value.
`hotkeys`	Yes/No	4	No	Setting this value to "`no`" will disable most keyboard shortcuts apart from the quit option.
`innerHeight`	Number	4	No	This will set the window to the height value measured inside the window border.
`innerWidth`	Number	4	No	This will set the window to the width value measured inside the window border.
`left`	Number	4	4	The left edge of the window will be positioned N pixels from the left edge of the screen.
`location`	Yes/No	2	4	The location bar is visible.
`menubar`	Yes/No	2	No	The menubar is fully populated with menus and menu items.
`outerHeight`	Number	4	No	This will set the window to the height value measured outside the window border.
`outerWidth`	Number	4	No	This will set the window to the width value measured outside the window border.
resizable	Yes/No	2	4	The window displays resize facilities according to the switch value.
`screenX`	Number	4	No	An alternative name for the `left` feature.
`screenY`	Number	4	No	An alternative name for the `top` feature.
`scrollbars`	Yes/No	2	4	Scroll bars are explicitly displayed according to the switch value.
`status`	Yes/No	2	4	The window displays a status bar according to the switch value.
`toolbar`	Yes/No	2	4	The window displays a toolbar according to the switch value.
`top`	Number	4	4	The top edge of the window will positioned N pixels from the top edge of the screen.
width	Number	2	4	This will set the window to the width value.
z-lock	-	4	No	This dictates that a window should always be at the same z-position in the stack of windows.

The following z-order feature switch values require the `UniversalBrowserWrite` privilege to be enabled when they are used in Netscape Navigator:

- `alwaysLowered`
- `alwaysRaised`
- `hotKeys`
- `z-lock`

Warnings:

- You must not include spaces in the feature list. If you do include spaces in the feature list attribute, the script may cause some versions of Netscape Navigator to crash horribly.
- Specifying a new window with a call to `window.open()` that has no arguments results in a window that is completely unadorned in MSIE and one that has a full complement of furniture (`location`, `toolbar`, etc.) in Netscape Navigator. Specifying even a single feature means the browser will assume all others are deactivated.
- For those features that require `UniversalBrowserWrite` privilege in Netscape Navigator, the time at which you request the feature may affect how the window is presented. This may be platform specific and Netscape Navigator may behave differently according to the UI rules and appearance of the hosting platform.
- In Netscape Navigator, on the Macintosh platform, setting the `alwaysLowered` feature will place a window at the bottom of the Z stacking order. That window will be permanently inactive as long as another window is open. It will be styled as a normal window. If the `alwaysRaised` feature is applied, the window will be placed on top and will be permanently active. In addition, the style is changed to that of a floating dialog (a Windoid in Macintosh UI parlance). A floating dialog in the Macintosh has a slimmer window border and a window title bar that is not as thick as a normal window.
- The `fullscreen` mode in the MSIE browser is not supported on the Macintosh platform.
- If you specify dimensions for the window, you must specify both the horizontal and vertical values otherwise Netscape Navigator will ignore the setting. MSIE will happily take only one of the values and provide a default for the other. Netscape Navigator requires both height and width but doesn't care what sort. You can mix `innerHeight` and `outerWidth` or `height` and `innerWidth` for example.
- Note that if the `top` or `left` values are specified on their own, the missing value will default to zero in both MSIE and Netscape Navigator.
- The `scrollbars` feature forces scroll bars to be present or not according its value in both browsers. However, scroll bars appear automatically if needed on MSIE even if the `scrollbars` feature is omitted. On Netscape Navigator, they will only be available if you explicitly ask for them.

See also:	Window furniture, `Window.open()`

Window furniture (Definition)

The various controls and scrollbars on a window border. Sometimes called window adornments or chrome.

The window furniture includes the following items:

- The location bar
- The active menu bar while the window is front-most
- The personal items bar
- Horizontal and vertical scrollbars
- The status bar at the bottom of the window
- The toolbar at the top of the window

These can all be controlled from scripts in Netscape Navigator. A script is always allowed to modify its own window with a call like this:

```
open("", "_top", aFeatureList)
```

It may require privileges to be enabled if it is going to alter another window (depending on the source of each window's documents). They can also be controlled in MSIE but only when a window is created with the `window.open()` method.

See also:	Window feature list, `Window.locationbar`, `Window.menubar`, `Window.personalbar`, `Window.scrollbars`, `Window.statusbar`, `Window.toolbar`

Window object (Object/browser)

An object representing a window or frame. This object exposes methods, properties, and events associated with it to the script.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
JavaScript syntax:	-	*myWindow* = *aFrameName*
	-	*myWindow* = frames[*anIndex*]
	-	*myWindow* = opener
	-	*myWindow* = parent
	-	*myWindow* = self
	-	*myWindow* = top
	-	*myWindow* = window
	-	*myWindow* = window.open()
	IE	*myWindow* = document.parentWindow
	IE	*myWindow* = frame

Argument list:	*anIndex*	An index to a `window` object
	aFrameName	The name of a frame in the window
Object properties:	`clientInformation, clipboardData, closed, crypto, defaultStatus, dialogArguments, dialogHeight, dialogLeft, dialogTop, dialogWidth, document, event, external, frame, frameRate, history, innerHeight, innerWidth, java, length, location, locationbar, Math, menubar, name, navigator, netscape, offScreenBuffering, opener, outerHeight, outerWidth, Packages, pageXOffset, pageYOffset, parent, personalbar, pkcs11, returnValue, screen, screenLeft, screenTop, screenX, screenY, scrollbars, secure, self, sidebar, status, statusbar, sun, toolbar, top, window`	
Object methods:	`alert(), attachEvent(), back(), blur(), clearInterval(), clearTimeout(), close(), confirm(), detachEvent(), disableExternalCapture(), enableExternalCapture(), execScript(), find(), focus(), forward(), home(), moveBy(), moveTo(), navigate(), open(), print(), prompt(), resizeBy(), resizeTo(), scroll(), scrollBy(), scrollTo(), setHotkeys(), setInterval(), setResizable(), setTimeout(), setZOptions(), showHelp(), showModalDialog(), showModelessDialog(), stop()`	
Functions:	`atob(), btoa(), captureEvents(), handleEvent(), releaseEvents(), routeEvent()`	
Event handlers:	`onAfterPrint, onBeforePrint, onBeforeUnload, onBlur, onDragDrop, onError, onFocus, onHelp, onLoad, onMouseMove, onMove, onResize, onScroll, onUnload`	
Collections:	`frames[]`	

The `window` object was introduced when JavaScript was made available at version 1.0. It has been revised several times and is likely to gain new functionality with every release.

This object is added to the scope chain as the global object when scripts are executed in a web browser. This means that the properties and methods are available without needing the `window` prefix.

In a web browser this IS the global object. Adding properties (variables) during script execution adds them to the window object for the window in which the page containing the script is loaded.

The window represents the browser container that the `document` object lives in.

Since the on-screen window persists as long as the window is open, you might think it may be a useful place to store some session state data between documents. Clearly, storing session data in a `document` object is no use if the document is going to be discarded and replaced. However, anything created by a script belonging to a window is going to get zapped when the document goes away, so you cannot store persistent values in the `window` object like that because the global object for a web page is recreated each time a page is loaded.

Storing session state data is best accomplished with a frame-set and some accessor scripts that are called within it.

Event handling support via properties containing function objects was added to `window` objects in version 1.1 of JavaScript.

Warnings:

- Be aware that if you store a reference to a `window` object and the window is closed, if you don't dispose of the reference to the window object then it cannot be garbage collected. A `window` object with no associated window is not much use unless you need to keep the object persistent due to having added some properties to it. If this is the case, then, arguably, the `window` object was the wrong place to put such things.

Window.alert() (Method)

Present an alerting dialog box.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`alert(`*`aString`*`)`
	-	*`myWindow`*`.alert(`*`aString`*`)`
Argument list:	*`aString`*	Some text to display in the alert box

This presents a dialog containing the warning message and an OK button.

Note that the text that is presented in the dialog is unformatted text and you cannot use HTML in the dialog box.

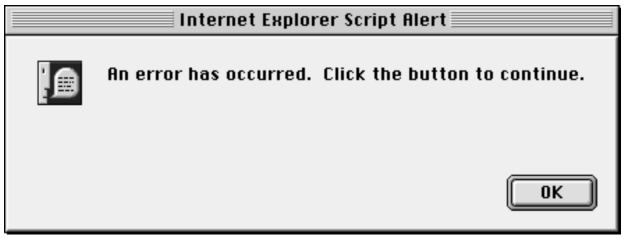
The title bar of the dialog box cannot be changed from its default setting that tells you that the dialog was invoked by JavaScript. In some browsers, it may just display the name of the browser. This is intended to stop script programmers from masquerading their dialog boxes as those of operating system diagnostics and login screens.

The `alert()` dialog box is modal on most platforms. It also blocks the script from continuing except on some versions of Netscape Navigator on Unix platforms. This behavior may become more common as desktop operating systems become more Unix-like and the Netscape Navigator core source code is deployed on newer operating systems. It is possible that this behavior will be exhibited on Mac OS X.

This method is useful for debugging. You can use it much like you would have used a `printf()` in C language debugging. Using `alert()` can sometimes be useful as an observable effect of calling a function or event handler. If you don't see the alert box, it's likely the event didn't call your handler.

You may be able to accomplish some rudimentary formatting but realistically due to font differences on platforms the only meaningful formatting is to place newline characters (`\n`) into the text to introduce a line break and to insert leading spaces for indentation.

This method does not return any meaningful value and if it is used in an assignment, the value `undefined` will be used.



Warnings:

- Be aware that the dialog may be modal but that the script may or may not continue while the `alert()` dialog is displayed. It depends on the platform. On Windows, the script execution pauses until the OK button is clicked. On UNIX, the alert is displayed by a different process or thread and the script execution continues. If you need truly modal behavior you should consider the `confirm()` or `prompt()` dialogs instead.

Wrox *Instant JavaScript* – page - 78

Window.atob() (Function)

Decode some base-64 encoded data.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`atob(`*`aBase64String`*`)`
	N	*`myWindow`*`.atob(`*`aBase64String`*`)`
Argument list:	*`aBase64String`*	A string containing base-64 encoded data

This function provides a means of decoding base-64 encoded values which represent an encoded form of some binary data. This encoding can be applied to text too, but is most useful where you have a block of non-textual content.

The base-64 data is decoded and converted to a block of binary data. This is then stored in a string primitive and returned to the caller as the result of the method.

To extract the binary data from the string, you will need to parse the string a character at a time and extract the numeric character value with the `String.charCodeAt()` method. You can modify the binary data directly by storing numeric values at each character position.

Note that the string will contain a sequence of 8-bit bytes and so you will need to be careful to range-limit any values that you store in the binary string.

The result is a block of binary data in a string primitive. This is somewhat cumbersome and not likely to be much used outside of a mail-reading client.

See also:	`String.charAt()`,`String.charCodeAt()`, `String.fromCharCode()`,`Window.btoa()`

Window.attachEvent() (Method)

A means of attaching events to windows and documents.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	IE	`attachEvent(`*`anEventName`*`, `*`anEventHandler`*`)`
	IE	*`myWindow`*`.attachEvent (`*`anEventName`*`, `*`anEventHandler`*`)`
Argument list:	*`anEventHandler`*	A reference to an event handler function
	`anEventName`	The name of an event to be handled

This is part of the behavior handling in MSIE which involves the use of style sheets and `.htc` files. It is a way of binding a function to an event so that when the event fires, the function is called. It can be applied in a more general way than just with behaviors.

The mechanism is quite straightforward to apply. First, create a style that can be used to attach the script to an HTML element. In that style, refer to a fragment of JavaScript contained in an external file. That external file is called an HTML Component or HTC. It is stored in an `.htc` file. The `.htc` file is invoked in a similar way to the `<SCRIPT SRC="...">` mechanism.

Then, in that `.htc` file, you create a handler script that attaches itself to whatever event you want the handler to be connected to. This `attachEvent()` method is what is used to accomplish that.

When the browser loads the page, the `.htc` file is loaded and installed and the script registers itself with the event trapping mechanisms in the browser. When the event fires, the handler script in the HTML component is executed.

There are many advantages regarding code re-use and efficiency that this technique facilitates. However, the downside is that the HTML components can result in a large number of additional requests for separate items from the web server and this can be detrimental to performance. So detrimental, in fact, that it is possible that the items may not all be loaded by the time the user is ready to interact with the page.

Two events are triggered which can be used to manage this scenario more elegantly. These are the `onContentReady` and `onDocumentReady` events. They are sent to the behavior script as a notification so you can take some action internally to prime your handler. These events would typically cause the behavior handler to set flags internally that can be checked when the handler is invoked by the user. Those flags can then lock out any interaction with the page until it is known that the content of the element and the rest of the document have been loaded. At the very least, the handler should wait until the first receipt of an `onContentReady` event.

Warnings:

- This functionality is unavailable on the Macintosh version of the MSIE browser up to at least version 5.

See also:	`<STYLE>,Document.attachEvent(), Document.detachEvent(),Window.detachEvent()`

Window.back() (Method)

A method that mimics the user clicking on the back button.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`back()`
	N	*`myWindow`*`.back()`

The browser will behave as if the user had clicked on the back button at the top of the window.

Warnings:

- If this is executed in a `<FRAMESET>` contained window, the behavior of the `Window.back()` method may not always be consistent with the `History.back()` method. One may simply affect the frame while the other may affect the entire browser window at the top of the frame-set hierarchy.

See also:	`Frame` object, `History.back()`, `Window` object, `Window.forward()`

Window.blur() (Method)

Send a `blur` event to the window object.

Availability:	DOM level - 1 JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`blur()`
	-	`myWindow.blur()`

This will take the input focus away from the receiving window, usually the one at the top of the window hierarchy. On some platforms, this will also make the window inactive and may put it to the back of the window hierarchy.

There are good arguments for using the `focus()` method on another window rather than the `blur()` method. Removing focus from a window should make it safe from inadvertent mouse clicks at the expense of making the window inactive altogether, which could be frustrating for the user.

Warnings:

- This method is not supported by MSIE version 3.
- It is possible that a window may become inactive with this method and since no window has focus you could have an active application with no active window. This is a fairly sloppy way of providing a UI interaction. A better technique is to use the `focus()` method to redirect the focus to the desired window which, by implication, `blurs()` any other that may previously have had the focus. This should result in a more consistent behavior for the user.

See also:	`Frame` object, `Input.blur()`, `Input.focus()`, `Window` object, `Window.focus()`, `Window.onblur`, `Window.onfocus`

Window.btoa() (Function)

Encode some data into base-64 form.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	N	`btoa(`*`aBinaryString`*`)`
	N	*`myWindow`*`.btoa(`*`aBinaryString`*`)`
Argument list:	*`aBinaryString`*	A string of binary data to be encoded

This function will encode the string passed as an argument and return a base-64 encoded version. Base-64 encoding is used to convert binary data into a form that survives transmission across a network, so the data passed in its input argument is really binary data. It is carried in a string value because JavaScript doesn't support a special binary container. However, JavaScript strings will happily accept 8 bit values and you can therefore store binary data in them. You would normally create the string of binary data by means of the `String.fromCharCode()` static method.

The result is a string of binary data escaped in such a way that it will survive a serial transfer through an "old-fashioned" connection. Network drivers and serial interfacing technology make this technique largely redundant and there can be few genuine applications for this other than to decode information from legacy systems or to interface to them somehow from a web browser. The functionality has very limited portability and will likely be deprecated at some stage in the future.

See also:	`String.fromCharCode()`, `Window.atob()`

Window.captureEvents() (Function)

Part of the Netscape Navigator event propagation complex.

Availability:	JavaScript - 1.2 Netscape - 4.0
Deprecated:	JavaScript - 1.5 Netscape - 6.0

Property/method value type:	undefined	
JavaScript syntax:	N	captureEvents(*anEventMask*)
	N	*myWindow*.captureEvents(*anEventMask*)
Argument list:	*anEventMask*	A mask constructed with the manifest event constants

This is part of the event management suite which allow events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method allows you to specify what events are to be routed to the receiving window object.

The events are specified by using the bitwise OR operator to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

A limitation of this technique is that, ultimately, only 32 different kinds of events can be combined in this way and this may limit the number of events the browser can support. If you need to build complex event handling systems in Netscape Navigator 4.x, you will have implement scripts using this technique. A different script will be required for MSIE.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers and can call common handling routines that can be shared between MSIE and Netscape.

This method is supported by virtually every object by virtue of the fact that it is available as a method of the `Global` object in Netscape Navigator. Therefore it gets inherited into the scope chain for every script and function (method).

Warnings:

- Since a bit mask is being used, this must be an `int32` value. This suggests that there can only be 32 different event types supported by this event propagation model.
- This capability is deprecated and is not supported in Netscape 6.0 . It has never been supported by MSIE which implements a completely different event model. As it turns out, the DOM level 2 event model converges on the MSIE technique.

Example code:

```
// Build and setup a mask for several events
myEventMask = Event.KEYDOWN | Event.MOUSEDOWN | Event.RESET;
window.captureEvents(myEventMask);
function EventHandler(anEventObject){//... some event handling code here}
window.onkeydown   = EventHandler;
window.onmousedown = EventHandler;
window.onreset     = EventHandler;
```

See also:	`captureEvents()`, `Document.captureEvents()`, `Element.onevent`, Event propagation, Event type constants, `Frame` object, `Layer.captureEvents()`, `onMouseMove`, `Window` object, `Window.releaseEvents()`

Window.clearInterval() (Method)

Cancel a previous `setInterval()` timer that caused a function to be called periodically.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`clearInterval(`*`anIntervalID`*`)`
	-	*`myWindow`*`.clearInterval(`*`anIntervalID`*`)`
Argument list:	*`anIntervalID`*	The ID of an interval returned by the `setInterval()` method

The interval timer mechanism can be used to repeat the execution of a block of script code at regular intervals. You can establish several blocks of repeating code at once if necessary, so there could be a number of pending interval timers. You must be able to identify the one that you want to clear.

When you create an interval timer with the `setInterval()` method, it will return back to you with a value that corresponds uniquely to that interval's set-up context. You can use that value later to clear the interval timer.

You must be careful not to clear an interval more than once.

Warnings:

- Be careful when clearing interval timers. If you try to clear one that does not exist, it can sometimes crash the browser.

See also:	`Frame` object, Interval handlers, Timeout handlers, Timer events, `Window` object, `Window.clearTimeout()`, `Window.setInterval()`, `Window.setTimeout()`

Window.clearTimeout() (Method)

Clear a previously established timeout function call.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0

Property/method value type:	undefined	
JavaScript syntax:	-	clearTimeout(aTimeoutID)
	-	*myWindow*.clearTimeout(*aTimeoutID*)
Argument list:	*aTimeoutID*	The ID of a timeout returned by the setTimeout() method

The timeout mechanism can be used to defer the execution of a block of script code. You can defer several blocks at once if necessary, so there could be a number of pending timeout triggers. You must be able to identify the one that you want to clear.

When you create a timeout trigger with the setTimeout() method, it will return back to you with a value that corresponds uniquely to that trigger's set-up context. You can use that value later to clear the timeout trigger.

You must be careful not to clear timeout triggers more than once.

Warnings:

- Be careful when clearing interval timers. If you try to clear one that does not exist, it can sometimes crash the browser.
- It is highly likely that the interval may have elapsed and the timeout no longer exists to be cleared. A more reliable technique that is less prone to browser crashes is to set a flag value in a global variable and then test that from within the timeout invoked function.

See also:	clearTimeout(), Frame object, Timeout handlers, Timer events, Window object, Window.clearInterval(), Window.setTimeout()

Window.clientInformation (Property)

This is another more appropriate name for the navigator object.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	Navigator object	
JavaScript syntax:	IE	clientInformation
	IE	*myWindow*.clientInformation

This is an alternative name for the window.navigator property.

Warnings:

- Note that the clientInformation reference is another name for the navigator object. We could be uncharitable and suggest that this is an attempt by Microsoft to avoid publicising a competitor's browser name in any scripts that they publish. It is likely that scripts written by and for Microsoft products would use this syntax rather than the navigator property, and will break on Netscape Navigator.

See also:	`Frame` object, `Window` object, `Window.navigator`

Property attributes:

`ReadOnly`, `DontEnum`.

Window.clipboardData (Property)

An object containing data that represents the contents of the clipboard.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`clipboardData object`	
JavaScript syntax:	IE	`clipboardData`
	IE	*`myWindow`*`.clipboardData`

If you want to move data in and out of the clipboard on a Windows platform from within the MSIE browser, this property will yield a reference to a `clipboardData` object that encapsulates the clipboard contents.

Example code:

```
// Example of how to use the clipboard object supplied by
// Martin Honnen.
clipboardData.setData('Text', 'All for Kibology');
alert(clipboardData.getData('Text'));
clipboardData.clearData();
alert(clipboardData.getData('Text'));
```

See also:	`clipboardData` object

Window.close() (Method)

This will close the window.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`close()`
	-	*`myWindow`*`.close()`

The method `window.close()` will attempt to close the window in which the script is executing. This is only possible without a user confirmation dialog if the script has the `UniversalBrowserWrite` privilege. The statement `self.close()` is effectively `window.close()` and will also attempt to close the window in which the script is executing.

A JavaScript running inside a window may close that window.

JavaScripts running outside a window may or may not be able to close that window. This may be implementation dependent and may also depend on the value of the `opener` property of the target window and the current security policy in force. Attempts to close windows that your JavaScript did not open will elicit a user dialog to get permission to close the window. This is so that people cannot write invasive scripts that wreak havoc on your browser session when they are loaded.

The default behavior is to allow JavaScript to close windows which were opened by scripts that were originally served from the same server and which were not opened by the user. This may be overridden if additional privileges are granted to scripts.

From version 1.1 of JavaScript, (generally speaking) you can only close windows that were opened by JavaScript from within a script. Although, certain browser privileges will allow you to close other windows and this behavior may be browser dependent.

Warnings:

- Do not confuse this method with the `document.close()` method. They are not the same.
- Do not call this for `Window` objects that represent frames, you cannot close a single frame within a window.

See also:	`Frame` object, `Frame.close()`, `UniversalBrowserAccess`, `UniversalBrowserWrite`, `Window` object, `Window.open()`, `Window.opener`

Window.closed (Property)

A property value that is `true` if the window is closed.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`closed`
	-	`myWindow.closed`

From JavaScript version 1.1 onwards, a `window` object may persist after it has been closed. This may seem odd but it is possible that the `window` object will have had other object references added to it and for it to be deleted, it must relinquish those references. Without this object persistence, a dangerous cascading delete effect may happen, inadvertently discarding all manner of objects within your script context.

The only valid thing you should access at this point is the `closed` property. This allows you to check for the window having been closed by the user before you try to do something with it.

Some programmers would argue that this is poor technique anyway and that a reference to a window held externally should be nulled by the closing function. That way you can test a variable that exists within the script's scope chain rather than an object that should probably have been purged from memory. Given the bugs in the implementation of this feature, that is a better way to determine whether a window is still in existence.

Warnings:

- This value can be read by an unsigned script in another window. However, Netscape Navigator (at least on the Macintosh platform) exhibits some bugs with this whole mechanism and the property value is of limited use in any case.
- For a start, you cannot access the `closed` property of the object that the `Window.open()` method returns because it is an `EventCapturer` object and not a `window` object. You can contrive to store a reference to the new window in the original window's properties by making it pass a reference to its `window.self` property which needs to be stored in a property belonging to its `window.opener`. However, if the child window is then closed, the object that refers to it becomes void and there is no access to any of its properties, let alone its `window.closed` property.
- There are sufficient problems in this area that without some quite tricky scripting you cannot make use of this facility in a portable manner.

See also:	`Frame` object, `Window` object

Property attributes:

`ReadOnly`.

Window.confirm() (Method)

Present a confirmation dialog box.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0
Property/method value type:	`Boolean primitive`

JavaScript syntax:	-	`myResult = confirm(aString)`
	-	`myResult = myWindow.confirm(aString)`
Argument list:	`aString`	Some text to explain what is to be confirmed

This presents a modal dialog containing the confirmation message and two buttons, OK and Cancel. This is useful because you often need confirmation from a user.

This method is useful for debugging. An example showing how it can be used for debugging a recursive function is given below.

Note that the text that is presented in the dialog is plain unformatted text and you cannot use HTML text in the dialog box.

The title bar of the dialog box cannot be changed from its default setting which tells you that the dialog was invoked by JavaScript. In some browsers, it may just display the name of the browser. This is intended to stop script programmers from masquerading their dialog boxes as those of operating system diagnostics and login screens.

The `confirm()` dialog box is modal and blocking. The script must wait for a response from the user.

When the user clicks on either of the buttons, the result returned by the method indicates which one was chosen. The `true` value indicates the OK button was clicked and `false` indicates the Cancel button.

Example code:

```
// Example showing the use of a confirm() dialog to
// debug recursive calls provided by Martin Honnen.
function showTime()
{
   if (confirm('Time is: ' + new Date() + '. Show again?'))
   {
      setTimeout('showTime()', 1000 * 5);
   }
}
showTime();
```

Cross-references:

Wrox *Instant JavaScript* – page - 78

Window.crypto (Property)

A reference to a `Crypto` object for security encoding.

Availability:	JavaScript - 1.2 Netscape - 4.04	
Property/method value type:	`Crypto object`	
JavaScript syntax:	N	`crypto`
	N	*`myWindow`*`.crypto`

The object referred to by this property is used with the browser security model. Refer to the topic that discusses the `Crypto` object for more details.

See also:	`Crypto` object

Property attributes:

`ReadOnly`.

Window.defaultStatus (Property)

A property containing the text displayed in the status bar.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	`defaultStatus`
	-	`defaultStatus = `*`aString`*
	-	*`myWindow`*`.defaultStatus`
	-	*`myWindow`*`.defaultStatus = `*`aString`*
Argument list:	*`aString`*	A new value for the default status

As the mouse rolls over active elements in the page, they may write values into the status bar. This is the value that is restored when the mouse rolls out of the object.

Although this is called the `defaultStatus` value, you can change its setting by writing a new value into the property.

A useful technique is to reset this value to an empty string using a `<BODY>` or `<FRAMESET>` `onUnload` handler.

As an example of a way to use this property, it may be useful to give the user some helpful message when loading a <FORM> into the window.

You can read or write the value in this property.

Because this also works with frames, you can set the value for this to be different according to the frame that the mouse is over. That way, the message can give the user some context sensitive hints on a frame by frame basis. You need to be careful about this because if you define the defaultStatus value in a top level window that contains frames, when the mouse is in the frames, the defaultStatus value will be that which is defined for the frame and not the window. The window's default status will only be displayed when the mouse is over the border in between the frames, hence you must define the defaultStatus value for all frames as well as the window.

If you only need to display a temporary message, then use the status property instead of the defaultStatus property.

Warnings:

- The default status value may not be properly restored on some platforms. Macintosh and X-Windows versions of Netscape 3 may exhibit this problem as may other browser and platform combinations.

See also:	Frame object, onMouseOut, onMouseOver, Status line, Window object, Window.status

Window.detachEvent() (Method)

A means of detaching events from windows and documents that were previously attached with the attachEvent() method.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
JavaScript syntax:	IE	detachEvent(*anEventName*)
	IE	*myWindow*.detachEvent(*anEventName*)
Argument list:	*anEventName*	The name of an event to be handled

This is part of the behavior handling in MSIE which involves the use of style sheets and .htc files.

See also:	<STYLE>, Document.attachEvent(), Document.detachEvent(), Window.attachEvent()

Window.dialogArguments (Property)

The arguments passed to a model dialog in a `showModalDialog()` call.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogArguments`
	IE	*`myWindow`*`.dialogArguments`

This is only available when the window is contained within a modal dialog. It is the value contained in the second argument of the `showModalDialog()` method. You can use this to pass values into the modal dialog and the `returnValue` property of the window object inside the modal dialog to return a value to the caller.

Refer to the `Window.showModalDialog()` topic for an example of how this works.

See also:	`Window.showModalDialog()`

Property attributes:

`ReadOnly`.

Window.dialogHeight (Property)

The height of a modal or modeless dialog window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogHeight`
	IE	*`myWindow`*`.dialogHeight`

Dialog windows are a special kind of window supported by MSIE, principally to provide a more sophisticated alternative to an `alert()`, `confirm()` or `prompt()` dialog.

This property yields the height of such a dialog window which can be changed by assigning a value to this property from a script running in the window.

The value returned will be a value and a measurement unit in the same style as would be used with a CSS positioning style property. This means it will be a string and not a numeric value and will need to be parsed carefully.

Window.dialogLeft (Property)

The left edge of a modal or modeless dialog window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogLeft`
	IE	*`myWindow`*`.dialogLeft`

Dialog windows are a special kind of window supported by MSIE, principally to provide a more sophisticated alternative to an `alert()`, `confirm()` or `prompt()` dialog.

This property yields the position of the left edge of such a dialog window which can be changed by assigning a value to this property from a script running in the window.

The value returned will be a value and a measurement unit in the same style as would be used with a CSS positioning style property. This means it will be a string and not a numeric value and will need to be parsed carefully.

Window.dialogTop (Property)

The top edge of a modal or modeless dialog window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogTop`
	IE	*`myWindow`*`.dialogTop`

Dialog windows are a special kind of window supported by MSIE, principally to provide a more sophisticated alternative to an `alert()`, `confirm()` or `prompt()` dialog.

This property yields the position of the top edge of such a dialog window which can be changed by assigning a value to this property from a script running in the window.

The value returned will be a value and a measurement unit in the same style as would be used with a CSS positioning style property. This means it will be a string and not a numeric value and will need to be parsed carefully.

Window.dialogWidth (Property)

The width of a modal or modeless dialog window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`dialogWidth`
	IE	*`myWindow`*`.dialogWidth`

Dialog windows are a special kind of window supported by MSIE, principally to provide a more sophisticated alternative to an `alert()`, `confirm()` or `prompt()` dialog.

This property yields the width of such a dialog window which can be changed by assigning a value to this property from a script running in the window.

The value returned will be a value and a measurement unit in the same style as would be used with a CSS positioning style property. This means it will be a string and not a numeric value and will need to be parsed carefully.

Window.disableExternalCapture() (Method)

Part of the Netscape Navigator 4 event propagation complex.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`disableExternalCapture()`
	N	*`myWindow`*`.disableExternalCapture()`

This method allows you to inhibit the receipt of events from other window objects that might have been loaded from a server other than the one that provided the script it is called from. You need higher than normal privilege to execute this method. However this method itself is quite harmless, the one that really requires the security interlocking is the `window.enableExternalCapture()` method.

Warnings:

- Although this method can be called without any special privilege being necessary, your script will need to be granted the `UniversalBrowserWrite` privilege to enable the external capture again.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.enableExternalCapture()`

Window.document (Property)

A reference to the document object that is contained in the window.

Availability:	DOM level - 1 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Document object`	
JavaScript syntax:	-	`document`
	-	*`myWindow`*`.document`

This property returns a reference to an object that represents the document that is currently loaded into the window.

Warnings:

- Beware of recursion effects by referring to the document belonging to the window and then referring back unintentionally via a property enumeration. The `document.parentWindow` property in MSIE will come straight back to the source window.
- Beware that this refers to an object that belongs to the window and not the object that the window belongs to.

See also:	`Document` object, `Document.parentWindow`, `Element.document`, `Frame` object, `Window` object

Property attributes:

`ReadOnly`.

Cross-references:

Wrox *Instant JavaScript* – page - 80

Window.enableExternalCapture() (Method)

Part of the Netscape Navigator 4 event propagation complex.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`enableExternalCapture()`
	-	*`myWindow`*`.enableExternalCapture()`

This method allows you to begin capturing events from other window objects that might have been loaded from a server other than the one that provided the script it is called from. This is not usually permitted because you could build a script that watches for users typing a password, for example. You need higher than normal privileges to execute this method.

Warnings:

- This method requires your script to be granted the `UniversalBrowserWrite` privilege to operate properly in Netscape Navigator.

See also:	`disableExternalCapture()`, `Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.disableExternalCapture()`

Window.event (Property)

During event handling, MSIE stores a reference to an event object in this variable.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`Event object`	
JavaScript syntax:	IE	`event`
	IE	*`myWindow`*`.event`

In MSIE, this property yields a reference to an event object. This only has any meaning during an event handler call and it is shared by all events which you would assume will cause some problems when multiple events are triggered. However, it seems to sort itself out most of the time. You will most likely refer to the event property as a member of the `Global` object, omitting the `window` prefix. The handler can acquire the object if it needs it to find out more about the context of the event.

In Netscape Navigator prior to version 6.0, the event object is passed as an argument to the event handler function. Netscape 6.0 implements the DOM level 2 event model which works like the MSIE technique.

This means your event handlers must be written slightly differently if they need to access an event object that pertains to the event itself.

To get a roughly portable handler together, the MSIE event can be stored in a local variable. Then, as it turns out, it is easier to convert the old style Netscape Navigator properties to MSIE compatible properties. You may not need to convert all of them and you may need to do some experimentation to see that the bit-masking of modifier keys is correctly set up for your target browser.

The `Closure()` object technique applies here when assigning function objects to be event handlers although that is not supported by MSIE version 4.

This entire event managing complex is under review and some work on standardization happens at DOM level 2 with more to come in DOM level 3. We may have to experience several more browser revisions before we can rely on a truly portable approach and that won't solve legacy browser issues until everyone has upgraded.

Warnings:

- The MSIE event-handling model is radically different to the Netscape Navigator event-handling model. Unless you are doing only very simple event handling you will likely need to code for both models and somehow make them both available in the same page.

Property attributes:

`ReadOnly`.

Window.execScript() (Method)

Execute a script on behalf of a window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	`execScript(`*`aSourceText`*`)`
	IE	`execScript(`*`aSourceText`*`, `*`aLanguage`*`)`
	IE	`myWindow.execScript(`*`aSourceText`*`)`
	IE	`myWindow.execScript(`*`aSourceText`*`, `*`aLanguage`*`)`
Argument list:	*`aSourceText`*	Some legal script source text
	`aLanguage`	The language to execute the script source in

This is somewhat like an `eval()` call except that the script runs in the context and scope chain of the target window and not the window whose script makes the call.

Because this is currently only supported in MSIE, you may not find it very useful.

See also:	`Frame` object, `Window` object

Window.external (Property)

Reference to an external object outside of the interpreter.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`External object`	
JavaScript syntax:	IE	`external`
	IE	*`myWindow`*`.external`

The MSIE browser supports a means of access to the surrounding object space that contains the browser and the desktop environment in which it executes. This of course is only available on the Windows platform and its use is discouraged for reasons of portability.

See also:	external

Window.find() (Method)

This duplicates the behavior of the FIND button on the Netscape Navigator button bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Deprecated:	Netscape - 6.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	`find()`
	-	`find(`*`aSearchKey`*`)`
	-	`find(`*`aSearchKey`*`, `*`aCaseSense`*`)`
	-	`find(`*`aSearchKey`*`, `*`aCaseSense`*`, `*`aDirection`*`)`
	-	*`myWindow`*`.find()`
	-	*`myWindow`*`.find(`*`aSearchKey`*`)`
	-	*`myWindow`*`.find(`*`aSearchKey`*`, `*`aCaseSense`*`)`
	-	*`myWindow`*`.find(`*`aSearchKey`*`, `*`aCaseSense`*`, `*`aDirection`*`)`
Argument list:	*`aCaseSense`*	A switch for case sensitivity
	`aDirection`	A direction to search
	`aSearchKey`	The text to search for

All of the arguments are optional. However, you must specify the first argument if want to specify the second and so on.

If no arguments are specified, a dialog box is presented to the user for them to specify the search attributes.

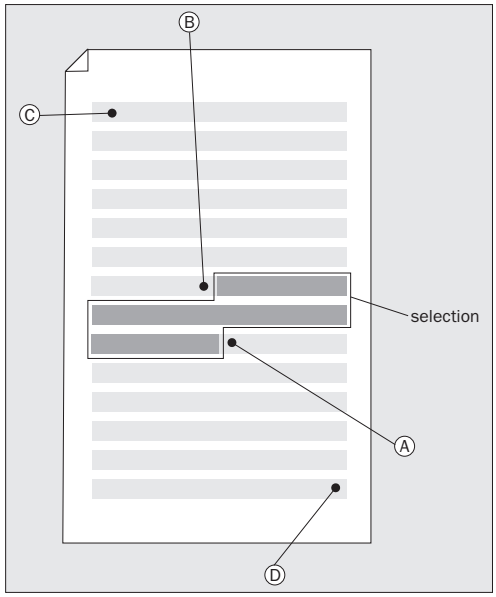
The search key is a arbitrary string of characters. The search facility will look for this string in the current page.

The case sensitive switch parameter must be `true` to force a case sensitive search and `false` to ignore case. By default a case insensitive search is carried out if this argument is omitted.

The direction switch is a `true` for a backwards search and `false` for a forwards search. The default is a forwards search if this argument is omitted.

Forward searches commence at the current cursor position or immediately after the current selection if there is one, see position A on figure overleaf. If there is no selection or the cursor has not been focussed into the page and positioned there, then the search begins at the top of the document, see position C on figure overleaf. In the case of a backwards direction, the search starts immediately in front of the selection if there is one , see position B on figure overleaf, or the end of the document if not, see position D on figure overleaf.

The result is `true` if the text was found in the page and `false` if it was absent.



See also:	`Frame` object, `Window` object, `Window.home()`, `Window.print()`, `Window.stop()`

Window.focus() (Method)

Send a `focus` event to the window object.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`focus()`
	-	*`myWindow`*`.focus()`

This restores focus to the receiving window or frame that the method is executed on. If the focus goes to a frame, then by implication, the window it belongs to becomes active too.

On some platforms this will bring the receiving window to the foreground if it is not already the active window. It is generally better technique to use the `focus()` method on another window rather than call the `blur()` method if you want to remove focus from a window. However, that may not always be possible if you want to completely remove focus from all windows. The consequence may be that the window becomes inactive and on some platforms it means the window will be placed at the rear of any other windows on the screen.

Warnings:

- This method is not supported by MSIE version 3.

See also:	`Frame` object, `Input.blur()`, Input.focus(), `Window` object, `Window.blur()`, `Window.onblur`, `Window.onfocus`

Window.forward() (Method)

Mimics the effect of the user clicking on the FORWARD button.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`forward()`
	N	*`myWindow`*`.forward()`

The browser will behave as if the user had clicked on the FORWARD navigation button.

Warnings:

- If this is executed in a `<FRAMESET>` contained window, the behavior of the `window.forward()` method may not always be consistent with the `history.forward()` method. One may simply affect the frame while the other may affect the entire browser window at the top of the frame-set hierarchy.

See also:	`Frame` object, `History.forward()`, `Window` object, `Window.back()`

Window.frame (Property)

This is another name for `self` and `window`.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`Window object`	
JavaScript syntax:	IE	`frame`
	IE	`myWindow.frame`

This property yields an object that represents the frame that contains this `window` object. This is the same value that the `window` property yields. It is another gratuitous extension that MSIE provides so that scripts to run inside frames can look more consistent with what they are doing and yet break on any non-MSIE browsers due to the frame property not being present.

`Frame` objects support all the methods and properties of `window` objects although they may not always be meaningful in the context of a frame living in a frame-set.

Of course, you can emulate this in other browsers by assigning the value of the `window.window` property to the `window.frame` property anyway.

This appears to be undocumented and does not appear in the Microsoft reference information. Nevertheless, the property is visible by enumeration of the `window` object and appears to work.

Warnings:

- Using this property renders your scripts non-portable unless you code around the missing property on non-MSIE browsers.

See also:	`Document.parentWindow`, `self`, `Window` object, `Window.self`, `Window.top`, `Window.window`

Property attributes:

`ReadOnly`.

Window.frameRate (Property)

An indication of the frame rate for the current display.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	`frameRate`
	N	*`myWindow`*`.frameRate`

This property was discovered accidentally by enumerating the properties of a window object in the Netscape Navigator browser.

The name of this property suggests that it should yield the rate at which the display is refreshed. This should be a constant value and you would expect this to be somewhere between 50 and 85.

Property attributes:

`ReadOnly`.

Window.frames[] (Collection)

An array containing `window` objects, each one referring to the content of a frame within the window.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0

Property/method value type:	Frames object	
JavaScript syntax:	-	frames
	-	*myWindow*.frames
HTML syntax:	<FRAME><IFRAME>	

The frames property yields an array containing objects, each one of which refers to a separate frame. You can count how many there are with the window.frames.length property. In MSIE, this also includes any inline floating frames created with an <IFRAME> tag.

You can cross-reference between frames in a window by means of the frames property. Every window refers to a frames array, which contains a list of frames within that window. Each frame contains a different window. This can get confusing, but it simply means that frames correspond to windows at the basic object level.

You can also use the opener, parent and top properties as well when you are cross-referencing between windows and frames.

Frames arrays may be nested where windows contain frames within frames. The frames array is like all others, its first element is at index 0. This means that something as confusing as this is legal:

```
frames[0].frames[2].frames[1]
```

As a window reference, that looks in the current window for the first frame, then into the third frame within that and then the second frame within that.

You can use the parent window reference to access windows that are all at the same hierarchical level as the current one. This would be accomplished like this:

```
parent.frames[ ... ]
```

Warnings:

- Be careful not to confuse this with the document.frames property supported by MSIE. That is intended just to list the inline frames within a document.
- In Netscape Navigator the window.frames property points back at the window object and the frame objects and frames.length property are stored there as global variables. This is arguably a bug although not all commentators agree. The MSIE implementation is much neater however in that environment, all elements having an ID HTML tag attribute are reflected as member properties of the window. This is not correct either since they should be members of the document and not the window.
- Strangely enough, it all seems to work from the scripting point of view. You can access the length value to count the frames and the individual frame objects are available associatively by name from the window.frames property.

See also:	<MAP TARGET="...">, Document object, Document.frames[], Frame object, Frames object, Window object, Window.opener, Window.parent, Window.top

Property attributes:

ReadOnly.

Cross-references:

Wrox *Instant JavaScript* – page - 80

Window.handleEvent() (Function)

Pass an event to the appropriate handler for the window.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	undefined	
JavaScript syntax:	N	handleEvent(*anEvent*)
	N	*myWindow*.handleEvent(*anEvent*)
Argument list:	*anEvent*	An event to be handled by this object

This applies to Netscape Navigator prior to version 6.0. From that release onwards, event management follows the guidelines in the DOM level 2 event specification.

On receipt of a call to this method, the receiving object will look at its available set of event handler functions and pass the event to an appropriately mapped handler function. It is essentially an event dispatcher that is granular down to the object level.

The argument value is an event object that contains information about the event.

See also:	Event object, Event propagation, Frame object, handleEvent(), SubmitButton.handleEvent(), TEXTAREA.handleEvent(), TextCell.handleEvent(), Window object, Window.routeEvent()

Window.history (Property)

This property returns a `history` object for this window.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`History object`	
JavaScript syntax:	-	`history`
	-	`myWindow.history`

This property yields a reference to a `history` object for the session in this window. The `history` object is somewhat like an array of history items. Netscape Navigator supports a slightly more sophisticated `history` object than MSIE.

On MSIE, you can access methods belonging to the `history` object with a construct like this:

```
window.history.go(0);
```

Nevertheless, you cannot access member properties of the `history` object to examine URL values as this contradicts the security requirements.

Warnings:

- This appears to be only partially supported on MSIE for Macintosh.

See also:	`Frame` object, `History` object, `Window` object

Property attributes:

`ReadOnly`.

Window.home() (Method)

This duplicates the behavior of the HOME button on the Netscape Navigator button bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`home()`
	N	*`myWindow`*`.home()`

The result of calling this method depends on what you have set up as your home page in the browser. By default, it is likely to be a page on the web site belonging to the browser manufacturer. Commonly though, it will be a blank page because after you have been irritated by your browser automatically dialling in to your ISP, you'll likely have told it not to go to any home page by default.

See also:	`Frame object`, `Window` object, `Window.find()`, `Window.print()`, `Window.stop()`

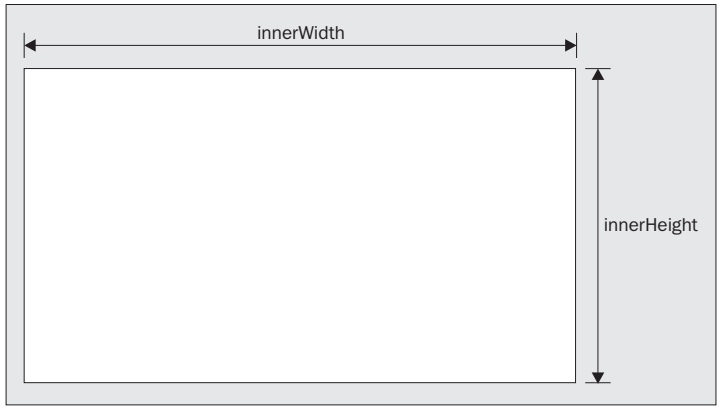
Window.innerHeight (Property)

The height of the window inside the frame.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`innerHeight`
	-	*`myWindow`*`.innerHeight`

This property is supported on Netscape Navigator and tells you what the current height of the content area of the window is set to.

Assigning a value to this property will resize the window on Netscape Navigator. On MSIE it will be ignored.



Warnings:

- This method requires your script to be granted the `UniversalBrowserWrite` privilege to set a window size smaller than 100x100 pixels.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.innerWidth`, `Window.outerHeight`, `Window.outerWidth`

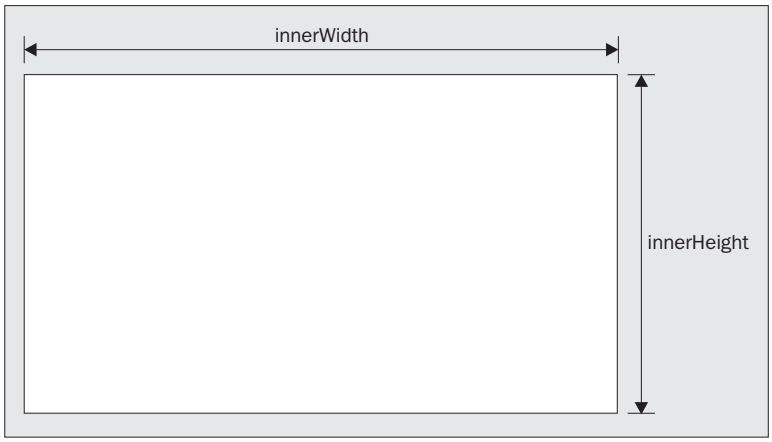
Window.innerWidth (Property)

The width of the window inside the frame.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`innerWidth`
	-	*myWindow*`.innerWidth`

This property is supported on Netscape Navigator and tells you what the current width of the content area of the window is set to.

Assigning a value to this property will resize the window on Netscape Navigator. On MSIE it will be ignored.



Warnings:

- This method requires your script to be granted the `UniversalBrowserWrite` privilege to set a window size smaller than 100x100 pixels.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.innerHeight`, `Window.outerHeight`, `Window.outerWidth`

Window.java (Property)

A reference to the Java package object that is the root of the '`java.*`' packages tree.

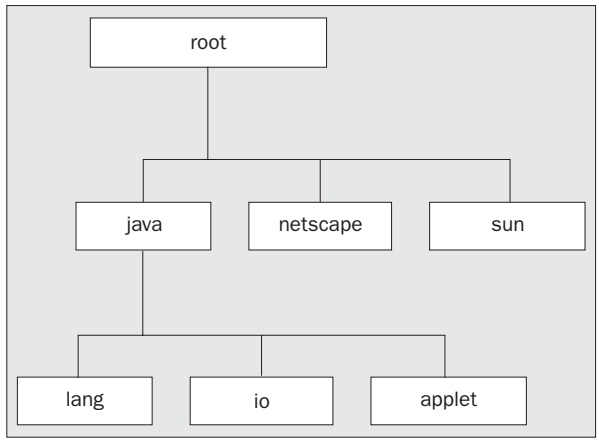
Availability:	JavaScript - 1.1 Netscape - 3.0	
Property/method value type:	`JavaPackage java`	
JavaScript syntax:	N	`java`
	N	*`myWindow`*`.java`
	N	*`myWindow`*`.Packages.java`
	N	`Packages.java`

The object referred to by this property sits at the top of the java package name hierarchy. It is through this property that you can access the java objects, properties and methods via LiveConnect.

This shortcut reference corresponds to a directory hierarchy where Java class, packages are stored. Thus the `java.lang.String class` lives in a file called `java/lang/String.class` which on some systems may be stored inside a ZIP archive.

The main shortcoming in this whole mechanism is that the browser cannot tell whether a reference to an object is a request for a JavaPackage or a JavaClass. It will assume you mean a package by default and if you misspell a class name, it won't tell you it couldn't find it.

The objects and classes supported by this access to the underlying Java engine cover a very wide topic base. We have examined only the top level functionality to try and establish points of connection between the two environments. For a full and in-depth reference coverage of the Java language environment, consult the Wrox book *"Java Programmer's Reference" by Grant Palmer*.



See also:	`JavaPackage` object, LiveConnect, `Packages.java`, `Window.netscape`, `Window.Packages`, `Window.sun`

Property attributes:

`ReadOnly`.

Window.length (Property)

The number of frames in the window.

Availability:	JavaScript - 1.0 JScript - 3.0 Internet Explorer - 4.0 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	`frames.length`
	-	`length`
	-	*`myWindow`*`.frames.length`
	-	*`myWindow`*`.length`

The same value as the `window.frames.length` property.

This property is maintained in MSIE for consistency with Netscape Navigator. The frames in MSIE are contained in a `FrameArray` object, but this does not prevent their names polluting the property namespace of the `Window` object.

See also:	`Collection.length`, `Frame` object, `length`, `Window` object

Property attributes:

`ReadOnly`.

Window.location (Property)

A reference to the `location` object that represents the URL of the current window content.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Location object`	
JavaScript syntax:	-	`location`
	-	*`myWindow`*`.location`

The attributes of the object referred to by this property can be read or written to cause the window content to be reloaded under script control.

The object itself ought to be considered read only but its properties are modifiable. Consult the document for the `location` object for details of what you can read or write. In particular, refer to the `window.location.href` value as a way to load a new document into the window.

Warnings:

- Do not confuse this location object with that belonging to the document. They are different.
- Older versions of the web browsers used to treat this property as a read/write string containing the URL. The access to the URL value is now via the properties of the object referred to by this property and not via the property itself.

See also:	`Document.location`, `Document.referrer`, `Document.URL`, `Frame` object, `Location` object, `Window` object, `Window.navigate()`

Property attributes:

`ReadOnly`.

Window.locationbar (Property)

A reference to an object that represents the location bar.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	`locationbar`
	-	*`myWindow`*`.locationbar`

This is a read only property containing a reference to a `Bar` object whose `visible` property contains a Boolean value that controls the visibility of the screen furniture represented by the object.

In this case, it is supposed to control the visibility of the location bar.

The example shows how this can be done in a secure way that requires privilege to be granted and in a non-secure way that does not.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the locationbar.

Example code:

```
// Request necessary
privilegesnetscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrit
e");
// Hide location barwindow.locationbar.visible = false;
// There is another way that works without requesting privilegewindow.open('',
'_top', 'location=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.menubar`, `Window.personalbar`, `Window.scrollbars`, `Window.statusbar`, `Window.toolbar`

Property attributes:

`ReadOnly`.

Window.menubar (Property)

A reference to an object that represents the menu bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	`menubar`
	-	`myWindow.menubar`

This is a read-only property containing a reference to a `Bar` object whose `visible` property contains a Boolean value that controls the visibility of the screen furniture represented by the object.

In this case, it is supposed to control the visibility of the menu bar.

The example shows how this can be done in a secure way that requires privilege to be granted and in a non-secure way that does not.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the menubar.
- The Macintosh version of Netscape Navigator requires that the window be made inactive and then active again after the status of this item has changed for there to be any noticeable effect.
- Even then, not all items in the menubar are hidden but most are.
- Be careful if you set the menubar and toolbar to invisible, you will then have no reload capability to be able to refresh the screen. You will then only be able to quit.

- On some platforms, there may still be a refresh capability available on the contextual menu inside the window. This will depend on whether the contextual menu is still available or whether it has been changed to remove the refresh item.

Example code:

```
// Request necessary privileges
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite");
// Hide menu bar
window.menubar.visible = false;

// There is another way that works without requesting privilege
// window.open('', '_top', 'menubar=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.locationbar`, `Window.personalbar`, `Window.scrollbars`, `Window.statusbar`, `Window.toolbar`

Property attributes:

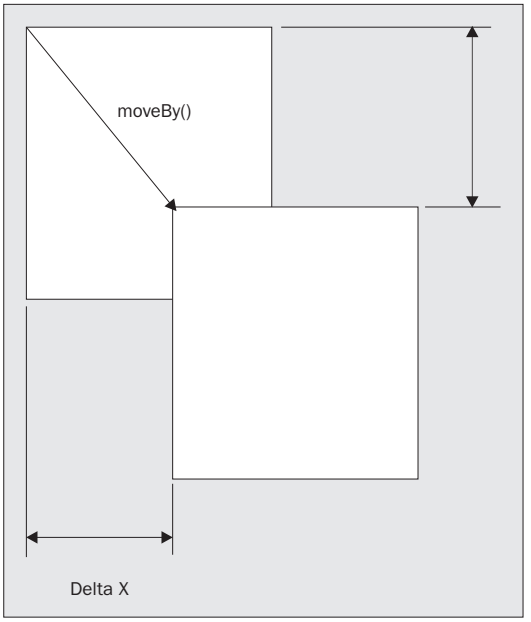
`ReadOnly`.

Window.moveBy() (Method)

Move the window by a specified distance.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`moveBy(`*`anOffsetX`*`, `*`anOffsetY`*`)`
	-	*`myWindow`*`.moveBy(`*`anOffsetX`*`, `*`anOffsetY`*`)`
Argument list:	*`anOffsetX`*	A distance in pixels
	`anOffsetY`	A distance in pixels

This method will translate a window across the screen. Positive values move the window to the right and down while negative values move the window to the left and up.



Warnings:

- There are some security implications for moving windows in Netscape 4. They are intended to stop you hiding a window by shifting it off-screen. Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to move the window outside the screen area.

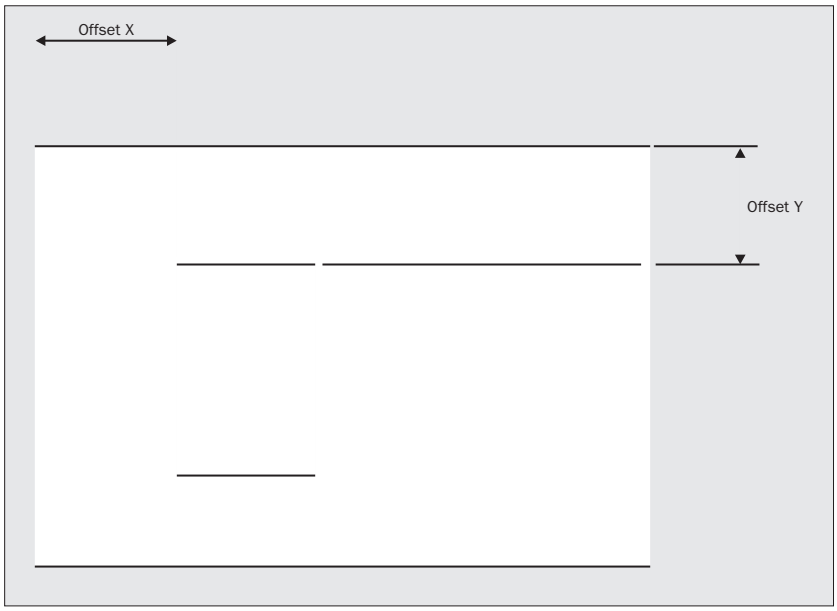
See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.moveTo()`, `Window.onmove`, `Window.pageXOffset`, `Window.pageYOffset`, `Window.resizeBy()`, `Window.resizeTo()`, `Window.scrollBy()`

Window.moveTo() (Method)

Move the window to a specific location.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`moveTo(aCoordX, aCoordY)`
	-	`myWindow.moveTo(aCoordX, aCoordY)`
Argument list:	*`aCoordX`*	A position in pixels
	`aCoordY`	A position in pixels

This method will locate a window at a specific position on screen.



Warnings:

- There are some security implications for moving windows in Netscape 4. They are meant to stop you hiding a window by shifting it off-screen. Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to move the window outside the screen area.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.moveTo()`, `Window.onmove`, `Window.pageXOffset`, `Window.pageYOffset`, `Window.resizeBy()`, `Window.resizeTo()`, `Window.scrollBy()`

Window.name (Property)

The name of the window either from the `<FRAME>` tag, the `Window.open()` method call or an assignment to this property.

Availability:	DOM level - 1 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0
Property/method value type:	`String primitive`

JavaScript syntax:	-	*myWindow*.name
	-	*myWindow*.name = *aString*
	-	name
	-	name = *aString*
	-	window.open(*aURL*, *aName*, ...)
HTML syntax:	<FRAME NAME="...">Window.open(...)	
Argument list:	*aName*	A name for the window
	aString	A string value containing the new name for the window
	aURL	A URL to load into the window

This name value can be used with the target attribute of the HTML <A> anchor tag or the <FORM> tag.

At version 1.0 of JavaScript this is a read-only property.

JavaScript version 1.1 introduces the capability of changing the name of a window and makes this property writable. This is particularly useful because the initial window has no name and cannot be targeted directly until it has. You can fix this with an onLoad handler.

The name of a window can be set when the window is created with the open() method. It is also assigned by the NAME="..." HTML tag attribute of a <FRAME> tag.

The example shows the window name being modified. Reload to see the persistence effect. Load another document and then load this script again to see how the name persists through intermediate document loads.

Warnings:

- This is not the title text for the window.
- Note that the name value persists through document loads and so you may need to be careful if you are using the name property in a document script. It might have been set by an earlier page. This also suggests that other window properties may be persistent between documents and might provide a way to pass messages between pages and maintain state during a session.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
document.write("***"+window.name+"<BR>");
window.name = "FRED";
document.write("***"+window.name+"<BR>");
</SCRIPT>
</BODY>

Window.navigate() (Method)

Load a new URL into the window.

Availability:	JScript - 1.0 Internet Explorer - 3.02	
Property/method value type:	`undefined`	
JavaScript syntax:	IE	`myWindow.navigate(`*`aURL`*`)`
	IE	`navigate(`*`aURL`*`)`
Argument list:	*`aURL`*	A new location to navigate the window to

This is functionally similar to assigning a new value to the `window.location.href` property. Because it is only available in MSIE you should avoid using this in cross-browser development.

Warnings:

- Because this is only supported in MSIE, you should not use it if you want to develop portable scripts. A more portable technique is to assign the URL value to the `href` property of the `location` object that is accessible from the `window.location` property.
- `window.navigate("index.html");` and `window.location.href = "index.html";` are functionally equivalent and guaranteed to be portable between Netscape Navigator and MSIE if not across all available browsers.

Example code:

```
// Reload the window with a new relative URL valuewindow.navigate("_Window.html");
```

See also:	`Location` object, `Window.location`

Window.navigator (Property)

A reference to a navigator object that describes the browser.

Availability:	JavaScript - 1.0 JScript - 3.0 Internet Explorer - 4.0 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Navigator object`	
JavaScript syntax:	-	*`myWindow`*`.navigator`
	-	`navigator`

The `navigator` object was originally provided by Netscape Navigator as a way of making client properties available to scripts.

Warnings:

- Microsoft have property named `clientInformation` that points at the same object. This then allows people to write scripts that are functionally identical but which will break on Netscape Navigator and Opera, although perhaps we should give them the benefit of the doubt because really this property should have been called `clientInformation` in the first place.

See also:	`Frame` object, `Navigator` object, `Window` object, `Window.clientInformation`

Property attributes:

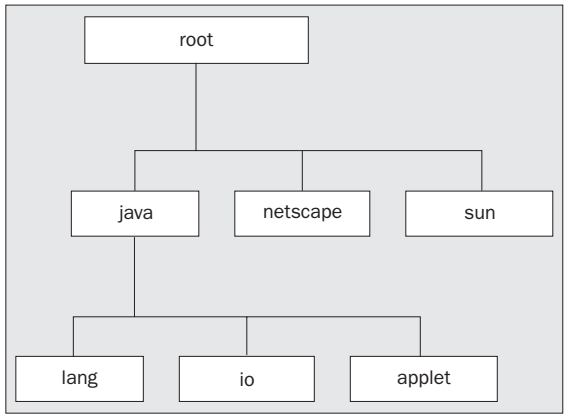
`ReadOnly`.

Window.netscape (Property)

A reference to the Java package object that is the root of the '`netscape.*`' Packages tree.

Availability:	JavaScript - 1.1 Netscape - 3.0	
Property/method value type:	`JavaPackage netscape`	
JavaScript syntax:	N	*myWindow*`.netscape`
	N	*myWindow*`.Packages.netscape`
	N	`netscape`
	N	`Packages.netscape`

The object referred to by this property sits at the top of the Netscape package name hierarchy. It is through this property that you can access the java objects, properties and methods via LiveConnect.



See also:	JavaScript to Java values, `Packages.netscape`, `Window.java`, `Window.Packages`, `Window.sun`

Property attributes:

`ReadOnly`.

Window.offscreenBuffering (Property)

A property that controls off-screen buffering effects.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`Boolean or String primitive`	
JavaScript syntax:	-	*myWindow*`.offScreenBuffering`
	-	*myWindow*`.offScreenBuffering = `*aSetting*
	-	`offScreenBuffering`
	-	`offScreenBuffering = `*aSetting*
Argument list:	*aSetting*	A new value to control this functionality

This property controls how screen updates are accomplished. This is especially useful with DHTML-based animation. An off-screen buffer is used to draw the new window contents and then copy it over the existing content when it is complete. This is much nicer to look at than the effects you get with a non-buffered redraw which clears the screen first and then draws the entire page in front of you.

The available settings are:

Boolean `true` - Activate off-screen buffering

Boolean `false` - Deactivate off-screen buffering

String "`auto`" - Let the browser decide for itself

In general, MSIE accomplishes slightly more attractive redraws with this facility enabled than Netscape Navigator. However, new versions of Mozilla 5 and Netscape 6 may surpass the MSIE version 5 support.

Warnings:

- Enabling this facility will slightly decrease CPU performance and consume more memory since a copy of the onscreen window needs to be maintained in the application memory.

See also:	`Frame` object, `Window` object

Window.onblur (Property)

This is called when the window loses input focus.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*.onblur
	-	*myWindow*.onblur = *aHandler*
	-	onblur
	-	onblur = *aHandler*
HTML syntax:	<BODY onBlur="*aHandler*"><FRAMESET onBlur="*aHandler*">	
Argument list:	*aHandler*	An event handler function object

A `blur` event is caused by the user clicking on another window or frame or the `window.blur()` method being called. When this event is triggered, an `onblur` event handler will be invoked.

The `onblur` event handler is a function which is represented by an object that is referred to by this property. Because it is stored in a property, you can change the handler by storing a reference to a different function object in this property. At least, you can on MSIE.

You cannot redefine the value of the `window.onblur` property from inside the `onblur` function handler. This means you can't modify the `onblur` behavior while a `blur` event is in progress.

The handler is registered either by assigning a function to the `onblur` property or by defining it with an HTML tag attribute.

Warnings:

- Do not use `<BODY ONBLUR="window.focus()">` to make sure the window is always on top. This does not work as you expect. The problem is caused because the `BODY` receives a `blur` event when any element inside the page takes the focus away from it (for example, when you click on a link or form element). The page becomes unusable because every attempt to click elements in the page triggers a javascript call that draws the focus straight back to the `BODY`/ window. So all you get is a window that permanently blocks all the other windows but does not allow any elements inside it to be used.
- In Netscape Navigator, the property is not enumerable if the value is defined with an `onBlur="..."` HTML tag attribute. However, it is enumerable if the property is assigned within JavaScript without there being a defining tag attribute. There may be a general rule that script defined properties are always enumerable, while internally created properties may not be.
- Displaying an `alert()`,`confirm()` or `prompt()` dialog takes focus away from a window. Don't forget that your `blur` handler will be called if this happens.
- The Macintosh version 4.7 of Netscape Navigator does not appear to support `blur` events.

See also:	onBlur,Window.blur(),Window.focus(), Window.onfocus

Property attributes:

DontEnum.

Window.ondragdrop (Property)

This event handler is called when an object is dropped into the browser window.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	Function object	
JavaScript syntax:	-	*myWindow*.ondragdrop
	-	*myWindow*.ondragdrop = *aHandler*
	-	ondragdrop
	-	ondragdrop = *aHandler*
HTML syntax:	<BODY onDragDrop="*aHandler*"><FRAMESET onDragDrop="*aHandler*">	
Argument list:	*aHandler*	An event handler function object

This event handler is invoked when the user drags an item onto a window in Netscape Navigator.

To access the details of the entity that has been dragged into and dropped on the window, you need to access the data property of the event object that is passed as an argument to the handler when it is called.

The data is a single URL when a single entity is dropped into the window or an array of strings, each containing an URL, when a collection of entities are dropped onto a window.

You will need UniversalBrowserRead privilege to access this data.

The handler is registered either by assigning a function to the ondragdrop property or by defining it with an HTML tag attribute.

Warnings:

- Note that this does not appear to work in Netscape 4.7 for Macintosh.

See also:	Event.data,onDragDrop

Property attributes:

DontEnum.

Window.onerror (Property)

A reference to an error event handler for this window object.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*`.onerror`
	-	*myWindow*`.onerror = `*aHandler*
	-	`onerror`
	-	`onerror = `*aHandler*
Argument list:	*aHandler*	An event handler function object

You can register an error handler function by assigning a function object to the window's `onerror` property so that when an error occurs in the JavaScript within the window, that function will be called.

This can be a useful way of trapping and completely inhibiting the display of error messages to the user. When the error handling function is called, it is passed three arguments:

- The textual message that explains the error
- The URL of the document that contains the error
- The line number within that document where the error occurred

The line number is the physical line number within the document, not a line number within a script, so you should be able to open the document in a text editor and go to the indicated line and identify the problem.

The only way to activate this error handling capability is to assign a function to the `onerror` property. There is no HTML tag attribute mechanism for defining an error handler for a window although you can associate one with the `<IMG>` tag with an attribute value.

You can return either `true` or `false` as a result of calling your handler:

`true` - Inhibit any further error processing and abort the script.

`false` - Hand control back to the browser to deal with the error in the normal way.

Deactivate error handling altogether by calling a function that simply returns `true`. To restore default error handling to the window later, assign a function handler to the property that merely returns a `false` value as its result without intervening in the error process in any way.

Warnings:

- Beware of the return values. Returning `true` from an error handler inhibits the browser from carrying out any further action. This is exactly opposite to the return value from a form element event handler, which requires that a `false` value be returned to inhibit any further action by the browser.
- This works on version 4 of Netscape Navigator. It is also fully supported by MSIE version 5. Version 4 of MSIE for Macintosh (and possibly other platforms) allows the error to be trapped but does not pass any meaningful argument values. They are all undefined.
- This is not supported on the WebTV platform.
- There is a problem with this event handler hook in the Netscape 6.0 browser. The values are not passed to the handler correctly although the handler is called.

See also:	Debugging - client-side, Error events, Error handler, JellyScript, `onError`

Property attributes:

`DontEnum`.

Window.onfocus (Property)

This event handler is called when a window gains the input focus.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*`.onfocus`
	-	*myWindow*`.onfocus = `*aHandler*
	-	`onfocus`
	-	`onfocus = `*aHandler*
HTML syntax:	`<BODY onFocus="`*aHandler*`"><FRAMESET onFocus="`*aHandler*`">`	
Argument list:	*aHandler*	An event handler function object

A `focus` event is caused by the user clicking on the receiving window or frame or the `window.focus()` method being called. When this event is triggered, an `onfocus` event handler will be invoked.

The `onfocus` event handler is a function which is represented by an object that is referred to by this property. Because it is stored in a property, you can change the handler by storing a reference to a different function object in this property. At least, you can on MSIE.

You cannot redefine the value of the `window.onfocus` property from inside the `onfocus` function handler. This means you can't modify the `onfocus` behavior while a `focus` event is in progress.

The handler is registered either by assigning a function to the `onfocus` property or by defining it with an HTML tag attribute.

Warnings:

- Displaying an `alert()`,`confirm()` or `prompt()` dialog may take focus away from a window on some platforms and browsers. Don't forget that your `focus` handler could be called when the dialog is dismissed if this happens.
- The Macintosh version 4.7 of Netscape Navigator does not appear to support `focus` events.

See also:	`onFocus`,`Window.blur()`,`Window.focus()`, `Window.onblur`

Property attributes:

`DontEnum`.

Window.onload (Property)

A reference to a loading completed event handler for this window object.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*`.onload`
	-	*myWindow*`.onload = `*aHandler*
	-	`onload`
	-	`onload = `*aHandler*
HTML syntax:	`<BODY onLoad="`*aHandler*`"><FRAMESET onLoad="`*aHandler*`">`	
Argument list:	*aHandler*	An event handler function object

This is called when a `<BODY>` or `<FRAMESET>` has completed loading. This event is generated when all document parsing is done, all script blocks are fully operational and all functions defined and accessible. The Document Object Model should have been fully constructed by this time.

The `onload` event handler is a function which is represented by an object that is referred to by this property. Because it is stored in a property, you can change the handler by storing a reference to a different function object in this property. However, because this is called when loading is completed and not again after that, you can logically only modify this value during page loading.

The handler is registered either by assigning a function to the `onfocus` property or by defining it with an HTML tag attribute.

Warnings:

- There are certain things you cannot do until this point in the page loading process. For example, you cannot use inline `document.write()` methods to construct an `<OBJECT>` embed in MSIE. You can however enclose a dummy `<OBJECT>` block inside a `<DIV>` and then replace the `innerHTML` of that `<DIV>` with a script generated `<OBJECT>` block that is provided in an `onload` event handler. There are some issues about how tightly that plugin is bound to the browser window. It is possible that a plugin that plays video may not track window drags with live updates to the screen quite as elegantly as an `<OBJECT>` block that is manifestly constant and not defined by a script.
- There is a bug in the way that the `onload` event handlers are invoked in Netscape Navigator 2. Logically, one would assume that the `onload` handler for the `<FRAMESET>` would be called once all of the individual frames within it have been fully loaded. However, Netscape 2 calls this prematurely and so you should make sure that you have a way to check that every one of your frames has loaded individually.

See also:	`onLoad`, `Window.onunload`

Property attributes:

`DontEnum`.

Window.onmove (Property)

This event handler is called when a window is moved.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*.onmove
	-	*myWindow*.onmove = *aHandler*
	-	onmove
	-	onmove = *aHandler*
HTML syntax:	`<BODY onMove="`*aHandler*`"><FRAMESET onMove="`*aHandler*`">`	
Argument list:	*aHandler*	An event handler function object

This is called when a window is moved on the screen to another location.

The handler is registered by defining it with an HTML tag attribute.

The event is also triggered when a window is moved under control of a script with the `moveTo()` or `moveBy()` methods.

Warnings:

- This is not supported by Netscape Navigator 4 on the Unix platform.
- On the Macintosh platform, Netscape Navigator calls the `onmove` handler twice when the window is moved.

See also:	`onMove`,`Window.moveBy()`,`Window.moveTo()`

Property attributes:

`DontEnum`.

Window.onresize (Property)

A reference to a resized window event handler for this `window` object.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*.onresize
	-	*myWindow*.onresize = *aHandler*
	-	onresize
	-	onresize = *aHandler*
HTML syntax:	`<BODY onResize="`*aHandler*`"><FRAMESET onResize="`*aHandler*`">`	
Argument list:	*aHandler*	An event handler function object

This is called when a window is enlarged or reduced in size.

The handler is registered by defining it with an HTML tag attribute. The handler can also be registered by assigning the function object to the `onresize` property of the window.

The event is also triggered when a window is resized under control of a script with the `resizeTo()` or `moveBy()` methods.

See also:	`onResize`,`Window.resizeBy()`,`Window.resizeTo()`

Property attributes:

`DontEnum`.

Window.onunload (Property)

This event handler is called when a document is cleared from a window.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Function object`	
JavaScript syntax:	-	*myWindow*.onunload
	-	*myWindow*.onunload = *aHandler*
	-	onunload
	-	onunload = *aHandler*
HTML syntax:	`<BODY onUnload="`*aHandler*`"><FRAMESET onUnload="`*aHandler*`">`	
Argument list:	*aHandler*	An event handler function object

This is called when a `<BODY>` or `<FRAMESET>` is about to be replaced by some new content.

The `onunload` event handler is a function which is represented by an object that is referred to by this property. Because it is stored in a property, you can change the handler by storing a reference to a different function object in this property.

The handler is registered either by assigning a function to the `onfocus` property or by defining it with an HTML tag attribute.

In a frame-set collection, the individual onunload handlers for each frame will be called in turn before the `onunload` event handler for the `<FRAMESET>` is called.

Use of this event handler is discouraged on the WebTV platform. There are limitations on its availability at certain times during alert and refresh actions.

See also:	JellyScript, `onLoad`, `onUnload`, `Window.onload`

Property attributes:

`DontEnum`.

Window.open() (Method)

A means of creating new windows under script control.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*aNewWindow* = *myWindow*.open()
	-	*aNewWindow* = *myWindow*.open(*aURL*)
	-	*aNewWindow* = *myWindow*.open(*aURL*, *aName*)
	-	*aNewWindow* = *myWindow*.open(*aURL*, *aName*, *aFeatureList*)
	-	*aNewWindow* = *myWindow*.open(*aURL*, *aName*, *aFeatureList*, *aFlag*)
	-	*aNewWindow* = open()
	-	*aNewWindow* = open(*aURL*)
	-	*aNewWindow* = open(*aURL*, *aName*)
	-	*aNewWindow* = open(*aURL*, *aName*, *aFeatureList*)
	-	*aNewWindow* = open(*aURL*, *aName*, *aFeatureList*, *aFlag*)
Argument list:	*aFeatureList*	A list of attributes for the new window
	aFlag	A flag to indicate how the history list is to be modified
	aName	The name of a new or existing target window
	aURL	A URL to load into the window

All arguments are optional. However, since they are also positional, you must use commas and empty strings as necessary to null out the entries you don't require if you need the later ones.

The URL value, if specified, will fetch and load the document into the window as the `window.open()` method is executed. You may omit or null the URL with an empty string. This will open a new window but not load anything into it.

The name identifies the target window. If that window name is not already used, then a new window will be created, otherwise the URL will replace the existing content. When you direct a null URL to an already open window being referenced by name just returns a reference to that `window` object. This may be useful if you know the name of a window but do not have a handle on its object representation. If you do not specify a name, then a new unnamed window will be created.

The feature list describes the attributes of the window. This may in some implementations allow you to change a window's appearance but this may not always be possible. The feature list must be comma separated and must not contain any spaces.

The flag value indicates what you want done with the history table for this window. Passing the Boolean `true` value indicates that the new URL should replace the existing history entry. A Boolean `false` value indicates that the new URL should be added to the tail of the history list. This facility is available from JavaScript version 1.1 onwards.

The value returned by this `open()` method is a reference to the `window` object that represents the window that has just been opened. You can store this in a variable so you can send messages to the window when necessary.

See the Window features list topic for a list of the window feature names and the values that they expect, and a discussion on the limitations and some subtle catch-outs and differences between the browsers.

This method returns a reference to the `window` object for the window that was created or updated. You should note this in some persistent variable if you plan to communicate with the window some time later during the session.

Warnings:

- Do not confuse the `window.open()` method with the `document.open()` method. It is probably a safer technique to explicitly refer to the `window.open()` method rather than rely on the implication of the `open()` method being sent to a `window` object. It might be possible to modify the scope chain to make this default to `document.open()` instead.
- A `window.open()` will create a new viewport window. A `document.open()` will clear the current window contents and start writing new HTML into it.
- If you include spaces in the feature list attribute, the script may cause some versions of Netscape Navigator to crash horribly and in others it will just ignore any features following the space character.
- Netscape Navigator returns an `EventCapturer` object instead of a `Window` object.
- The `window.open()` method will behave differently in JellyScript on a WebTV set-top box when compared with the behavior in a normal computer based web browser. It creates a pseudo-window in an `<IFRAME>` and appends it to the end of the current display. The user can then scroll down to this window.

See also:	`Document.open()`, `EventCapturer object`, `Frame object`, JellyScript, Window feature list, `Window object`, `Window.close()`, `Window.name`, `Window.opener`

Cross-references:

Wrox *Instant JavaScript* – page - 74

Window.opener (Property)

A reference to the window that contained the link that opened this one.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	`myWindow.opener`
	-	`opener`

This allows you to build a hierarchy of parent and child windows. A window has a `null` value for this property if the window was opened directly by the user.

If necessary, you can modify the value in this property since it supports read and write access.

Warnings:

- Not supported by Netscape 2 or version 3 of MSIE. You could simulate this property by storing the self property of the opening window in a property of your own that belongs to the object representing the new window. You could also check for the existence of this property and create it yourself if it is missing. Refer to the example to see how you can do this.
- This value is meaningful for a top level window that contains a frame-set but it is not meaningful for frames within that window. Logically, if this is to indicate a window parentage, it should also refer to a top level window and not a frame within one, even if the `window.open()` method was executed from within a frame.
- Although the value is apparently writable, it is difficult to think of a circumstance where you would want to redefine the parent window object.

Example code:

```
// Create the new window
var myNewWindow = open('http://www.wrox.com', 'windowName');
// Now set its opener property if it doesn't already exist
if (!myNewWindow.opener)
{
myNewWindow.opener = window;
}
```

See also:	Browser version compatibility, `Document` object, `Frame` object, `Window` object, `Window.close()`, `Window.frames[]`, `Window.open()`

Property attributes:

`ReadOnly`.

Window.outerHeight (Property)

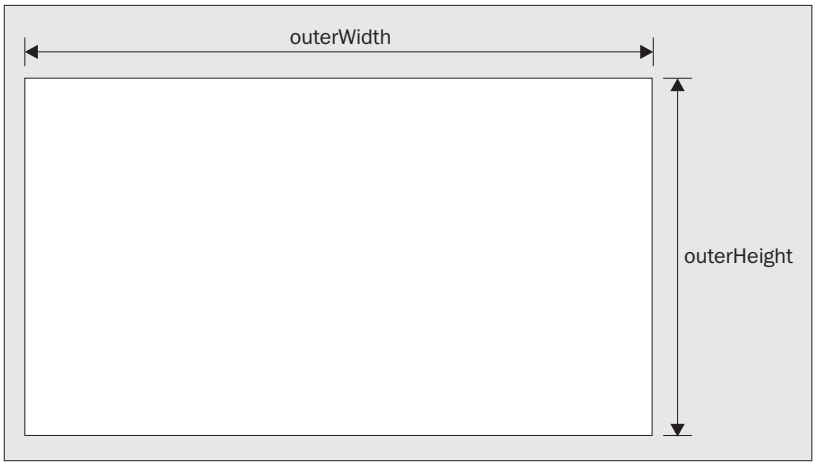
The height of the window including the frame.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myWindow*`.outerHeight`
	-	`outerHeight`

This property is supported on Netscape Navigator and tells you what the current height of the outer bordered area of the window is set to.

Assigning a value to this property will resize the window on Netscape Navigator. On MSIE it will be ignored.

Note that the content window will be much smaller than the bordered area. The content area can be controlled directly with the `innerHeight` and `innerWidth` properties.



Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to set the window size to less than 100x100 pixels.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.innerHeight`, `Window.innerWidth`, `Window.outerWidth`

Window.outerWidth (Property)

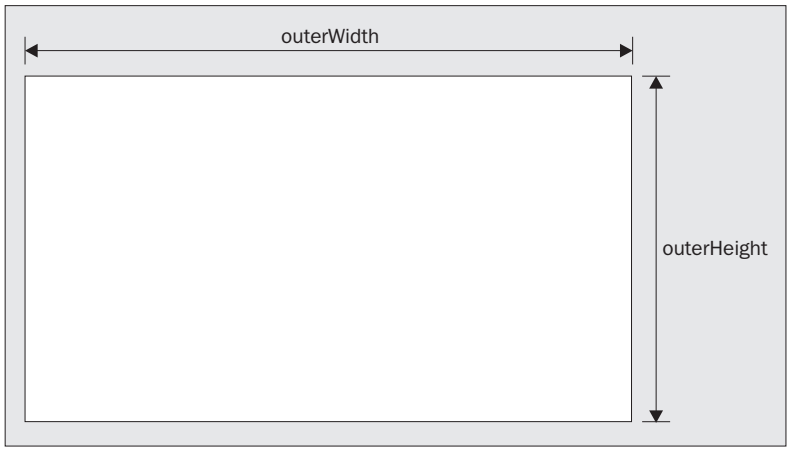
The width of the window including the frame.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myWindow*.outerWidth
	-	outerWidth

This property is supported on Netscape Navigator and tells you what the current width of the outer bordered area of the window is set to.

Assigning a value to this property will resize the window on Netscape Navigator. On MSIE it will be ignored.

Note that the content window will be much smaller than the bordered area. The content area can be controlled directly with the innerHeight and innerWidth properties.



Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to set the window size to less than 100x100 pixels.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.innerHeight`, `Window.innerWidth`, `Window.outerHeight`

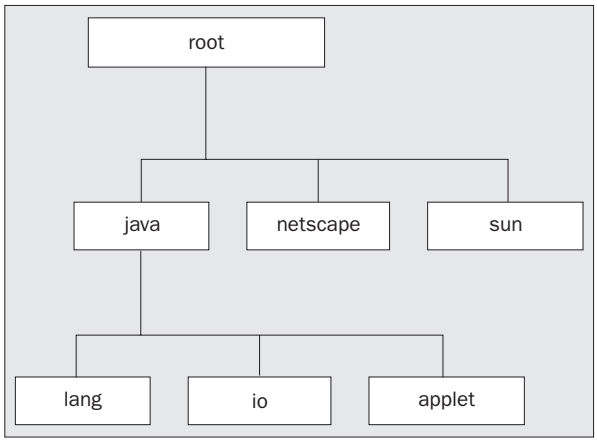
Window.Packages (Property)

A top level `JavaPackage` object that is the root of a tree of Java packages.

Availability:	JavaScript - 1.1 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`JavaPackage object`	
JavaScript syntax:	N	*myWindow*`.Packages`
	N	`Packages`

This property contains a read-only reference to a `JavaPackage` that sits at the top of the Java package hierarchy; the root node of the tree. A `JavaPackage` is a container for other `JavaPackage` objects and `JavaClass` objects. By default, the Netscape Navigator browser will have three packages belonging to this top level node (`java`, `sun` and `Netscape`). Each of these is a package and will contain other packages. There may be additional externally supplied packages over and above these default three items.

MSIE supports different mechanisms for encapsulating Java code.



See also:	`JavaArray` object, `JavaClass` object, `JavaObject` object, `JavaPackage` object, `Packages`, `Window.java`, `Window.netscape`, `Window.sun`

Property attributes:

`ReadOnly`.

Window.pageXOffset (Property)

The amount that a window has been scrolled to the right.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myWindow*.pageXOffset
	N	pageXOffset

This read-only integer value tells you how far the window content has been scrolled in the horizontal direction.

Note that Netscape Navigator is somewhat picky about whether you can even scroll the content of a window. It insists on the scrollbars being visible even though the content may not cause them to be active.

Netscape Navigator 4 will let you scroll layers and Netscape 6 provides sufficient DOM standardized CSS positioning controls to satisfy your requirements.

In the MSIE browser, a similar value is available in the `document.body.scrollLeft` property.

See also:	`Document.body`, `Frame` object, `Window` object, `Window.moveBy()`, `Window.moveTo()`, `Window.pageYOffset`, `Window.scrollBy()`

Property attributes:

`ReadOnly`.

Window.pageYOffset (Property)

The amount that a window has been scrolled downwards.

Availability:	JavaScript - 1.2 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	N	*myWindow*.pageYOffset
	N	pageYOffset

This read-only integer value tells you how far the window content has been scrolled in the vertical direction.

Note that Netscape Navigator is somewhat picky about whether you can even scroll the content of a window. It insists on the scrollbars being visible even though the content may not cause them to be active.

Netscape Navigator 4 will let you scroll layers and Netscape 6 provides sufficient DOM standardized CSS positioning controls to satisfy your requirements.

In the MSIE browser, a similar value is available in the `document.body.scrollTop property`.

See also:	`Document.body`, `Frame` object, `Window` object, `Window.moveBy()`, `Window.moveTo()`, `Window.pageXOffset`, `Window.scrollBy()`

Property attributes:

`ReadOnly`.

Window.parent (Property)

A reference to the parent window in a framed pane.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*`.parent`
	-	`parent`

For top level windows, the `parent` property is the same as the `self` property.

For framed windows the parent will be a `Window` object.

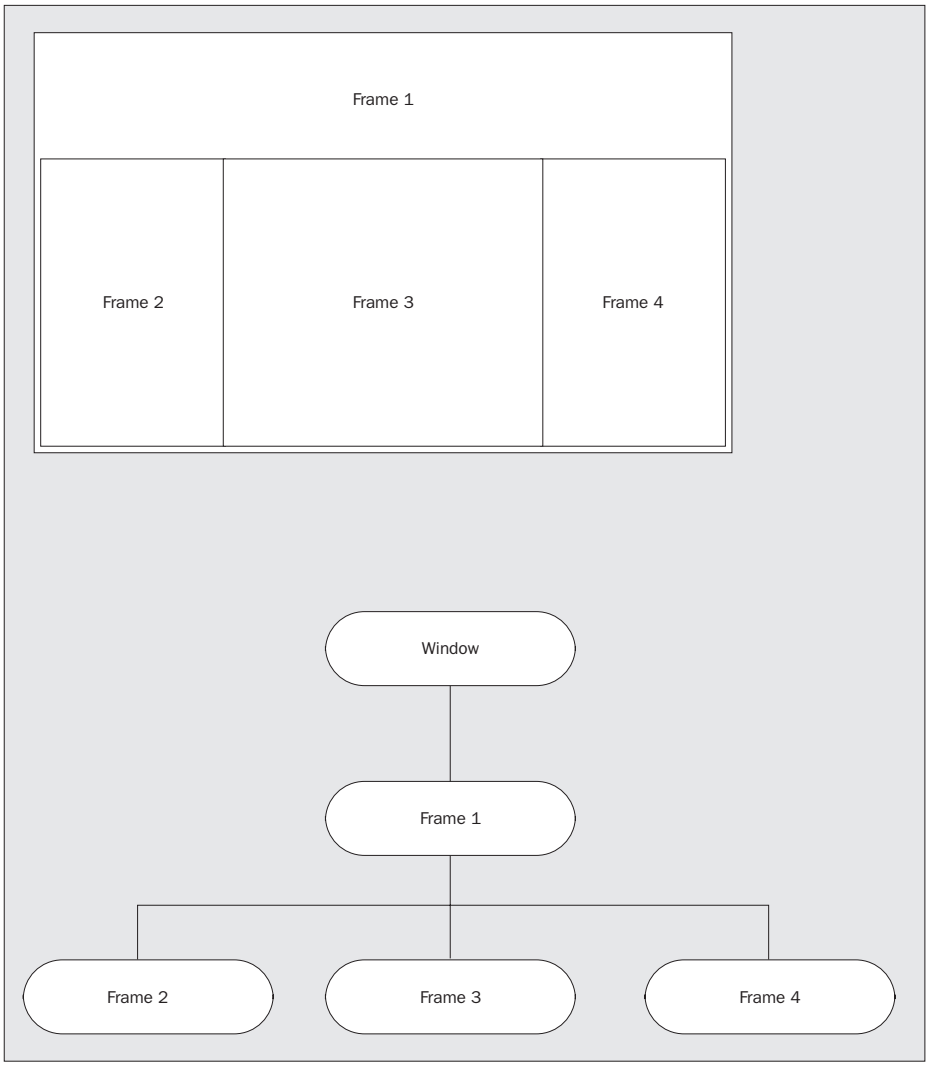
In the same way that you can walk downwards through the frames hierarchy with a `frames[ ... ].frames[ ... ]` construct, a `parent.parent` construct will walk upwards through the hierarchy.

It is important to know where you are so that this is as useful as possible. Relative locations in trees need to have some awareness of the root. If you don't detect this, you might have problems.

Detecting whether you have reached the root can be accomplished by testing whether the parent property of a window refers to the same object as the window itself.

When you reach the top of the tree, the `parent` property should yield the same value as the `self` property. This means that the property will be equivalent to `self` for all windows unless they are inside frames. In MSIE, this also means that they are possibly inside an `<IFRAME>` as well.

Inside a modal dialog window, the parent will be a `Dialog` object.



Warnings:

- Be careful when building tree walking scripts that traverse the window hierarchy. You can reach the top level and continue in an endless loop referring to the parent of an object that is the object itself. You should test to see whether `parent = self` and then exit your tree walker knowing that you have reached the root node.

See also:	`Dialog` object, `Frame` object, `Window` object, `Window.frames[]`, `Window.top`

Property attributes:

`ReadOnly`.

Window.personalbar (Property)

A reference to an object that represents the personal preferences bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	*myWindow*`.personalbar`
	-	`personalbar`

This is a read-only property containing a reference to a `Bar` object whose visible property contains a Boolean value that controls the visibility of the screen furniture represented by the object.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the personal bar.

Example code:

```
// Request necessary privileges
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite");
// Hide personal bar
window.personalbar.visible = false;
// There is another way that works without requesting privilege
window.open('', '_top', 'directories=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.locationbar`, `Window.menubar`, `Window.scrollbars`, `Window.statusbar`, `Window.toolbar`

Property attributes:

`ReadOnly`.

Window.pkcs11 (Property)

A hitherto undocumented property of a Netscape Navigator Window object.

Availability:	JavaScript - 1.2 Netscape - 4.04
Property/method value type:	`Pkcs11 object`

JavaScript syntax:	N	*myWindow*.pkcs11
	N	pkcs11

This is part of the Netscape Navigator security model. It's not something you would expect to interact with from JavaScript as a rule.

There are some quite extensive documents covering the use of this facility on the Netscape web site in the developer area.

Some examination with diagnostic scripts does not yield any useful properties, or at least none that can be enumerated. There is a constructor which has a name and prototype property. The prototype of the constructor points back at the `Pkcs11` object itself.

It is somewhat worrying that this object is visible from JavaScript unless there is a genuine reason for being able to access it from script. It may be related to the `crypto` property and also used in conjunction with signed scripts.

If this is a subject you are interested in, there is more information to be studied which is available from a variety of sources. A web search through www.altavista.com yielded over 150 references, some of which document the availability of a Java interface to the PKCS11 security support.

Security in MSIE is supported via other mechanisms and you should search the MSDN web site for relevant links. Links to topics in the MSDN site are relocated from time to time and it is best to search there directly.

See also:	`Pkcs11` object

Property attributes:

`ReadOnly`.

Web-references:

http://developer.netscape.com/support/faqs/pkcs_11.html

Window.print() (Method)

This duplicates the behavior of the Print button on the Netscape Navigator or MSIE button bar.

Availability:	JavaScript - 1.2 JScript - 5.0 Internet Explorer - 5.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*.print()
	-	print()

This is supposed to behave as if the user had clicked on the Print button or selected the Print item from the pull-down menu.

Warnings:

- This does not appear to work on the Macintosh at version 4.7 of Netscape Navigator.

See also:	`Frame` object, `Window` object, `Window.find()`, `Window.home()`,`Window.stop()`

Window.prompt() (Method)

Present a text input prompt box.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*`myResult`* = *`myWindow`*`.prompt(`*`aString`*`,` *`aDefaultValue`*`)`
	-	`myResult = prompt(aString, aDefaultValue)`
Argument list:	*`aDefaultValue`*	An initial content for the text box
	`aString`	Some text to explain what to enter

This presents a modal dialog containing the prompting text message, a text cell to type into and two buttons, OK and Cancel.

This method is useful for debugging where you need to enter values.

Note that the text that is presented in the dialog is unformatted text and you cannot use HTML in the dialog box.

The title bar of the dialog box cannot be changed from its default setting which tells you that the dialog was invoked by JavaScript. In some browsers, it may just display the name of the browser. This is intended to stop script programmers from masquerading their dialog boxes as those of operating system diagnostics and login screens.

The `prompt()` dialog box is modal and blocking. The script must wait for a response from the user.

The value returned by the method is the text typed into the box by the user before pressing the OK button to dismiss the dialog. If the Cancel button is clicked, the method will return `null` instead.

Warnings:

- Earlier documentation refers to the presence of a Clear button but this is not in evidence when testing this function on MSIE and Netscape Navigator. The Clear button is unnecessary since the text is automatically selected and typing into the box clears any previous content. Pressing the Delete key will also clear the text.

See also:	Debugging - client-side, `Dialog` boxes, `Dialog` object, `Frame` object, `Window` object, `Window.alert()`, `Window.confirm()`

Cross-references:

Wrox *Instant JavaScript* – page - 78

Window.releaseEvents() (Function)

Part of the Netscape Navigator 4 event propagation complex.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`myWindow.releaseEvents(anEventMask)`
	N	`releaseEvents(anEventMask)`
Argument list:	*`anEventMask`*	A mask defined with the manifest event constants

This is part of the event management suite which allows events to be routed to handlers other than just the one that defaults to being associated with an event.

The events to be captured are signified by setting bits in a mask.

This method provides a means of indicating which events are no longer needing to be captured by the receiving window object.

The events are specified by using the bitwise OR operator to combine the required event mask constants into a mask that defines the events you want to capture. Refer to the Event Type Constants topic for a list of the event mask values.

We have to implement scripts using this capability if we need to build complex event handling systems on Netcsape 4.x. A different script will be required for MSIE.

You may be able to factor your event handler so that you only have to make platform specific event dispatchers and can call common handling routines that can be shared between MSIE and Netscape.

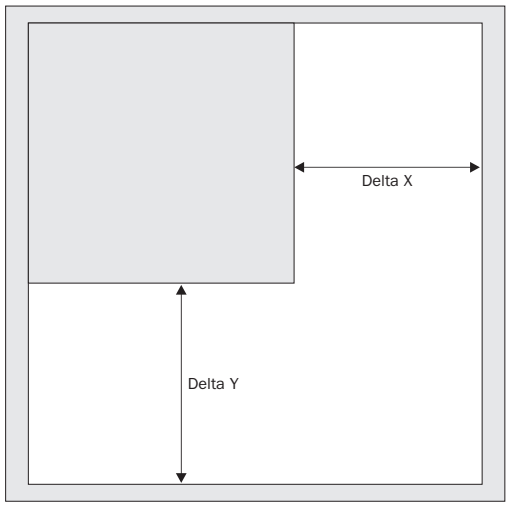
See also:	`captureEvents()`, `Document.captureEvents()`, `Document.releaseEvents()`, `Element.onevent`, Event names, Event propagation, Event type constants, `Event.modifiers`, `Frame` object, `Layer.captureEvents()`, `Layer.releaseEvents()`, `onMouseMove`, `Window` object, `Window.captureEvents()`

Window.resizeBy() (Method)

Resize the window by a specified amount.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.resizeBy(`*aChangeX*`, `*aChangeY*`)`
	-	`resizeBy(`*aChangeX*`, `*aChangeY*`)`
Argument list:	*aChangeX*	A difference in pixels
	aChangeY	A difference in pixels

The window size will be altered by the horizontal and vertical amounts specified in the two parameters. The left and top edges will stay in the same place but the right and bottom edges will be adjusted to the new positions.



Warnings:

- There are some security implications for resizing windows in Netscape 4. This is to prevent you hiding a window by making it too small.
- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to set the window size to less than 100x100 pixels.

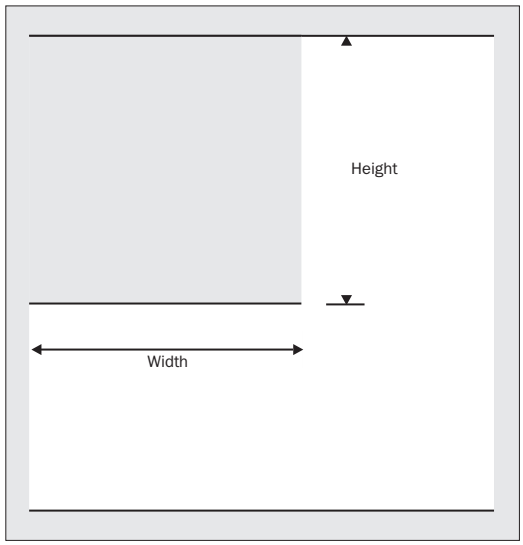
See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.moveBy()`, `Window.moveTo()`, `Window.onresize`, `Window.resizeTo()`

Window.resizeTo() (Method)

Resize the window to specified dimensions.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`myWindow.resizeTo(aSizeX, aSizeY)`
	-	`resizeTo(aSizeX, aSizeY)`
Argument list:	*`aSizeX`*	A distance in pixels
	`aSizeY`	A distance in pixels

The window size will be altered to the horizontal and vertical values specified in the two parameters. The left and top edges will stay in the same place but the right and bottom edges will be adjusted to reflect the new width and height.



Warnings:

- There are some security implications for resizing windows in Netscape 4. This is to prevent you hiding a window by making it too small.
- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to set the window size to less than 100x100 pixels.

See also:	`Frame` object, `UniversalBrowserWrite`, `Window` object, `Window.moveBy()`, `Window.moveTo()`, `Window.onresize`, `Window.resizeBy()`

Window.returnValue (Property)

The return value for a modal dialog window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`User defined`	
JavaScript syntax:	IE	`returnValue`
Argument list:	*`aNewValue`*	The value to be returned when the modal dialog closes

The MSIE browser supports a special kind of window called a Modal Dialog. This is similar to using the `open()` method to create a new window except that it is forced to always be on the top and you cannot click outside of it to bring focus to another window within the browser.

When the modal window exits, you have the opportunity to store a value in the `returnValue` property. Since the window is instantiated by a method call, the caller will expect a value to be returned. This value will be null unless you specify something yourself.

Since you can pass arguments into the modal window, this provides a way to transmit user interaction dependent values back to the caller.

Warnings:

- How this behaves in a truly multi-process environment such as Windows NT or Mac OS X may be slightly different. In an operating system such as those, modality may only extend within the application and it may be possible to switch to a different application. However on returning to the MSIE browser, the modality will still be in force.

See also:	`Frame` object, `Window` object, `Window.showModalDialog()`

Window.routeEvent() (Function)

Part of the Netscape Navigator 4 event propagation complex.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	`myWindow.routeEvent(`*`anEvent`*`)`
	N	`routeEvent(`*`anEvent`*`)`
Argument list:	*`anEvent`*	An event object

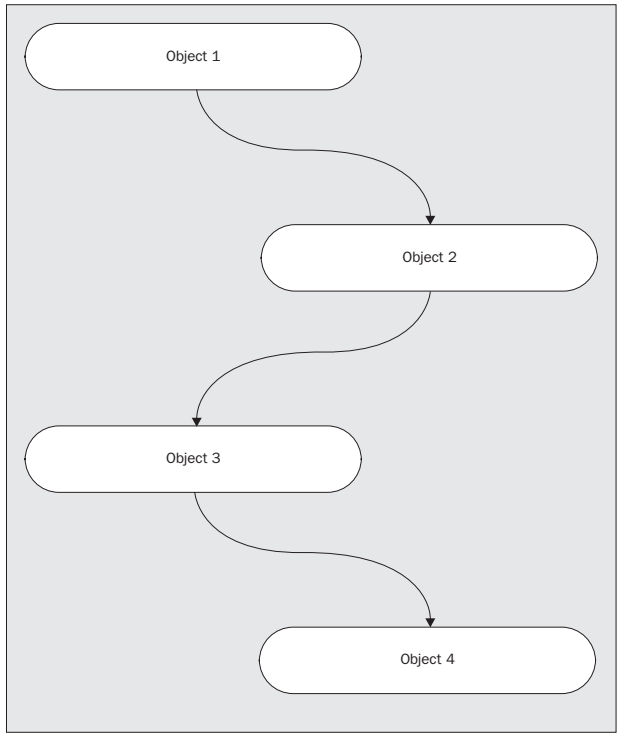
This is part of the event management suite which allows events to be routed to handlers other than just the one that defaults to being associated with an event.

Depending on the current setting of the event type mask for the receiving object, an event may be available for processing with this method. An initial mask that enumerates the events to be received might have been set up with the `captureEvents()` method. Then perhaps sometime later, some of those events may have been deselected by means of the `releaseEvents()` method. The remaining mask defines the finite set of events that will be visible to the object.

So, when a suitable event arrives and is captured, it can be passed on to the appropriately mapped event handler function belonging to the next object in the event handling hierarchy or to another handler belonging to the receiving object.

This means that an event can be processed via several handlers within an object before being passed to the next object in sequence. The order in which handlers and objects are visited by the event is controlled by Netscape Navigator. However, whether the event is passed on or not is controlled by the script in the handler. If it chooses not to pass on the event, then no subsequent handlers will see it, nor will any other objects.

This trickle-down effect is somewhat clumsy and uncontrolled. You can gain some control over the way that events are propagated with the `handleEvent()` method and applying it to the various objects that need to take the event. This does disperse the event handling around the scripts somewhat and can be difficult to maintain.



Warnings:

- This entire mechanism may become obsolete when the W3C standardizes the event handling process for the Document Object Model.

See also:	`captureEvents()`, Event handler, Event management, Event propagation, `Frame` object, `handleEvent()`, `Layer.routeEvent()`, `Window` object, `Window.handleEvent()`

Window.screen (Property)

A reference to a `Screen` object that the window is being displayed in.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0 Opera - 5.0	
Property/method value type:	`Screen object`	
JavaScript syntax:	-	`myWindow.screen`
	-	`screen`

The object returned by this property is shared by all windows since there is only one `Screen` object for the entire browser.

Refer to the `Screen` object topic for details of how you can examine its properties. There are some minor differences between MSIE and Netscape Navigator regarding the properties that their `Screen` objects support.

The WebTV box yields an object that describes the properties of a device that operates at TV display resolution.

Warnings:

- This may not behave the same on all platform configurations. Consider the possibility of having several monitor screens. Some OS platforms insist on all screens being the same size and resolution in which case a single `Screen` object will suffice.
- In the case of the Macintosh Operating System, you may have several screens, each of which can be a different size, orientation and color depth. Indeed, you can even mix monochrome and color screens. One will be the main screen by virtue of it having the menubar placed on it. The screens can be positioned relative to one another in any orientation.
- So for an OS such as Mac OS, a single `Screen` object may not suffice. However, the browser manufacturers may not fully support this. You will need to test this if it is important to your application. It is possible there will still be a single `Screen` object and that it will represent the master screen. However it might represent the screen that the window is positioned on.

- The Macintosh OS is somewhat unique in that a window may span several screen displays. This would make it difficult for any `Screen` object (or even several) to accurately represent the real world.

See also:	JellyScript, `Screen` object

Property attributes:

`ReadOnly`.

Window.screenLeft (Property)

The left edge of the screen.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myWindow*`.screenLeft`
	IE	`screenLeft`

This is the offset of the left edge of the window from the edge of the screen display.

The equivalent value in Netscape Navigator can be obtained from the `Window.screenX` property.

See also:	`Window.screenX`

Property attributes:

`ReadOnly`.

Window.screenTop (Property)

The top edge of the screen.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myWindow*`.screenTop`
	IE	`screenTop`

This is the offset of the top edge of the window from the top of the screen display.

The equivalent value in Netscape Navigator can be obtained from the `Window.screenY` property.

See also:	Window.screenY

Property attributes:

ReadOnly.

Window.screenX (Property)

The X coordinate of the window within the screen display.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myWindow*.screenX
	N	*myWindow*.screenX = *aCoordinate*
	N	screenX
	N	*screenX* = *aCoordinate*
Argument list:	*aCoordinate*	A pixel position on the screen

This is the horizontal coordinate of the left edge of the Netscape Navigator window. For a Window object that represents the contents of a frame in a frame-set, this value will be the left edge of the containing top level window.

The equivalent value in MSIE can be obtained from the Window.screenLeft property.

See also:	Window.screenLeft

Window.screenY (Property)

The Y coordinate of the window within the screen display.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	Number primitive	
JavaScript syntax:	N	*myWindow*.screenY
	N	*myWindow*.screenY = *aCoordinate*
	N	screenY
	N	screenY = *aCoordinate*
Argument list:	*aCoordinate*	A pixel position on the screen

This is thevertical coordinate of the top edge of the Netscape Navigator window. For a `Window` object that represents the contents of a frame in a frame-set, this value will be the top edge of the containing top level window.

The equivalent value in MSIE can be obtained from the `Window.screenTop` property.

See also:	`Window.screenTop`

Window.scroll() (Method)

This is equivalent to the `scrollTo()` method but has been retained for backwards compatibility.

Availability:	JavaScript - 1.1 JScript - 3.0 Internet Explorer - 4.0 Netscape - 3.0 Opera - 3.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	`myWindow.scroll(aPositionX, aPositionY)`
	-	`scroll(aPositionX, aPositionY)`
Argument list:	*`aPositionX`*	A position in pixels
	`aPositionY`	A position in pixels
Deprecated:	JavaScript - 1.2	

The window content will be scrolled by the amount specified in the X and Y values.

Warnings:

- You should use the `scrollTo()` method in preference to this one as it is now deprecated.
- Vertical scrolling in Netscape Navigator moves in the reverse direction to MSIE. Because the standard is ambiguous on this point, you will need to check this on other implementations.
- Netscape Navigator will only permit a document to be scrolled if the scroll bars are active and visible. MSIE does not care whether the scroll bars are visible or whether you are scrolling the document past its end point. Netscape Navigator however allows layers to be scrolled anyhow.

See also:	`Frame` object, `Window` object, `Window.scrollBy()`, `Window.scrollTo()`

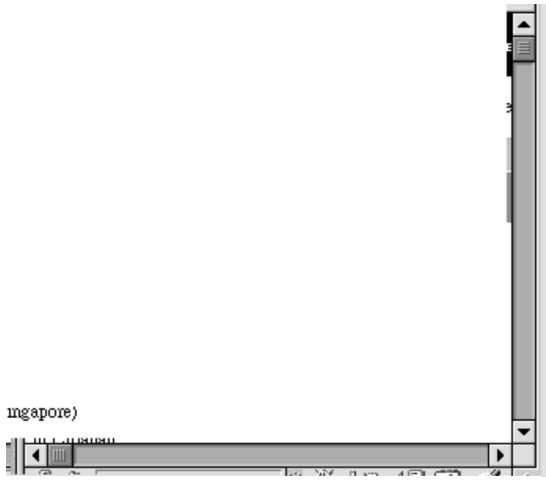
Window.scrollbars (Property)

A reference to an object that represents the scroll bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	*myWindow*.scrollbars
	-	scrollbars

This is a read-only property containing a reference to a `Bar` object whose visible property contains a Boolean value that controls the visibility of the screen furniture represented by the object.

In this case, it is supposed to control the visibility of the scroll bars.



Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the scrollbars.

Example code:

```
// Request necessary privileges
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite");
// Hide scroll bars
window.scrollbars.visible = false;
// There is another way that works without requesting privilege
window.open('', '_top', 'scrollbars=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.locationbar`, `Window.menubar`, `Window.personalbar`, `Window.statusbar`, `Window.toolbar`

Property attributes:

`ReadOnly`.

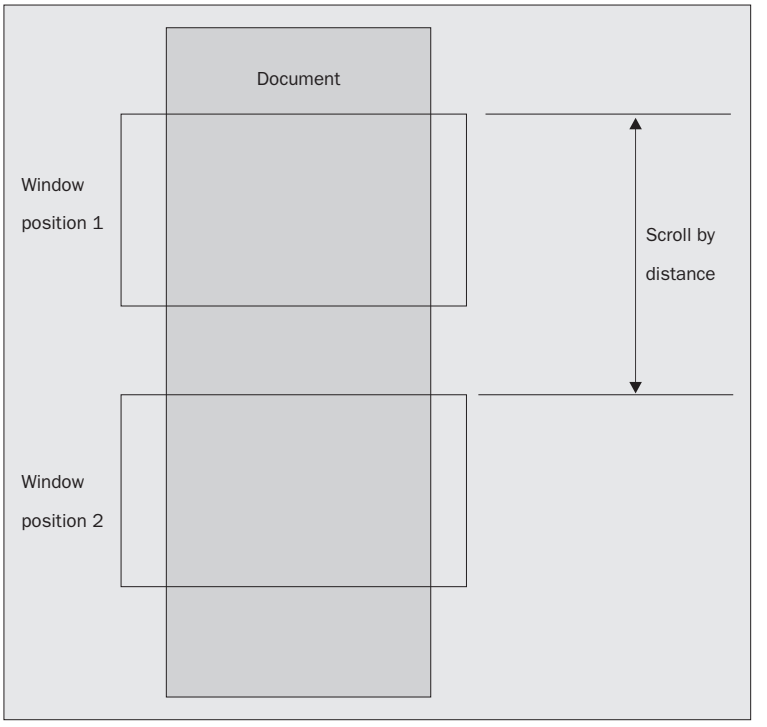
Window.scrollBy() (Method)

Scroll the document in the window by a specific amount.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.scrollBy(`*anOffsetX*`,` *anOffsetY*`)`
	-	`scrollBy(`*anOffsetX*`,` *anOffsetY*`)`
Argument list:	*anOffsetX*	A distance in pixels
	anOffsetY	A distance in pixels

This method will scroll the window relative to its current position by the indicated amount. You can scroll in either the horizontal or vertical axis or even both at once.

Although the method is supported by MSIE and Netscape Navigator, they scroll in opposite directions vertically. It was probably too much to expect them to support the feature in the same way.



Warnings:

- Vertical scrolling in Netscape Navigator moves in the reverse direction to MSIE. Because the standard is ambiguous on this point, you will need to check this on other implementations.
- Netscape Navigator will only permit a document to be scrolled if the scroll bars are active and visible. MSIE does not care whether the scroll bars are visible or whether you are scrolling the document past its end point. Netscape Navigator however allows layers to be scrolled anyhow.

See also:	`Frame` object, `Window` object, `Window.moveBy()`, `Window.moveTo()`, `Window.pageXOffset`, `Window.pageYOffset`, `Window.scroll()`, `Window.scrollTo()`

Window.scrollTo() (Method)

Scroll the document in the window to a specific location.

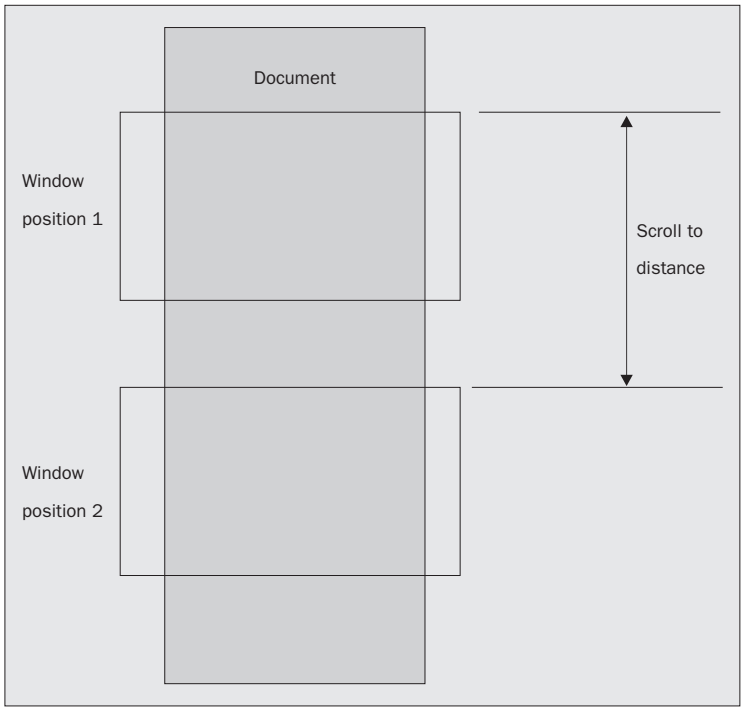
Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.scrollTo(`*aPositionX*`,` *aPositionY*`)`
	-	`scrollTo(`*aPositionX*`,` *aPositionY*`)`
Argument list:	*aPositionX*	A location in pixels
	aPositionY	A location in pixels

This method will scroll the window to an absolute position specified by the two values. You can scroll in either the horizontal or vertical axis or even both at once.

Although the method is supported by MSIE and Netscape Navigator, they scroll in opposite directions vertically.

You can use this scrolling facility to bring a specific anchor into view. You would do this by enquiring of the anchor what its X and Y coordinates are and then using that as a scroll destination.

You should use this method in preference to the `window.scroll()` method which is now deprecated.



Warnings:

- Vertical scrolling in Netscape Navigator moves in the reverse direction to MSIE. Because the standard is ambiguous on this point, you will need to check this on other implementations.
- Netscape Navigator will only permit a document to be scrolled if the scroll bars are active and visible. MSIE does not care whether the scroll bars are visible or whether you are scrolling the document past its end point. Netscape Navigator however allows layers to be scrolled anyhow.

See also:	`Anchor` object, `Frame` object, `Window` object, `Window.scroll()`, `Window.scrollBy()`

Window.secure (Property)

A flag indicating that a window was loaded from a secure source.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	N	*myWindow*`.secure`
	N	`secure`
Argument list:	*false*	Window is not currently securely served
	true	Window was loaded from a secure location

This value will be set to `true` if the window contents were delivered from a secure source (probably via the `https:` protocol). Normally this value will be `false`, as is the case if the window is loaded from a local file. That would seem a little strange in that you probably have to have local access control permissions to reach a file on the local file system and one would have thought that would be secure and meriting a `true` value in this property.

Property attributes:

`ReadOnly`.

Window.self (Property)

A reference to the window itself.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*`.self`
	-	`self`

This is another name for the `window.window` property in this context. However, `self` is useful because you can build reusable scripts with it that can be used with a variety of object types and instances. Don't forget that this can also refer to a frame as well as a window since they are both represented by the `window` object.

The `self` property can be used without the `window` prefix because it belongs to the global object in a web browser window. Using the `self` keyword like this makes no difference to the functionality of your script but it does make it easier to understand. For the same reason, you may want to use the `window` property in the same way.

See also:	Frame object, `self`, `Window` object, `Window.frame`, `Window.window`

Property attributes:

`ReadOnly`.

Window.setHotkeys() (Method)

Activate or deactivate keyboard shortcuts for this window.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.setHotKeys(`*aSwitch*`)`
	N	`setHotKeys(`*aSwitch*`)`
Argument list:	*aSwitch*	A Boolean switch value

This provides a way to turn keyboard short-cuts on and off. For windows that you create with the `window.open()` method, you can control this with the feature list that you pass to the `open()` method.

Pass a `true` value to activate the hot keys and a `false` value to deactivate them.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to call this method in Netscape Navigator.
- Beware of the spelling, the word 'keys' is not capitalized inside this function name.

See also:	`UniversalBrowserWrite`

Window.setInterval() (Method)

Schedule a function to be executed at regular intervals.

Availability:	JavaScript - 1.2 JScript - 3.0 Internet Explorer - 4.0 Netscape - 4.0
Property/method value type:	`Number primitive`

JavaScript syntax:	-	*myWindow*.setInterval(*aFunction*, *anInterval*)
	-	*myWindow*.setInterval(*aFunction*, *anInterval*, *someArguments*)
	-	myWindow.setInterval(*aFunction*, *anInterval*, *someArguments*, *aLanguage*)
	-	myWindow.setInterval(*aSourceText*, *anInterval*)
	-	myWindow.setInterval(*aSourceText*, *anInterval*, *someArguments*)
	-	*myWindow*.setInterval(*aSourceText*, *anInterval*, *someArguments*, *aLanguage*)
	-	setInterval(*aFunction*, *anInterval*)
	-	setInterval(*aFunction*, *anInterval*, *someArguments*)
	-	setInterval(*aFunction*, *anInterval*, *someArguments*, *aLanguage*)
	-	setInterval(*aSourceText*, *anInterval*)
	-	setInterval(*aSourceText*, *anInterval*, *someArguments*)
	-	setInterval(*aSourceText*, *anInterval*, *someArguments*, *aLanguage*)
Argument list:	*aFunction*	A function object
	aLanguage	A scripting language to execute the script source (MSIE only)
	anInterval	A time interval in milliseconds
	aSourceText	Some valid script source text
	someArguments	The arguments to the function object (not supported in MSIE version 4)

The `setInterval()` method establishes a periodically scheduled execution timer that runs the same fragment of script continuously with a delay timer between each cycle.

If you only want to delay the execution of some code and you want it to be executed just once, then use the `setTimeout()` method instead. That will defer execution and clear its timer automatically when it executed.

Passing a function as one of the arguments is only supported in MSIE from version 5.0 upwards and Netscape Navigator from version 4 upwards. You can only specify the scripting language in MSIE however.

The simpler form in which a script source text can be passed in a string with a second argument to specify the interval is much more portable and recommended for use. You can pass a multiple line script fragment in this argument as long as each line is separated by a semi-colon. Functionally, this is very similar to the `eval()` method with an extra repeat periodicity value.

Be careful that you note the value returned by this method if you intend to deactivate the periodic execution. Without that value, you have no way to identify which one of possibly several timers you want to cancel, and take care not to cancel the timer more than once. Cancelling a non-existent periodic timer or deferred action is likely to crash your browser.

The result of this method is an identifying value that can be used with the `clearInterval()` method to cancel this periodic execution.

Warnings:

- The functionality of this method is more limited in MSIE version 4. It does not support the passing of a function object and its arguments in separate parameters. However since you can define a fragment of JavaScript to call a function there are few circumstances where this will be a problem. It does prevent you from manufacturing a function object and calling it though.
- On the other hand, implementing something that is non-portable across the MSIE and Netscape Navigator browsers is a bad idea anyway.
- Be careful how you operate on these interval timers. You can store an identifier, which you can later use to cancel the timer. However, if the timer has already been fired, some browsers may crash due to you trying to cancel a non-existent timer.
- Write your periodically executed code carefully to avoid memory leaks, as any repetitive code that leaks memory will rapidly slow the performance of the user's browser. It is not hard to leak as much as 50K bytes per loop in JavaScript. This will rapidly fill your memory and eventually the browser may crash. Even worse, memory leaks have a nasty habit of bringing the operating system down as well.

See also:	`eval()`, `Frame` object, Interval handlers, Memory leak, Timeout handlers, `Window` object, `Window.clearInterval()`, `Window.setTimeout()`

Window.setResizable() (Method)

Enable or inhibit the window resize capability.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.setResizable(`*aSwitch*`)`
	N	`setResizable(`*aSwitch*`)`
Argument list:	*aSwitch*	A Boolean value to control the functionality

This provides a way to allow or deny user access to window resizing facilities.

This switches the resize feature on and off, which is something you can control in new windows you create with the `open()` method when you specify the resizable feature.

Your script needs `UniversalBrowserWrite` privileges to use this method.

Warnings:

- Some platforms will not support this facility due to the way their window manager operates. This is likely to be supported on desktop systems and less likely to work on workstations that use X-Windows.

See also:	`UniversalBrowserWrite`

Window.setTimeout() (Method)

A timeout control method.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	-	*myWindow*.setTimeout(*aFunction*, *aWaitTime*)
	-	*myWindow*.setTimeout(*aFunction*, *aWaitTime*, *someArguments*)
	-	*myWindow*.setTimeout(*aFunction*, *aWaitTime*, *someArguments*, *aLanguage*)
	-	*myWindow*.setTimeout(*aSourceText*, *aWaitTime*)
	-	*myWindow*.setTimeout(*aSourceText*, *aWaitTime*, *someArguments*)
	-	*myWindow*.setTimeout(*aSourceText*, *aWaitTime*, *someArguments*, *aLanguage*)
	-	setTimeout(*aFunction*, *aWaitTime*)
	-	setTimeout(*aFunction*, *aWaitTime*, *someArguments*)
	-	setTimeout(*aFunction*, *aWaitTime*, *someArguments*, *aLanguage*)
	-	setTimeout(*aSourceText*, *aWaitTime*)
	-	setTimeout(*aSourceText*, *aWaitTime*, *someArguments*)
	-	setTimeout(*aSourceText*, *aWaitTime*, *someArguments*, *aLanguage*)
Argument list:	*aFunction*	A function object
	aLanguage	A scripting language to execute the script source (MSIE only)
	aWaitTime	A time interval in milliseconds
	aSourceText	Some valid script source text
	someArguments	The arguments to the function object (not supported in MSIE version 4)

The `setTimeout()` method provides a way to defer the execution of a fragment of script source text. It is analogous to the `eval()` method with a delay before execution. Although this method returns an ID value that can then be used with the `clearTimeout()` method to cancel the execution, it is very likely that the deferred code will have executed already. You should set a flag accordingly so that you can avoid killing a deferred task that has already been completed. Attempting to kill deferred tasks that are no longer pending can crash your browser.

Code executed by this deferred mechanism will only be executed once. If you want it to be executed continuously then `setInterval()` is a better alternative. On the other hand, you may want to conditionally defer it again in which case you should call a handler function and, before exiting it, make another call to `setTimeout()` to activate another deferred task.

As is the case with `setInterval()` and `eval()`, you can execute multiple statements as long as they are separated by semi-colons.

Passing a function as one of the arguments is supported by MSIE in version 5 upwards and by Netscape Navigator in version 4 upwards. The scripting language can only be defined in MSIE.

This facility may be used to present a message in the status bar and then clear it again after some period of time has elapsed. It can be used to generate some animation in the status bar, although many people consider this to be a design cliche and much overused. If you do animate the status bar, you should consider whether it is useful and not distracting.

These timed animations are generally best triggered by an `onLoad` event handler.

Note that the deferred code is executed in the context and scope chain of the `window` object that received the method call to set up the deferred task.

The example is a cut down version of the ticker script used in the BBC News Online web site. The display techniques are the same but the example only shows one story. To see the real ticker in operation, refer to http://www.bbc.co.uk/news and view it with an MSIE browser. In the News Online ticker, many coding compromises were necessary to work round object boundary bugs in the MSIE for Macintosh browser. Because the ticker is constantly being updated, the object boundary is changing all the time and although this was played in an `<IFRAME>`, the mouse enter and mouse out events caused the MSIE browser to crash frequently. Earlier versions of the ticker also did a large amount of string creation/destruction which caused somewhat massive memory leaks. You can alleviate this by using meta refresh tags to force the garbage collection to happen.

Warnings:

- Be careful how you operate on these interval timers. You can store an identifier, which you can later use to cancel the timer. However, if the timer has already been fired, some browsers may crash due to you trying to cancel a non-existent timer.
- This method leaks somewhat badly in Netscape 2.

Example code:

```
<HTML>
<HEAD>
<STYLE  TYPE="text/css">
<!--
A
{
   font-family: Verdana, Arial, Helvetica, sans-serif, "MS sans serif";
   font-size: 11px;
   line-height: 11px;
   text-decoration: none;
   color: #333366;
   font-weight: bold;
}

A.latest
{
   color: #CC3300;
}

A:hover
{
   color: #CC3300;
}
-->
</STYLE>
<SCRIPT LANGUAGE=JAVASCRIPT>
// This script will only work on MSIE
var theTickerText       = "The ticker text goes here and plays out until it is
finished before repeating again.";
var theCharacterTimeout = 45;
var theStoryTimeout     = 5000;
var theEnumerator       = 0;
// --- Run the ticker
function doTheTicker()
{
   if((theEnumerator % 2) == 1)
   {
      writeTicker("_");
   }
   else
   {
      writeTicker("*");
   }

   theEnumerator++;

   if(theEnumerator == theTickerText.length+1)
   {
      writeTicker("");
      theEnumerator = 0;
      setTimeout("doTheTicker()", theStoryTimeout);
   }
   else
   {
      setTimeout("doTheTicker()", theCharacterTimeout);
   }
}
```

```
function writeTicker(aWidget)
{
   document.all.hottext.innerHTML = theTickerText.substring(0,theEnumerator) +
aWidget;
}
</SCRIPT>
</HEAD>
<BODY onLoad="doTheTicker();">
<A ID="latest" CLASS="latest" HREF="/" target=_top>LATEST: </A><A ID="hottext"
HREF="/"></A>
</BODY>
</HTML>
```

Window.setZOptions() (Method)

Define the window stacking behavior.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	N	*myWindow*`.setZOptions(`*anOptionValue*`)`
	N	`setZOptions(`*anOptionValue*`)`
Argument list:	*anOptionValue*	One of a range of possible settings for the feature

When you call the `window.open()` method, there are several feature values that can be used to control the Z-Ordering of the windows. This method provides a way to modify the settings of the Z-Ordering after the window has already been created.

The option value should be one of the following:

Feature	Description
`alwaysRaised`	The window should always be at the top of the stack of windows even when it does not have input focus.
`alwaysLowered`	The window should always be at the bottom of the stack of windows even when it does have the input focus.
`z-lock`	The window should always be at the same Z position in the stack of windows regardless of which window has the focus.
empty	The window exhibits normal stacking behavior; it is brought to the top when it has the focus.

These options are spelled the same as they are when you use them in the `window.open()` method. Naturally, they are mutually exclusive and you can use only one of them at a time.

With this special Netscape Navigator functionality and some careful use of the `window.open()` method, you can effectively simulate the same behavior as that of the MSIE supported modal window. You will need to use global variables and intra-window method calls to pass arguments, however.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to call this method in Netscape Navigator.

See also:	`UniversalBrowserWrite`, `Window.showModalDialog()`

Window.showHelp() (Method)

Display the help window.

Availability:	JScript - 3.0 Internet Explorer - 4.0	
Property/method value type:	`Window object`	
JavaScript syntax:	IE	`myWindow.showHelp(`*aURL*`)`
	IE	`showHelp(`*aURL*`)`
Argument list:	*aURL*	The URL of a help page

This will call up the online help facility of the browser.

Warnings:

- This is not supported on the Macintosh platform.

See also:	Dialog boxes, `Dialog` object

Window.showModalDialog() (Method)

Display a modal dialog.

Availability:	JScript - 3.0 Internet Explorer - 4.0
Property/method value type:	`User defined`

JavaScript syntax:	IE	*myWindow*.showModalDialog(*aURL*, *someArguments*)
	IE	*myWindow*.showModalDialog(*aURL*, *someArguments*, *someFeatures*)
	IE	showModalDialog(*aURL*, *someArguments*)
	IE	showModalDialog(aURL, *someArguments*, *someFeatures*)
Argument list:	*aURL*	A URL to load into the modal dialog
	someArguments	Aggregated arguments to pass to the modal dialog
	someFeatures	Window adornment features

The MSIE browser supports a special window that behaves like a normal window, except that it does not permit any other action until it is dismissed.

To present a modal dialog, you call this method which does not return until the window is dismissed. When the window is dismissed, whatever the `returnValue` property of that window was set to will be returned as the result of this method call.

You must specify a URL to be loaded into the window and you can also pass arguments to it to control the behavior of any content with some scripts that get loaded with the page. It is that script code which will ultimately store something in the `returnValue` property of the window before calling `window.close()` to dismiss the window. The arguments are passed by aggregating them into an array or object which is then 'unpacked' inside the modal dialog's context.

This is only supported on MSIE but you can simulate most of its functionality quite easily in Netscape Navigator. Passing values in and out becomes somewhat tricky but you can accomplish that by passing property values via calls to scripts in other windows or by setting properties belonging to objects that you know will persist long enough for them to be retrieved. However, note that you may not be able to simulate the interlocking modality quite as easily.

A third optional argument can be specified in a similar way to the feature list of a `window.open()` method. You might put values such as this in the third argument to control the size of the new dialog:

```
"dialogWidth:5cm; dialogHeight:10cm; dialogTop:0cm; dialogLeft:0cm"
```

Note that they are a number and a measurement unit in the manner of the CSS positioning style controls. If you don't specify a measurement unit, then MSIE 4 assumes you are measuring in ems and MSIE 5 assumes pixels.

Here is a list of the features that can be applied to a modal dialog window as it is opened:

Feature	Range	Default	Description
`center:`	`yes`, `no`, `1`, `0`, `on`, `off`	`yes`	Controls dialog window centering within the desktop.
`dialogHeight:`	height value	none	Sets the dialog window height
`dialogHide:`	`yes`, `no`, `1`, `0`, `on`, `off`	`no`	Controls the dialog window visibility when printing or using print preview. This feature is only available when a dialog box is opened from a trusted application.
`dialogLeft:`	left position	none	Sets the left edge coordinate of the dialog window relative to the upper-left corner of the desktop.
`dialogTop:`	top position	none	Sets the top edge coordinate of the dialog window relative to the upper-left corner of the desktop.
`dialogWidth:`	width value	none	Sets the dialog window width
`edge:`	`sunken`, `raised`	`raised`	Defines the dialog window edge style
`help:`	`yes`, `no`, `1`, `0`, `on`, `off`	`yes`	Controls the context-sensitive Help icon.
`resizable:`	`yes`, `no`, `1`, `0`, `on`, `off`	`no`	Controls the resize box.
`scroll:`	`yes`, `no`, `1`, `0`, `on`, `off`	`yes`	Defines whether the dialog window has scrollbars.
`status:`	`yes`, `no`, `1`, `0`, `on`, `off`	Varies	Defines whether the dialog window has a status bar. The default is `yes` for dialog windows that aren't trusted and `no` for trusted dialog windows.
`unadorned:`	`yes`, `no`, `1`, `0`, `on`, `off`	`no`	Controls the border window chrome. This feature is only available when a dialog box is opened from a trusted application.

The result of this method call is the value stored in the `returnValue` property of the modal window before it is dismissed.

The example demonstrates how to pass some argument values in an array and how to return a value entered by the user.

Warnings:

- Note that the feature list for a modal dialog is different to the feature list used in a `window.open()` method.
- The Macintosh version of MSIE does not appear to support the dialog sizing controls although you can write and then read back values in the properties that control size and position.
- On the Macintosh variant of MSIE version 5, a modal dialog is displayed but if its contents are scrolled, they can degenerate the off-screen buffer resulting in weird tearing effects in the image data. This may be due to having an <IFRAME> in the window or it may be caused by a timing problem with multiple clicks on the scroll bar in rapid succession.

Example code:

```
<!-- Save this in demo.html -->
<HTML>
<HEAD>
</HEAD>
<BODY>
<SCRIPT>
myArray = new Array(100, 200, "XXX", "YYY");
myReturnValue = showModalDialog("./page.html", myArray);
alert("Value returned from window is "+myReturnValue);
</SCRIPT>
</BODY>
</HTML>
-----------------------------------------------------------------
<!-- Save this in page.html in the same folder -->
<HTML>
<HEAD>
</HEAD>
<BODY>
Hi there!!<HR>Input values are:
<BR>
<BR>
<SCRIPT>
for(myEnum=0; myEnum<dialogArguments.length; myEnum++){   document.write(myEnum);
document.write(" - ");   document.write(dialogArguments[myEnum]);
document.write("<BR>");
}
returnValue = prompt("What do you want to send back");
</SCRIPT>
</BODY>
</HTML>
```

See also:	Dialog boxes, `Dialog` object, `Frame` object, `Window` object, `Window.dialogArguments`, `Window.returnValue`, `Window.setZOptions()`

Window.showModelessDialog() (Method)

Display a modeless dialog window.

Availability:	JScript - 5.0 Internet Explorer - 5.0	
Property/method value type:	`Window object`	
JavaScript syntax:	IE	*myWindow*.showModelessDialog(*aURL*, *someArguments*)
	IE	*myWindow*.showModelessDialog(*aURL*, *someArguments*, *someFeatures*)
	IE	showModelessDialog(*aURL*, *someArguments*)
	IE	showModelessDialog(*aURL*, *someArguments*, *someFeatures*)

Argument list:	*aURL*	A URL to load into the modeless dialog
	someArguments	Arguments to pass to the modeless dialog
	someFeatures	Window adornment features

The MSIE browser supports a special window that behaves like a modal dialog but can be switched into the background. This is therefore a modeless dialog. Because it does not operate in a modal fashion, it does not lock out other activity in the browser. Having called this method to display a modeless dialog, the function returns immediately and the script that called it will continue execution. The opening window can continue to receive input if necessary, which you might find useful for opening palette windows, for example.

The result of this method call is a reference to the window object that represents the modeless dialog.

You must specify a URL value in the first argument for a document to be loaded into the window.

The second argument passes some arguments to the modeless dialog in the same way as you might to a modal dialog.

A third optional argument can be specified in a similar way to the feature list of a `window.showModalDialog()` method. However, note that the feature list is different to that for a normal window created with a `window.open()` method call. Refer to the `window.showModalDialog()` topic for details of the feature list for modal or modeless dialog windows.

See also:	Dialog boxes, `Dialog` object`Window.showModalDialog()`

Window.sidebar (Property)

A reference to an object that represents the sidebar frame in Netscape 6.0.

Availability:	JavaScript - 1.5 Netscape - 6.0	
Property/method value type:	`Sidebar object`	
JavaScript syntax:	N	`myWindow.sidebar`
	N	`sidebar`

This is a new property introduced to support the sidebar in Netscape 6. In essence this introduces a permanent second frame that can be used to hold navigational content. Actually its capabilities seem quite powerful and since it can have HTML loaded into it and can be addressed with JavaScript some interesting possibilities await us as we explore it further.

See also:	`Sidebar` object

Window.status (Property)

A property containing the text displayed in the status bar.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	-	*myWindow*.status
	-	*myWindow*.status = aString
	-	status
	-	status = *aString*
Argument list:	*aString*	A string to display in the status bar

This property should be used to set a transient value for the status bar when providing some rollover management.

This is ideal for use in event handlers or fragments of code being executed with a deferred task. Normally setting this from a script would display the status text only momentarily until the user moved the mouse or the document finished loading.

When the status text is erased, the defaultStatus value of the window will usually be the text that overwrites it, unless some other text is called in the meantime. It really depends on what event handlers are invoked as the mouse moves.

In Netscape Navigator, setting the status value in a submit button `onClick` handler instantly updates the value displayed in the status bar. However as soon as you roll off the button, the `defaultStatus` value is displayed instead and the transient status value is lost. Rolling back onto the submit button won't display it again because it was set by the `onClick` handler.

In MSIE, the behavior of the status and `defaultStatus` properties is so nearly identical as to be hard to distinguish one from the other.

The status message box belongs to the top level window. This means that it behaves with some slight differences if there are multiple frames and the status and `defaultStatus` properties are set from inside them. This is also prone to differences between browsers and it is recommended that you experiment somewhat to achieve exactly the desired behavior you want to make sure it is consistent across the two main browsers.

Setting this value in the `onMouseOver` event handler requires that you signal the browser to not immediately update the status bar value when the handler exits. To do this, return a Boolean `true` value to inhibit any further browser activity. Likewise, you'll also need to do this in a `onMouseMove` handler. The example illustrates a simple "mouse'O'meter" to display the current mouse coordinates as the mouse moves. This only works in MSIE, however, and then only while the window has focus. This might be useful when working out where to position objects with dynamic HTML.

Frame-set contents that run script to set status bar values might operate better if you explicitly tell them to set the status property that belongs to the top level window. That is accessible via the top property, thus:

```
top.status = "ABCD";

window.top.status = "ABCD";

top.defaultStatus = "ABCD";

window.top.defaultStatus = "ABCD";
```

Warnings:

- Beware that some browsers do not correctly restore the status bar to its default condition after the rollover is deactivated by moving the mouse pointer somewhere else. This is the case for Netscape 2 and 3 on the Windows platform. Adding an `onMouseOut` handler may provide a satisfactory work around.

Example code:

```
<BODY onMouseMove="mouseOmeter();">
<SCRIPT>
// An example mouse coordinate display for MSIE

function mouseOmeter()
{
   window.status = window.event.x + "," + window.event.y;
   return true;
}
```

See also:	`Frame` object, `onMouseOut`, `onMouseOver`, Status line, `Window` object, `Window.defaultStatus`

Window.statusbar (Property)

A reference to an object that represents the status bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`Bar object`	
JavaScript syntax:	-	*myWindow*`.statusbar`
	-	`statusbar`

This is a read-only property containing a reference to a `Bar` object whose `visible` property contains a Boolean value that controls the visibility of the screen furniture represented by the object, in this case, the status bar.

Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the status bar.

Example code:

```
// Request necessary privileges
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite");
// Hide status bar
window.statusbar.visible = false;
// There is another way that works without requesting privilege
// window.open('', '_top', 'status=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.locationbar`, `Window.menubar`, `Window.personalbar`, `Window.scrollbars`, `Window.toolbar`

Property attributes:

`ReadOnly`.

Window.stop() (Method)

This duplicates the behavior of the Stop button on the Netscape Navigator button bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	`undefined`	
JavaScript syntax:	-	*myWindow*`.stop()`
	-	`stop()`

This is a means of immediately halting the script being executed. It's likely this will mainly be used in an error handler, although you may want to conditionally prevent a form from being submitted.

It is effectively the same as clicking on the Stop button in the toolbar.

Warnings:

- Since this is only supported on Netscape Navigator, it is not a portable feature and not recommended for deployment.

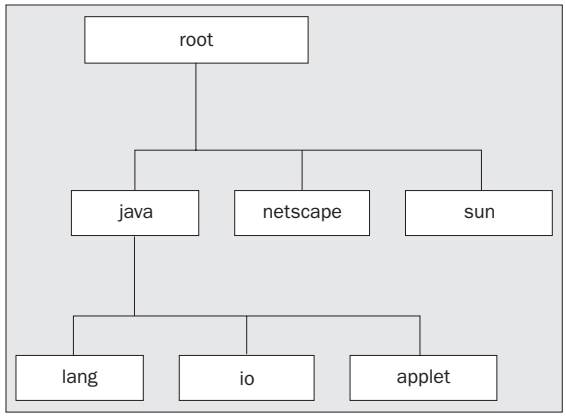
See also:	`Frame` object, `Window` object, `Window.find()`, `Window.home()`, `Window.print()`

Window.sun (Property)

A reference to the Java package object that is the root of the 'sun.*' Packages tree.

Availability:	JavaScript - 1.1 Netscape - 3.0	
Property/method value type:	JavaPackage sun	
JavaScript syntax:	N	*myWindow*.Packages.sun
	N	*myWindow*.sun
	N	Packages.sun
	N	sun

The object referred to by this property sits at the top of the sun package name hierarchy. It is through this property that you can access the java objects, properties and methods via LiveConnect.



See also:	JavaPackage object, Window.java, Window.netscape, Window.Packages

Property attributes:

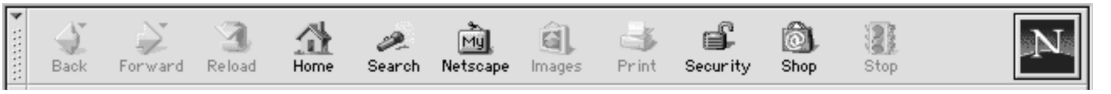
ReadOnly.

Window.toolbar (Property)

A reference to an object that represents the tool bar.

Availability:	JavaScript - 1.2 Netscape - 4.0	
Property/method value type:	Bar object	
JavaScript syntax:	-	*myWindow*.toolbar
	-	toolbar

This is a read-only property containing a reference to a `Bar` object whose `visible` property contains a Boolean value that controls the visibility of the screen furniture represented by the object, which, in this case, is the toolbar.



Warnings:

- Your script will need to be granted the `UniversalBrowserWrite` privilege to allow it to change the visibility of the toolbar.
- Be careful if you set both the menubar and toolbar to invisible, you will then have no reload capability to be able to refresh the screen. You will then only be able to quit.
- In the Netscape Navigator 4 browser for Macintosh, setting the toolbar invisible and then visible restores the tool bar but hides the menu items. On that platform, hiding the toolbar also hides all the other window furniture such, as locationbar and statusbar.

Example code:

```
// Request necessary
privilegesnetscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrit
e");// Hide tool barwindow.toolbar.visible = false;// There is another way that
works without requesting privilegewindow.open('', '_top', 'toolbar=0');
```

See also:	`Bar` object, `Frame` object, `UniversalBrowserWrite`, Window furniture, `Window` object, `Window.locationbar`, `Window.menubar`, `Window.personalbar`, `Window.scrollbars`, `Window.statusbar`

Property attributes:

`ReadOnly`.

Window.top (Property)

The topmost window in a framed hierarchy.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*`.top`
	-	`top`

The `top` property should consistently refer to the window at the top of the hierarchy. The `window` property refers to the current window.

You can test attributes of the top window against attributes of the current window to see if your script is running in a correctly framed context. This may be useful if you have a frame dependent page that may have been linked to by a search engine. You can force the page into the correct frame-set if you can detect that it has been invoked outside of it.

```
if(top != window)
{
// The window is in a frameset
}
```

This property will contain a meaningful value regardless of whether the window is in a frame or not.

If the pages are known to come from the same server, you may want to check the `window.location.href` property against the `top.location.href property`. However, this may cause problems if the pages come from different servers and cause the script to throw a security related exception.

Warnings:

- Note that this value is not necessarily the same as the `parent` property.

See also:	`Frame` object, `Window` object, `Window.frame`, `Window.frames[]`, `Window.parent`, `Window.window`

Property attributes:

`ReadOnly`.

Window.window (Property)

Another name for the `self` property.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Opera - 3.0	
Property/method value type:	`Window object`	
JavaScript syntax:	-	*myWindow*`.window`
	-	`window`

This is another name for the `window.self` property in this context. However, `window` is useful because you can remove the ambiguity associated with accessing global object properties and methods. Don't forget that this can also refer to a frame as well as a window since they are both represented by the `window` object.

If the script is running in the topmost window of a frame-set or within a non-frame-set window, the top property will also be set to the same value.

This property is slightly odd, because the `window` object is also the global object for a web browser. The global object is always placed in the scope chain for a script's execution context. So, all properties that belong to the window are available without requiring the `window` object prefix.

So, these all refer to the same thing:

```
window

window.self

self

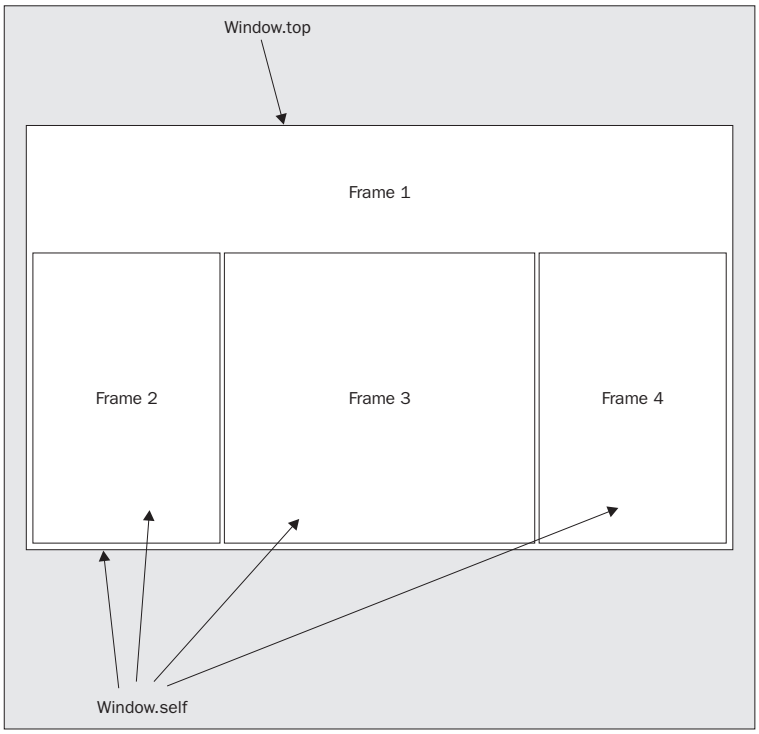
window.window

self.self

self.window.self

window.window.window.window.window.self.window
```

The main use of this property is to yield slightly better readability and clarity in the code you write. The same applies to the `self` property. It is better to explicitly call `window.open()` rather than just `open()`. Explicitly calling `window.open()` avoids an inadvertent call to `document.open()`. You might not be aware of an `open()` method belonging to another object that has been placed into the scope chain ahead of the `window` object.



Warnings:

- Be careful if you are building recursive scripts to walk the window hierarchy, as you could find yourself in an endless loop simply walking via the `window` property of the top level window.

See also:	`Frame` object, `Window` object, `Window.frame`, `Window.self`, `Window.top`

Property attributes:

`ReadOnly`.

Windows Script Host (Product)

A scripting environment available on the Windows platform.

On the Apple Macintosh, the AppleScript operating system extension has provided a way for applications to exploit AppleEvents and execute script-based control over one another.

On Windows, Microsoft introduced Windows Script Host (WSH), which provides a script-driven interface to the underlying COM model. This is a great improvement on the DOS batch commands that were available prior to this. Its still doesn't integrate applications in the way that AppleScript does, instead it integrates data objects with one another, which in some ways may be more powerful as it is a document-centric system. However, it can be difficult to exploit specific capabilities of applications unless they are COM related.

Like AppleEvents, WSH is language independent and you have a choice of languages that you can use for scripting. JScript is becoming more favored lately, although much has been made of VBScript, although it's not as powerful as Visual Basic, on which it is based.

For an in-depth discussion on WSH, consult the Wrox Professional JavaScript book, where a whole chapter is devoted to WSH.

with ... (Statement)

Adds an object to the front of the scope chain for use in the following block of script code.

Availability:	ECMAScript edition - 2 JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.02 Netscape - 2.0 Netscape Enterprise Server - 2.0 Opera - 3.0	
JavaScript syntax:	-	`with( anObject ) { someCode };`
Argument list:	*someCode*	Some code to execute with the enhanced scope chain
	anObject	A reference to an object to add to the scope chain

This statement is provided as a convenience mechanism to simplify your script code and save time and trouble.

When a statement executes, your line of script is running in one context or another. Each context is created and destroyed as functions are called and exit respectively. The contexts are added to an inheritance chain, which allows variables to be shared globally or locally.

The `with` keyword adds an object to the front of the scope chain for the current execution context. This saves you having to describe the full object reference since it is placed in the scope chain and always available and implicitly provided by JavaScript when resolving references to identifiers.

The code in the statement block is then executed while this augmented scope chain is in place. The object that is added to the scope chain is computed by the expression value in parentheses.

When the statement block is executed, the scope chain is restored to its original condition. This happens regardless of how the statement block is completed. Although the ECMA standard is ambiguous on this point, the implication is that a `break` might be appropriate in this context. A `continue` or `return` in the statement block would be inappropriate unless perhaps the `with()` construct is used within an iterator or function. Because of this ambiguity, you may find this behaves differently according to the implementation you are using.

The `with` statement can save you effort typing object names over and over again.

Warnings:

- Even though it is very convenient, it is considered somewhat bad form to use this construct. The code is hard to optimize inside the interpreter, which means it will likely run more slowly. Functions and variables instantiated inside a `with` block do not behave consistently, so it is recommended that you avoid using this construct.

Example code:

```
// Create a new object
var myObject = new Object;
// Add a property containing another object
myObject.itsObject = new Object;
// Add a property to that object
myObject.itsObject.someProperty = "String text";
// Now enhance the scope chain
with(myObject.itsObject)
{
   document.write(someProperty);
}
```

Wrox *Instant JavaScript* – page - 35

WML (Standard)

Wireless Mark-up Language.

This is the markup language used to describe cards (analogous to pages) in a wireless mobile device. This is the framework in which the WScript code will run. This is variously referred to as WScript and WMLScript and should not be confused with the WScript that Microsoft refer to as being a component of WSH.

See also:	Interpret, WAP, WScript

WScript (Standard)

Otherwise known as WMLScript or WAP Script – a variation of JavaScript for use in mobile devices.

This is the somewhat modified version of JavaScript, which is used in WAP mobile devices such as cellphones.

Warnings:

- Be aware that Microsoft have implemented a WScript object as part of the WSH environment. That object has absolutely nothing to do with WAP or mobile telecommunications. It is a container for an object model that is fundamental to WSH.

See also:	Host environment, Interpret, Platform, Script execution, WAP, WML

WScript object (Object/WSH)

An object that represents the object model of the WSH framework.

Availability:	JScript - 3.0	
JavaScript syntax:	WSH	`WScript`
Object properties:	`Application, Arguments, FullName, Name, Network, Path, ScriptFullName, ScriptName, StdErr, StdIn, StdOut, Version`	
Object methods:	`CreateObject(), DisconnectObject(), Echo(), GetObject(), Quit(), Sleep()`	

Property	JavaScript	JScript	N	IE	Opera	Notes
`Application`	-	3.0 +	-	-	-	-
`Arguments`	-	3.0 +	-	-	-	-
`FullName`	-	3.0 +	-	-	-	-
`Name`	-	3.0 +	-	-	-	-
`Network`	-	3.0 +	-	-	-	-

Table continued on following page

Property	JavaScript	JScript	N	IE	Opera	Notes
Path	-	3.0 +	-	-	-	-
ScriptFullName	-	3.0 +	-	-	-	-
ScriptName	-	3.0 +	-	-	-	-
StdErr	-	3.0 +	-	-	-	-
StdIn	-	3.0 +	-	-	-	-
StdOut	-	3.0 +	-	-	-	-
Version	-	3.0 +	-	-	-	-

Method	JavaScript	JScript	N	IE	Opera	Notes
CreateObject()	-	3.0 +	-	-	-	-
DisconnectObject()	-	3.0 +	-	-	-	-
Echo()	-	3.0 +	-	-	-	-
GetObject()	-	3.0 +	-	-	-	-
Quit()	-	3.0 +	-	-	-	-
Sleep()	-	3.0 +	-	-	-	-

WScript.Application (Property)

Access to the IDispatch interface for the object.

Availability:	JScript - 3.0	
Property/method value type:	IDispatch object	
JavaScript syntax:	WSH	*myApplication* = WScript.Application

This mechanism describes how to gain access to the objects, properties, and methods belonging to an external application.

See also:	WScript.GetObject()

WScript.Arguments (Property)

This returns a collection of argument items.

Availability:	JScript - 3.0	
Property/method value type:	WshArguments object	
JavaScript syntax:	WSH	myArguments = WScript.Arguments

The arguments are passed to the WSH script when it is executed. This collection provides a way to access the arguments, possibly by way of an enumerator.

Arguments from the command line or specified by the shortcut that executed the script are passed by means of this collection.

WScript.CreateObject() (Method)

Creates an instance of an automation object.

Availability:	JScript - 3.0	
Property/method value type:	`WScript object`	
JavaScript syntax:	WSH	*`myObject`* `= WScript.CreateObject(`*`aProgID`*`);`
	WSH	*`myObject`* `= WScript.CreateObject(`*`aProgID`*`,` *`aPrefix`*`);`
Argument list:	*`aProgID`*	An application programme ID
	`aPrefix`	A hook into the event model

Calling this method yields an object which can be used to communicate with another application residing in the same computer.

For example, this code creates an object that references the Word application:

```
myWord = WScript.CreateObject("Word.Application");
```

From here we can reference the application via the object. This makes the Word application we just instantiated visible to the user:

```
myWord.Visible = true;
```

WScript.DisconnectObject() (Method)

Discards an object.

Availability:	JScript - 3.0	
JavaScript syntax:	WSH	`WScript.DisconnectObject(`*`anObject`*`)`
Argument list:	*`anObject`*	An object previously created by WSH

This method is used to get rid of objects previously created with the `CreateObject()` and `GetObject()` methods.

WScript.Echo() (Method)

Echoes some output to the caller via standard output.

Availability:	JScript - 3.0	
Property/method value type:	`WScript object`	
JavaScript syntax:	WSH	`WScript.Echo(`*`anArg`*`)`
	WSH	`WScript.Echo(`*`anArg`*`, ...)`
Argument list:	*`anArg`*	A string or numeric value

This works just like the `echo` command in a shell scripting environment.

It takes a variable number of arguments which can be strings or numbers.

The behavior depends on which interpreter is being used. In the cscript interpreter, the results are concatenated together into the output stream. In the wscript interpreter, each `Echo()` call results in an `alert()` dialog box which must be manually dismissed.

WScript.FullName (Property)

The full path and name for the file being executed.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	*`myName`* `= WScript.FullName`

This property contains the full name and path for the file being executed.

See also:	`WScript.ScriptFullName`

WScript.GetObject() (Method)

Access an already existing object rather than creating a new one.

Availability:	JScript - 3.0	
Property/method value type:	`WScript object`	
JavaScript syntax:	WSH	`WScript.GetObject(`*`aPath`*`)`
	WSH	`WScript.GetObject(`*`aPath`*`, `*`aProgID`*`)`
	WSH	`WScript.GetObject(`*`aPath`*`, `*`aProgID`*`, aPrefix)`

Argument list:	*aPath*	The path to an already existing document
	aProgID	An application programme ID
	aPrefix	A hook into the event model

You can use this method to access an object that you know already exists without needing to create a fresh instance. An example of the difference is that `CreateObject()` is used to manufacture new documents via the application while `GetObject()` is used to access existing documents.

Given the object that encapsulates the document, since it is a WScript object, you can access its `Application` property to control the owning application.

See also:	`WScript.Application`

WScript.Name (Property)

A human readable name for the script.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	*myName* `= WScript.Name`

Computers are happy to use arcane names for scripts but WSH provides a way to give your script a human-friendly name. This property returns such a value.

WScript.Network (Property)

A reference to a network management object.

Availability:	JScript - 3.0	
Property/method value type:	`WshNetwork object`	
JavaScript syntax:	WSH	*myNet* `= WScript.Network`

With the object returned by this property, you can manage the network within the computer, mapping in new drives or unmapping existing ones, for instance.

WScript.Path (Property)

The path to the activating WSH executive.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	*myPath* `= WScript.Path`

This property yields a string that describes which, of several, WSH run-time environments is used.

WScript.Quit() (Method)

Terminates the script and returns an error code.

Availability:	JScript - 3.0	
JavaScript syntax:	WSH	`WScript.Quit(`*`anErrCode`*`)`
Argument list:	*`anErrCode`*	An error code to be sent back to the caller

The current instance of cscript or wscript is killed and an error returned to the calling shell.

WScript.ScriptFullName (Property)

The full path and script name.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	*`myName`* `= WScript.ScriptFullName`

With this property, you can dismantle the path to the file and generate relative paths that locate temporary files adjacent to the script that is being executed. If the script is moved, the relative locations move with it.

See also:	WScript.FullName

WScript.ScriptName (Property)

A string containing the name of the script.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	*`myName`* `= WScript.ScriptName`

With this property, you can create scripts that will behave differently according to the name under which they are executed.

WScript.Sleep() (Method)

Suspend the script execution for a while.

Availability:	JScript - 3.0	
JavaScript syntax:	WSH	`WScript.Sleep(aDuration)`
Argument list:	*aDuration*	A value specified in milliseconds

With this method, you can suspend execution for a while without creating a 'busy waiting' loop.

WScript.StdErr (Property)

A write-only stream used for output.

Availability:	JScript - 3.0	
Property/method value type:	`TextStream object`	
JavaScript syntax:	WSH	*myStream* `= WScript.StdErr`

This is only available to WSH scripts being executed from a command line interface. It provides a way for the scripts to communicate error messages back to the caller.

WScript.StdIn (Property)

A read-only stream used for input.

Availability:	JScript - 3.0	
Property/method value type:	`TextStream object`	
JavaScript syntax:	WSH	*myStream* `= WScript.StdIn`

This is only available to WSH scripts being executed from a command line interface. It provides a way for the scripts to receive messages input from the caller.

WScript.StdOut (Property)

A write-only stream used for output.

Availability:	JScript - 3.0	
Property/method value type:	`TextStream object`	
JavaScript syntax:	WSH	*myStream* = `WScript.StdOut`

This is only available to WSH scripts being executed from a command line interface. It provides a way for the scripts to communicate messages back to the caller.

WScript.Version (Property)

A string containing the WSH version number.

Availability:	JScript - 3.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	WSH	`myVersion = WScript.Version`

With this, you can write version dependent code.

WSH (Object model)

The object model used in Windows Script Host.

See also:	WScript.GetObject(), `WScript` object

WSH (Product)

Windows Script Host.

See also:	`.htc`, Scriptlet, Web browser, Windows Script Host

wysiwyg: (Request method)

Special URL method to handle page content when resized in Netscape Navigator.

If a page is generated using JavaScript, then if the page is subsequently resized, this special method is used to encapsulate the previous page location and invoke special handling to ensure that the page is printed properly.

XML (Standard)

Extensible Mark-up Language.

This is gradually becoming commonplace as a way to exchange data between systems. It is also supported by the MSIE browser and you can load in XML documents directly.

It is the future direction that HTML will evolve towards, beginning with XHTML.

This topic is the entry point to complete new subject area. Its too vast to attempt to cover it meaningfully in just a few pages and yet it's probably going to become one of the most important parts of the web programming landscape.

Refer to the Wrox XML reference manual for details of how to use it in earnest. Here we will just scratch the surface to begin to see what it looks like.

This creates a new XML document via ActiveX:

```
myXMLDoc = new ActiveXObject("Microsoft.XMLDOM");
```

Having created it, now we can load the contents of a URL into the object:

```
myXMLDoc.load("http://xmlserver.domain.com/reports.xml");
```

This is useful because one big problem with JavaScript in a web browser is that it's very hard to download a data file from a web server to a script without having to work around lots of security issues. This might solve that problem a lot more elegantly.

Now we can begin to look at the contents of the file and extract information from it.

```
myXMLDoc.loadXML("JoeSmith");
```

Now that we have acquired the document we can use the DOM navigation techniques that already work for HTML documents to walk through the XML structures:

```
var myXMLNodeList = myXMLDoc.getElementsByTagName(strNodeName);
```

XML name (Definition)

A strict convention for naming items within an XML compliant document with a well formed token.

An XML name may start with a letter, underscore or colon. However the colon is reserved for use with namespaces and is not fully standardized as of XML version 1.

Subsequent characters in the name may be any one of:

- Letter
- Digit
- Dot (period/full stop)
- Dash (minus sign)
- Underscore
- Colon
- CombiningChar
- Extender

Your name values should not begin with the string "XML" or any sequence of characters that might degenerate to it after case conversion or international character substitution.

Combining characters and Extenders are enumerated in Appendix B of the XML version 1.0 standard.

See also:	`Event.type`

XML object (Object/JScript)

An object that represents a block of XML page content within an HTML document.

Availability:	JScript - 5.0 Internet Explorer version - 5.0		
Inherits from:	`Element` object		
JavaScript syntax:	IE	`myXML = myDocument.all.anElementID`	
	IE	`myXML = myDocument.all.tags("XML")[anIndex]`	
	IE	`myXML = myDocument.all[aName]`	
	-	`myXML = myDocument.getElementById(anElementID)`	
	-	`myXML = myDocument.getElementsByName (aName)[anIndex]`	
	-	`myXML = myDocument.getElementsByTagName ("XML")[anIndex]`	
Argument list:	*`anIndex`*	A reference to an element in a collection	
	`aName`	An associative array reference	
	`anElementID`	The ID value of an Element object	

Object properties:	canHaveHTML, defer, event, htmlFor, src, text, type
Event handlers:	onDataAvailable, onDatasetChanged, onDatasetComplete, onReadyStateChange, onRowEnter, onRowExit, onRowsDelete, onRowsInserted

The MSIE browser can now cope with pages delivered as arbitrary blocks of XML. If it encounters an <XML> tag, then it will instantiate one of these objects to provide JavaScript binding to it. This can also be used to build a small island of XML based content in the middle of an HTML page.

The XML data can sit in an HTML page like this:

```
<XML ID="myBlock">

<METADATA>

<OWNER>Wrox</OWNER>

<DATATYPE>Example</DATATYPE>

<ABSTRACT>This is an example block of text</ABSTRACT>

</METADATA>

</XML>
```

Accessing the text property of the XML object will return all the inner text inside it. To access the components you will need to access the XMLDocument property to expose a DOM document interface. This can be explored using DOM compatible methods and properties.

See also:	Document.readyState, onRowEnter, onRowExit

Property	JavaScript	JScript	Nav	IE	Opera	Notes
canHaveHTML	-	5.0 +	-	5.0 +	-	-
defer	-	5.0 +	-	5.0 +	-	-
event	-	5.0 +	-	5.0 +	-	-
htmlFor	-	5.0 +	-	5.0 +	-	-
src	-	5.0 +	-	5.0 +	-	-
text	-	5.0 +	-	5.0 +	-	-
type	-	5.0 +	-	5.0 +	-	-
onDataAvailable	-	3.0 +	-	4.0 +	-	-
onDatasetChanged	-	3.0 +	-	4.0 +	-	-

Event name	JavaScript	JScript	Nav	IE	Opera	Notes
onDatasetComplete	-	3.0 +	-	4.0 +	-	-
onReadyStateChange	-	3.0 +	-	4.0 +	-	-
onRowEnter	-	3.0 +	-	4.0 +	-	-
onRowExit	-	3.0 +	-	4.0 +	-	-
onRowsDelete	-	3.0 +	-	4.0 +	-	-
onRowsInserted	-	3.0 +	-	4.0 +	-	-

Inheritance chain:

`Element` object, `Node` object

Web-references:

http://msdn.microsoft.com/xml/xmlguide/dom-guide-document.asp

XML.defer (Property)

A property containing a deferral status for the XML block.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myXML.defer`

This can defer the processing of an XML object until later in the page loading and display process.

See also:	SCRIPT.defer

XML.event (Property)

An event object associated with the XML block.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
Property/method value type:	`Event object`	
JavaScript syntax:	IE	`myXML.event`

Events can be associated with an XML object in much the same way that they would be used with others. The model is slightly different because it is more generalised.

The Microsoft documentation lists these event handlers as being appropriate for an XML object:

- `onDataAvailable`
- `onDatasetChanged`
- `onDatasetComplete`
- `onReadyStateChange`
- `onRowEnter`
- `onRowExit`
- `onRowsDelete`
- `onRowsInserted`

See also:	`onDataAvailable, onDataSetChanged, onDataSetComplete, onReadyStateChange, onRowEnter, onRowExit, onRowsDelete, onRowsInserted`

XML.src (Property)

The URL where the contents of the XML block are to be loaded from.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myXML.src`

You may be able to redefine this property value and reload the XML block from a different source.

XML.text (Property)

The textual content of the XML block.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myXML.text`

Any textual content will be yielded up by this property, because XML support is still evolving this property and the XML object may change.

For now, you will get all the text contained within the node and its children.

This means that for the example:

```
<XML ID="myBlock">
<METADATA>
<OWNER>Wrox</OWNER>
<DATATYPE>Example</DATATYPE>
<ABSTRACT>This is an example block of text.</ABSTRACT>
</METADATA>
</XML>
```

The text for the top level object will be:

Wrox Example This is an example block of text.

The text for the object presented by the XMLDocument property will be the same as the text for the contained <METADATA> node.

The text for <OWNER>, <DATATYPE> and <ABSTRACT> nodes will be their individual content.

This means it is important to walk down the tree to the node or group of nodes you want before trying to extract the text.

XML.type (Property)

The MIME type of the XML data file.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
Property/method value type:	`String primitive`	
JavaScript syntax:	IE	`myXML.type`

The MIME type of the document associated with the XML object is accessible through the value of this property.

Refer to the MIME type topic for details of the available MIME types you will likely see in this property.

See also:	MIME types

XML.XMLDocument (Property)

A reference to the top of a DOM hierachy that describes the content of the XML data island.

Availability:	JScript - 5.0 Internet Explorer version - 5.0	
JavaScript syntax:	IE	*myXML*.XMLDocument

Given the example of a block of XML in an HTML document:

```
<XML ID="myBlock">

<METADATA>

<OWNER>Wrox</OWNER>

<DATATYPE>Example</DATATYPE>

<ABSTRACT>This is an example block of text.</ABSTRACT>

</METADATA>

</XML>
```

individual nodes in that so called data island can be accessed through this XMLDocument property. The object returned by this property responds to the `selectSingleNode()` method. The argument to this is the slash separated path to the node within the document you are looking for. The slash separated values are the XML tagnames used to construct the document.

In this example, they all begin with the string `"METADATA"` and since the document only contains one layer inside that, all nodes can be reached with the following strings:

- `METADATA/OWNER`
- `METADATA/DATATYPE`
- `METADATA/ABSTRACT`

Given that our XML block has an ID value of "`myBlock`" this line of script code should yield a reference to an object that encapsulates the `<ABSTRACT>` node:

```
myBlock.XMLDocument.selectSingleNode("METADATA/ABSTRACT")
```

Having accessed the DOM node you want, its content can be examined by looking at its text property.

The example code illustrates this concept as it might be assembled together in a simple form.

Warnings:

- This property returns an undefined value in the Macintosh version of MSIE 5.0 instead of a reference to a DOM document.

Example code:

```
<HTML>
<HEAD>
</HEAD>
<BODY>

<!-- Create an XML island -->
<XML ID="myBlock">
   <METADATA>
      <OWNER TYPE="PUBLISHER">Wrox</OWNER>
      <DATATYPE>Example</DATATYPE>
      <ABSTRACT>This is an example block of text.</ABSTRACT>
   </METADATA>
```

```
</XML>

<SCRIPT>
// Get the DOM document
myXMLDocument = myBlock.XMLDocument;

// Find the node
myNode = myXMLDocument.selectSingleNode("METADATA/ABSTRACT");

// Display the text in the node
alert(myNode.text);

// Now access node attributes and content
myOwner = myXMLDocument.getElementsByTagName('OWNER')[0];
alert(myOwner.getAttribute('TYPE') + ': ' + myOwner.text);
</SCRIPT>
</BODY>
</HTML>
```

XMP object (Object/HTML)

A deprecated object that has been replaced by the PRE object.

Availability:	JavaScript - 1.0 JScript - 1.0 Internet Explorer - 3.0 Netscape - 2.0 Deprecated	
JavaScript syntax:	IE	`myXMP = myDocument.all.anElementID`
	IE	`myXMP = myDocument.all.tags("XMP")[anIndex]`
	IE	`myXMP = myDocument.all[aName]`
	-	`myXMP = myDocument.getElementById(anElementID)`
	-	`myXMP = myDocument.getElementsByName(aName)[anIndex]`
	-	`myXMP = myDocument.getElementsByTagName ("XMP")[anIndex]`
HTML syntax:	`<XMP>`	
Argument list:	*anIndex*	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The ID value of an Element object
See also:	PRE object	

XRay() (Filter/visual)

A visual filter that displays only the element edges.

Availability:	JScript - 3.0 Internet Explorer version - 4.0
See also:	filter - `XRay()`

Year from time (Time calculation)

A date and time algorithm defined as part of ECMAScript.

Availability:	ECMAScript edition –2
Property/method value type:	`Number primitive`

Given a time value, it is helpful to be able to compute a year number from it. The ECMA compliant implementations use the extrapolated Gregorian system to map days to years and compute a time relative to the reference date of 01-January-1970 UTC. From there the year number can be established.

All non-leap years have 365 days with the usual number of days in each month. Leap years have an extra day in February. The calculation shown below uses known leap years and non-leap years to adjust the day numbers and yield the day number of the first day of the given year and then use that to work out the time in milliseconds when the year started:

```
DayFromYear(y) =

365 * (y - 1970) +

floor((y - 1969) / 4) -

floor((y - 1901) / 100) +

floor((y - 1601) / 400)

msPerDay = 86400000

TimeFromYear(y) = msPerDay * DayFromYear(y)

YearFromTime(t) = The largest integer y to make TimeFromYear(y) less than or equal
to t.
```

Example code:

```
<HTML>
<BODY>
<SCRIPT>
// Work out year number from time
var msPerDay = 86400000;
var myMilliseconds = Number(new Date());
document.write(yearFromTime(myMilliseconds));
// Return year number based on time value
function yearFromTime(aMilliseconds)
{
   var myStartYear = 1970;

   while(timeFromYear(myStartYear) < myMilliseconds)
   {
      myStartYear++
   }

   return myStartYear-1;
}

// Work out milliseconds at start of year
function timeFromYear(aYear)
{
   var myTime = msPerDay * dayFromYear(aYear);
   return myTime;
}

// Work out day number from milliseconds
function dayNumber(aMillisecondTime)
{
   var myDay = Math.floor(aMillisecondTime/msPerDay);

   return myDay;
}

// Day from year function
function dayFromYear(aYear)
{
   var myDay = 365 * (aYear - 1970)             +
   Math.floor((aYear - 1969) / 4)   -
   Math.floor((aYear - 1901) / 100) +
   Math.floor((aYear - 1601) / 400);
   return myDay;
}
</SCRIPT>
</BODY>
</HTML>
```

Year number (Time calculation)

A date and time algorithm defined as part of ECMAScript.

Availability:	ECMAScript edition – 2
Property/method value type:	`Number primitive`

In calculating year numbers, ECMA compliant implementations should use an extrapolated Gregorian system. This allows for leap years and non leap years at the turn of the century, 3 out of every four.

There are various calculations related to year numbers. Refer to the various example calculations:

- Days in year
- Day from year
- Time from year
- Year from time
- In leap year

See also:	Broken down time, Days in year, In leap year, Time from year, Year from time

ECMA 262 edition 3 – section – 15.9.1.3

Zero value (Definition)

ECMAScript interpreters must be able to distinguish between +0 and -0.

Availability:	ECMAScript edition - 2
Property/method value type:	`Number primitive`

In the real world, Zero is Zero is Zero. Inside a JavaScript interpreter, certain calculations (most notably `Math.pow()` functions) require the sign of the zero value to be taken into account.

Internally, an ECMA compliant interpreter must be able to distinguish between +0 and -0 although from a mathematical standpoint the values are identical. Where calculations involve the likelihood of +infinity and -infinity, the sign can affect the outcome and so can the sign of the zero value. For example the reciprocal of a very small number.

We have quietly ignored the sign of a zero value where it would make no difference. There are some discussions where it becomes important and so the sign is retained here for illustrative purposes.

See also:	Infinity, Math.pow()

!= (NOT equal) (Operator/equality)

Inequality operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`
See also:	Equal to (==), Equality operator, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), Logical NOT – complement (!), NOT Equal to (!=), NOT Identically equal to (!==), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.9.2

ECMA 262 edition 3 – section – 11.9.2

!== (NOT identical) (Operator/identity)

Compares two values for non-equality and identical type.

Availability:	ECMAScript edition – 3 JavaScript – 1.3 JScript – 1.0 Internet Explorer – 3.02 Netscape – 4.06
Property/method value type:	`Boolean primitive`
See also:	Equal to (==), Equality expression, Equality operator, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Identity operator, Less than (<), Less than or equal to (<=), NOT Equal to (!=), NOT Identically equal to (!==)

Cross-references:

ECMA 262 edition 3 – section – 11.9.5

" (Double quote) (Delimiter)

Double quote string literal delimiter.

Availability:	ECMAScript edition – 2 Opera – 3.0
Property/method value type:	`String primitive`

Refer to:

String literal

Cross-references:

ECMA 262 edition 2 – section – 7.7.3

ECMA 262 edition 3 – section – 7.8.4

$ (Dollar) (Symbol)

A special character allowed to be used in an identifier name.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Opera – 3.0

Refer to:

Identifier

Cross-references:

ECMA 262 edition 2 – section – 7.5

ECMA 262 edition 3 – section – 7.6

$n (Numbered argument) (Property/static)

A property of the global `RegExp` object.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0	
JavaScript syntax:	-	`RegExp.$n`
Argument list:	*n*	An index number

Property attributes:

`ReadOnly`.

Refer to:

`RegExp.$n`

% (Modulo/remainder) (Operator/multiplicative)

Divides one operand by another and yields the remainder.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Divide (`/`), Multiplicative operator, Remainder (`%`), Remainder then assign (`%=`)

Cross-references:

ECMA 262 edition 2 – section – 11.5.3

ECMA 262 edition 3 – section – 11.5.3

%= (Modulo assign) (Operator/assignment)

Divides one operand by another and stores the result in the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Assignment operator, LValue, Multiplicative operator, Remainder (`%`), Remainder then assign (`%=`)

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

& (Bitwise AND) (Operator/bitwise)

Bitwise AND of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Binary bitwise operator, Bitwise AND (`&`), Bitwise AND then assign (`&=`), Logical AND (`&&`)

Cross-references:

ECMA 262 edition 2 – section – 11.10

ECMA 262 edition 3 – section – 11.10

&& (Logical AND) (Operator/logical)

Logical AND of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`

See also:	Binary logical operator, Bitwise AND (`&`), Bitwise AND then assign (`&=`), Logical AND (`&&`)

Cross-references:

ECMA 262 edition 2 – section – 11.11

ECMA 262 edition 3 – section – 11.11

&= (Bitwise AND assign) (Operator/assignment)

Bitwise AND of two operands, and assigns the result to the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Assignment operator, Bitwise AND then assign (`&=`), Bitwise operator, Logical AND (`&&`), LValue

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

' (Single quote) (Delimiter)

Single quote string literal delimiter.

Availability:	ECMAScript edition – 2 Opera – 3.0
Property/method value type:	`String primitive`

See also:	ASCII, Escape sequence (`\`), Line terminator, Literal, Punctuator, String, String literal, Unicode, `var`

Cross-references:

ECMA 262 edition 2 – section – 7.7.3

ECMA 262 edition 3 – section – 7.8.4

( ) (Argument delimiter) (Delimiter)

Delimits the arguments of a function call.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	*`myFunction(someArguments)`*
Argument list:	*`someArguments`*	An optional collection of arguments to the function

See also:	Function, `function( ... ) ...`, Function call, Grouping operator `( )`, Operator, Operator Precedence, Parentheses `( )`, Postfix operator, Primary expression

Cross-references:

ECMA 262 edition 2 – section – 11.2

ECMA 262 edition 3 – section – 11.1.6

( ) (Grouping operator) (Delimiter)

Control of expression operator execution precedence and `Function` argument delimiters.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

See also:	Function, Function call, `function( ... ) ...`, Grouping operator `( )`, Operator, Operator Precedence, Parentheses `( )`, Postfix operator, Primary expression

Cross-references:

ECMA 262 edition 2 – section – 11.1.4

ECMA 262 edition 3 – section – 11.1.6

* (Multiply) (Operator/multiplicative)

Multiply one operand by another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

Property/method value type:	`Number primitive`

See also:	Multiplicative operator, Multiply (`*`)

Cross-references:

ECMA 262 edition 2 – section – 11.5.1

ECMA 262 edition 3 – section – 11.5.1

*/ (Close comment block) (Delimiter)

Closing token for a multi-line comment.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

See also:	Comment, Comment (`//` and `/* ... */`)

Cross-references:

ECMA 262 edition 2 – section – 7.3

ECMA 262 edition 3 – section – 7.4

*= (Multiply assign) (Operator/assignment)

Multiplies two operands and assigns the result to the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Assignment operator, LValue, Multiplicative operator, Multiply then assign (*=)

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

+ (Add) (Operator/additive)

Adds two operands together.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Add (+), Additive operator, Positive value (+), String concatenate (+), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.6.1

ECMA 262 edition 3 – section – 11.6.1

+ (Concatenate) (Operator/string)

Joins string operators by concatenation.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`String primitive`

See also:	Add (+), Additive operator, Positive value (+), `String.concat()`, String concatenate (+), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.6.1

ECMA 262 edition 3 – section – 11.6.1

+ (Unary plus) (Operator/unary)

Indicates positive value or numeric cast a non-numeric value.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Add (+), Additive operator, Positive value (+), String concatenate (+), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.6

ECMA 262 edition 3 – section – 11.4.6

++ (Post increment) (Operator/postfix)

Incrementing operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Decrement value (--), Increment value (++), Postfix increment (++), Prefix increment (++), Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.3.1

ECMA 262 edition 3 – section – 11.3.1

++ (Pre increment) (Operator/prefix)

Increments an operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server– 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Additive operator, Decrement value (--), Increment value (++), Postfix increment (++), Prefix increment (++), Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.4

ECMA 262 edition 3 – section – 11.4.4

+= (Add assign) (Operator/assignment)

Adds the second operand to the first, modifying the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Additive operator, Add then assign (+=), Assignment operator, Concatenate then assign (+=), Increment value (++), LValue

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

, (Comma) (Delimiter)

Comma separated argument list. The comma operator provides a way to evaluate several assignment expressions at once.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
See also:	Comma operator (,), `Document.write()`, `Document.writeln()`, `var`

Cross-references:

ECMA 262 edition 2 – section – 11.14

ECMA 262 edition 3 – section – 11.14

- (Minus) (Operator/additive)

Subtracts one operand from another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Additive operator, Negation operator (-), Subtract (-), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.6.2

ECMA 262 edition 3 – section – 11.6.2

- (Unary minus) (Operator/unary)

Negates the value of an operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server– 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Additive operator, Negation operator (-), Subtract (–), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.7

ECMA 262 edition 3 – section – 11.4.7

– (Post decrement) (Operator/postfix)

Decrementing operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Decrement value (--), Increment value (++), Postfix decrement (--), Prefix decrement (--), Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.3.2

ECMA 262 edition 3 – section – 11.3.2

– (Pre decrement) (Operator/prefix)

Decrements an operand's value.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Additive operator, Decrement value (--), Increment value (++), Postfix decrement (--), Prefix decrement (--), Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.5

ECMA 262 edition 3 – section – 11.4.5

-= (Minus assign) (Operator/assignment)

Subtracts the right value from the left modifying the left.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
See also:	Additive operator, Assignment operator, LValue, Subtract (–), Subtract then assign (–=)

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

. (Decimal point) (Delimiter)

A delimiter character.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
See also:	Floating point, Object property delimiter (.), Property accessor, Decimal point (.)

Cross-references:

ECMA 262 edition 2 – section – 7.7.3

ECMA 262 edition 3 – section – 7.8.3

. (Period) (Delimiter)

A token to delimit object properties from their object or a decimal point.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
See also:	Member, Object property delimiter (`.`), Property accessor

Cross-references:

ECMA 262 edition 2 – section – 8.6

ECMA 262 edition 2 – section – 11.2

ECMA 262 edition 3 – section – 11.2.1

/ (Divide) (Operator/multiplicative)

Divides one operand by another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Arithmetic operator, Divide (`/`), Multiplicative operator, Remainder (`%`)

Cross-references:

ECMA 262 edition 2 – section – 11.5.2

ECMA 262 edition 3 – section – 11.5.2

/ (Slash) (Delimiter)

A delimiter character for regular expressions.

Availability:	JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0

Refer to:

`RegExp` literal

/* ... */ (Comment block) (Delimiter)

A multi-line comment delimiting token.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
JavaScript syntax:	-	`/*someCommentText*/`
Argument list:	`someCommentText`	Any arbitrary comment text required

See also:	Comment, Comment (`//` and `/* ... */`), Multi-line comment

Cross-references:

ECMA 262 edition 2 – section – 7.3

ECMA 262 edition 3 – section – 7.4

/*@ ... @*/ (Pre processing block) (Delimiter)

A special form of the comment delimiters for enclosing pre-processor directives.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	-	`/*@someDirectives@*/`
Argument list:	*`someDirectives`*	One or more pre-processor directives

Refer to:

Pre-processing – `/*@ ... @*/`

// (Comment line) (Delimiter)

A single line comment delimiting token.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server– 2.0 Opera – 3.0
See also:	Comment, Comment (`//` and `/* ... */`), Single line comment

Cross-references:

ECMA 262 edition 2 – section – 7.3

ECMA 262 edition 3 – section – 7.4

/= (Divide assign) (Operator/assignment)

Divides one operand by another, leaving the result in the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Arithmetic operator, Assignment operator, Divide then assign (`/=`), LValue, Multiplicative operator, Remainder (`%`)

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

: (Colon) (Delimiter)

A delimiter used with labels and conditional operators.

Availability:	ECMAScript edition – 2 JavaScript – 1.2 JScript – 3.0 Internet Explorer – 4.0 Netscape – 4.0 Netscape Enterprise Server – 3.0
See also:	Colon (`:`), `switch( ... ) ... case: ... default: ...`

Cross-references:

ECMA 262 edition 2 – section – 7.4.3

ECMA 262 edition 3 – section – 7.5.2

; (Semicolon) (Delimiter)

Semicolon characters are used to separate one executable statement from another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
See also:	Empty statement (;), Expression statement, Punctuator, Semicolon (;), Statement

Cross-references:

ECMA 262 edition 2 – section – 12.2

ECMA 262 edition 2 – section – 12.3

ECMA 262 edition 3 – section – 12.3

ECMA 262 edition 3 – section – 12.4

< (Less than) (Operator/relational)

Compares two operands to determine which is nearer to `-Infinity`.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`

See also:	Equal to (==), Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), NOT Equal to (!=), NOT Identically equal to (!==), Relational operator

Cross-references:

ECMA 262 edition 2 – section – 11.8.1

ECMA 262 edition 3 – section – 11.8.1

<!– … –> (Comment block) (Object/HTML)

HTML comments can be used to hide scripts.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
Inherits from:	`CharacterData` object	
JavaScript syntax:	IE	*myDocument*`.all.tags("!")[`*anIndex*`]`
HTML syntax:	`<!-- `*someCommentText*` -->`	
Argument list:	*anIndex*	A reference to an element in a collection

See also:	`COMMENT` object, `Element` object, Hiding scripts from old browsers

Inheritance chain:

`CharacterData` object, `Node` object

<% … %> (Server side code block) (ASP tag)

This is a special tag to delimit server-side code to be executed in the ASP back end of an IIS server.

Refer to:

ASP

<< (Bitwise shift left) (Operator/bitwise)

Bitwise leftwards shift one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Bitwise shift left then assign (<<=), Bitwise shift operator, Bitwise shift left (<<), Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=), Shift operator

Cross-references:

ECMA 262 edition 2 – section – 11.7.1

ECMA 262 edition 3 – section – 11.7.1

<<= (Bitewise shift left assign) (Operator/assignment)

Destructively bitwise leftwards shift the first of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Assignment operator, Bitwise operator, Bitwise shift left (<<), Bitwise shift left then assign (<<=), Bitwise shift operator, Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=), LValue

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

<= (Less than or equal to) (Operator/relational)

Compares two operands to determine which is nearer to `-Infinity` or whether they are equal.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0	
Property/method value type:	`Boolean primitive`	
JavaScript syntax:	-	*`anOperand <= anOperand`*
Argument list:	*`anOperand`*	An operand that can be compared for magnitude

See also:	Equal to (==), Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), NOT Equal to (!=), NOT Identically equal to (!==), Relational operator

Cross-references:

ECMA 262 edition 2 – section – 11.8.3

ECMA 262 edition 3 – section – 11.8.3

= (Assign) (Operator/assignment)

Assigns the right value to the left operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server version – 2.0 Opera – 3.0
Property/method value type:	`Depends on right value`

Warnings:

- The operand to the left of the operator must be an `LValue`. That is, it should be able to take an assignment and store the value.
- Be careful not to confuse the single equals with the double equals. Placing a double equals in place of an assignment will not assign the value and may be considered to be a syntax error, since it may perform a comparison in entirely the wrong context. The interpreter may be forgiving enough that a run-time error isn't generated though, but the side effects could be subtle and make it hard to diagnose the cause.

See also:	Assign value (=), Assignment operator, Equal to (==), Equality operator, Lvalue, var, Variable statement

=== (Identical to) (Operator/identity)

Compares two operands for equality and identical type.

Availability:	ECMAScript edition – 3 JavaScript – 1.3 JScript – 1.0 Internet Explorer – 3.02 Netscape – 4.06
Property/method value type:	`Boolean primitive`

See also:	Equal to (==), Equality expression, Equality operator, Greater than (>), Greater than or equal to (>=), Identically equal to (===), Identity operator, Less than (<), Less than or equal to (<=), NOT Equal to (!=), NOT Identically equal to (!==)

Cross-references:

ECMA 262 edition 3 – section – 11.9.4

> (Greater than) (Operator/relational)

Compares two operands to determine which is nearer to `+Infinity`.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`
See also:	Equal to (==), Greater than (>), Greater than or equal to (>=), Identically equal to (===), Less than (<), Less than or equal to (<=), `NOT` Equal to (`!=`), NOT Identically equal to (`!==`), Relational operator

ECMA 262 edition 3 – section – 11.8.4

>> (Bitwise shift right) (Operator/bitwise)

Bitwise rightward shifts one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Bitwise shift left (<<), Bitwise shift left then assign (<<=), Bitwise shift operator, Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=), Shift operator

>>> (Bitwise unsigned shift right) (Operator/bitwise)

Bitwise rightward shifts one operand according to another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server `version` – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`

See also:	Bitwise shift left (<<), Bitwise shift left then assign (<<=), Bitwise shift operator, Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=), Shift operator

Cross-references:

ECMA 262 edition 2 – section – 11.7.3

ECMA 262 edition 3 – section – 11.7.3

>>>= (Bitwise unsigned shift right assign) (Operator/assignment)

Destructively bitwise rightward shifts the first of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Assignment operator, Bitwise operator, Bitwise shift left (<<), Bitwise shift left then assign (<<=), Bitwise shift operator, Bitwise shift right (>>), Bitwise shift right and assign (>>=), Bitwise unsigned shift right (>>>), Bitwise unsigned shift right and assign (>>>=), `LValue`

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

?: (Conditional block) (Operator/conditional)

Conditionally executes one code branch or another. Otherwise known as the Ternary operator.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Depends on arguments`
See also:	Conditionally execute (`?:`), `if( ... ) ..., if( ... ) ... else ...`

Cross-references:

ECMA 262 edition 2 – section – 11.12

ECMA 262 edition 3 – section – 11.12

@*/ (Pre-processor)

The closing pre-processor directive comment delimiter.

Availability:	JScript – 3.0 Internet Explorer – 4.0	
JavaScript syntax:	IE	`/*@someDirectives@*/`
Argument list:	`someDirectives`	One or more directives

See also:	Pre-processing, Pre-processing – `/*@ ... @*/`

@<variable_name> (Pre-processor)

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`User defined`

Refer to:

Pre-processing – `@<variable_name>`

@_alpha (Pre-processor)

A pre-processor constant indicating whether the script is running in a DEC alpha workstation.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_alpha`

@_jscript (Pre-processor)

A pre-processor constant indicating whether the script is executing in a JScript interpreter.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_jscript`

@_jscript_build (Pre-processor)

A pre-processor constant indicating the build version of the JScript environment.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Number primitive`

Refer to:

Pre-processing – `@_jscript_build`

@_jscript_version (Pre-processor)

A pre-processor constant indicating the version number of the JScript interpreter.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Number primitive`

Refer to:

Pre-processing – `@_jscript_version`

@_mac (Pre-processor)

A pre-processor constant indicating whether the script is running in a Macintosh workstation.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_mac`

@_mc680x0 (Pre-processor)

A pre-processor constant indicating whether the system contains a Motorola 68000 CPU.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_mc680x0`

@_PowerPC (Pre-processor)

A pre-processor constant indicating whether the system contains a Motorola PowerPC CPU.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_PowerPC`

@_win16 (Pre-processor)

A pre-processor constant indicating whether the script is running in a 16 bit Windows environment.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_win16`

@_win32 (Pre-processor)

A pre-processor constant indicating whether the script is running in a 32 bit Windows environment.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_win32`

@_x86 (Pre-processor)

A pre-processor constant indicating whether the system contains an Intel X-86 series CPU.

Availability:	JScript – 3.0 Internet Explorer – 4.0
Property/method value type:	`Boolean primitive`

Refer to:

Pre-processing – `@_x86`

@cc_on (Pre-processor)

A switch to activate the pre-processor phase of the script interpreter.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@cc_on`

@elif(...) ... (Pre-processor)

An optional `else-if` pre-processor token.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@elif( ... ) ...`

@else ... (Pre-processor)

Part of the conditional code use directive.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@else ...`

@end (Pre-processor)

Terminator for a conditional code block.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@end`

@if(...) ... (Pre-processor)

Conditionally includes a block of code.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@if( ... ) ...`

@set (Pre-processor)

Sets the contents of a pre-processor variable.

Availability:	JScript – 3.0 Internet Explorer – 4.0

Refer to:

Pre-processing – `@set`

[ ] (Array index) (Delimiter)

Array index delimiting tokens.

Availability:	ECMAScript edition – 2 JavaScript – 1.1 JScript – 3.0 Internet Explorer – 4.0 Netscape – 3.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Depends on array content`
See also:	Array index delimiter (`[ ]`), Property accessor

Cross-references:

ECMA 262 edition 2 – section – 7.6

ECMA 262 edition 2 – section – 11.2

ECMA 262 edition 3 – section – 7.7

[ ] (Property accessor) (Delimiter)

Properties can be accessed as if they were elements in an array.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0
See also:	Property accessor, Property name

Cross-references:

ECMA 262 edition 2 – section – 8.6.1

ECMA 262 edition 3 – section – 6

ECMA 262 edition 3 – section – 7.7

^ (Bitwise XOR) (Operator/bitwise)

Bitwises XOR one operand with another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Binary bitwise operator, Bitwise XOR (^)

Cross-references:

ECMA 262 edition 2 – section – 11.10

ECMA 262 edition 3 – section – 11.10

^= (Bitwise XOR assign) (Operator/assignment)

Bitwises XOR two operands and stores the result in the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Assignment operator, Bitwise operator, Bitwise XOR and assign (`^=`), `LValue`

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

_ (Underscore) (Symbol)

A special character allowed to be used in identifier names.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

Refer to:

Identifier

Cross-references:

ECMA 262 edition 2 – section – 7.5

ECMA 262 edition 3 – section – 7.6

__parent__ (Property)

A Netscape special scope chain inheritance property.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`ScopeChain` object	
JavaScript syntax:	N	`myClosure.__parent__`

With the `__parent__` property in Netscape, you can explicitly initialize the scope chain in your own custom functions.

Using this facility is somewhat inelegant, and since it is not portable its use is likely to be fairly restricted.

Warnings:

- It is unclear whether this property will be added to the ECMA standard. For now it is only available in Netscape.

Example code:

```
// Create an objectvar myObject =
{ aaa:"Some text" };// A fragment
of script to place that object into
the scope chainmyObject.__parent__ =
 this.__parent__;this.__parent__ = myObject;
```

See also:	`__proto__`, Lexical scoping, Scope, Scope chain

__proto__ (Property)

A Netscape special prototype inheritance property.

Availability:	JavaScript – 1.2 Netscape – 4.0	
Property/method value type:	`Function` object	
JavaScript syntax:	N	*myClosure*`.__proto__`

With the `__proto__` property in Netscape, you can explicitly initialize the prototype inheritance chain in your own custom constructors.

Warnings:

- It is unclear whether this property will be added to the ECMA standard. For now it is only available in Netscape.

Example code:

```
// Create a cuboid objectvar AAA = { length:100,
width:200, height:300 };// Create a cuboid that
shares the height valuevar BBB = { length:50,
width:100, __proto__:AAA };
```

See also:	`__parent__`, Subclasses

` (Backquote) (External code call)

Calls some external code during server side execution.

Refer to:

Backquote (`)

{ } (Braces) (Delimiter)

A delimiting token for a block of executable script source text.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0

See also:	`if( ... ) ...`,`if( ... ) ... else ...`, Code block delimiter {}

Cross-references:

ECMA 262 edition 2 – section – 12.5

ECMA 262 edition 3 – section – 12.1

| (Bitwise OR) (Operator/bitwise)

Bitwises `OR` one operand with another.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Binary bitwise operator, Bitwise OR (`|`)

Cross-references:

ECMA 262 edition 2 – section – 11.10

ECMA 262 edition 3 – section – 11.10

|= (Bitwise OR assign) (Operator/assignment)

Bitwises OR two operands storing the result in the first.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Assignment operator, Bitwise operator, Bitwise `OR` then assign (`|=`), `LValue`

Cross-references:

ECMA 262 edition 2 – section – 11.13

ECMA 262 edition 3 – section – 11.13

|| (Logical OR) (Operator/logical)

Logical `OR` of two operands.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server – 2.0 Opera – 3.0
Property/method value type:	`Boolean primitive`
See also:	Binary logical operator, Logical OR (||)

Cross-references:

ECMA 262 edition 2 – section – 11.11

ECMA 262 edition 3 – section – 11.11

~ (Bitwise NOT) (Operator/bitwise)

Bitwise `NOT` of an operand.

Availability:	ECMAScript edition – 2 JavaScript – 1.0 JScript – 1.0 Internet Explorer – 3.02 Netscape – 2.0 Netscape Enterprise Server– 2.0 Opera – 3.0
Property/method value type:	`Number primitive`
See also:	Bitwise NOT – complement (~), Bitwise operator, Logical NOT – complement (!), Unary expression, Unary operator

Cross-references:

ECMA 262 edition 2 – section – 11.4.8

ECMA 262 edition 3 – section – 11.4.8

! object (Object/HTML)

An object representing a `<!DOCTYPE>` DTD statement tag at the front of a document.

Availability:	DOM level – 1 JScript – 5.0 Internet Explorer – 5.0	
Inherits from:	`Element` object	
JavaScript syntax:	IE	*myDoctype* = *myDocument*.all.tags("!")[0]
	IE	*myDoctype* = *myDocument*.all[*anIndex*]
	IE	*myDoctype* = *myDocument*.getElementById (*anElementID*)
	IE	*myDoctype* = *myDocument*.getElementsByName(*aName*) [*anIndex*]
	IE	*myDoctype* = *myDocument*.doctype
	IE	*myDoctype* = *myDocument*.getElementsByTagName("!") [*anIndex*]
HTML syntax:	`<!DOCTYPE aDocumentDescription>`	
Argument list:	*aDocumentDescription*	A reference to a DTD for this document
	anIndex	A reference to an element in a collection
	aName	An associative array reference
	anElementID	The `ID` value of an `Element` object
Object properties:	`accessKey, tabIndex`	
Event handlers:	`onClick, onDblClick, onHelp, onKeyDown, onKeyPress, onKeyUp, onMouseDown, onMouseMove, onMouseOut, onMouseOver, onMouseUp`	

The MSIE implementation creates an object that has a constructor name that suggests its class is "!". This is very odd, and if you intend to do any work on object classes, then naming a class with what might be interpreted as a special character in the script source may lead to some problems.

This is really a `Doctype` object and is specified in the DOM standard as a `<!DOCTYPE>` element.

The recommended means of access is to retrieve the value of the `doctype` property of the document you want to operate on. This is normally `document.doctype` for the current window but in the case of multiple frames, layers or windows you may be referring to the doctype of a different `document` object.

This object appears to inherit all of the properties of an HTML element.

See also:	`!.tabIndex`, `Document.doctype`, `Element` object, `Input.accessKey`

Property	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
accessKey	-	5.0 +	-	5.0 +	-	1 +	-	-
tabIndex	-	5.0 +	-	5.0 +	-	-	-	Warning

Event name	JavaScript	JScript	N	IE	Opera	DOM	HTML	Notes
onClick	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onDblClick	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onHelp	-	5.0 +	-	5.0 +	-	-	-	Warning
onKeyDown	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onKeyPress	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onKeyUp	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onMouseDown	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onMouseMove	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onMouseOut	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onMouseOver	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning
onMouseUp	-	5.0 +	-	5.0 +	-	-	4.0 +	Warning

Inheritance chain:

`Element` object, `Node` object

!.tabIndex (Property)

A tab index for a DTD statement.

Availability:	JScript – 5.0 Internet Explorer – 5.0	
Property/method value type:	`Number primitive`	
JavaScript syntax:	IE	*myDTD*`.tabIndex`

You'll likely only need to access properties of this object if you are writing 'extreme' JavaScript code. Most script writers will never encounter this object.

Warnings:

- This property is probably a mistake. It appeared when enumerating the properties of this object but the DTD contains no sensible tab accessible content nor is it part of a `<FORM>`. Under tests with normal DTD values this returned a zero.

See also:	`!` object, `Document.doctype`

Cross Reference by Entry Type

Each entry in this reference has a type or class, for example, 'object/HTML' for the A object. This cross-reference is ordered by entry type, with corresponding entries listed alphabetically beneath.

The collections, events, methods and properties entry types are slightly different because they list the collection, event, method or property name first and the actual entry name (which incorporates the object name) second.

Collections, events, methods and properties often have their own detailed entries, but information on browser support for them is also provided in the entry for the object to which they belong. References to both entries are listed where they exist.

An asterisk is used to show which entries are in the book. Entries without an asterisk will be found on the CD only.

Operator/additive
- (Minus)
+ (Add)
Add (+)*
Minus (-)
Subtract (-)*

Operator/assignment
%= (Modulo assign)
&= (Bitwise AND assign)
*= (Multiply assign)
/= (Divide assign)
^= (Bitwise XOR assign)
|= (Bitwise OR assign)
+= (Add assign)
<<= (Bitewise shift left assign)
= (Assign)*
-= (Minus assign)
>>= (Bitwise shift right assign)
>>>= (Bitwise unsigned shift right assign)
Add then assign (+=)*
Assign value (=)*
Bitwise AND then assign (&=)*
Bitwise OR then assign (|=)*
Bitwise shift left then assign (<<=)*
Bitwise shift right and assign (>>=)*
Bitwise unsigned shift right and assign (>>>=)*
Bitwise XOR and assign (^=)*
Concatenate then assign (+=)*
Divide then assign (/=)*
Minus then assign (-=)
Multiply then assign (*=)*
Remainder then assign (%=)*
Subtract then assign (-=)*

Operator/bitwise
& (Bitwise AND)
^ (Bitwise XOR)
| (Bitwise OR)
~ (Bitwise NOT)
<< (Bitwise shift left)
>> (Bitwise shift right)
>>> (Bitwise unsigned shift right)
Bitwise AND (&)*
Bitwise NOT - complement (~)*
Bitwise OR (|)*
Bitwise shift left (<<)*
Bitwise shift right (>>)*
Bitwise unsigned shift right (>>>)*
Bitwise XOR (^)*
Left shift
Right shift

Operator/conditional
?: (Conditional block)
Conditionally execute (?:)*

Operator/equality
!= (NOT equal)
== (Equal to)
Equal to (==)*
NOT Equal to (!=)*

Operator/identity
!== (NOT identical)
=== (Identical to)
Exactly equal to (===)
Identically equal to (===)*
NOT Identically equal to (!==)*
Strictly equal to (===)

Operator/internal
ToBoolean*
ToInt32*
ToInteger*
ToNumber*
ToObject*
ToPrimitive*
ToString*
ToUint16*
ToUint32*

Operator/logical
! (Logical NOT)
&& (Logical AND)
|| (Logical OR)
in*
instanceof*
Logical AND (&&)*
Logical NOT - complement (!)*
Logical OR (||)*
Logical XOR*

Operator/multiplicative
% (Modulo/remainder)
* (Multiply)
/ (Divide)
Divide (/)*
Modulo
Multiply (*)*
Remainder (%)*

Operator/postfix
-- (Post decrement)
++ (Post increment)
Decrement value (--)*
Increment value (++)*
Postfix decrement (--)*
Postfix expression*
Postfix increment (++)*

Operator/prefix
-- (Pre decrement)
++ (Pre increment)
Prefix decrement (--)*
Prefix expression*
Prefix increment (++)*

Operator/relational
< (Less than)
<= (Less than or equal to)
> (Greater than)
>= (Greater than or equal to)
Greater than (>)*
Greater than or equal to (>=)*
Less than (<)*
Less than or equal to (<=)*

Operator/string
+ (Concatenate)
Concatenate (+)
String concatenate (+)*

Operator/unary
- (Unary minus)
+ (Unary plus)
delete*
Negation operator (-)*
new*
Positive value (+)*
typeof*
void*
